APPENDIX

Table 2 Examples of standards.

Categories of standards	Remarks
Rigid Standard	Objective standards such as denoted by measuring *units* (meter, gram, etc.).
Species Standard	The *attribute value ordinary* for a species. A *short train* is ordinarily longer than a *long pencil*.
Proportional Standard	'*Oblong*' means that the width is greater than the height at a physical object.
Individual Standard	*Delicious* food for one person can be too *poor* for another.
Purposive Standard	One room *comfortable* enough for a person's *sleeping* may be *uncomfortable* for his *jogging*.
Declarative Standard	The origin of an order such as 'next' must be declared explicitly just as 'next *to him*'.

Abstract: An optical microscope commonly has the magnification from tens times to thousands times, and is often used for the observation of a micro specimen. The three-dimensional (3-D) form measurement of the specimen surface is broadly demanded of fields, such as medical treatment, pharmacy, life science, and materials science. On the conventional methods, the focus distance is regulated with great precision or the system is complex and the operation and observation is simply by the skilled personnel. In order to solve these problems, we propose a high-sensitivity 3-D shape measurement method with microscope. The measurement system is consisted of a normal microscope, a line laser, and a computer can obtain the high precision of target. The method is unnecessary to regulate the focus distance with great precision, simply project the laser source onto the surface of target and obtain the reflection image with the camera of microscope, and by using the image processing to obtain the center point of waveform of the intensity distribution of reflection image, finally calculate the 3-D shape information based on the triangulation method. The experimental results show the proposal method is available.

Keywords: Laser, 3-D measurement, Microscope.

1 INTRODUCTION

An optical microscope commonly has the magnification from tens times to thousands times, and is often used for the observation of a micro specimen. The three-dimensional (3-D) shape measurement of the specimen surface is broadly demanded of fields, such as medical treatment, pharmacy, life science, and materials science and so on.

The methods of 3-D shape measurement with microscope are various. For instance, laser-scanning confocal optical microscopy[9], strength is spatial resolution is high; weakness is the focus distance is regulated with great precision, and it cost time and observation is simply by the skilled personnel. AOD-based two-photon microscopy[10], strength is high-speed in vivo; weakness is the system is complex and the operation and observation is simply by the skilled personnel. Laser-induced fluorescence (LIF) detection system[5], strength is to provide effective high-throughput flow cytometry measurements; weakness is simply available for the direction. Shape from focus[1], strength is the system is simple and inexpensive; weakness is not available for the non-uniform spatial resolution, and the observation view is limited and performance affected by ambient light. And holographic optical element[6], strength is the calculation method is simple; weakness is the system is complex that the various mirror and microscope are used, the operation is difficult.

In order to solve these problems described on above methods, we propose a high-sensitivity 3-D shape measurement method with microscope.

The papers are formed with 5 sections as the following:

Section 2 introduces the composition, principle and methods of the 3-D measurement system we presented.

Section 3 shows the experimental results by using the method we proposed.

Section 4 introduces the conclusion for the method we proposed.

2 COMPOSITION, PRINCIPLE AND METHODS

The composition, principle and methods of the 3-D measurement system we presented is shown as following.

2.1 System composition

The measurement system on our proposal method is consisted of a microscope, a line laser, and a computer. It is shown as Figure. 1.

The operation of the method we proposed is as the following. At first, the line laser source is projected onto the surface of the micro target by the line laser. And next,

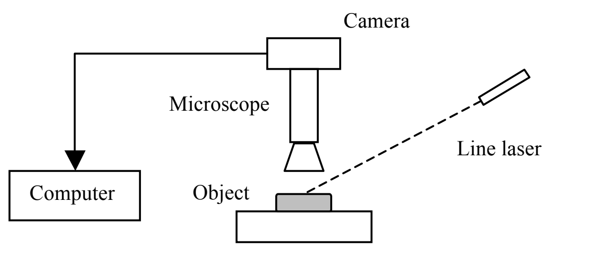

Fig. 1 Microscope 3-D measurement system

we regulate the microscope to observe the reflection image of target, and then, the camera of the microscope photographs the reflection image, and the image is inputted into the computer. Finally, the measurement image is obtained through the image processing on the computer, and the 3-D shape information of the target is calculated from the measurement image by using the triangulation.

2.2 Measurement principle

The measurement method is based on an optical principle - the intensity distribution of a reflection light likes a cosine waveform. For the cosine waveform, we can simply detect the top point of it. (On our research "Accuracy Improvement for Projection Patterns in 3-D Measurement" (Ref. [4], [5]), the top-point analysis method is introduced on detail.)

On the basis of the principle, when the microscope observes the reflection image, the focus distance can be regulated within great precision. It means the observation time and operation degree are reduced. It's the prominent strength of proposal method.

The cause is for the reflection image at any station, we can use the image processing to process the image, and obtain the ideal the cosine waveform of the intensity distribution of it. For the cosine waveform, we can easily detect the top point – the real center point of the waveform. And then, we can calculate the correct 3-D shape information of the observation point.

2.3 Measurement methods

2.3.1 Microscope observation

At first, in order to observe the target clearly, we put the specimen on the microscope stage, and move location of the stage to make the target on the center of the visual field of the microscope. And then, we regulate the focal distance of the objective of microscope to obtain the distinct image of the target, and regulate the light source of the microscope to obtain the primitive image of the target.

2.3.2 Laser projection

Second, we regulate the distance and rotation angle of the laser to make the line laser project onto the surface of the target and the reflection image on the visual field of the microscope. And then, we can obtain the reflection image intermix with the reflection light of laser source and light source of the microscope. The image is called the laser and light source image.

2.3.3 Camera photographs

And then, we close the light source of the microscope, and obtain the reflection image of the laser source by using the camera of the microscope. The image is called the laser source image.

2.3.4 Image processing

Be aimed at the laser source image, we will use the image processing to obtain the measurement image.

In order to obtain the channel had the maximum value of R, G, B, we use the method choose the measurement channel and generate a measurement image (Ref. [2], [3]).

In every pixel of the extracted object image, the color and intensity distributions are detected. The channel of the initial observation pattern image intensity maximum is chosen to be the measurement channel of the pixel by

$$\bar{I}(x,y) = \max\{\bar{I}_R(x,y), \bar{I}_G(x,y), \bar{I}_B(x,y)\} \qquad (1)$$

where the (x,y) is the image coordinate of current pixel, $\bar{I}(x,y)$ is intensity of the (x,y), $\bar{I}_R(x,y)$, $\bar{I}_G(x,y)$, $\bar{I}_B(x,y)$ is respectively intensity of the Red, Green channel of the (x,y), Blue of (x,y).

The result image is called the monochrome image.

2.3.5 Center point detection

Through using the moving average method, we can obtain the cosine waveform of the intensity distribution of the reflection light.

For the cosine waveform, we can easily detect the top point of it. The result is shown as Fig. 2.

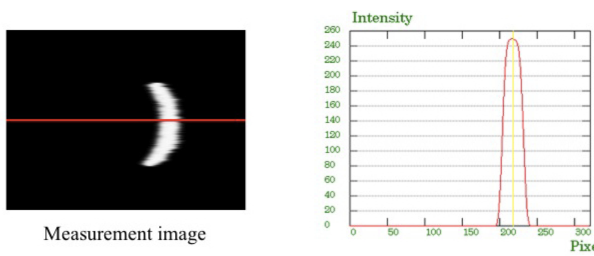
Where the yellow line on the Intensity distribution figure is the top point position of reflection light on the red line of the measurement light.

2.3.6 3-D information calculation

Fig. 3 is the diagram used the proposal method based on the triangulation method. On the basis of the diagram, we obtain the equations calculated the 3-D information of the target, they are shown as the (2), (3) and (4)

$$X = Z \times \frac{x}{f} \qquad (2)$$

$$Y = X \times \frac{y}{x} \qquad (3)$$



Measurement image

Intensity distribution figure

Fig. 2 Detection results of the object

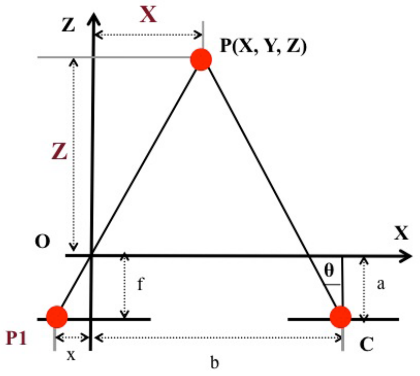


Fig. 3 The principle of triangulation method

$$Z = \frac{b - a\tan\theta}{\tan\theta \pm x/f} \tag{4}$$

Where P is the observation point on the target, C is the projection point from the laser, and P1 is the reflection point of the projection point from the target to the camera. X is the horizontal distance from P to the mid-perpendicular line of camera. Y is the vertical distance from P to the mid-perpendicular line of camera. Z is the depth distance from P to the image plane of camera. x is the horizontal distance from P1 to the mid-perpendicular line of camera. y is the vertical distance from P1 to the mid-perpendicular line of camera. b is the distance between the laser and camera. a is the distance from the laser to the lens of the microscope. tan θ is the angle between the projection laser source and the vertical line. f is the focal distance of camera.

By using the equations (2), (3) and (4), we can calculate the 3-D information of each top point on the reflection light.

3 EXPERIMENTAL RESULTS

The experimental conditions: The microscope is the pinhole confocal optical system; the magnification is from 25 to 175. The spatial resolution of the camera of the microscope is 320 × 240, the CCD is the ½ type 900,000 pixel CCD series. The laser is the semiconductor line laser.

For test the proposal method, we make a series experiments for various specimens. The experimental results are shown as following. (Because the time is not enough on the deadline of the manuscript, the experiment from 3.2 to 3.4, we only obtain the analysis result and can't calculate the depth distance.)

3.1 Pine needle

The experiment is on the pine needle; the specimen is the section of a pine needle. For the case, the magnification of microscope is 175. The result is shown as the Fig. 4.

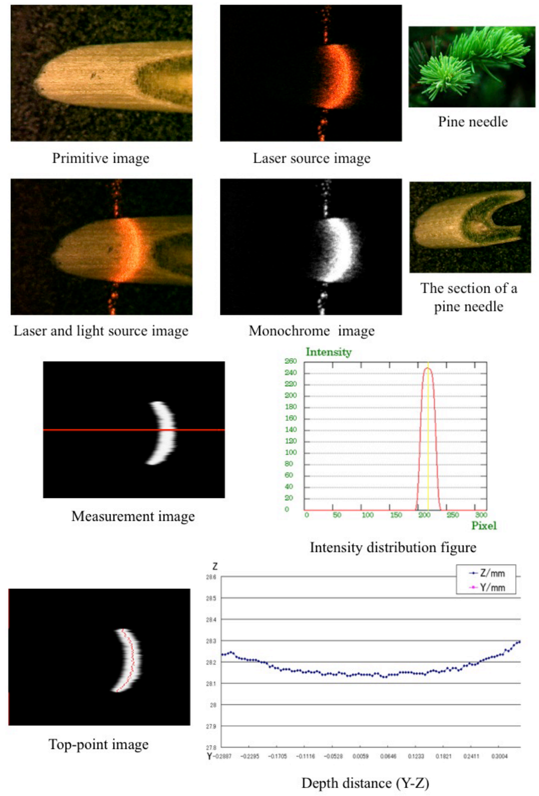

Fig. 4 Measurement results of a Pine needle

Where, the red point on the Top-point image is the top point position of each line of the reflection light.

3.2. Drawing pin

The experiment is on the pine needle; the size of the specimen is shown as the "Drawing pin". For the case, the magnification of microscope is 25. The result is shown as

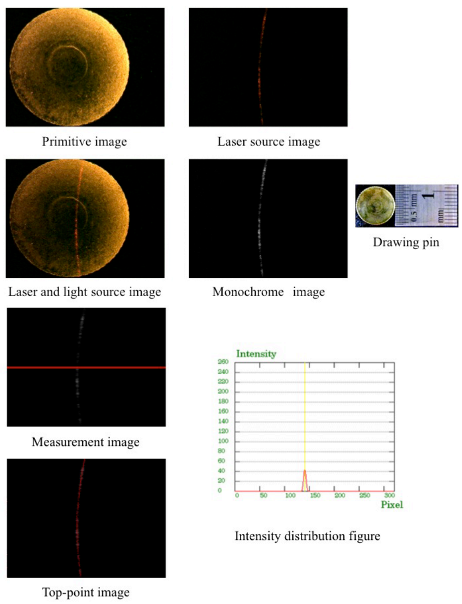

Fig. 5 Measurement results of a Drawing pin

the Fig. 5.

On the case, for the smooth surface of target, the results are very well.

3.3 Flat head tapping screw

The experiment is on the flat head tapping screw; the size of the specimen is shown as the "Flat head tapping screw". For the case, the magnification of microscope is 25. The result is shown as the Fig. 6.

On the "Section image", we can see the problem for the concave surface, the reflection light has the loss, and the 3-D information of the loss can be not measured in reality.

3.4 Self-tapping screw

The experiment is on the self-tapping screw; the size of the specimen is shown as the "Self tapping screw". For the case, the magnification of microscope is 25. The result is shown as the Fig. 7.

On the "Analysis image", we can see the problem for the concave-convex surface, the reflection light not only has the loss, but also has the two waveform, the case become more complex, to calculate the 3-D information is too difficult in reality.

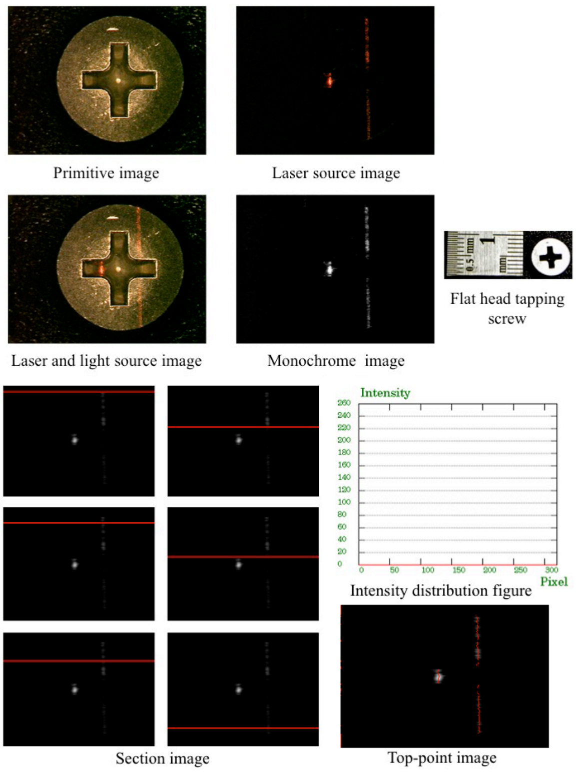

Fig. 6 Measurement results of a Flat head tapping screw

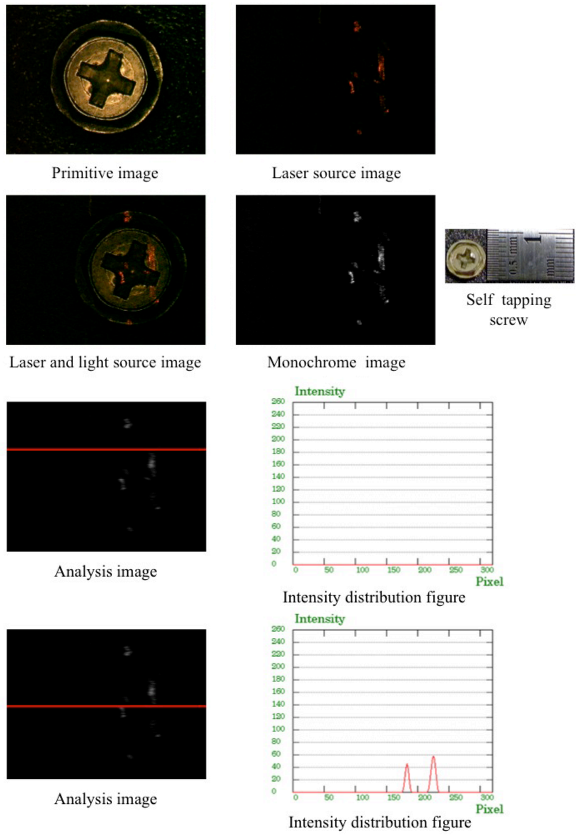

Fig. 7 Measurement results of a Self-tapping screw

4 CONCLUSION

On the research, we combine a simple, inexpensive and easy operation system, and lead the top-point analysis method for the system.

At present, through a series experiments, we can prove the method is available for the system. And from the experiment 3.2, 3.3 and 3.4, we can see: for the uniform, smooth surface shape, the method is well. For the free-form shapes, the reflection light has loss. For the complex shapes, the reflection light becomes too complex to detect the top-point of the intensity distribution.

And at the further, we will be aimed at these problems to perfect the proposal method.

Abstract: In remote collaborative work via WAN, share various high-quality visual contents such as photography, visualization image, and real video streaming, and recognizing these contents clearly is extremely important. Supporting a high-quality display of these contents on a large-scale display system is necessary to support intellectual remote collaborative work. However, these contents are currently magnified in low resolution on a general projector using large-sized display equipment, and a sufficient quality of the contents is not obtained. In this paper, we focus on a tiled display wall using two or more LCD panels on a large-sized display system to display realistic high-resolution visual contents to solve these issues. We have constructed a tele-immersive environment with a tiled display wall, and have studied the availability for intuitive operation and understanding in remote collaborative work by implementing various collaborative applications for the effective display of high-resolution contents as well as developing interaction techniques for enormous visual contents in this environment. As a result, we have showed that the practical use of a tiled display wall is useful in the construction of intellectual remote collaborative environment.

Keywords: Tele-immersion, Tiled display wall, Remote collaborative work

1 INTRODUCTION

Remote collaborative work utilizing enormous quantity of data between multi-field researchers is very useful, and supports new intellectual discovery and knowledge-creation in many research fields. To realize intellectual remote collaborative work with participants at remote sites via WAN, sharing various high-quality visual contents is important, in addition to the existence of remote participants using video streaming to promote remote communication with high realistic sensation [1].

The use of large-scale display system with tele-immersion technology [2] is effective in order to realize the sharing of high-quality enormous quantity of visual contents with video-conference system and it is considered to use display equipment such as projectors and large-sized monitors. However, the display of video streaming and these contents with sufficient quality is difficult because the specification of a commercial projector and large-sized display equipment is low-resolution.

We have focused on the tiled display wall by two or more LCD and tried to display realistic high-resolution visual contents as effective large-sized display system in order to solve these issues. In this paper, we construct a tele-immersive environment with a tiled display wall to display realistic high-resolution video streaming and visual contents on the tiled display wall. In addition, we study the possibility of realizing intuitive operation and understanding in remote collaborative work by implementation of various collaborative applications for this environment.

2 RELATED WORKS

2.1 Tele-immersion Technique

Tele-immersion is defined as a new type of telecommunication media in which virtual reality has been incorporated into video-conference systems. In the 3D tele-immersion system, a user wears polarized glasses and a head tracker and a view-dependent scene is rendered in real-time on a large stereoscopic display in 3D [5].

Recently, Immersive Projection Technology (IPT) such as the CAVE system has become popular, and tele-immersive virtual environments have been constructed by several IPT environments [6]. Video avatar technology has been studied to realize real-world-oriented 3D human images for remote communication with high-presence tools between remote places [7]. The video avatar is a technique that represents a human image with a high-presence by integrating live video images of humans into the 3D virtual world. However, remote collaborative works in an IPT environment require deflection glasses and HMD. Under such conditions, carrying out smooth remote communication between participants is usually difficult.

Therefore, we use a tiled display wall to display higher quality visual contents which realize remote collaborative work with highly realistic sensation. In this research, we construct tele-immersive collaborative environment with tiled display wall to realize intuitive operation and understanding in remote collaborative work, and implement various applications for remote collaborative work in the environment.

2.2 Tiled Display Wall

Tiled display wall is a technology to display high-resolution visual contents on a large-sized screen with two or more LCD panels in order to construct effective large-sized display system. Much research has been done on tiled display walls and remote displays by using a distributed rendering technique for virtual walls.

For example, Chromium has designed and built a system that provides a generic mechanism for manipulating streams of graphic API commands [8]. This system can be used as the underlying mechanism for any cluster graphics algorithm by having the algorithm use OpenGL to move geometry and imagery across a network as required. In addition, Chromium's DMX extension allows execution of multiple applications and window control. However, it has a single source, and its design is not suitable for data streaming over a long-distance network.

In this research, we apply a Scalable Adaptive Graphics Environment (SAGE) developed by EVL at the University of Illinois [3]. SAGE is a graphics streaming architecture for supporting collaborative scientific visualization environments with potentially hundreds of mega-pixels of contiguous display resolution. In collaborative scientific visualization, it is crucial to share high-resolution visualization image as well as high-quality video streaming between participants at local or remote sites. The network-centered architecture of SAGE allows collaborators to simultaneously run various applications on local or remote clusters, and share them by streaming.

We constructed a tiled display wall environment consisting of 1 master node, 8 display nodes, and 16 LCD panels (17inch, SXGA). The tiled display wall's LCDs are located at 4x4 arrays as shown in Fig. 1. Master node and all display nodes are connected by gigabit Ethernet network, and 2 LCDs are connected to 1 display node with DVI cables.

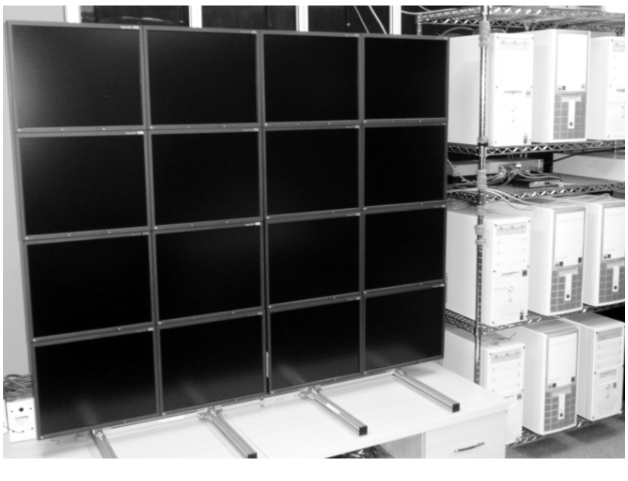

Fig. 1. Tiled display wall in this research.

3 MULTI-VIDEO STREAMING ON TILED DISPLAY WALL

We have implemented an application of high-resolution real video streaming by adding the API code of the SAGE Application Interface Library (SAIL) in a source program of application. In the application, pixel information obtained from a small camera is rendered as a video image by glDrawPixels on the tiled display wall. The video image captured by a camera located at frame of the LCDs on the tiled display wall is transmitted to remote sites, and its video image is displayed on the tiled display wall in a remote site.

We believe the display of the workspace in remote site with real video streaming by applying the ultra high-resolution display technique is an advantage of tiled display wall. We have showed that an ultra high-resolution video streaming with tiled display wall is effective to display the existence of participant and ambiance in remote place as a result from current experiments [9]. However, the video image captured by a single small camera is difficult to display with realistic high-resolution on a tiled display wall, because there is a limit in the display resolution of the video image captured by a single small camera. In addition, the magnified view of original video image on tiled display wall causes to degrade the quality of video image.

In this research, we have constructed an environment to display realistic high-resolution video streaming on a tiled display wall. In this environment, each piece of video image data captured by multiple cameras is transmitted to display nodes of the tiled display wall in remote sites from each application node. In addition, a high-resolution video which is generated by compositing these transmission video images are displayed on the tiled display wall. Fig. 2 shows that transmission multi-video streaming captured by 2 sets of small cameras (Pointgray Flea: XGA, 30fps) located at remote site in LAN. The display resolution of each video is set at 2048 1536 pixels. From this result, we showed to display a clear video image of a remote site over a wide range. As future work, we will study the technique to display more high-quality video image of workspace in remote site on tiled display wall by increasing number of captured camera.

In addition, we have measured the network throughput performance for each transmission video in the environment. The measured results, shown in Fig. 3, are the network throughput of the transmission video about for 20 minutes, and we plot the average value for measurement results for every 2 seconds. From the measurement results, the steady throughput of about 500 Mbps on average, which is considered a full performance of the camera, is gained in each video streaming. Moreover, the transmission delay between each video image is not seen in the observation of each display video on the tiled display wall.

Fig. 2. Multi-video streaming on tiled display wall.

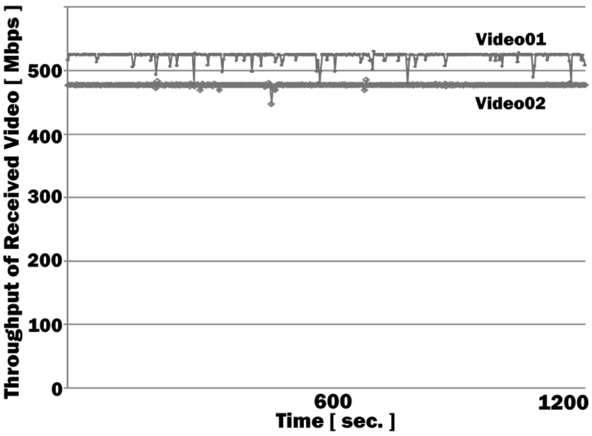

Fig. 3. Network throughput of each video streaming.

4 REALISTIC DISPLAY OF HIGH-RESOLUTION OBSERVATION DATA

We have applied this environment with tiled display wall to the field of astronomy as an effective application to realize a realistic high-resolution display of observation image data on a tiled display wall. Recently, Space Weather Forecast research has been able to predict flares, which occur on the sun's surface and influence the environment globally. In order to establish a high-precision forecast model, it is necessary to analyze a large amount of phenomena with high-resolution observation image data. We have executed realistic display processing of high-resolution astronomical observation image data.

In general, the Flexible Image Transport System (FITS) is used as standard image format for astronomical observation images. FITS is now used as an universal image format which can handle ordinary data in the field of astronomy. In this research, the observation data (resolution of image: 4,096 4,096 pixels) by the Solar Magnetic Activity Research Telescope (SMART), located in Kwasan and Hida Observatories, Kyoto University, is used as image data. The astronomical observation data saved in the local site is transmitted via WAN, and displayed on the tiled display wall in remote sites. An example of observation data by realistic resolution on a tiled display wall is shown in Fig. 4.

These results allow to observe the entire image of the high-resolution observation data on the tiled display wall. It may possible to promote new discoveries from the observation data through remote collaborative work because the data can be observed by multiple users at the same time in this environment. In addition, this environment can display a large amount of observation data that can be expanded and reduced in scale at free positions on the tiled display wall. Therefore, an analysis for these observation images by various techniques can be expected. The construction of a new environment according to user requirements will be examined in the future work.

5 COLLBORATIVE LEARNING USING TILED DISPLAY WALL IN GROUPWORK

As an example of practical use for a remote collaborative environment with the tiled display wall in this paper, we have executed collaborative learning using multi LCDs , and the tiled display wall in discussions to display student materials (Fig. 5:(top)). In addition, distance learning with the tiled display wall has been used in cooperation with classes given at the same time in other buildings, as shown in Fig. 5:(bottom).

From this approach, we understood that additional study on an effective display method for visual contents such as video streaming and presentation materials is important, even though each student used it effectively for the presentation and the discussion through the collaborative environment. In addition, we recognized that the demands for effective tech-

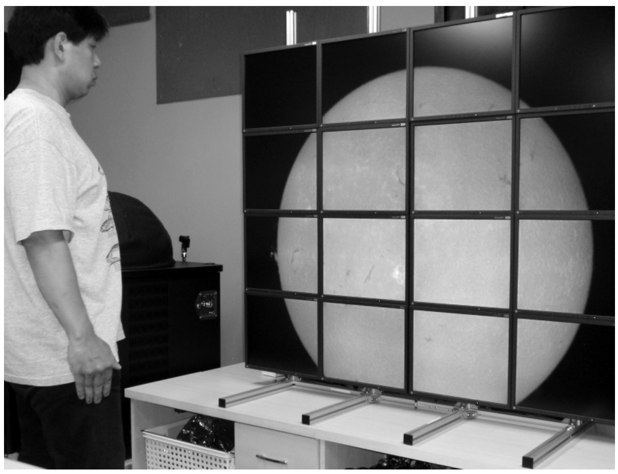

Fig. 4. Realistic display of astronomical observation image (4,096 4,096 pixels).

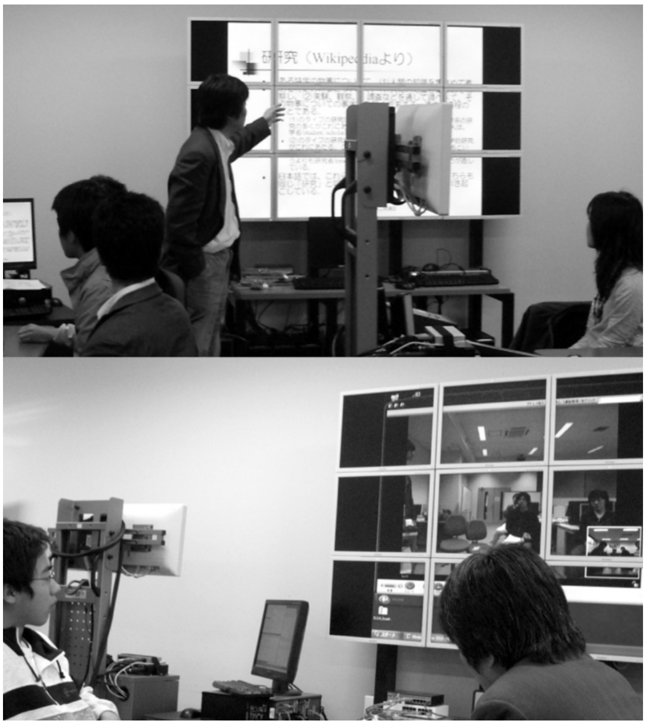

Fig. 5. Collaborative learning using tiled display wall in group work.

niques to display enormous quantity of experimental data and visualization images simultaneously to realize more intelligent collaborative work has risen from the collaborative learning approaches.

On the other hands, an advantage of tiled display wall is that multiple users can look at information at the same time. To utilize the advantage, we have developed a Graphical User Interface (GUI) for a mobile PC to control the enormous quantity of visualization contents on the tiled display wall by multiple users at the same time [10]. However, the GUI is difficult to execute while viewing various contents data on the tiled display wall when users operate the interactive control with a mobile PC. As a result, the use of GUI is expected to interfere by confusing the operation in collaborative works while viewing contents data on tiled display wall among some users.

Therefore, we need to develop a new user interface system to operate interactively with enormous amounts of content on the tiled display wall by some users while viewing the screen of the tiled display wall. An example of the user interface system that allows users to control for each piece of content on tiled display wall are functions such as movement of display location, scaling of window size, and hand-written annotation for each contents by holding or wearing the user interface in a natural state. For the future work, we propose an implement a mechanism to achieve these functions to support intellectual collaborative work using the tiled display wall.

6 CONCLUSION

In this paper, we have constructed tele-immersive environment with tiled display wall, and have studied the possibility of realizing intuitive operation and understanding in remote collaborative work by implementation of various collaborative applications such as the effective display of high-resolution visual contents and the interaction techniques for enormous contents in the environment. As a result, we have showed that the practical use of tiled display wall is useful in the construction of intellectual remote collaborative environment.

How does the network structure of standard-setters affect its standard-setting activity?

Kensuke Ogata[1]

[1]University of Nagasaki, 123 Kawashimo, Sasebo, 858-8580, Japan
(Tel: 81-956-47-6831)
[1]ogata@sun.ac.jp

Abstract: This article aims to explain the following question: how does the network structure of standard-setters affect their performance? This paper focuses on the activities and structures of FASB and IASB. It presumes that the standard-setters strategically alter the organizational structure and consequently change the activities. To identify the structures, this paper uses coreness analysis in network theory. According to the analyses, it follows as below. First, the FASB has recognized the survival-crisis due to the rise of IASB. Preventing from the crisis, the Board has sought to take alliances with the users and attempted to set lots of innovative standards. Second, to reinforce its position as a global ruler, the IASB has needed to acquire the trust of global and local regulators as well as the businesses. Then, the IASB has had to play as a coordinator with the preferences of broad constituencies and adopted the compromised standards slowly.

Keywords: accounting standard-setting, FASB, IASB, network theory

1 INTRODUCTION

The U. S. financial reporting standards setter, the Financial Accounting Standards Board (FASB) and the international counterpart, the International Accounting Standards Board (IASB) agreed upon the Norwalk Agreement, which both Boards decided to develop big projects, for examples, financial presentation, revenue recognition, financial instruments, fair value measurement, post-retirement benefits, lease, and business combinations, on September 2002. However, these projects except for business combinations project have been still under deliberation; furthermore each Board made different decisions in the business combinations project. The reason why both Boards couldn't obtain their consensus in developing these projects is thought that they should respectively have different preferences and ideas of accounting methods, and different standard-setting activities. How can we explain difference of the activities between FASB and IASB?

Throughout the history of FASB (Zeff [1]), it is founded that standard-setters could strategically alter the organizational structure by means of the shift of the member composition and the selection of members, in order to take care of problems which the Board faces. With this concept, it is thought that the difference of standard-setting activities between the FASB and the IASB could be explained on the difference of the facing issues and/or organizational structures. That is, the scheme is shown as follows: the facing issues affect the strategies of standard-setters; the strategies alter the organizational structures of the setters; and the structures change the activities of the setters. Following the premise, this paper aims to make clear what kinds of problems each Board face and what kinds of strategies they have respectively.

2 THE BEHABIOR MODEL OF THE STANDARD-SETTERS

2.1 The Characteristics of the Accounting Standard-Setting

Financial reporting standards are originally rules or guidelines which have to be followed when the management would prepare their financial statements for providing to various stakeholders and when the accountants audit these statements. Most importantly, these standards are thought to be necessary for the users of financial statements to help their making decisions on investment or credit. Therefore, the creation of new standards and the revisions or removals of existing standards can alter the quality and quantity of the accounting information; such information consequently make some kinds of stakeholders change their decision-makings and behaviors. Among these actors, the following two ones are significant: the public regulator and the business community.

2.2 The Behaviors of the Regulatory Agency and the Business Community

The regulatory agency delegates the authority of setting the standards to a specific standard-setter instead of providing them *per se*. In delegating the authority to the setter, the agency might usually be trust to the setters considerably; at the same time, the setter would develop the standards which are consistent with the agency's policy targets for the purpose of establishing its credibility. This mutual confidence consequently gives the setters discretion of setting standards (Büthe [2]). Obtaining the discretion, the setter comes to give considerations to the business community unduly and to establish the standards which are undesirable to the original policy targets and aims. With the frequent occurrence of such cases, the agency might make a judgment that the current setter could no longer fulfill their tasks, and decide to crate a new setter.

The accounting regulations are essentially meant to reduce discretion of companies on selecting accounting techniques in preparing their financial statements in order to increase the comparability among companies and to improve the companies' transparency. The business community is thus inclined to become opponents against the standard-setters. However, excessive opponents could not be rational to the business community, because these consequences replace the existing private-sector regulation with the public-sector to which the community can't easily access in developing standards (Kelly-Newton [3]; Mattli and Büthe [4]).

2.3 The Regulatory Behavioral Model of the Accounting Standard-Setter

Recognizing needs of certain standards, the setters would initially set the standards based on the fundamental theory or thought, i.e. the conceptual framework. In a large proportion of cases where the setters would establish significant standards, they face heavy oppositions from constituencies. Suppose that the setters would strategically take the most suitable action under every situation, it seems that they could change their behaviors depending on how they recognize the positions in which they are (see Figure 1).

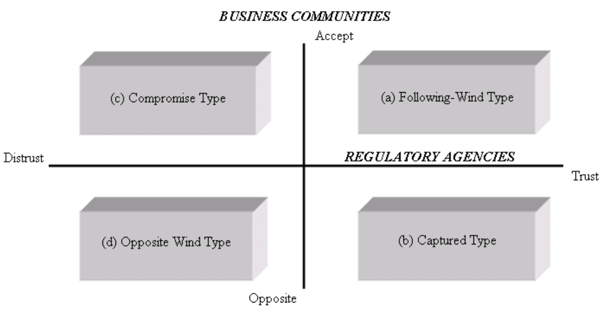

Figure 1: Behavioral Model of the Accounting Standard-Setters

Table 1 shows the behavioral model of standard-setter. This model illustrate as below: the setter at first recognizes the situation surrounding to it; based on the recognition, the setter prescribes its regulatory motivation; corresponding to the motivation, the setter strategically constructs the network; finally following the network, the setter sets the standards. Additionally, Figure 2 illustrates each network type in the behavioral model.

3. THE PERFORMANCES OF BOTH BOARDS

Table 2 shows the number of standards which each Board has respectively issued during 1991 to 2010. The FASB had issued 93 publications and the IASB had issued 98 standards during this term. The FASB had set less than 5 standards every year from 1991 to 2008; and thus it is hard to describe that the Board was the activist for setting accounting standards during this term. In contrast, the IASB had had two significant periods for actively issuing the standards: (a) from 1998 to 2000, for making ready to the completion of Core Standards, and (b) from 2003 to 2004, for providing the adoption of IASs/IFRSs in the EU jurisdiction.

Table 1: The Behavioral Model of Accounting Standard-Setter

	Following-Wind Type	Captured Type	Compromise Type	Opposite Wind Type
Situation	Regulatory agency trusts; Business community accepts.	Regulatory agency trusts; Business community opposites.	Regulatory agency distrusts; Business community accepts.	Regulatory agency distrusts; Business community opposites.
Regulatory Motivation	The setter would establish the standards, which it believes valid, based on the idea of investors' protection, because of growing its legitimacy. For the same reason, it would collect voices from some kinds of interested parties.	The setter would recover the acceptance from business leaders.	The setter would recover the trust from the regulatory agency. At the same time, it takes account of the business community for preserving the support from the community. Without its support, it might not set the standards.	The setter pursues to closely and directly formulate a new alliance with investors for keeping them on its side.
Network Structure	The setter attempts to build up the open network in order to easily gather the voices and ideas of various constituencies.	The setter would form the network with closer relations to business communities comparative to other stakeholders.	The setter would form the network with close relationship to business community as well as regulatory agency and investors.	The setter would form the network with closer and more directly relationships to investors rather than other stakeholders.
Activity of Setting Standards	The number of standards issued by the setter might be almost as same as the necessary number. Also, the contents can be similar to what it originally proposed to.	The number of standards issued by the setter would be less than what the setters need to establish. Also, in the case of being heavily criticized from the business leaders, the setter decides to cancel or postpone the projects or sets the standards which should have no real impacts.	The setter would establish the compromise standards which are incorporated into both preferences of the regulatory agency and the community at the same time. Also, the number of standards issued by the setter would be less than what the setter need to set because of spending considerable time and efforts for coordinating with some kinds of the interested parties.	The setter should establish the standards which it believes true. Therefore, the setter would establish standards as much as possible.

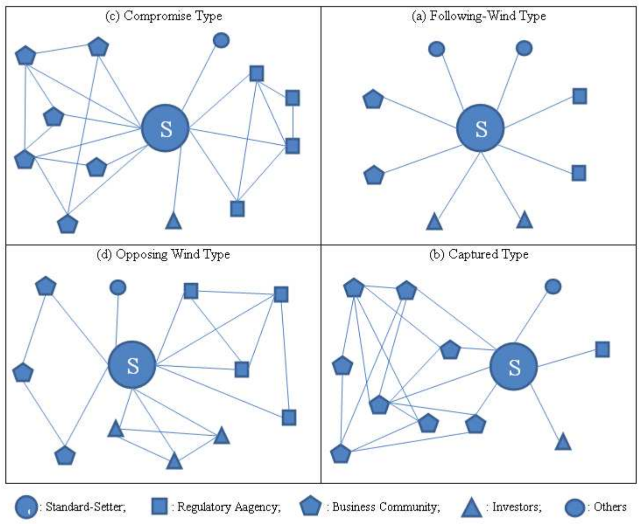

Figure 2: Four Types of Network Structures

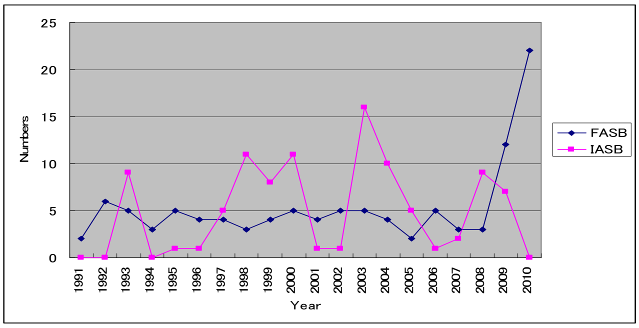
Focus on the activity of each Board in the last two years, 2009 and 2010. While the FASB had issued 21 standards and published the most number of standards in last 20 years, the IASB had set mere seven standards and hardly published the ones. The composition is drawn that the FASB actively attempts to set the standards; on the other hand, the IASB takes a passive stance for setting standards

Table 2: The Number of the Standards Issued by FASB and IASB



Next, turn to the preference of each Board in the standard-setting. According to some projects which have already completed recent years and has deliberated at this moment, it is noted that the FASB strongly aims to adopt the innovative standards which have been rarely used at present or never done by now; in contrast, the IASB takes negative attitude for setting these standards and thus has a tendency for permitting the current practices as alternatives with the innovative techniques.

4. METHODOLOGY AND DATA

4.1 Analytical Method

To illustrate the network structure of standard-setters, this article uses graph theory or network theory for specifying the structure of standard-setters. The researches applying the network theory to the accounting arena are listed as below: Perry and Nöelke [5], Richardson [6], and Ogata [7]. Network theory usually quantifies the relations measured among actors in the network and provides descriptions of structural properties of actors, subgroups of actors, or groups (Wasserman and Faust [8]). In addition, the theory attempts to describe the network structure and the relationship using a graph shown by nodes and edges.

This paper applies the continuous coreness analysis to identify the network structure of each Board. Here, the "coreness" mentions that who have a high density of ties within the network by many events in common. The coreness analysis can capture a density continuously (Borgatti and Everett [9]).

4.2 Using Data

In analyzing the network structure respectively, this article focuses on the "career path" which means that each member who belongs to any organizations of each Board would arrive at the organization with his/her backgrounds on the basis of their previous jobs and extracts the organization-to-organization relationship from such a data. By manifesting such relationships, it could seem to be clear that what organizations could take on the central positions of and establish their influence on each Board.

As of January 2011, the FASB had four main organizations (FAF, FASB, FASAC, and EITF) and six advisory groups (ITF, ITAC, NAC, PCFRC, SBAC, and VRG); the IASB had four organizations (IFRS Foundation, IASB, Advisory Council, and Interpretations Committee) and five groups (ARG, GPF, EBWG, IWG, and FIWG); and both Boards had some joint advisory groups (FCAG, LAWG, JIG, and FIAG). This research traced the careers of all members in these organizations and groups through their curriculum vitae disclosed in their belonging organizations as of January 2011. As a result, this article could gain the following data: on the FASB, 208 members had gotten engaged in 540 organizations; for the IASB, 233 members had related to 496 organizations.

5. ANALYTICAL RESULTS

5.1 The Results on FASB

Table 3 shows the result of coreness analysis on FASB. The shaded parts on this table indicate organizations and groups relating to the FASB. Also, Graph 1 depicts the network of FASB.

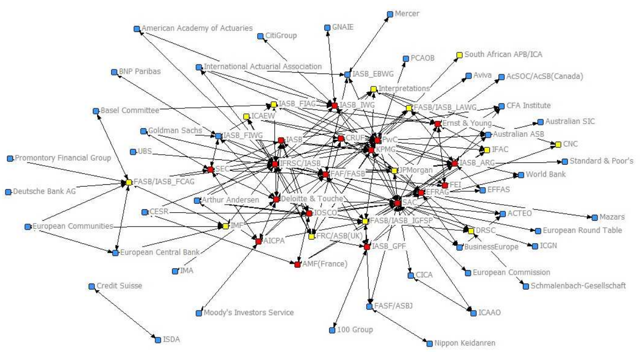
19	Interpretations member	0.092	47	Australian Securities and Investments Commission	0.039	75	Institute of International Finance	0.026
20	JPMorgan Chase & Co.	0.092	48	CNC (France)	0.039	76	International Corporate Governance Network	0.026
21	AICPA	0.089	49	European Round Table of Industrialists	0.039	77	Ministry of Economy, Trade and Industry(Japan)	0.026
22	Ernst & Young	0.089	50	Trustees	0.038	78	Ceylon Electricity Board	0.025
23	AMF (Financial Market Authority, France)	0.084	51	ASOC/AcSB (Canada)	0.037	79	Independent Television Network (Sri Lanka)	0.025
24	FEI	0.084	52	Bear Stearns & Co	0.037	80	Institute of Chartered Accountants of Sri Lanka	0.025
25	Lease Accounting Working Group (LAWG)	0.080	53	Mazars	0.037	81	Post Graduate Institute of Management (Sri Lanka)	0.025
26	DRSC e.V.(German Accounting Standard Committee)	0.078	54	South African APB/South African ICA	0.037	82	South Asian Federation of Accountants	0.025
27	Employee Benefits Working Group (EBWG)	0.076	55	PCAOB	0.036	83	Sumitomo Corporation	0.025
28	ICAEW	0.072	56	Credit Suisse First Boston	0.035	84	UK Financial Services Authority	0.025

By the analysis of the IASB, it follows that (1) similar to the case of FASB, the accounting professions are core actors within the IASB network; (2) the international authority actors like IOSCO, IMF, World Bank, and the Basel Committee naturally stand on core positions; (3) European actors comprised of (a) the administrative agencies and the corresponding bodies like EC, CESR, EFRAG,, and European Central Bank, and (b) the national standard-setters in the EU like ASB (U. K.), CNC (France), and DRSC (Germany); (4) the business community actors including FEI, BusinessEurope, European Round Table, and Nippon Keidanren construct a broad network; and (5) the user actors are not so core and shouldn't build up a broad network.

Graph 2: The Network of IASB as of January 2011



6. DISCUSSION

Above results suggests some following points. First, both Boards are in close contact with accounting professions. It means that, in the case of standard-setting called for high degree of expertise, accounting professions could play key roles. Second, the FASB of course makes tight relationship with the national actors; by contrast, the IASB establishes close ties to the European actors. It is generally predicted that local actors applying a specific set of standards which are endorsed in the jurisdiction stand on the central stances. In that case, with respect to the IASB, it is noted that European actors would be responsible for actively setting standards. Third, the IASB comes to formulate the tight relations with the international organizations, especially the international financial agencies. In fact, the IASB includes the representatives of IOSCO and Basel Committee as observers in the FIWG (IFRS Foundation 2011). Fourth, each Board constructs discrete relationship between the business community actors and the user actors. For the FASB, though being core, the business community actors have a closed network; being not so core, the user actors are created a broad network. For the IASB, the business community actors, especially European industrial associations establish a broad and close network; the user actors build up a coreless and closed network. From the viewpoint of the range of network, it can be stated as follows: the FASB seeks to formulate a more friendly relationship with investor actors in comparison with the business community actors; the IASB attempts to construct a more comfortable network for the business community actors than the user actors.

Such a structural outline is consistent with the description of performance of each Board from the quantitative and qualitative perspectives, as mentioned above: the FASB strongly proposes to adopt innovative techniques; the IASB develops a negative attitude for establishing such techniques. Although causing the businesses to impose heavy burdens including the increment of the amount of liabilities, the extreme volatility of earnings or losses, and the increasing costs of preparing for their financial statements, these techniques could provide the users with transparent and useful information.

In sum, it is noted as follows: for the FASB, putting weight on the user actors rather than the business community actors; the Board stands on the stage that it would issue a lot of innovative standards; in the case of the IASB, coordinating with the preferences of the European and the international actors as well as the business community actors, the Board couldn't positively develop so many standards and adopted the compromised standards allowing either the current practices or the innovative methods.

7. CONCLUSION

From the viewpoint of the behavioral model in this paper, the story of each Board is presumed as described below. First, the

FASB has recognized the crisis of its survival by itself due to the rise of IASB in the U. S. and global accounting standard-setting. To prevent from the survival-crisis, the Board has sought to take a new alliance with the users and consequently has tried to set lots of innovative standards. Second, having faced the endorsement problem, the IASB has needed to reinforce its position as a global ruler by means of acquiring the trust of international regulators and national and jurisdictional administrative agencies. In addition, on conducting its tasks, the Board can't afford to lose the support from the businesses, because the lost of their supports possibly causes these agencies to evaluate the inadequacy against the Board. Therefore, the IASB has had to play as a coordinator with the preferences of various kinds of the constituencies and has adopted the compromised standards at a slow pace.

There seem to be some implications of this paper. First, the behaviors of the accounting standard-setters have a possibility to depend on their network structures. Second, the networks have prospects of being strategically constructed by the standard-setters. And third, the strategies might be dependent on the situations with which the setters are facing. However, it is necessary to furthermore consider the validity of the model developed in this paper. To do so, we attempt to focus on the time-series transition of the network on the same organization.

Abstract: Stability is one of the important issues in the system studies of economic structures, investment's decisions, and government expenditures. We simplify the model of the stability and control of economic systems in this paper. Two important variables, the GDP and investment, are included in economic systems. We build a model to identify the stability in economic systems including these two variables. The stable control shows that the control should have inverse relation to the state of the systems. A system will be exploded if an immense control shock makes it reach an unstable equilibrium state. It indicates that the government investments or expenditures should decrease but not increase when the economic or government expenditure continues increasing.

Keywords: Government Investment or Expenditure, Euler Equation, Approximate Control

I. INTRODUCTION

Stability is very crucial for the system studies, such as economic structures, investment's decisions, and government expenditures.

Only recently has performance, which is based on graph theory, been extended and analyzed to assess structural change of network organizations.

Intuitively speaking, the stability is that the systems will keep some characteristics of its structure when its form or initial value varies in different ways. Hence, it is necessary to control the systems in order to keep it stable. In other words, the stability is to design a control such that a small perturbation does not have a great influence on the system [1].

Many researchers suggest different perturbation techniques in mathematics, physics and engineering. How should we, however, consider the stability to design a control in the economic systems?

Two very important variables, the GDP and investment, are included in the economic systems. Considering a system at any time *t*, its state can be described as a differential equation,

$$\frac{du}{dt} = g(u,v), u(0) = c \qquad (1)$$

where $u(t)$ represents a function for the GDP, du/dt=u', that is the derivative of $u(t)$, can be thought of as the investment, *v* is a control variable, and *c* is the initial state of $u(t)$. Since the function *g* is undetermined, this gives us a few troubles for analytically dealing with the stability and control. Therefore, we may let the function *g* be a simple form, for example, $g(u,v) = v$. Although this simple form can not quite illustrate the complex of the real economic systems, this is enough for our purpose of research

The main contribution of this paper is to suggest that for stability of the above simple form, the control is $u' = -u$, that is, the investment (for example, the government investment to rescue the market) should have inverse relation to the state of the GDP. The second contribution shows that the simple economic structure would become unstable when a big control perturbation (say, the government investment) happened.

The structure of this paper is as follows. In section 2, we build a new model and show the solution of the stability in economic systems. Section 3 analyzes stability of control. In section 4, we make a brief discussion about economic systems including government investment and expenditures. Section 5 contains some concluding remarks.

II. MODEL, SET-UP, SOLUTION and APPROXIMATE CONTROL

1. Model

Assume an economic system is described as equation (1), where we make $du/dt = g(u,v) = v$. We choose control variable $v(t)$ such that the variations of u and u' are very small on average. For instance, we want to determine a $v(t)$ such that

$$\min_{u'}\left\{\int_0^T [u^2+(u')^2]dt\right\} \qquad (2)$$

We may denote the functional $J(u)$ by $J(u):=\int_0^T [u^2+(u')^2]dt$.

2. Set-up

The basic problem is to determine the functional $J(u)$ well-defined. Our set-up here is $u'(t)\in L^2[0,T]$.

To make equation (2) have solution u, it is necessary to satisfy the Euler equation

$$-u''+u=0,\ u(0)=c,\ u'(T)=0 \qquad (3)$$

We see that this variation problem (2) becomes the Euler equation.

3. Solution and approximate control

Solute equation (3) and get the analytical solution

$$u=c\left(\frac{e^{t-T}+e^{-(t-T)}}{e^{-T}+e^{T}}\right)=c\frac{ch(t-T)}{chT} \qquad (4)$$

What we sometimes want to know is the characteristics of the control v (or u') when $T\to\infty$.

By equation (4), we obtain

$$u'=c\frac{sh(t-T)}{shT} \qquad (5)$$

After algebraic calculation, we further have $|u'+ce^{-t}|\le 2|c|e^{-T}$. In equations (4) and (5), we may explain the parameter c as the initial value of the equation system, that is, c is also the constraint or initial endowment for the system. If T is very large, we can get the approximate control $u'=-u$ [2].

III. MSTABILITY of CONTROL

C To illustrate the stability of control, we consider the following equation of pendulum

$$u''+au'+\sin u=g(t) \qquad (6)$$

where $g(t)$ is a control variable. In fact, the behavior of economic is somewhat similar to the motivation of pendulum. We know that $u(t)=0$ is one of its solutions, which correspond to its equilibrium if $g(t)=0$.

Could this system keep stable when a large control perturbation $g(t)$ is imposed on the system such that the system even reaches another equilibrium state, $u(t)=\pi$. After $g(t)$ disappears, then the new equation becomes

$$u''+au'+\sin(\pi+u)=0 \qquad (7)$$

In addition, assume that $u(0)=e_1$ and $u'(0)=e_2$.

$\sin(\pi+u)=-\sin u\approx -u$ when u is small. Therefore, we approximately have

$$u''+au'-u=0,\ u(0)=e_1,\ u'(0)=e_2 \qquad (8)$$

Characteristic roots of this differential equation is

$$\lambda_1,\lambda_2=\frac{-a\pm(a^2+4)^{0.5}}{2}$$

One of characteristic roots is positive and the other negative for whatever value of a. Hence $u(t)$ will explode when $t\to\infty$, that is, the system is unstable at $u(t)=\pi$ [3].

IV. DISCUSSION

In order to get a stable control, Section 2 shows that approximate control, for example, the government investment, should have inverse relation to the state of the GDP. Section 3 suggests that the system likely becomes more volatile if imposing an immense shock on it.

As a national GDP always continue highly increasing, decreasing instead of increasing government investment may stabilize the economic systems. There is surprisingly increasing in Chinese economic system in last decade as we know. 4 trillion Chinese Yuen (?) of economic stimulus plans, however, launched out into business in various government investments from 2008 to 2011. Does this stabilize or rescue the market? The answer seems to be obvious because high inflation, which could destroy the stability of economic systems, had occurred in 2011 in China.

Another example is London riots in 2011. Between 6 and 10 August 2011, many London districts and some other cities and towns in England suffered widespread rioting, looting and arson. Possible causes for the riots of many, however, it is not to be neglected that while a great deal of domestic expenditures had to pay, England government has paid a lot of war bills, such as Afghan, Iraq, and Libya wars. This violates the rule of stable control, which means that the control should have inverse relation to the state of the system, $u'=-u$.

V. CONCLUSION

We simply model the stability and control for economic systems. By Euler equation of variation method, we obtain the analytical solution for this system and the approximate control rule for stability. The stable control shows that the control should have inverse relation to the state of the system. Furthermore, by the analysis of pendulum's motivation, we see that a system will explode after an immense control shock makes the system reach an unstable equilibrium state.

These indicate that the government investments or expenditures should decrease but not increase when the economic or government expenditure continues increasing.

Abstract: Performance—an indicant of corporate efficient and effectiveness—is determined by many different factors, such as economic environment and coordination of managerial resources. Only recently has performance, which is based on graph theory, been extended and analyzed to assess structural change of network organizations. Only a few indexes based on graph theory have applied and analyzed in most recent research to measure the structural changes of network organizations. In order to develop a rational model, this empirical research attempts to establish the inter-relational linkages among multiple corporate performance indices. Specially, this paper seeks to assess corporate efficiency using the DEA analysis. Accordingly, the contribution of this research is to propose a new way to build a quantitative model that identifies the efficiency of each individual firm in Mazda's Yokokai Keiretsu.

Keywords: Degree, Closeness, Influence, Efficiency, the DEA

1 INTRODUCTION

Performance—an indicant of corporate efficient and effectiveness—is determined by many different factors, such as economic environment and coordination of managerial resources. Only recently has performance, which is based on graph theory, been extended and analyzed to assess structural change of network organizations. Only a few indexes based on graph theory have applied and analyzed in most recent research to measure the structural changes of network organizations. One of the important issues is to improve the efficiency in corporate management. The position of each individual firm in the Keiretsu instead of the input is calculated using graph theory in this paper. The contribution of this research is to propose a new way to build a quantitative model that identifies the efficiency of each individual firm in Mazda's Yokokai Keiretsu.

2 BACKGROUND

Recently most of the research on network analysis focused on a few indices to determine the position of each individual firm in the Keiretsu. Single index usually express only one aspect of the position. Much more indexes should be used to determine the precise position. Therefore, the authors selected the relevant indexes based on the previous research, and built a quantitative model called ICB (In-degree, Closeness and By-influence) model under the measurement results of the correlation coefficient in this paper.

Many useful indexes to identify the factors of the position have been developed recently.

Centrality index is one of the useful indexes. Basically it includes degree, closeness and betweenness. Degree is one of the centrality indexes to express a firm's potential communication activity. In transaction network, degree includes two categories: in-degree and out-degree, because transaction network is an asymmetric network organization. In-degree means a firm purchases the parts from other firms, and out-degree means a firm sells the parts to other firms. Closeness is another centrality index to express the distance from a firm to all other firms linking with it direct and indirectly. Two indexes are included in transaction networks. They are in-closeness and out-closeness. In-closeness is the summation of the length from a firm to all other reachable firms, and out-closeness is summation of the length from all other reachable firms to it. In transaction network, the firm is located at an easy position if its closeness value is low.

Table 1. Matrix of correlation coefficients between network indexes and corporate performance

		Out-degree	In-degree	Betweenness	Closeness	Influence	By-influence	Sales	Profit
Out-degree	Pearson’ correlation coefficient	1							
	Significant Probability (Two side)								
	N	89							
In-degree	Pearson’ correlation coefficient	-0.433**	1						
	Significant Probability (Two sid	0							
	N	89	89						
Betweenness	Pearson’ correlation coefficient	0.112	0.035	1					
	Significant Probability (Two sid	0.295	0.746						
	N	89	89	89					
Closeness	Pearson’ correlation coefficient	-0.329**	-0.389**	-0.194	1				
	Significant Probability (Two sid	0.002	0	0.068					
	N	89	89	89	89				
Influence	Pearson’ correlation coefficient	0.977**	-0.420**	0.101	-0.328**	1			
	Significant Probability (Two sid	0	0	0.348	0.002				
	N	89	89	89	89	89			
By-influence	Pearson’ correlation coefficient	-0.433**	0.999**	0.03	-0.386**	-0.419**	1		
	Significant Probability (Two sid	0	0	0.778	0	0			
	N	89	89	89	89	89	89		
Sales	Pearson’ correlation coefficient	-0.468**	0.766**	-0.018	-0.325**	-0.449**	0.794**	1	
	Significant Probability (Two sid	0	0	0.873	0.003	0	0		
	N	80	80	80	80	80	80	80	
Profit	Pearson’ correlation coefficient	-0.302**	0.676**	0.025	-0.345**	-0.288*	0.706**	0.916**	1
	Significant Probability (Two sid	0.009	0	0.834	0.003	0.013	0	0	
	N	74	74	74	74	74	74	74	74

Betweenness is another useful as an index of the potential of a firm to control communication, and it is also useful as an index of the network structure. Ito et al once measured centrality index including degree, closeness and betweenness to determine the positions of each individual firm [1]-[3].

Influence is a power to have impact on other firms. The power is called by-influence when the firm is affected by other firms. Therefore, influence will be divided into two parts: influence and by–influence in transaction networks. Kimura et al once proposed and calculated the influence in 2007 [4][5].

3 METHOD

3.1 Variables selection

Corporate performance index plays important roles in strategy formation. Not only labor productivity and return on investment, but also sales and profit are considered as the index of corporate performance. In this paper, the authors use sales and profit to express the corporate performance.

The following step is needed to build up an effective model.

1. Select the relevant variables which have potential effect on position-determination.
2. Calculate the correlation coefficients between the selected variables and corporate performance.
3. Determine framework of the model.

In this paper, all of these indexes are used as the input factor to determine sales and profit, the output of each firm.

The authors selected the degree, closeness and influence, and calculated the correlation coefficients between the selected variables and corporate performance.

3.2 Data collection

In order to measure all member firms’ capacity in networks, transaction data in the Yokokai Keiretsu was collected from personal interviews with senior managers as well as publications of the Japan Auto Parts Industries Association and Automotive Parts Publishing Company [6][7]. In addition, corporate performance as measured by Mazda’s revenues and profits for fiscal year 2004 was obtained.

In 2004, 177 component-parts suppliers were members of Mazda’s Yokokai Keiretsu. Seventy-two parts suppliers and Mazda have reciprocal transactional relationships, whereas 105 parts suppliers are singletons. A singleton means a firm which has no relationship with other firms in the network. Furthermore, a singleton is an isolate company whose in-degree and out-degree are both zero.

3.3 Outline of the ICB model

The transactional relationships among the companies were identified through graph modeling. A tie shows the percentage of the transaction between each pair of firms. We collected directed and weighted data to measure the selected indexes of each firm.

Table 2. Top ten firms of the selected firms in Yokokai

		In-degree (rank)		Closeness (rank)		By-influence (rank)	
1	Mazda Motor Corporation	774.277	(1)	0.0076	(1)	7.8296	(1)
2	Toyota Motor Corporation	648.605	(2)	0.0065	(3)	7.3868	(2)
3	Nissan Motor Co., Ltd.	541.188	(3)	0.0061	(7)	5.5561	(3)
4	Mitsubishi Motors	508.601	(4)	0.0068	(2)	5.1719	(4)
5	Honda Motor Co., Ltd.	487.596	(5)	0.0065	(4)	5.0799	(5)
6	Suzuki Motor Corporation	231.424	(6)	0.0058	(11)	2.4179	(6)
7	Denso Corporation	190.379	(7)	0.0061	(6)	1.9112	(7)
8	Fuji Heavy Industries Ltd.	172.414	(8)	0.0055	(35)	1.7821	(8)
9	Daihatsu Motor Co., Ltd.	129.521	(9)	0.0051	(60)	1.3638	(9)
10	Hino Motors Ltd.	52.446	(10)	0.0047	(66)	0.547	(10)
17	NSK Ltd.	4.026	(17)	0.0062	(15)	0.0403	(17)
12	Calsonic Kansei Corporation	12.278	(12)	0.0058	(8)	0.1233	(12)
40	Nisshinbo Industries, Inc.	0	(*)	0.0058	(9)	0	(*)
11	Hitachi, Ltd.	13.474	(11)	0.0058	(10)	0.1356	(11)

*: less than 21

All of the selected indexes are calculated as follows.

1) Degree

$$C_D(p_k) = \sum_{i=1}^{n} a(p_i, p_k); \quad k = 1, 2, \cdots, n$$

where

$a(p_i, p_k) = 1$; if and only if p_i and p_k are connected by a line

$= 0$; otherwise

2) Closeness

$$C_C(p_k)^{-1} = \sum_{i=1}^{n} (p_i, p_k); \quad k = 1, 2, \cdots, n$$

where

d(pi,pj): the number of edges in the geodesic linking p_i and p_j

3) Betweenness

$$C_B(p_k) = \sum_{i}^{n}\sum_{j}^{n} \frac{g_{ij}(p_k)}{g_{ij}} = \sum_{i}^{n}\sum_{j}^{n} b_{ij}(p_k)$$

where

$i>j$; $i \neq j \neq k$;

$g_{ij}(p_k)$: the geodesics linking p_i and p_j that contains p_k

g_{ij}: the geodesics linking p_i and p_k

4) Influence

$$T = A + R = A(I - A)^{-1}$$

where

A: direct influence

I: Identity matrix

In order to determine a significant relationship between input and output, then matrix of correlation coefficients is shown as Table 1. In-closeness and out-closeness cannot be calculated technically because the distance between two firms is infinity even when they are connected separately. For instance, Sumino sells the parts to NSK Co., Ltd, and NSK sells parts to Mazda, but Mazda sells nothing to Sumino. In this case, the distance between Sumino and Mazda is not computable because the distance is infinity. Therefore, the authors modified the transaction network as symmetric organization, and then calculated closeness.

It is easy to find that in-degree or by-influence has positive strong impact when out-degree or influence has negative impact on sales and profit in Table 1. Betweenness means a firm purchase parts from other firms and sells its products to other firms. Thus betweenness should have impact on sales and profit. Unfortunately no significance could be found between betweenness and sales, profit. It is obviously that sales

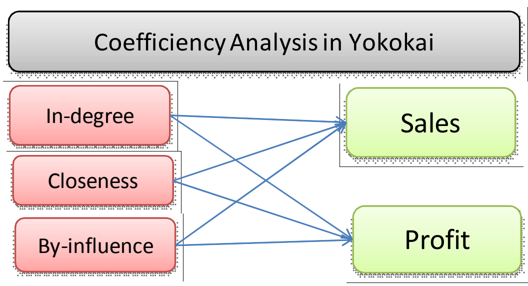

Fig. 1. Framework of the efficiency analysis

and profit are affected by degree, closeness and influence. In this paper, in-degree, closeness and by-influence is used as the input of efficiency. The framework is shown as follows.

4 RESULTS AND DISCUSSIONS

All of the selected indexes are measured based upon on the collected data. Top ten firms of the selected indexes are shown in Table 2. Figure 2 shows the position of all firms including the Yokokai.

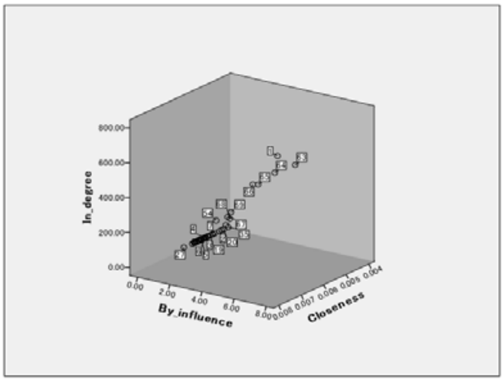

Fig. 2. Efficiency of the firms in Mazda's Keiretsu

The efficiencies of all the firms including parts makers and 11 car-makers are shown in Figure 3.

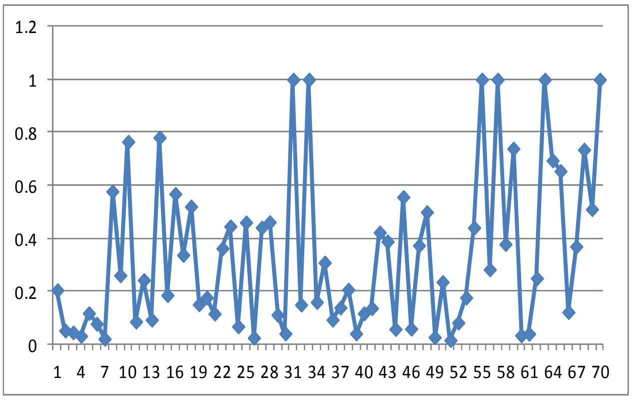

Fig. 3. Efficiency of each firm in Yokokai

In Figure 3, 6 firm's efficiency is 1. They are Pioneer Corporation (31), Hitachi, Ltd. (33), Tokai Rika Co., Ltd. (55), Toyota Gosei Co., Ltd. (57), Toyota Motor Corporation (64), and Hino Motors Ltd. (71). All of these companies are belong to the Toyota group. It is considered as the evidence that Keiretsu is no more centralized or integrated as it was before 1990. It is called loosening of Keiretsu alliance.

Ten firms with lowest value of efficiency are Kokusan Parts Industry Co., Ltd. (0.017), Nippon Thermostat Co., Ltd. (0.022), Ring Techs Hiroshima Co., Ltd. (0.023), Owari Precise Products Co., Ltd. (0.026), Hanshin Electric Co., Ltd.(0.031), Meiwa Industry Co., Ltd. (0.036), Sumino Kogyo Co., Ltd. (0.038), Hikari Seiko Co., Ltd. (0.043), and Kurashiki Kako Co., Ltd. (0.048). In order to improve the efficiency, the detailed relationship between the selected network indices and corporate performance should be analyzed.

5 CONCLUSION AND FUTURE WORKS

In this paper, the authors proposed a new model of efficiency analysis based upon the calculation of the position of each individual firm, such as degree, betweenness, closeness and influence. And the efficiency of all individual firms in the Yokokai is calculated. Further studies such as the solution to improve the input indices, the relationship between selected network indices and corporate performance are considered as the future works of this research.

Abstract: We think that recently, due to the advances in many application areas such as computer graphics, computer vision, image processing, robotics, and so on, it is useful for analyzing computation of three-dimensional information processing to explicate the properties of three-dimensional automata. From this point of view, we have investigated many properties of three-dimensional automata and computational complexity. On the other hand, the class of sets accepted by probabilistic machines have been studied extensively. As far as we know, however, there is no results concerned with three-dimensional probabilistic machines. In this paper, we introduce three-dimensional probabilistic finite automata, and investigate some accepting powers of them.

Keywords: Accepting power, Alternation, Chunk, Probabilistic finite automaton, Three-dimensional input tape

1 INTRODUCTION

Computer science is the systematized field of knowledge and technology concerning computation. Its realistic beginnings can be traced back to the formalization of the concept of an effective procedure and the advent of excellent digital computers. In theoretical computer science, the Turing machine has played a number of important roles in understanding and exploiting basic concepts and mechanisms in computing and information processing. It is a simple mathematical model of computers which was introduced by Turing [17] in 1936 to answer fundamental problems of computer — 'What kind of logical work can we effectively perform ?' If the restrictions in its structure and move are placed on the Turing machine, the restricted Turing machine is less powerful than the original one. However, it has become increasingly apparent that the characterization and classification of powers of the restricted Turing machines should be of great important. Such a study was active in 1950's and 1960's. On the other hand, many researchers have been making their effects to investigate another fundamental problems of computer science — 'How complicated is it to perform a given logical work ?' The concept of computational complexity is a formalization of such difficulty of logical works. In the study of computational complexity, the complexity measures are of great importance. In general, it is well known that the computational complexity has originated in a study of considering how the computational powers of various types of automata are characterized by the complexity measures such as space complexity, time complexity, or some other related measures. After that, the growth of the processing of pictorial information by computer was rapid in those days. Therefore, the problem of computational complexity was also arisen in the two-dimensional information processing. Blum and Hewitt first proposed two-dimensional automata — two-dimensional finite automata and marker automata, and investigated their pattern recognition abilities in 1967 [1]. Since then, many researchers in this field have been investigating a lot of properties about automata on a two-dimensional tape [17]. By the way, the question of whether processing three-dimensional digital patterns is much difficult than two-dimensional ones is of great interest from the theoretical and practical standpoints. In recent years, due to the advances in many application areas such as computer graphics, computer-aided design / manufacturing, computer vision, image processing, robotics, and so on, the study of three-dimensional pattern processing has been of crucial importance. Thus, the study three-dimensional automata as the computational model of three-dimensional pattern processing has been meaningful. However, it is conjectured that the three-dimensional pattern processing has its own difficulties not arising in two-dimensional case. One of these difficulties occurs in recognizing topological properties of three-dimensional patterns because the three-dimensional neighborhood is more complicated than two-dimensional case. Generally speaking, a property or relationship is topological only if it is preserved when an arbitrary 'rubber-sheet' distortion is applied to the pictures. For example, adjacency and connectedness are topological; area, elongatedness, convexity, straightness, etc. are not. During the past thirty years, automata on a three-dimensional tape have been proposed and several properties of such automata have been obtained. We have also studied about three-dimensional automata, and introduced many computational models on three-dimensional input tapes. On the other hand, the classes of sets recognized by one- or two-dimensional probabilistic finite automata and probabilistic Turing machines have been studied extensively [2-15, 18-22]. As far as we know, however, there is no results concerning with three-dimensional probabilistic machines. In this paper, we introduce three-dimensional probabilistic finite automata, and investigate some their accepting powers.

2 PRELIMINARIES

Let Σ be a finite set of symbols. A *three-dimensional tape* over Σ is a three-dimensional array of elements of Σ. The set of all three-dimensional tapes over Σ is denoted by $\Sigma^{(3)}$. Given a tape $x \in \Sigma^{(3)}$, for each integer $j(1 \leq j \leq 3)$, we let $l_j(x)$ be the length of x along the jth axis. The set of all $x \in \Sigma^{(3)}$ with $l_1(x)$=n_1, $l_2(x)$=n_2, and $l_3(x)$=n_3 is denoted by $\Sigma^{(n_1,n_2,n_3)}$. When $1 \leq i_j \leq l_j(x)$ for each $j(1 \leq j \leq 3)$, let $x(i_1,i_2,i_3)$ denote the symbol in x with coordinates (i_1,i_2,i_3). Furthermore, we define x [(i_1,i_2,i_3), (i'_1,i'_2,i'_3)], when $1 \leq i_j \leq i'_j \leq l_j(x)$ for each integer $j(1 \leq j \leq 3)$, as the three-dimensional input tape y satisfying the following conditions : (i) for each $j(1 \leq j \leq 3)$, $l_j(y) = i'_j - i_j + 1$; (ii) for each r_1, r_2, r_3, $(1 \leq r_1 \leq l_1(y)$, $1 \leq r_2 \leq l_2(y)$, $1 \leq r_3 \leq l_3(y)$, $y(r_1, r_2, r_3) = x(r_1 + i_1 - 1, r_2 + i_2 - 1, r_3 + i_3 - 1)$.

A *three-dimensional probabilistic finite automata* (denoted by 3-*PFA*) is a 6-tuple $M = (Q, \Sigma, \delta, q_0, q_a, q_r)$, where Q is a finite set of *states*, Σ is a finite set of *input symbols*, δ is a *transition function*, $q_0 \in Q$ is the *initial state*, $q_a \in Q$ is the *accepting state*, and $q_r \in Q$ is the *rejecting state*. An *input tape* for M is a three-dimensional tape over Σ surrounded by the *boundary symbols* $\#$'s (not in Σ). The transition function δ is defined on $(Q - \{q_a, q_r\}) \times (\Sigma \cup \{\#\})$ such that for each $q \in Q - \{q_a, q_r\}$ and each $\sigma \in \Sigma \cup \{\#\}$, $\delta[q, \sigma]$ is a *coin-tossing distribution* on $Q \times$ { East, West, South, North, Up, Down, Stay }, where East means ' moving east ', West ' moving west ', South ' moving south ', North ' moving north ', Up ' moving up ', Down ' moving down ', and Stay ' staying there '. The meaning of δ is that if M is in state q with the input head scanning the symbol σ, then with probability $\delta[q, \sigma]$ (q', d) the machine enters state q' and either moves the input head one symbol in direction d if $d \in$ { East, West, South, North, Up, Down } or does not move the input head if $d =$ Stay. Given an input tape $x \in \Sigma^{(3)}$ M starts in state q_0 with the input head on the upper northwest corner of x. The computation of M either accepts by entering the accepting state q_a or rejects by entering the rejecting state q_r. We assume that δ is denoted so that the input head never falls off an input tape out of the boundary symbols $\#$'s. M halts when it enters state q_a or q_r.

A *three-dimensional alternating finite automaton* (denoted by 3-*AFA*) is an alternating version of a three-dimensional finite automaton. See [1, 6, 7] for the formal definition of 3-*AFA*'s [16, 17].

Let $\mathcal{L}$[3-*PFA*] = $\{T \mid T = T(M)$ for some 3-*PFA* M $\}$. $\mathcal{L}$[3-*AFA*] is defined in the same way as $\mathcal{L}$[3-*PFA*].

3 RESULTS

This section shows that the 3-*PFA* is incomparable with 3-*AFA*. We first give several preliminaries to get our desired results. Let M be a 3-*PFA* and Σ be the input alphabet of M. For each $l, m, n \geq 1$, a three-dimensional type in $\Sigma^{l \times m \times n}$ is called an $(l, m, n) - chunk$ over Σ. For any (l, m, n)-chunk v with $l \geq 1$, $m \geq 1$, and $n \geq 2$, we denote by v($\#$) the pattern obtained from v by attaching the boundary symbols $\#$'s to v. Below, we assume without loss of generality that M enters or exits the pattern v($\#$). Thus, the number of the entrance points to v($\#$) (or the exit points from v($\#$)) for M is $4m + 8$. Let PT(v($\#$)) be the set of these entrance points (or exit points). .

Lemma 3.1. *Let* $L_1 = \{x \in \{0,1\}^{(3)} | \; l_3(x) \geq 2$ $\exists \; k \; (2 \leq k \leq l_3(x)) \; [x[(1,1,1),(l_1(x),l_2(x),1)] = x[(1,1,k),(l_1(x),l_2(x),k)]]$ *(i.e., the top plane of* x *is identical with some another plane of* x)]. *Then,* $L_1 \in$ 3-*AFA* — 3-*PFA*.

Proof: L_1 is accepted by the 3-*AFA* M with acts as follows. Given an input tape x with $l_3(x) \geq 2$, M existentially tries to check that, for each $i, j (1 \leq i \leq l_1(x)$, $1 \leq j \leq l_1(x)$ $x(i,j,k) = x(i,j,1)$. That is, ont the kth plane of $x(1 \leq i \leq l_1(x)$, $1 \leq j \leq l_2(x)$, $1 \leq k \leq l_3(x)$, M enters a universal statoe to choose one of two further actions. One action is to pick up the symbol $x(i,j,k)$, move up the symbol store in the finite control, compare the stored with the symbol $x(i,j,1)$, and enter an accepting state if both symbols are identical. The other action is to continue to move next tape cell (in order to pick up the symbol $x(i+1,j+1,k)$ and compare it with the symbol $x(i+1,j+1,k)$ and compare it with the symbol $x(i+1,j+1,1)$. It will be obvious that M accepts L_1.

We next show that $L_1 \notin$ 3-*PFA*. Suppose to the contrary that there exsts a 3-*PFA* M' recognizing L_1 with error probability $\epsilon < \frac{1}{2}$. For large m, let V(n) be the set of all the (2^n, 2^n, n)-chunks over $\{0, 1\}$. We shall below consider the computations of M' on the input tapes x with $l_1(x) = l_2(x) = 2^n$ and $l_3(x) = n$. Let c be the number of states of M'. Consider the chunk probabilities p(v, σ, τ) defined above. For each (2^n, 2^n, n)-chunk v in V(n), there are a table of

$$d(n) = c \times | \text{PT(v(}\#\text{))} | \times (c \times | \text{PT(v(}\#\text{))} | + 5) = O(n^2)$$

chunk probabilities, where fo any S, $\mid S \mid$ denotes the number of elements of S. Fix some ordering of the pairs (σ, τ) of starting and stopping conditions and let **p**(v) be the vector of these d(n) probabilities according to this ordering. By using the counting argument and reduction to absurdity, we can derive the following lemma. □

Lemma 3.2. *Let* $L_2 = \{x \in \{0,1\}^{(3)} \mid l_3(x) = 1\&$ (x *is of the form* 0^n1^n *for some* $n \geq 1$) $\}$. *Then,* $L_2 \in$ 3-*PFA* — 3-*AFA*.

Proof: It is showed the L_2 is recognized by a two-way probabilistic finite automaton with error probability ϵ for any $\epsilon < \frac{1}{2}$ [1, 3]. On the other hand, it is showed that alternating finite automata accept only regular sets. Thus $L_2 \in \mathcal{L}$[3-*PFA* — 3-*AFA*] by using the same technique. □

From Lemmas 3.1 and 3.2, we have the following theorem.

Theorem 3.1. 3-*PFA is incomparable with* 3-*AFA*.

4 CONCLUSION

It was introduced three-dimensional probabilistic finite automata 3-*PFA*^{c}'s and shown their some properties in this paper. We conclude this paper by giving the following open problems.

(1) Let 3-*PFA*^{c} (resp. 3-*AFA*^{c}) be the class of sets of cubic tapes recognized by 3-*PFA*^{c}'s with error probability less than $\frac{1}{2}$ (resp., accepted by 3-*AFA*^{c}'s). Is 3-*PFA*^{c} incomparable with 3-*AFA*^{c} ?

(2) Let T^c be all the three-dimensional connected tapes. Is Tc recognized by 3-*PFA*^{c}'s ?

(3) It will be interesting to investigate the properties of various three-dimensional probabilistic Turing machines.

(4) It will be also interesting to deal with the closure properties of 3-*PFA*^{c}'s.

Abstract: *To compete successfully in today's marketplace, it has become that success cannot rely solely on improving the efficiency of internal operations, and that collaboration with trading partners can build the foundation for a competitive advantage and substantially improve the bottom line. Companies need to efficiently manage the activities of design, manufacturing, distribution, service and recycling of their products, and services to their customers. The coordination and integration of these flows within and across companies are critical in effective supply chain management (SCM). In this paper, we define a two-stage supply chain model (a retailer and supplier). Based on results of simulations, we identify the factors*

Keywords: Supply Chain Management, Bullwhip Effect, Information sharing.

1 INTRODUCTION

Supply Chain Management deal with the management methods in World-Wide. For example, it is known as s uccess in DELL, Wal-Mart and so on. According to success auto-mobile industry in Japan, the company can be reduction cost by information exchange from phases of development to a close rate in many *keiretsu* companies.

In the auto-mobile industry of Japan, it is a group in the pr operties such as the system, and the subsidiary company succeeded in cost reduction by information exchange being performed frequently from phases of development to sales stage. We share management resources and information as one of the process in supply chain, and this is because, it is possible to reduce "waste" by optimizing the supply chain.

Based on the case study of the supply chain management, there are many theoretical studies in the bullwhip effect. Th e Supply Chain subjected to information distortion as demand information is processed and passed on from one part of the chain to another.

Information sharing among companies in a supply chain is regarded as an effective measure, the relations of WIN-WIN and the management strategy to relieve the Bullwhip Effect. In previous study, there are effective with the information sharing as measures to control Bullwhip Effect. However, it may be hard to do information sharing because there is not a clear standard and does not succeed in particular with the thing such as the profit allocation.

In this paper, we perform analysis about the effectiveness of the information sharing with the factor of inventory control. Moreover, using Excel Statistical software, we approach order policy and inventory cost with information sharing in management for decision making.

In Section2, we consider the study of Bullwhip Effect. We define the model for simulation in Section3.

In finally, we describe the inspection of information s haring with numerical analysis.

2 LITERATURE

The previous studies of Supply Chain Management co nsider two points. There are the cause and existence o f Bullwhip Effect, the reduction of Bullwhip Effect.

It was recognized that the inventory in the company played a role as the buffer which controlled uncertain demand conventionally. Therefore, it was thought that degree should be smaller than a change of the demand as for the change of the quantity of ordering of the company by holding extends stock.

In contrast, Forrester (1961) showed that width was rather bigger than a change of the demand to the company to the change of the quantity of ordering of the company using empirical evidence in American energy industry [3]. This phenomenon was called "Forrester phenomenon" using his name. These were pointed out in the TV production industry by Holt, Modigliani and Shelton (1968) and the auto-mobile industry by Blanchard (1983) [2], [4].

In a phenomenon to contradict it for such a previous way, Caplin (1985) [5] and Blinder (1986) [6] performed theoretical inspection and proved the existence. For example, it was considered that the model of the ordering (S, s) policy [5]. As a result, the fluctuation of the ordering by the retail proved the thing that was bigger than fluctuation of the demand when demand to retail was independent each other.

As an advanced study for Supply Chain became popular, it was cleared that the phenomenon occurred in an individual type of industry. This phenomenon was named "Bullwhip phenomenon" in American P&G Corporation.

In the cause study of Bullwhip phenomenon, we showed that the optimal stock quantities of the retail were correlation to demand in a period, and Kahn (1987) [7] derived that raise Bullwhip phenomenon by a backlog in the excessive demand. Sterman (1989) [8] considered the cause of Bullwhip phenomenon using a production distribution game (i.e. beer game). This game noted that fluctuation of the ordering is appeared; one of the causes in Bullwhip phenomenon is an information distortion. There were four mains. That is the error in demand forecasting, failure of supplies and the device of leadtime, price fluctuation.

Chen et al. (1998)[11] considered the influence of the Bullwhip phenomenon using two forecasting models in the moving average and exponential smoothing method. Moreover, Cheung and Zhang (1999) [12] described the cancellation of the customer ordering with being a cause of Bullwhip phenomenon. It is because that the canceled demand is similar with dummy demand. The customer and the Supply Chain partner considered it what kind of factor damaged retail and an upstream (wholesale, maker and so on).

Therefore, Chen et al. (2000) examined the influence of the demand forecasting to become the factor to cause Bullwhip phenomenon in the Supply Chain model consisting of one stage (retail) or two stages (e.g.between retail and manufacturer) in [14].

3 MODEL

In this section, we define three information sharing m ethods: demand information, demand forecasting and or der information (See Fig.1, 2 and 3).

3.1 The method of Information Sharing

The models of study consist of three information sharing methods. First, DIS is to approach for ordering in Stage 2 using a data of demand in Stage 1. Second, FIS is to use moving average method in the order of Stage 2 based on the trend of demand. Third, OIS is to approach ordering using the data of order in Stage1.

Therefore, If Stage2 exists out of stock, approach for using the data of order in Stage1. If not, used for Stage 2 directly as a data of order in Stage1.

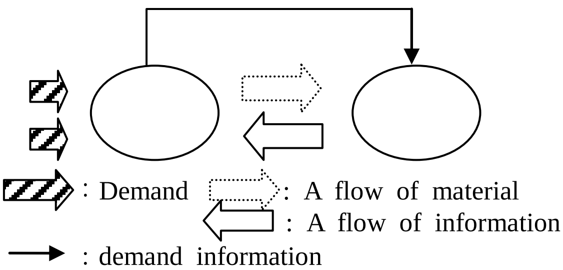

Fig1. DIS（Model 1）

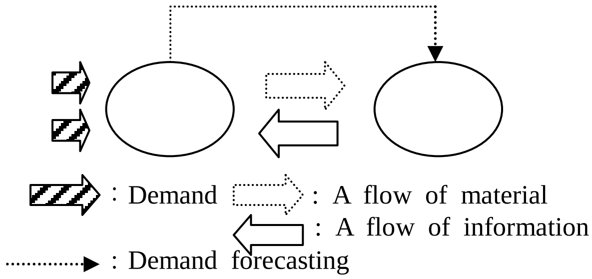

Fig2. FIS（Model 2）

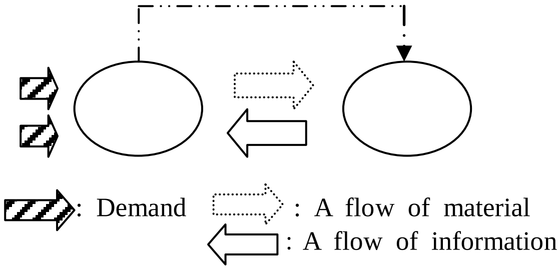

Fig3. OIS（Model 3）

3.2 Simulation

Using the model from Figure 1 to 3, we demonstrate simulation. The design of simulation is as follows.

Definition:

1. The simulation software use Microsoft Excel.
2. The number of trying simulation is fifty.
3. The data use average of simulation until fifty.

4 NUMERICAL ANALYSIS

In this section, we discuss inspection about the information sharing. At first, we inspect the Bullwhip Effect about three information sharing models.

In next sections, it considers the inventory cost and short age cost and inspects the elements of which inventory control are influenced by management strategy using the correlation.

Table1. The degree of phase1 until phase5

level / PA	phase1	phase2	phase3	phase4	phase5
MAP	3	5	10	15	20
LE	2	3	4	5	6
DA	55	60	65	70	75
DV	9	12	15	18	21
SS	1.65	1.76	1.89	2.05	2.33
OC	1	2	3	4	5

e.g) parameter stand for "PA", the moving average peri od stand for "MAP", the leadtime stand for "LE", the demand average stand for "DA", the demand variance stand for "DV", the safety stock stand for "SS", the o rdering cycle stand for "OC".

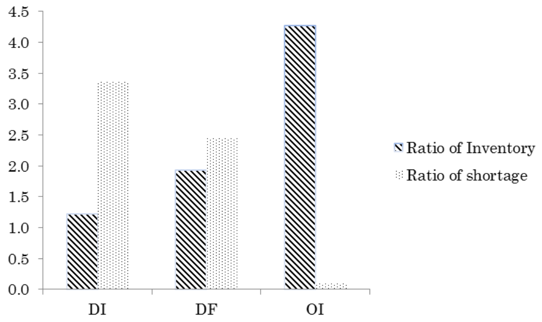

Fig4. Inspection of Information Sharing

4.1 Inspection of Bullwhip Effect

At first we discuss the inspection of the Bullwhip Effect. The inspection method uses the value that divided standard deviation of the quantity of ordering of Stage1 by standard deviation of the quantity of ordering of Stage2. It understands that an ordering information sharing is more effective to protect the degree of Bullwhip (See Fig.4).

4.2 Inspection of inventory and Shortage Cost

The inventory ratio consists of inventory cost ratio in Stage1 and Stage2. At first, the demand information sharing understands that the ratios out of stock increase. This can control the inventory to use information of the final demand for an ordering policy of Stage2, however, trend of the quantity of demand changes increases out of inventory cost. As the demand forecasts see the cost of the inventory and shortage inventory, we can understand balance.

4.3 Inspection of management

We consider the amount of change from phase1 to phase2 in three information sharing models.

The case of demand information is to optimal the moving average period parameter in ratio of inventory, ratio of standard deviation and ratio of shortage. Moreover, in the case of demand forecast and ordering information, the ratio of inventory and standard deviation optimal the moving average period parameter and ordering cycle parameter, respectively.

Finally, the correlation describes the higher significant relation in demand information and demand forecast sharing.

5 CONCLUSION

In this study, we performed inspection of the information sharing from three models. When demand forecasting and ordering information sharing were the same tendencies and changed two factors.

It is understand that demand information sharing and demand forecasting should discuss about a strategy with the same tendency.

Abstract: Robots have been playing an important roles on our life. In various field such as entertainment, military, space and medical fields, the precise control is required according to the increase of the importance on robot. In robot manipulator position control problem, modeling robot inverse dynamics is important because it can allow accurate robot control using computed torque control and PD control with computed feedback. However, modeling rigid-body inverse dynamics is not simple and not accurate in some case, because of unmodeled nonlinearities such as hydraulic cable dynamics, complex friction or actuator dynamics. Instead of rigid-body dynamics, nonparametric regression such as Locally Weighted Projection Regression (LWPR), Gaussian Process Regression (GPR) is proposed as alternative. Locally Weighted Projection Regression is fast, but it is difficult to tune because of many user-parameters. Gaussian Process Regression has high accuracy but low computation speed. In other word, high complexity of computation is drawback of Gaussian process regression. In Gaussian Process Regression, the inverse of Gram matrix is a significant problem and it dominates the computation time. To improve the low computation speed, there are many methods such as approximation method and Local Gaussian Process Regression (LGPR). In approximation method, the approximation of inverse of Gram matrix is proposed and in local Gaussian Process Regression, the training data is divided into local training data using Gaussian kernel. It generates M local models. After partitioned the training data, the local model is trained. When test data is given, each local model predicts the local prediction. The total prediction value is weighted average of M local prediction values. The weight is a similarity measure and it can be calculated by Gaussian kernel. Local Gaussian Process Regression In this paper, Modified Local Gaussian Process Regression (MLGPR) is suggested for improving accuracy and computation time of Local Gaussian Process Regression. Modified Local Gaussian Process Regression is used adaptive method for partitioning the training data. Modified Local Gaussian Process Regression uses multiple model generation threshold w_{gen} values depending on the local target variance. Proposed method is demonstrated by 2-dimension regression example and learning inverse dynamics of SARCOS arm. The result of simulations will be compared with other method such as Gaussian Process Regression, Local Gaussian Process Regression. As a result, the accuracy of Modified Local Gaussian Process Regression is improved and computation cost is reduced. The result represent Modified Local Gaussian Process Regression has low computation cost as compared with Local Gaussian Process Regression.

Keywords: inverse dynamics, machine learning, Gaussian Process Regression, Local Gaussian Process Regression

1 INTRODUCTION

Robots have been studied and applied in various field such as entertainment, military, space and medical fields. The precise control is required according to the increase of the importance on robot. For more precise control, more precise models of inverse dynamics is needed. In other word, precise models of inverse dynamics allow the effective control [1] [2]. However, finding precise models of inverse dynamics is difficult in some cases because of unmodeled nonlinearity. This modeling error comes from hydraulic cable dynamics, complex friction or actuator dynamics [3]. To solve this problem, the alternative method which is using nonparametric regression method is proposed. The nonparametric regression method is a kind of supervised learning, and it is more flexible than parametric regression. This method predicts inverse dynamics model from pre-measured data [6]. The most common used nonparametric regression methods are Locally Weighted Projection Regression (LWPR) [4], Gaussian Process Regression (GPR) [5] and Support Vector Regression (SVR). Although LWPR is fast ,accurate and incremental learning is possible, it is hard to tune due to many user parameters. GPR has high accuracy but its computation cost is increased when the data is large. To overcome the high computation cost, Local Gaussian Process Regression (LGPR) [3][7][8][9] is proposed. LGPR is an algorithm which combines the accuracy of GPR method on one region with the good capability of LWPR to split the input domain into regions [6]. The more detail regression methods are well organized and summarized in [6].

In this paper, Modified Local Gaussian Process Regression (MLGPR) is suggested for improving accuracy and computation time of LGPR. In section 2, Gaussian Process Regression and Local Gaussian Process Regression are presented in detail. I propose Modified Local Gaussian Process Regression (MLGPR) in section 3. MLGPR is used adaptive method for partitioning the training data. In section 4, the simulation of modified local Gaussian Process Regression is demonstrated. The result of simulation will be compared with other method such as Gaussian Process Regression, Local Gaussian Process Regression. In section 5, we suggest conclusion.

2 LOCAL GAUSSIAN PROCESS REGRESSION

2.1 Gaussian Process Regression

A Gaussian Process is completely specified its mean function and covariance function. The covariance function $k(\mathbf{x}, \mathbf{x}')$ can be any positive semi-definite functions. The square exponential(SE) covariance function is frequently used and are given by:

$$k(\mathbf{x}_p, \mathbf{x}_q) = \sigma_f^2 \exp(-\frac{1}{2}(\mathbf{x}_p - \mathbf{x}_q)^T \mathbf{M}(\mathbf{x_p} - \mathbf{x_q})) \tag{1}$$

where σ_f^2 is data variance and $\mathbf{M}$ is the symmetric matrix and it represent distance measure. $\theta = [\sigma_f^2, \{\mathbf{M}\}]^\mathbf{T}$ is the hyperparameters of a Gaussian Process.

Consider a set of *n* training data $\mathbf{X} = [\mathbf{x}_1, \mathbf{x}_2, ..., \mathbf{x}_n]$ and $\mathbf{y} = [y_1, y_2, ..., y_n]$. Using the training data $(\mathbf{X}, \mathbf{y})$ and a new data point $\mathbf{x}_*$, we want to know the predictive distribution of the corresponding $\mathbf{y}_*$. The joint distribution of the training outputs, $\mathbf{y}$ and the test outputs, $\mathbf{y}_*$ is

$$\begin{bmatrix} \mathbf{y} \\ \mathbf{y}_* \end{bmatrix} \sim N\left(\mathbf{0}, \begin{bmatrix} K(\mathbf{X},\mathbf{X}) & K(\mathbf{X},\mathbf{x}_*) \\ K(\mathbf{x}_*,\mathbf{X}) & K(\mathbf{x}_*,\mathbf{x}_*) \end{bmatrix}\right) \tag{2}$$

From the joint distribution, the predictive distribution is

$$\begin{aligned} &\mathbf{y}_*|\mathbf{x}_*, \mathbf{X}, \mathbf{y} \sim N(\bar{\mathbf{y}}_*, \mathrm{cov}(\bar{\mathbf{y}}_*)) \\ &\bar{\mathbf{y}}_* = K(\mathbf{x}_*, \mathbf{X})K(\mathbf{X}, \mathbf{X})^{-1}\mathbf{y} = k_*{}^T \boldsymbol{\alpha} \\ &\mathrm{cov}(\bar{\mathbf{y}}_*) = K(\mathbf{x}_*, \mathbf{x}_*) - K(\mathbf{x}_*, \mathbf{X})K(\mathbf{X}, \mathbf{X})^{-1}K(\mathbf{X}, \mathbf{x}_*) \end{aligned} \tag{3}$$

The computation cost for predictition is dominated by inverse of K^{-1}. It is about $O(n^3)$, where n is the number of training data. For large problem, computation cost increases rapidly. This is main weakness in Gaussian Process Regression. For solving this problem, Local Gaussian Process Regression [3] is suggested.

2.2 Local Gaussian Process Regression

A Local Gaussian Process Regression(LGPR) proposed for reducing computation cost of GPR is inspired by local weighted regression and Gaussian Process Regression. The procedure of LGPR is as follows: Firstly, the training data is partitioned into M local training data. here, the weight w_i which is similarity measure can be used for partitioning the training data. After local Gaussian Process model is partitioned, for each test data $\mathbf{x}_*$ the prediction of local model $\bar{y}_i(\mathbf{x}_*)$ can be calculated by using eq(3). Finally, the prediction of entire model $\hat{y}(\mathbf{x}_*)$ is given by weighted mean of all local model predictions.

$$\hat{y}(\mathbf{x}_*) = \frac{\sum_{i=1}^M w_i(\mathbf{x}, \mathbf{c_i})\bar{y}_i(\mathbf{x}_*)}{\sum_{i=1}^M w_i(\mathbf{x}, \mathbf{c_i})} \tag{4}$$

where, i is the number of local models. The partitioning algorithm of LGPR is represented in Algorithm 1 and the prediction algorithm of LGPR is represented Algorithm 2. The method for updating Cholesky matrix $\mathbf{L}$ and prediction vector $\boldsymbol{\alpha}$ is presented in [3].

Using LGP regression the computation cost can be reduced from $O(n^3)$ to $O(n_1^3 + n_2^3 + ... + n_k^3)$ where k is the number of local model, $n_1 + n_2 + ... + n_k = n$.

3 MODIFIED LOCAL GAUSSIAN PROCESS REGRESSION

3.1 Issue of Local Gaussian Process Regression

In the preceding sections the computation cost which is the problem of GPR can be reduced by using local weighted regression. But now the problem of LGPR is how to choose the number of local model, in other word, how to divide the training data. According to determination of local training data, the computation cost and accuracy of LGPR can be changed. This represents the importance for dividing of local model. In LGPR algorithm, the training data is partitioned by using similarity measure w, and model generation threshold value w_{gen}. The w_{gen} is open parameter and there's no rule to choose w_{gen}. If w_{gen} is too large, many local model will be generated and the number of training data in each local model is too small. Although it takes small computation cost, the local model with small data makes a ill distribution, i.e. accuracy of LGPR is decreased. If w_{gen} is too small, small local model with large training data is generated. Accuracy of LGPR will be increased but the computation cost will be high. LGPR loses the advantage of computation cost.

3.2 Adaptive method for partitioning of Training Data

In LGPR, every local model has only one fixed model generation threshold w_{gen}. Because the accuracy and computa-

Algorithm 1 Partitioning the training data with incremental model learning(Modified)

Input: new data point $\{\mathbf{x}_{new}, y_{new}\}$
for $i = 1$ to number of local models **do**
  Compute proximity to the ith local model:
    $w_i = k(\mathbf{x}_{new}, \mathbf{c}_i)$
end for
Take the nearest local model: $v(i) = \max_i w_i$
if $v(i) < w_{gen}(i)$ **then**
  Insert $\{\mathbf{x}_{new}, y_{new}\}$ into the nearest local model:
    $\mathbf{X}_{new} = [\mathbf{X}_i, \mathbf{x}_{new}]$, $\mathbf{y}_{new} = [\mathbf{y}_i, y_{new}]$
  Update the corresponding center: $\mathbf{c}_{new} = mean(\mathbf{X}_{new})$
  Update the Cholesky matrix, $\mathbf{L}_{new}$ and the prediction vector, $\boldsymbol{\alpha}_{new}$ of local model
  if the maximum number of data point is reached **then**
    delete another point randomly
  end if
  Compute $\boldsymbol{\alpha}_{new}$ by back-substitution
  Update w_{gen} {This is the new part of MLGP}
  if $\mathrm{Var}(\mathbf{y}_{new}) > \mathrm{E}(\mathrm{Var}(\mathbf{y}))$ **then**
    $w_{gen}(i) = w_{gen}(i) - \delta$
  else
    $w_{gen}(i) = w_{gen}(i) + \delta$
  end if
else
  Create new model:
    $\mathbf{c}_{i+1} = \mathbf{x}_{new}$, $\mathbf{X}_{i+1} = [\mathbf{x}_{new}]$, $\mathbf{y}_{i+1} = [y_{new}]$
  Initialize of new Cholesky matrix $\mathbf{L}$ and new prediction vector $\boldsymbol{\alpha}$
end if

Algorithm 2 Prediction for a query point

Input:query data point $\mathbf{x}_*$, M
Determine M local models closest to $\mathbf{x}_*$
for $i = 1$ to M **do**
  Compute proximity to the ith local model:
    $w_i = k(\mathbf{x}_*, \mathbf{c}_i)$
  Compute local prediction using kth local model:
  $\bar{y}_i(\mathbf{x}_*) = \mathbf{k}(\mathbf{X_i}, \mathbf{x}_*)^T \boldsymbol{\alpha}_i$
end for
Compute weighted prediction using M local models:
$\hat{y}(\mathbf{x}_*) = \frac{\sum_{i=1}^{M} w_i \bar{y}_i(\mathbf{x}_*)}{\sum_{i=1}^{M} w_i}$

tion cost of LGPR are changed depending on w_{gen}, using same w_{gen} on all local model is inefficient. When a local target variance $\mathrm{Var}(\mathbf{y}_{new})$ is large, the result of LGPR can't predict the original distribution. To use small w_{gen} for improving accuracy of LGPR makes the number of local training data large and makes computation cost high. On the other hand, when a local target variance $\mathrm{Var}(\mathbf{y}_{new})$ is small, the result of LGPR is good, even use of large w_{gen}. So it is required change of w_{gen} depending on local target variance $\mathrm{Var}(\mathbf{y}_{new})$ and use different w_{gen} for local models. Therefore it makes a sense to set large w_{gen} to reduce computation cost, when local target variance is small. When local target variance is large, small w_{gen} is used for improving accuracy of prediction. This is a key idea of MLGPR. Now every model has own w_{gen} values and it can be changed according to local target variance. If the w_{gen} of ith local model is bigger than mean of local target variance $\mathrm{E}(\mathrm{Var}(\mathbf{y_i}))$, w_{gen} is decreased as much as δ. It means that accuracy of LGPR is increased using more training data, when the target variance is high. If the w_{gen} of ith local model smaller than mean of local target variance $\mathrm{E}(\mathrm{Var}(\mathbf{y_i}))$, w_{gen} is increased as much as δ. It means that computation cost of LGPR is decreased by reducing the number of training data, when the target variance is low. Modified method for partitioning training data is included in Algorithm1.

3.3 Accuracy and Computation Cost of MLGP

Table.1 shows a comparison of computation cost GPR, LGPR and MLGPR. In GPR, computation cost for calculation of K^{-1} is about $O(n^3)$. In LGPR, the computation cost can be reduced from $O(n^3)$ to $O(n_1^3 + n_2^3 + ... + n_M^3)$ due to using a local prediction, where n is the number of training data, M is the number of local model and n_i the number of local training data. In MLGP, the computation cost for calculation of K^{-1} is $O(n_{m1}^3 + n_{m2}^3 + +n_{mM}^3)$ where n_{mi} the number of local training data , mM is the number of MLGPR local model. The computation cost for prediction is $O(n)$ in GPR, $O(n_iM)$ in LGPR and $O(n_{mi}M)$ in MLGPR. Here, n_{mi} is bigger than n_i, when the variance of ith model is bigger than variance of target. Otherwise n_{mi} is smaller than n_i. Thus the computation cost of MLGPR is usually lower than one of LGPR.

Table 1: The table of computation cost

Method	For calculation of K^{-1}	For prediction
GPR	$O(n^3)$	$O(n)$
LGPR	$O(n_1^3 + n_2^3 + ... + n_M^3)$	$O(n_iM)$
MLGPR	$O(n_{m1}^3 + n_{m2}^3 + +n_{mM}^3)$	$O(n_{mi}M)$

4 SIMULATION

In this section, simulation of Modified Local Gaussian Process Regression is demonstrated by 2-

dimension regression example and learning inverse dynamics of SARCOS arm. 500 noisy training data comes from the two dimensional function[4]: $y = \max\left[\exp(-10{x_1}^2), \exp(-50{x_2}^2), 125\exp(-5({x_1}^2 + {x_2}^2))\right] + N(0, 005)$. Fig.1 shows the result of regression using MLGPR. Its nMSE is 0.012 and it is lower than the LPGR one.

Fig.2 shows the result for inverse dynamics learning of SARCOS arm. The data set consists of 45,000 training data and 5,000 test data[1]. Fig.2(a) shows the nMSE of each link of robot. Fig.2(b) is Computation cost of MLGPR and LGPR. nMSE of MLGPR is lower than one of LGPR,

Fig. 2: Learning inverse dynamics of SARCOS arm

5 CONCLUSION

Modified Local Gaussian Process Regression(MLGPR) uses multiple model generation threshold w_{gen} values depending on the local target variance. It means each local model has own w_{gen}. If the w_{gen} of ith local model is bigger than mean of local target variance , w_{gen} is decreased for improving the accuracy. Otherwise, w_{gen} is increased for reducing computation cost. MLGPR is compared with GPR and LGPR. As a result, the accuracy of MLGP is improved and computation cost is reduced in simulation results.

Abstract: Biological systems in nature went through long evolution process that led to highly effective and efficient systems with excellent performance. Biomimetics is an interdisciplinary scientific research focuses on making nature as new sources of inspiration to study, analyze and design of creative and efficient engineering systems supported by innovative technologies. Smart materials are the foundation supporting the development of creative bioinpiration. Wide range of biologically inspired systems have been developed. However, engineering such biomimetic intelligent creatures were hampered by physical and technological constraints, and it is still a challenge. Actuators are essential elements within Mechatronical systems due to their important role in motion control systems and hence the development of modern actuators can be inspired from biological actuation systems in nature associated with different level of control. Making intelligent creatures that are actuated by biologically inspired modern actuators and artificial muscles would create new reality with great potentials. This paper provides the concept of Biomimetic as an interdisciplinary field, discusses the enabling technologies, and presents the development of biologically inspired actuators.

Keywords: Bioinspiration, Biomimetic, Intelligent creature, Modern actuators, and Artificial muscles.

I. INTRODUCTION

The evolution of nature led to the introduction of highly effective and power efficient biological systems in general and mechanisms in specific. Nature tested every field of science and engineering leading to inventions that work well, can adapt and last. Biological systems exhibit remarkable physical properties and have been a source of inspiration. Adopting mechanisms and capabilities from nature and the use of scientific approaches led to effective materials, structures, tools, mechanisms, processes, algorithms, methods, systems and many other benefits. Nature has always served as a model for mimicking and inspiration to humans in their efforts to improve their life. Humans throughout history have always sought to mimic the appearance, mobility, functionality, intelligent operation, and thinking process of biological creatures [1].

Maturing conventional technologies are associated with constraints and inadequate performance and this foster the demand for new solutions to maximize functionality while minimizing costs in energy and materials. The need to seek for new solutions is driving science to consider nature as biologically inspired model. The driving force behind attempting to merge biological principles and physics applications stems from the recognition that there are a number of areas where biological methods are more efficient, environmentally and ecologically friendly, and overall superior to current technology. Hence, understanding biological systems presents unique opportunities for wide range development of innovative ideas, paradigms, concepts and methods for engineering solutions, and helps to create new generations of smart materials, novel advanced structures, intelligent devices and technologies. Engineers are increasingly turning to biologists to understand and learn how living organisms function and solve problems. This leads to fuse the best solutions from nature with artificially engineered components to develop systems that are better in functions and efficiency than existing conventional approaches, and this science and technology became known as "Biomimetics" or the 'Mimicry of Nature'. Researchers diverge in precisely how they define biomimetics [2]. However, the use of inspiration instead of mimics is a more accurate description since mimicry is neither possible nor desirable.

Biomimetics can be defined as a new interdisciplinary scientific field featured by technology outcome (hardware and software), and it lies at the interface between biology, physics, chemistry, information, and engineering sciences [3]. Biomimetics focuses on making nature as a model of inspiration that would immensely help conscious abstraction of new principles and ideas, foster innovative design collections, find out new techniques and functionalities, seek new paradigms and methods, develop new materials, and design new streams of intelligent machines, robots, systems, devices, algorithms, etc. Biomimetics incorporates building novel materials at nature's scale and techniques drawn from naturally made substances, and resembles biological systems in structure and/or function as necessary. In the field of sensing and actuations, biomimetics devices can provide an efficient way of converting mechanical energy into electrical or chemical forms and vice versa. Scientists hope this blending may one day lead to stronger, cost- and energy-efficient, and intelligent products that are attractive ecologically.

Making creatures that look and behave like biological models, such as robots and toys that are greatly inspired by science fiction, have established perceptions and expectations that are far beyond the reach of current engineering capabilities, which are constrained by laws of physics and current state-of-the-art. The accelerating pace of the advancements in the field of biomimetics seems to make evident that the emergence of machines as our peers is imminent. Further advancement and the actual realization of these possibilities depends on a number of factors, including local acceptance of technological change, levels of technology and infrastructure investments, market drivers and limitations, and technology breakthroughs and advancements.

II. Biologically inspired Actuation

Actuation presents constraints to novel designs of intelligent mechanisms. Different types of actuators have been developed and used. Three types of conventional actuation are considered as the core of motion and force power for all motion based systems: Hydraulic, Pneumatic, and Electromagnetic actuators. These three come from two main types of power conversion. The first two are considered fluid machines in that they use fluid to create mechanical motion whereas the electric motor converts electrical energy into mechanical energy. Electromagnetic actuators are considered as practical solution for some applications, but these actuators are not ideal in providing the necessary and comparatively high torque and their overall power density is typically low. In addition, most electromagnetic devices cannot supply sufficient energy in a single stroke. Hence various complex transmissions means such as gear boxes, pulleys, etc. are required. However, heavy and inefficient electromagnetic actuation and mechanisms remain the convention not only for robots but also for other motion devices in general. The challenges of energy inefficiency, flexibility, stability and maneuverability, robustness and other technical motivations have been many in getting robots to perform bio-inspired motion, such as that of human, animal, insect, etc (The properties of the muscles vary by species). Hence, there are demands to develop technologies that would drive robots with efficient, high power density actuation, stability and speed in a variety of natural environment to achieve lifelike motion performance. The most significant difficulty in achieving lifelike performance or appearance is the lack of actuator technology that can truly mimic natural muscles even at its most basic performance.

Natural muscles are essential to the mobility and manipulation capabilities of biological creatures. Skeletal muscle accounts for nearly half of the total mass of the average adult human and is unique in its ability to actively modify its mechanical properties within tens of milliseconds to allow human and animals to rapidly react to different environment needs. Muscle is a linear actuator technology whose properties are very well suited to provide intermittent displacements and variable stiffness in organisms ranging from micrometers to meters in length. In addition, muscle is a multifunctional and a 3D nanofabricated element with integrated circulation system (delivers energy (fuel) and removes heat and waste), good work density, act as energy absorber and repair mechanisms. The efficiency and plasticity that characterize muscles arise from the properties of biomolecular motors. Muscle cells serve to self-organize, maintain, repair, and control the mechanical actions of large arrays of biomolecular motors. Tendon tissue is an extension of the extracellular matrix muscle (ECM) and muscle tendon junctions at the ends of each muscle fiber. The mechanical structures that make up this transition from muscle to tendon are critical for the transduction of force, work, and power between muscle tissue and the external environment [4]. In order to achieve desirable bio-inspired motion, such as human, animal, insect, etc. like motions, actuators must be able to reproduce the important features of natural muscle such as adaptable stiffness, high energy, moderate stress and large strain, response speed, efficiency, controllability and high cycle life. Although tremendous technological progress has been made and some artificial actuator technologies are already matching or exceeding muscle in strain, stress, and specific power they cannot yet perform as well as their biological counterparts, whether in terms of stability, fatigue-life or speed [5]. Biomimetics is not limited in mimicking the appearance of natural organisms and surpass the general properties of natural muscles, rather to achieve natural superior behavior and performance. The hope is to develop intelligent robots and machines that are independent, flexible, light in weight, high level of autonomy with capability to learn and adjust their behavior within their dynamic environment. This highlights the need and the necessity to develop actuators that emulate and supersede the behavior and performance of natural muscles. The potential to make such actuators is increasingly becoming feasible with the emergence of new development and technologies.

Many new types of actuators and materials have been used or currently under development to provide the necessary motion and force input. Examples of these actuators are Shape Memory Alloys, Electro-Rheological Fluids, Magneto-Active Transducers, single Crystal Piezoelectric ceramics, Carbon nanotubes, Electrostatic, and Electroactive Polymers. Although natural muscle is not the best in many individual categories of performance, such as strain, actuation power/stress, density, efficiency, actuation speeds, etc, they are still superior in their behavioral performance. This leads to the observation that conventional technologies fail to achieve lifelike motion not because they cannot match or exceed natural muscle performance in any given performance measure, but rather they fall short because their overall performance is not yet comparable to that of natural muscle [6]. In addition, the comparison between the available technologies shows that the electrostatic actuators meet all the stated individual categories of performance requirements for an artificial muscle except in actuation stress. The same comparison shows that dielectric elastomers (DE) can also achieve good overall performance compared to that of natural muscles. Elastomers are sufficiently compliant that large strains are induced and there is efficient coupling between the electrical energy input and mechanical energy output. Electroactive polymers artificial muscles (EPAM), and dielectric elastomers, electro-elastromers are two terms used to indicate to electroactive polymers. Hence, it would be possible to view dielectric elastomer technology as a way to increase actuation stress in electrostatic actuators or as a muscle-like actuator technology in its own right. Research into natural muscle shows that muscle has a number of important passive properties, such as passive elasticity, damping, braking functions (actively absorbing mechanical energy beyond simple damping), and even integrated sensing [7, 8], which help organisms achieve remarkable dynamic performance in the presence of obstacles and unexpected perturbations. While probably not all these functions are needed simultaneously to achieve lifelike motion and/or performance in many cases, the biomimetic actuator designer must consider the range of natural muscle capabilities and how they relate to the capabilities of a given actuator technology. While dielectric elastomers are not an exact analogue of natural muscle, they capture many of the important general features of natural muscle such as stress, high fracture toughness, damage tolerance, inherent vibration damping, large actuation strains, and elasticity. Dielectric elastomers have been operated successfully between 250 ^{o}C, and at -100 ^{o}C for silicones and -10 ^{o}C and 90 ^{o}C for acrylic [9]. However, there are still some of the limitations associated with this technology such as, the need to convert line or battery voltages, which adds cost and consumes volume. Also, pre-stretching mechanisms currently add substantial mass and volume. In addition, the dielectric breakdown can limit actuator yield especially when imperfections exist within films [9].

Synthetic and tissue based technologies of smart materials, such as the category of electroactive polymers (EAP), which includes EPAM, and the electrostrictive polymers [10-12] which, change its dielectric constant as part of the actuation mechanism. These technologies are rapidly emerging as quantitatively functional equivalents to muscle tissue. Electrostrictive polymers have comparable performance to many types of EPAM, but they are typically stiffer and have lower strains. EPAM has demonstrated promise for a variety of applications since it represents a significant difference not only from the conventional electromagnetic actuators but also from other emerging technologies like piezoelectric crystals and shape memory alloys (SMA). Piezoelectric polymers, such as PVDF material have found some non-robotic applications, but for robots, it has relatively low power and energy density. More recently, other types of polymers have been investigated, such as electrochemically actuated conducting polymers and gels (sometimes referred as ionic polymers) that are actuated through the use of chemical changes driven by low voltage signal [10]. In spite of the attractive features of these polymers in terms of low voltage operation and good actuation pressure, they have limited performance in relation to robotic applications because of their relatively slow speeds and low efficiency. Nickel Titanium (NiTi or Nitinol) are the most extensively studied SMA and used as artificial muscles because of their relative nontoxicity, reasonable cost and an electrical resistivity [13, 14]. Martensitic transformations are at the heart of the shape memory effect. Shape memory alloys can exert very large forces per unit area, operate at very high strain rates and undergo relatively large deformations [13, 14]. One of the difficulties that limit the use of SMA as impede their use as muscle-like actuators is the difficulty of controlling the length of NiTi fibers as they undergo a phase transformation (usually run between fully contracted and fully extended but not between). In addition, NiTi actuators have a limited cycle life and their shape memory effect degrades significantly at very large strains.

The most significant advantage EPAM has over electromagnetic actuators is energy density, i.e., more energy created per unit mass of the actuator itself. EPAM demonstrated energy density of 3.4 [J/g] and this density is about 21 times that of single crystal piezoelectric. The energy density gains from EPAM will bring mobility and flexibility to robots and other intelligent machines. In addition, with regards to shape memory alloy and piezoelectric technology, EPAM has a significant direct displacement advantage. While shape memory alloy and piezoelectric technology might get a 1 per-cent direct displacement, EPAM actuators can reach 20-30 per cent levels over long life cycles. With respect to conventional electromagnetic motors, EPAM has a significant advantage in power density. EPAM will provide the same level of power as an EM motor device but with a much smaller and lower weight form factor, much like the human muscle [15]. Furthermore, one can have multi layer of EPAM to get additional displacement or stroke as well as getting higher exerted forces. These layers can be constructed in multiple planar configurations or in linear rolls. In addition, EPAM can be patterned to pinpoint actuation in multiple locations. The overall displacement is a function of the area of EPAM, and the force exerted is a function of the number of layers of EPAM. These layers can be constructed in multiple planar configurations. The electrode layer of the EPAM can be patterned to achieve specific envelopes of motion. Further work will undoubtedly improve the match of EPAM to natural muscle.

Most of the presented newly developed actuator technologies require electrical energy and will generally rely on batteries when used in autonomous systems such as autonomous mobile robots. Cost, energy density and cycle life of fuel cells will alleviate this issue in systems on ground and space. Submersible use is challenging as both fuel cells and chemical oxidation reactions require the harvesting of dissolved oxygen and of air bubbles. Though batteries can be used for autonomous robots, current battery technology store too little energy and deliver it at too low a rate for prolonged or intense activity. The most advanced battery can only store about one-thirtieth of the energy that is stored chemically in fuels such as methanol. To solve these problems, new muscle fibers have been developed just like real muscles [6]. They can power themselves instead of relying on external electrical power. Among the developed artificial muscles of this type is a nickel-titanium alloy coated with platinum, which causes the fuel, currently methanol (hydrogen or alcohol could work, too) to react with oxygen, producing heat. The metal shrinks; the muscle flexes. The artificial muscle can apply 100 times as much force as real muscle. The other artificial muscle, currently less powerful, is made of a sheet of carbon nanotubes, tiny but super strong cylindrical molecules of carbon. Carbon nanotubes are hollow cylinders that are typically 1.2 nm in diameter or larger. Their structure is that of a single rolled sheet of graphite that can have lengths on the micrometer scale [16, 17]. The reaction of fuel and oxygen releases electrical charges that repel each other and cause the nanotube sheet to expand. In order to put such artificial muscles into robots will require solving other problems, like how to control the amount of fuel going to the muscles. In addition, the small to moderate strains characterizing current carbon nanotube actuators require some mechanical amplification, while the electromechanical coupling is poor and require energy recovery to achieve better efficiency. It is expected to overcome many of these issues and promise to provide better performance [17].

III. Biomimetics: challenges and Innovations

None of the available intelligent systems and mechanisms has yet reached the flexibility, adaptability and performance of biological systems, such as human, cheetah, bees, ants, birds, fish, etc. This has motivated researchers to look further into biological systems, navigation mechanisms and sensing capabilities that can be inspired and lead to better ways in the design and implementation of intelligent and autonomous system. Systems synthesis must guarantee an eventual consensus and coherence between behavioral and structural domains, as well as ensure descriptive and integrative features in the design. These can be achieved by applying the evolutionary biological systems developments. A highlight for some of the challenges may include the following,

a) Deep understanding of the diversity and efficiency of structure-function relationships in natural/biological systems at the element/component, subsystems and system levels. The interest lies not just in the abstraction of new and useful ideas from nature but also in the process by which this is done,
b) It is important to understand that nature may evolve different biological mechanisms to solve real world problems in different environments and circumstances,
c) Biological inspiration does not mean that the weaknesses of biology must be adopted along with the strengths,
d) Biological adaptation to a given environment emerge from a natural selection and evolving process that depends on the environment and the entire historical evolution,
e) It is necessary to keep in mind that the relation between understanding of biological organisms and developing engineered solutions is cyclic. Solutions arrived at by natural selection are often a good starting point in the search for answers to problems. The use of a biological metaphor to inspire new approaches does not necessarily imply that the biological side is well understood,
f) When seeking for an effective solution, it is important to identify the needs from engineering side and then try to match them with most effective biologically inspired solution(s) and find-out how best to implement them,
g) Biological systems are multifunctional and they cannot be optimized for any individual function separately. Hence, successful implementation of a particular biological function requires the ability to isolate irrelevant parts that do not contribute to the desired function.
h) Innovative solutions may require to consider the possibility of combining functions from different biological systems,
i) Biomimetic and bioinspiration demand to integrate biological materials and elements with man-made components/modules through bio-interfacing.

.

IV. Conclusions

By studying and analyzing biological systems, one may be able to derive or understand the relevant principles and use them to help solve engineering problems. However, the main challenge facing the development of biologically inspired actuators is the available technology, materials and the methods of fabrication as it is still in their infancy compared to nature's evolution. Biomaterials are expected to become the dominant focus of materials research, as it would lead to down-sizing of engineered components and the up-scaling incorporation of biomimetic concepts and processes. Finally, in order to achieve desirable lifelike motion, actuators must be able to reproduce the important features of natural muscle.

Abstract: Many ubiquitous systems and technologies have been developed as of now. As known the goal of ubiquitous computing is to achieve the well-being life. There are four different aspects for achieving ubiquitous computing, namely, they are within the computing paradigm, technical principle, application domain and application space. Nowadays, ubiquitous city (U-City) is the most applicable domain in the world. Therefore, the talk will mainly introduce and discuss an overview of the U-City idea and the known ubiquitous computing systems as well as new trends in this field.

Keywords: Ubiquitous computing, intelligent system, smart computing, ubiquitous city

1 INTRODUCTION

Ubiquitous computing was started in 1984 by Mark Weiser in USA [1]. Ubiquitous computing is roughly the opposite of virtual reality**.** Usually, virtual reality puts people inside a computer-generated world, but ubiquitous computing forces the computer to live out here in the world with people. Virtual reality is primarily a horse power problem; ubiquitous computing is a very difficult integration of human factors, computer science, engineering, and social sciences. Ubiquitous computing is a post-desktop model of human-computer interaction in which information processing has been thoroughly integrated into everyday objects and activities.

The core technology of ubiquitous computing is an autonomic collaboration model for ubiquitous fusion services in ubiquitous computing environment. To do some action in ubiquitous computing, many elements coordinate to complete such action. Ubiquitous networking in ubiquitous computing is completed by the collaboration of many types of networks, city technologies, city sociology and governance.

Therefore, in this paper I will explain and the main technologies and applied services in ubiquitous computing, particularly within the developing aspect of ubiquitous cities. I will also give more details and explain in examples more about the new trends of ubiquitous computing at the present time and what is expected to take place in this area of research in the near future.

2 UBIQUITOUS COMPUTING PARADIGM

2.1 Ubiquitous essential elements

In Fig.1, in computerized generation, industrial society paradigm was popular. That means that making some products by industry was so important at that time.

After that as time goes by, in 'e' generation and 'u' generation, information society paradigm is more popular. That mans that information is very important thing.

Nowadays new paradigm is necessary. Smart society is dawning. If we disregard this changes or needs, we will degenerate from informatization ages. Smart paradigm is just an extension of ubiquitous paradigm, so called post-ubiquitous age.

Main keywords in new paradigm are the power of people, collective intelligence and new ecosystem. The power of people use Mobile device and social media increasing the power of people in life. Collective Intelligence is the creation of value by collective intelligence as well as collective power. New Ecosystem is the creation of additional value by new ecosystem using open as well as sharing.

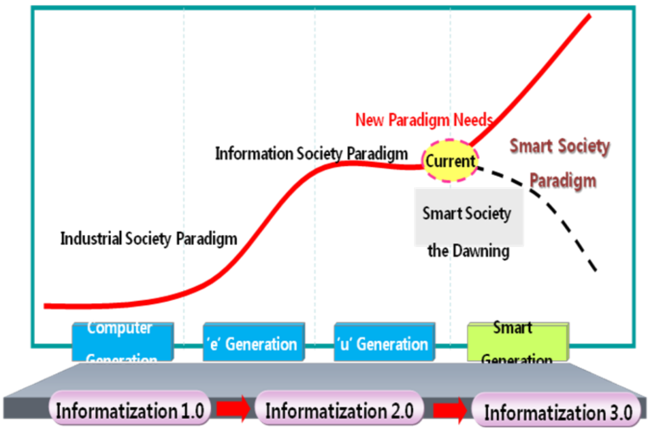

Fig.1. IT generation

Actually, the goal of ubiquitous computing is to make the safety, security and peace of mind society. The key technology to be a ubiquitous society is ubiquitous sensor network, in short USN. There are many application areas that use USN, such as home control, health medical care, welfare, hospital, school or education, traffic, culture, sports, environments, tracking of produce, anti-disaster, city security, etc.

Human will, in an ambient intelligent environment, be surrounded by intelligent interfaces supported by computing and networking technology that is embedded in everyday objects such as furniture, clothes, vehicles, roads and smart materials-even particles of decorative substances like paint. Ambient intelligent is the vision of the world in which different classes of smart players are proactively assisted by the environment [2].The environment is able to aware of the smart player's current situation and his interact within his environment and of its own current state. And then the interpretation of those occurrences into smart player's goals and accordingly into possible reactions is activated. The translation of the interpreted goal into strategies to adapt itself to the smart player's needs is performed in ubiquitous computing. Ubiquitous Space [2] is the space that objects collaborate seamlessly and automatically to achieve user's or community's goal for supporting u-Society and u-Life in Fig.2.

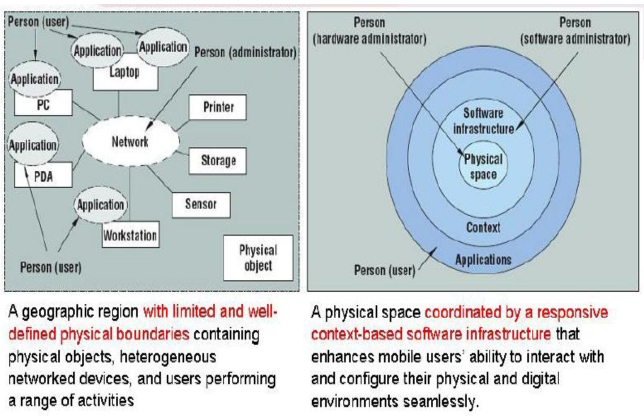

Fig. 2. Ubiquitous space

To be in intelligent ubiquitous system, there are three technical principles of ubiquitous space: infrastructure with situation-awareness, system with autonomic management, service with self-growing intelligence. Already, the mega trend goes with the ubiquitous scenario according to the suggestions given by Mark Weiser 20 years ago [1].

Before 21 the century, person-to-person is the mainstream of multimedia intelligence. After 2002, many devices using person-to-machine are developed for multimedia intelligence. Also many types of ubiquitous networked machine-to-machine devices are developed. Nowadays, in 4G, object-to-object mannered devices are developed for our convenience.

There are 4 types of viewpoints in ubiquitous computing in Fig.2. In the aspect of computing paradigm, the technology is changed from static community to automatic community. In the aspect of technical principle, the technology is changed from situation aware to self growing. However, in the aspect of application domain, the technology is changed from healthcare to environment preservation. The fourth aspect concerns the application space, the technology is changed from home or building to society.

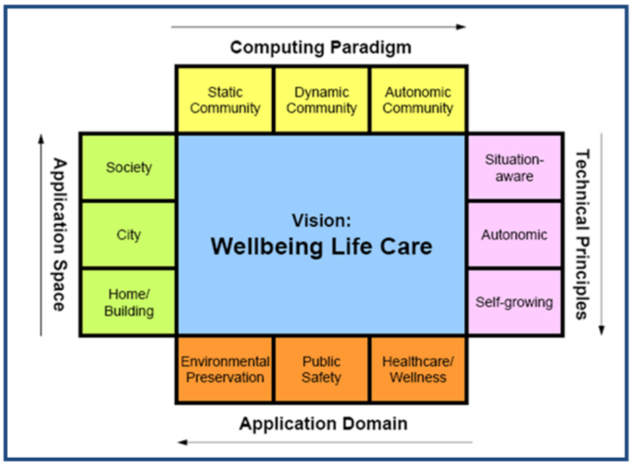

Fig.2. Ubiquitous goal

Recently, especially ubiquitous society, IT paradigm is shifting from hard tool to soft construction tool. Hard computing and soft computing have very different application areas. However, soft computing is more suited to ubiquitous computing than hard computing, because of the intelligent characteristics of ubiquitous computing.

2.2 Ubiquitous integrated control center and platform

All of organs or elements in a Human body are fully connected to compose a real Human. Likewise, from one building to a large building, every elements are connected to compose a city. If a man wants to do some action, many elements in a body coordinate to complete such action, even if we can see or not.

U-City is ubiquitous based City for service through City Integrated Center, for example u-transfortation, u-environment etc.

The main components of U-City are the integrated control center and platform.

Platform is the structure and law for easy transaction among groups. Usually U-City platform is as important as services. Platform is a system structure for information service of special area. The role of platform is like Fig.4. For communication between side A and side B, they have to have platform having architecture and some rule for protocol. If not, it is hard to communicate each other as well as share some information. The goal of U-City is for collaboration. To reach this goal, the platform should prepared first of all.

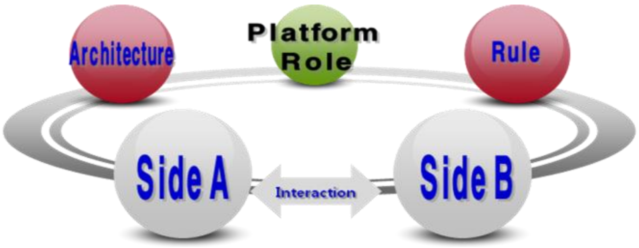

Fig.4. The role of U-City platform

The integrated control center is the place for providing the Integrated IT Infra environment by structuring of U-City IT elements. Definitely, the platform should prepare in the integrated control center.

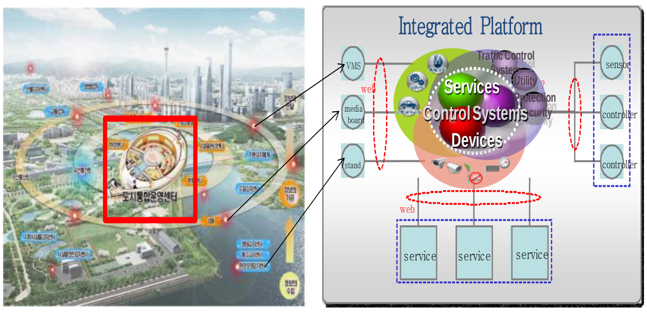

Fig.5. The U-City platform and integrated

What kind of services are provided or developed is as important as anything u-city construction. The row represents a classification by personal life in Fig.6, and the column represents a classification by land and facilities. From the list, you can choose U-city services for your purpose.

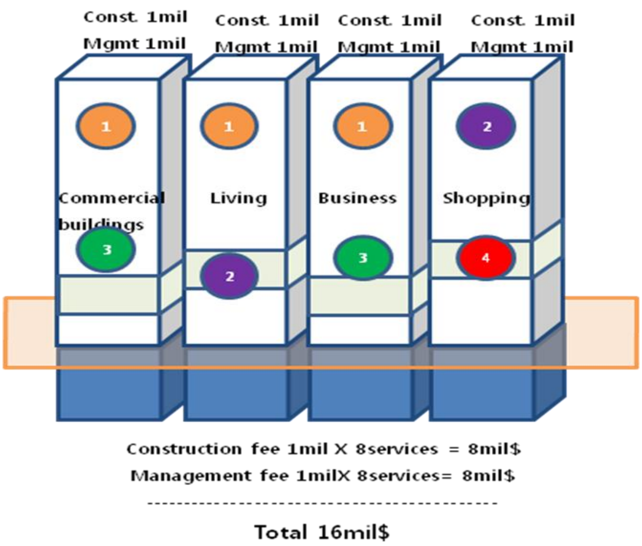
Fig.6. U-City services

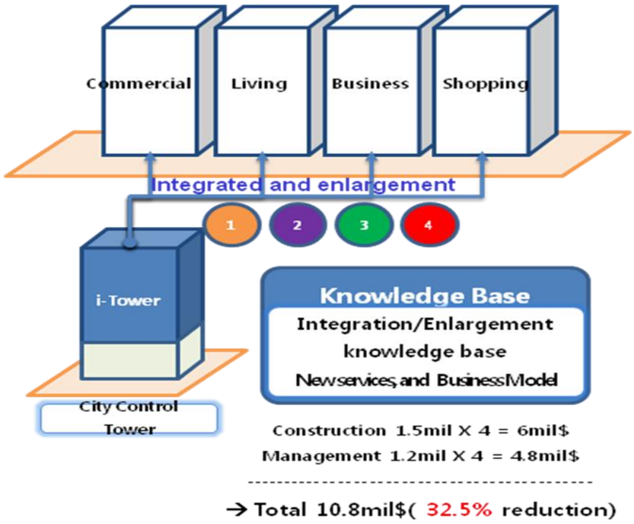
The Fig.7 is about the comparison of the cost between with U-City and without U-City. In Fig.7(a), let the service construction cost of each building is 1million$ and service management cost is 1million$. Let 8 different services are here. In Fig.7, the circle typed numbers are specified U-City services.

If there are 4 buildings, the total cost will be 16million$(service construction cost is 8million$ + service management cost is 8million$).

However, if U-City integrated control center is used, the total cost will be reduced to 10.8million$(service construction cost is 6million$ + service management cost is 4.8million$). It makes about 32.5% reduction effect in U-City construction as well as management.



(a) Without U-City



(b) With U-City

Fig.7. Comparison cost between with U-City and without U-City

3 UBIQUITOUS CITY AND FUTURE RESEARCH THEMES

Among many application areas, ubiquitous city, in short U-City, is the most applicable area. U-City is the constructed city by ubiquitous technologies and paradigm. To be the U-City, there are many ubiquitous services and hybrid technologies using RFID, USN, IPv6, sensing devices, monitoring, auto-control, real-time management etc. Usually, U-City is the same as smart city because smart has intelligent concept.

There are some examples of U-City like the media hub city and cool town in Singapore, cyber port in Hong Kong, Finland as well as Korea [3].

The U-City application service models are still being developed. I would suggest some matrix style service model according to the classification by personal life as well as the classification by land and facilities. The details will be given in my talk at the conference,

In the future we still need to develop what has already been done so far. The first theme is the research about the infra structure of U-City such as platform, security, pattern, service scenario etc. The second theme is the research about the paradigm of `U-City such as role play between government and local government to perform U-City etc. The third theme is the research about the consulting of U-City such as the best service model according to many types of organs, and business model, and so on.

As a result, ubiquitous society is a combination of safety and security for the sake of peaceful society. Now, many services of IT mobile devices are provided with personalized manners. For completion of real ubiquitous space through U-City, the standard model and some platforms should be a prerequisite condition for success.

4 CONCLUSION

Firstly, I explained about IT paradigm shift. Main keywords in IT changes are the power of people, collective intelligence, and new ecosystems.

Secondly, I explained is about ubiquitous society. Real as well as virtual world are combined to be the safe, security, peace of mind society

Finally, I explained about inevitable IT trend. For completion of real ubiquitous space through U-City, the standard model and some platforms should be a prerequisite condition.

Now we are going to cloud and computing. So we have to adopt to the changes and develop some appropriate services and paradigm.

Abstract: The paper deals with simultaneous optimization of path planning of mobile robots and flow shop scheduling problem. The goal of the path planning problem is to determine an optimal collision-free path between a start and a target point for a mobile robot in an environment surrounded by obstacles. The objective is to minimize the path length without colliding with an obstacle. On the other hand, shop scheduling problems deal with processing a given set of jobs on a given number of machines. Each operation has an associated machine on which it has to be processed for a given length of time. The problem is to minimize the makespan, i.e., the overall time demand of the whole process. In this paper we deal with two robots carrying items between the machines. Bacterial memetic algorithm is proposed for solving the problem.

Keywords: path planning, flow shop scheduling, memetic algorithm

1 INTRODUCTION

Path planning is an essential task in mobile robotics. The goal is to find an optimal, collision-free path between a start and a target point for a mobile robot in an environment composed of walls and obstacles. The objective is to minimize the path length without colliding with an obstacle. Sometimes the optimization of the smoothness of the path (i.e., the number of robots turns) is also a goal of the path planning problem. For its practical importance many approaches have been suggested in the literature [1, 2].

In shop scheduling problems there are n jobs to be processed on m machines. There is a matrix specifying how much time needed for a job to be processed on a given machine. The processing times of operations of a job cannot overlap. Each machine can process at most one operation at a given time. In case of flow shop scheduling problems the number of operations of each job is the same as the number of machines (one operation per machine), and the order in which they must be processed is same for all the jobs [3, 4]. The problem is to minimize the makespan, i.e., the overall time demand of the whole process.

The above problems belong to the group of hard combinatorial optimization problems which can be approached by modern optimization techniques such as evolutionary algorithms. Evolutionary algorithms can explore large search spaces, however, their convergence speed is low. By incorporating problem domain knowledge the evolutionary process can be accelerated converging faster to the global optimum. Memetic algorithms combine evolutionary algorithms with local search heuristics in order to speed up the evolutionary process. In this paper the Bacterial Memetic Algorithm (BMA) is proposed for solving the path planning and flow shop scheduling problem simultaneously. We apply two robots making the optimization problem even more complicated.

In the next section we describe the problem. Section 3 presents our proposed algorithm. Simulation experiments are shown in section 4. Section 5 draws the conclusions of the paper.

2 PROBLEM STATEMENT

In case of flow shop problems there is more than one machine and each job must be processed on each of the machines. The number of operations for each job is equal to the number of machines. The processing order of the operations of the job is predefined and it is the same for each job. In case of permutation flow shop problems the machines process the jobs in the same order, so the order of the jobs on each machine is the same. The task here is to find a permutation of the jobs which permutation will fit on every machine. There are n jobs, m machines and two robots. The inputs of the problem are the map with obstacles and machines, and a matrix containing the processing time for each job on each machine. There are three subproblems:

- Finding the permutation of jobs
- Task assignment for the robots
- Path planning for the robots with collision avoidance

The machines are processing the jobs, while the robots are carrying the items between the machines. After a job is finished on a machine the job will be carried to the next machine by one of the two robots. The job can be processed on this next machine only after the robot is reached the machine with the job related items and the previous job according to the schedule on the machine is already finished. Thus the results of the problem will be the schedule of the jobs, the task assignment for the robots explaining which job (item) has to be carried by which robot between two given machines, and the paths for the robots in order they can find an optimal, collision-free way between the machines.

The goal is to minimize the makespan, i.e., the completion time of the whole process. The time consists of the jobs' processing time on the machines and the time needed for the robots for carrying items from one machine to another one. We use cell decomposition based map for the path planning and we assume that the time needed for the robot from one cell to a neighboring cell is one unit, and the processing times in the processing time matrix are in the same unit. A collision means that the two robots occupy the same cell on the map except the positions of the machines where we assume that the two robots can be together at the same time. In order to calculate the makespan considering the difficulty of the whole scenario we need state matrices describing the states of the machines, the current job times on the machines and the states of the robots. We also developed a visualization software to illustrate the scenario.

3 THE PROPOSED ALGORITHM

Nature inspired evolutionary optimization algorithms are often suitable for global optimization of even non-linear, high-dimensional, multi-modal, and discontinuous problems. Bacterial Evolutionary Algorithm (BEA) [5] is one of these techniques. BEA uses two operators, the bacterial mutation and the gene transfer operation which are based on the microbial evolution phenomenon. The bacterial mutation operation optimizes the chromosome of one bacterium; the gene transfer operation allows the transfer of information between the bacteria in the population. Each bacterium represents a solution for the original problem.

Evolutionary algorithms are global searchers, however in most cases they give only a quasi-optimal solution to the problem, because their convergence speed is low. Local search approaches can give a more accurate solution, however they are searching for the solution only in the neighborhood of the search space. Local search approaches might be useful in improving the performance of the basic evolutionary algorithm, which may find the global optimum with sufficient precision in this combined way. Combinations of evolutionary and local-search methods are usually referred to as memetic algorithms [6]. A new kind of memetic algorithm based on the bacterial approach is the bacterial memetic algorithm (BMA) proposed in [7]. The method can be applied for path planning problem of mobile robots [8] and for the traveling salesman problem [9] which is similar to the flow shop scheduling problem.

The algorithm consists of four steps. First, a random initial population with N_{ind} individuals has to be created. Then, bacterial mutation, local search and gene transfer are applied, until a stopping criterion (number of generations, N_{gen}) is fulfilled.

3.1 Encoding method and evaluation

When applying evolutionary type algorithms first of all the encoding method must be defined. The evaluation of the individuals (bacteria) has to be discussed, too. The operations of the algorithm have to be adapted to the given problem. The evaluation of a solution can be done by state matrices as mentioned above. The encoding of the problem is illustrated in Fig. 1.

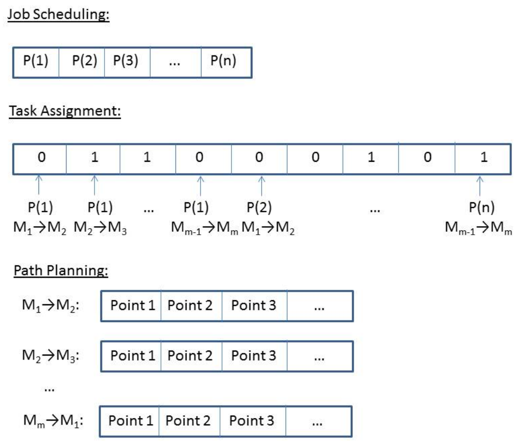

Fig. 1. Encoding

In Fig. 1 we can see the three different subproblems. In the permutation flow shop scheduling problem one individual corresponds to one job permutation. $P(1), P(2) \ldots P(n)$ in Fig. 1 means a possible permutation of the jobs. In the task assignment problem the transportation tasks are assigned to the robots. There are n jobs and $m-1$ transportation tasks for each job (from the first machine to the second, from the second to the third etc.), so $n \cdot (m-1)$ is the chromosome length in case of task assignment problem. The zeros in the chromosome refer to one of the robots while the ones refer to the other robot. In case of path planning there are lots of different path planning tasks. The robots can move not only from machine i to machine $i+1$ because the robots also have to come back empty for starting their next task. The total number of possible path planning tasks is $(m-1) \cdot (m+2)/2$. In case of three machines, the following five paths have to be planned: $M1 \to M2$, $M2 \to M3$, $M2 \to M1$, $M3 \to M1$, $M3 \to M2$. In the path planning problems the chromosome contains intermediate points between the start and target points. The length of the chromosome of the path planning subproblem can change during the evolutionary process. Not every neighboring points are stored in the chromosome, only some intermediate points, and between this intermediate points the path is linearly approximated based on the cells on the map [8]. The paths can be evaluated independently from each other and from the other two chromosome parts related to the job permutation and task assignment. The evaluation of a path is based on the number of neighboring cells the path covers from the start point to the target point, on the number of collisions with obstacles and on the number of turns, i.e., number of direction change of the robot [8]. This evaluation gives an idea about how good is the path alone, however the different chromosome types have to be used together in order to evaluate a solution for the whole problem.

3.2 Bacterial mutation

To find a global optimum, it is necessary to explore new regions of the search space not yet covered by the current population. This is achieved by adding new, randomly generated information to the bacteria using bacterial mutation.

Bacterial mutation is applied to all bacteria one by one. First, N_{clones} copies (clones) of the bacterium are created. Then, a random segment of length l_{bm} is mutated in each clone except one clone which is left unmutated. After mutating the same segment in the clones, each clone is evaluated. The clone with the best evaluation result transfers the mutated segment to the other clones. These three steps operations (mutation of the clones, selection of the best clone, transfer of the mutated segment) are repeated until each segment of the bacterium has been mutated once. When a clone is mutated the other kinds of chromosomes are left unchanged. For example if the chromosome related to the job permutation is mutated in a job permutation type clone, then the other kinds of chromosomes do not change during this time. In case of the path planning subproblem the mutation may not only change the content, but also the length. The length of the new elements is chosen randomly as $l_{bm} \in \{l_{bm}-l^\star, \ldots, l_{bm}+l^\star\}$, where $l^\star \geq 0$ is a parameter specifying the maximal change in length. At the end, the best clone is kept as the new bacterium and the other clones are deleted. The mutation in a permutation type individual alters the segment of the individual by producing a random permutation on the segment. The segment do not need to consist of consecutive elements [9]. The mutation in the binary type individual randomly changes the bits in the mutated segment. In the integer type individual the numbers are changed in the possible interval (positions in the map) and when changing a segment of a clone, we must take care that the new segment is unique within the clone.

3.3 Local search

Local search is performed between the bacterial mutation and the gene transfer operators. The local search has a probability, which is a parameter reflecting the chance for a bacterium to be local searched in a given generation. Too frequent local search can drive the population into local optimum, but if its probability is too small then it will not sufficiently accelerate the evolutionary process.

In case of path planning type chromosome four different local search strategy is proposed [8]. The insertion inserts a new point between those two intermediate points where the insertion has the biggest benefit. The deletion deletes that point from the individual which removal's has the biggest benefit. The swap operation tries to swap each pair of consecutive points in the individual's chromosome. The local improvement tries to improve each point in the chromosome in a given radius, which is a parameter of the algorithm.

In case of the job permutation and task assignment type chromosomes the swap operation is applied.

3.4 Gene transfer

The bacterial mutation operator optimizes the bacteria in the population individually. To ensure the information flow in the population, gene transfer is applied.

First, the population must be sorted and divided into two halves according to their evaluation results. The bacteria with better result are called superior half, the bacteria with worse result are referred to as inferior half. Then, one bacterium is randomly chosen from the superior half and another from the inferior half. These two bacteria are called the source bacterium, and the destination bacterium, respectively. A segment of length l_{gt} from the source bacterium is randomly chosen and this segment overwrites a random segment of the destination bacterium. The above steps (sorting the population, selection of the source and destination bacteria, transfer the segment) are repeated N_{inf} times, where N_{inf} is the number of "infections" per generation.

In contrast with the bacterial mutation, in the gene transfer in case of the permutation problem, the segment can contain only consecutive elements within the bacterium. The reason for that is the segment containing consecutive elements representing sub-scheduling in the bacterium, and transferring good sub-scheduling is the main goal of the gene transfer operation.

4 SIMULATION RESULTS

In the simulation experiment we used 10 jobs and 3 machines with the processing time matrix presented in Table 1.

The map size is 20×20 and can be seen in Fig. 2, where the optimal solution is illustrated with the simulator program.

In Fig. 2 the black cells are obstacles or walls, the blue cells are the machines, and the red and orange cells are the robots. We can also see the current job time matrix and the state matrix used for the evaluation. In the simulation we

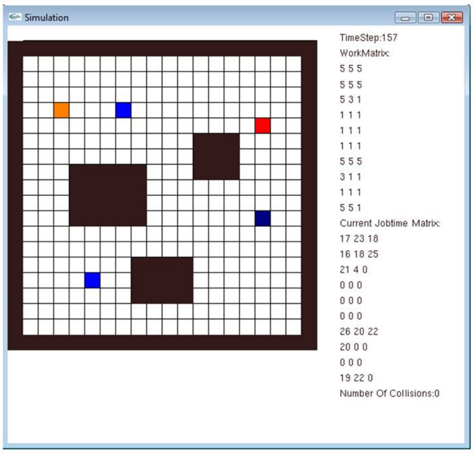

Fig. 2. Simulation

applied 25 generations, 25 bacteria, 5 clones and 5 infections in case of path plannings and 3 clones and 5 infections in case of job permutation and task assignment. The mutation and infection segment lengths are 2 in case of path plannings and 3 for the other two types. The local search probability is 20%. The collision penalty between robots is 10, which means that for every collision of the robots 10 time unit is added to the solution as penalty. The average of best solutions based on 10 simulations for the makespan is 379.7, the best is 376, the worst is 383. In the best solution the job permutation is (2,1,6,8,4,3,10,9,7,5) and the task assignment is 00101010101100101011. The path lengths are 19,18,19,17,18, respectively.

5 CONCLUSION

In this paper the bacterial memetic algorithm was proposed for simultaneous optimization of path planning and flow shop scheduling in case of two robots. The algorithm effectively combines the bacterial operators with local search heuristics and can speed up the evolutionary process in this way. The operators can handle different type of encodings at the same time, like permutation type chromosome, binary, and integer encoding.

Our future work is to extend the technique for more than two robots and for other kind of shop scheduling problems, too.

Abstract: This paper proposes a lateral control system for an unmanned vehicle to improve the responsiveness of the system with a PD control. Heading error can be stabilized and the transient response characteristics can be improved with the controller. In this paper, a mathematical modeling of the vehicle dynamics using two degrees of freedom is used for the controller design. Waypoint tracking method of autonomous navigation was done with the Point to Point algorithm with position and heading measurements from GPS receivers via Kalman filtering. Performance of the designed controller was verified through experiment with a real vehicle**.**

Keywords: Lateral control, PD controller, Unmanned vehicle, P to P algorithm, Kalman filtering.

1 INTRODUCTION

Even though societies have become more convenient with the rapid development of transportation, traffic congestion and accidents are increasing the seriousness of the traffic problems. The cause of most accidents is considered to be the carelessness of an individual. So safety-devices to prevent accidents are being developed [1], [6]. Research and development of unmanned vehicles are also being conducted in many countries [2], [3], [5], [7].

In this paper, a lateral control method using a proportional-derivative (PD) controller for point to point (P to P) driving is studied. In proportional controllers for P to P navigation, the heading angle error is used to determine the steering value. However, stable driving is not guaranteed with this controller due to the rapid changes of the steering value near the waypoints which are renewed along the path.

PD controller can stabilize steering motions and reliable driving can be expected with it. In the main part of this paper, two wheel steering (2WS) model and PD-controller design is described. PD-controller and P-controller are applied to unmanned waypoint tracking experiments and test results are analyzed and compared.

Due to the excellent navigation results of the designed PD controller, this system was used to compare the existing GPS and Kalman filtering systems. To improve the precision of the unmanned vehicle navigation, results of GPS signals reception and results of the signal reception combined with Kalman filtering were analyzed.

2 2WS MODEL

In 2WS model, the car has two front steering wheels while the rear wheels are fixed. According to general steering characteristics of the car when driving [4] a linear model of two degrees of freedom can be used to obtain accurate results if the lateral acceleration is less than 0.4G. The linear model uses lateral displacement and yaw to describe the mechanical system. Since a 2WS vehicle model is used in this study, the roll and pitch motions and the difference between the yaw directions of the wheels are ignored in the controller design.

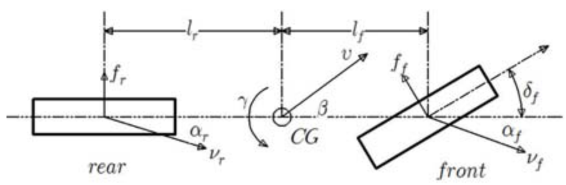

Fig. 1. 2WS bicycle model

Slip angles α_f and α_r can be calculated with the speed of vehicle υ, distances of the front-wheel and rear-wheel from the center of gravity l_f and l_r, yaw rate γ, lateral velocity of the center of gravity ν, rear-wheel steering angle δ_r, and front-wheel steering angle δ_f as shown in Fig. 1 such that

$$\alpha_f = \delta_f - \frac{\nu + \gamma l_f}{\upsilon} \tag{1}$$

$$\alpha_r = \delta_r - \frac{\nu + \gamma l_r}{\upsilon} \tag{2}$$

Since a linear tire model is used, the cornering forces f_f and f_r acting on the front tire and rear tire can be calculated as

$$f_f = c_f \cdot \alpha_f \tag{3}$$

$$f_r = c_r \cdot \alpha_r \tag{4}$$

where c_f and c_r are the cornering stiffnesses. Therefore, using equations (3) and (4), the equations of vehicle motion can be derived from the equilibrium conditions of the vehicle's lateral and yaw moment as follows:

$$m(\dot{\nu} \quad \cdots \quad {}_f \cdot \alpha_f + c_r \cdot \alpha_r \tag{5}$$

$$J\dot{\gamma} \quad \cdots \quad \alpha_f - c_r \cdot l_r \cdot \alpha_r \tag{6}$$

where m is the mass of the vehicle and is the vehicle's yaw moment of inertia. From equations (1), (2), (5), and (6), linear equations of motion can be expressed as follows:

$$\dot{} \quad \cdots \quad t) + Bu(t)$$

$$x(t) = \left\{ \frac{\nu}{\gamma} \right\}, \qquad u(t) = \left\{ \frac{\delta_f}{\delta_r} \right\}$$

$$A = \begin{bmatrix} a_{11} & a_{12} \\ a_{21} & a_{22} \end{bmatrix}, \qquad B = \begin{bmatrix} b_{11} & b_{12} \\ b_{21} & b_{22} \end{bmatrix} \tag{7}$$

$$\begin{bmatrix} \dot{\nu} \\ \dot{\gamma} \end{bmatrix} = \begin{bmatrix} \cdots & a_{12} \\ \cdots & a_{22} \end{bmatrix} \begin{bmatrix} \nu \\ \gamma \end{bmatrix} + \begin{bmatrix} b_{11} & b_{12} \\ b_{21} & b_{22} \end{bmatrix} \begin{bmatrix} \delta_f \\ \delta_r \end{bmatrix} \tag{8}$$

with

$$b_{11} = -\frac{(c_r + c_f)}{m\upsilon}, \quad b_{12} = -\frac{(c_r l_f + c_r l_r)}{m\upsilon} - \upsilon$$
$$b_{21} = -\frac{(c_r l_f + c_r l_r)}{J\upsilon}, \quad b_{22} = -\frac{(c_r l_f^2 + c_r l_r^2)}{J\upsilon} - \upsilon \tag{9}$$

$$b_{11} = \frac{c_f}{m}, \qquad b_{12} = \frac{c_r}{m}$$
$$b_{21} = \frac{c_r l_f}{J}, \qquad b_{22} = -\frac{c_r l_r}{J} \tag{10}$$

In the four wheel steering system, to increase the response during fast speed driving, the rear wheel is steered in-phase with the front wheel. During low speed, to increase the maneuverability, the rear wheel is steered anti-phase of the front wheel.

In this study, when the vehicle navigates at low or equal speed, the revolving radius is reduced and to increase the maneuverability, the anti-phase steering system is used. The equivalent of the front wheel steering value is the anti-phase of rear wheel steering. The multi-input multi-output (MIMO) system, Eq. (8), where input values of δ_f, are entered independently, can be simplified into single input single output(SISO) system of Eq. (11). Where δ_{fr} is $\delta_f - \delta_r$ because of assuming to the anti-phase steering system. In this study to obtain the position of vehicle, θ is gained with Eq. (12) and output $y(t)$ is given by Eq. (14).

$$\begin{bmatrix} \dot{\nu} \\ \dot{\gamma} \end{bmatrix} = \begin{bmatrix} \cdots & a_{12} \\ \cdots & a_{22} \end{bmatrix} \begin{bmatrix} \nu \\ \gamma \end{bmatrix} + \begin{bmatrix} b_{11} - b_{12} \\ b_{21} - b_{22} \end{bmatrix} \begin{bmatrix} \delta_{fr} \end{bmatrix} \tag{11}$$

$$\dot{\theta} \quad \cdots \tag{12}$$

$$\begin{bmatrix} \dot{\nu} \\ \dot{\gamma} \\ \dot{\theta} \end{bmatrix} = \begin{bmatrix} \cdots & a_{12} & 0 \\ \cdots & a_{22} & 0 \\ \cdots & 1 & 0 \end{bmatrix} \begin{bmatrix} \nu \\ \gamma \\ \theta \end{bmatrix} + \begin{bmatrix} b_{11} - b_{12} \\ b_{21} - b_{22} \\ 0 \end{bmatrix} \begin{bmatrix} \delta_{fr} \end{bmatrix} \tag{13}$$

$$y(t) = [0 \quad 0 \quad 1][\upsilon \quad r \quad \theta]' + \nu(t) \tag{14}$$

Here $\nu(t)$ is (0, R) and R is 5cm.

3 PD-CONTROLLER DESIGN AND IMPLEM ENTATION OF KALMAN FILTERING

PD-Controller reduces controller errors effectively since the error rate is taken into account in the controller. As a result, the damping ratio is increased and the overshoot is suppressed. Considering the effect of these differential controls in the controller design, the system can improve the transient response characteristics. Transfer function $K(s)$ of controller is

$$K(s) = K_p(1 + T_d s) \tag{15}$$

The Table 1 shows the dynamic parameters of the unmanned vehicle.

Table 1. Unmanned Vehicle Parameters

Parameter	Value
$m(kg)$	2,055
$\upsilon(m/s)$	2.78~8.33

$J(kgm^2)$	2568.75
$c_f(kN/rad)$	74.1
$c_r(kN/rad)$	62.2
$l_f(m)$	1.158
$l_r(m)$	1.737
$L(m)$	2.895

4 EXPERIMENTS

In this study, a PD-controller is applied to a two-wheel steering unmanned vehicle. P to P driving algorithms using P and PD controllers are experimentally compared. A general vehicle can run on curved paths with the speed of 20km/h without exceeding the lateral acceleration of 0.4G if the maximum steering angle is less than 20 degrees.

Fig. 2 shows the vehicle used in the experiment, and driving tests were carried out with it at the speeds of 10km/h and 20km/h. The vehicle used in the experiments was a Hyundai-Kia MOHAVE. The experiments were conducted in the school field. GPS measurements were obtained in the experiments in which the vehicle was running on an elliptical course.

Fig. 2. Equipment used in the experiment

The waypoints to be passed by the vehicle were prepared with DGPS. Tests were conducted with various driving speeds from 10km/h to 20km/h. The resulting vehicle traces were compared with the waypoints.

Table 2. Error values of unmanned vehicle to reference path

Test Controller / Velocity	P Controller		PD Controller	
	Maximum Error	RMS Error	Maximum Error	RMS Error
10km/h	0.56 m	0.54 m	0.47 m	0.38 m
20km/h	1.94 m	1.06 m	0.94 m	0.51 m

Table 3. Specifications of gyro Sensor.

Specification	Value
Range: Yaw(°/sec)	±100
Bias: Yaw (°/sec)	< ±1.0
Scale Factor Accuracy(%)	< 1
Non-Linearity(% FS)	< 0.3
Resolution (°/sec)	< 0.025
Bandwidth (Hz)	> 25
Random Walk (º $/hr^{1/2}$)	< 2.25
Operating Temperature(º C)	-40 to +70
Non-Operating Vibration (g rms)	6
Non-Operating Shock (g)	1000

The last test is executed with the IMU and position is calculated with dead-reckoning. Fig. 3 shows the results of the path positioning tests along the reference path.

Table 4 represents the maximum error and the root mean square (RMS) error values of path tracking tests using GPS and Kalman filtering in the test area shown in Fig. 4 with the speed of 30km/h. Kalman filtering method has improved the maximum error by 400% and the RMS error by 20% compared to those of using GPS.

Table 4. Tracking errors of tests using GPS and kalman filtering to unmanned vehicle at 30km/h, respectively

Test / Velocity	GPS		Kalman Filtering	
	Maximum Error	RMS Error	Maximum Error	RMS Error
30km/h	3.93 m	0.64 m	0.77 m	0.54 m

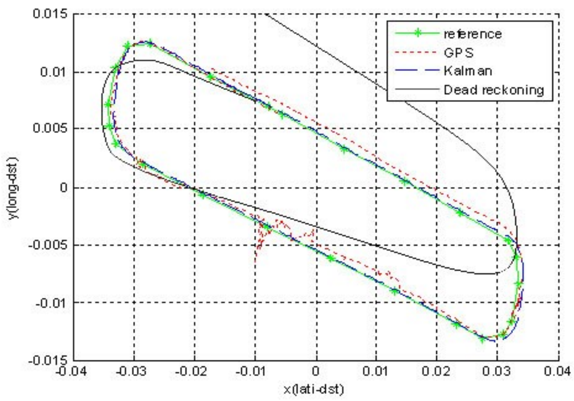

Fig. 3. Experimental results of positioning tests

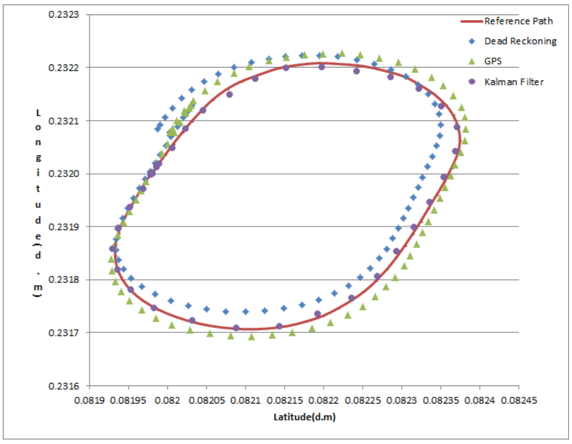

Fig. 4. Experimental results of the downtown in busan

Table 5. Tracking errors of rest using dead reckoning, GPS and kalman filtering to unmanned vehicle 30km/h at downtown, respectively

Test / Velocity	Dead Reckoning		GPS		Kalman Filtering	
	Maximum Error	**RMS Error**	**Maximum Error**	**RMS Error**	**Maximum Error**	**RMS Error**
30km/h	9.75 m	5.78 m	3.85 m	1.5 m	0.42 m	0.25 m

In navigations using only dead reckoning, the errors increased in the recognition of the standard path as time passed. Comparing the navigation trail when using only the GPS and that of the Kalman filter, the Kalman filter trail was found to be closer to the standard path in Table 5. When the allowable error was established to be 0.45m half radius, which considered the width of the vehicle(1.915m), the Kalman filter navigated the path within the acceptable error range of test results in Table 5.

5 CONCLUSION

When the waypoints and the traces of the vehicle obtained from the tests were compared, the turning radii of the traces were larger than those of waypoints. This error seemed to occur because the dynamic elements of the vehicle were not properly considered. In the future research the dynamic elements of the vehicle need to be reflected in the controller design so that reliable path tracking can be performed with various vehicle velocities.

In this paper, we suggest an autonomous vehicle's positioning method for navigation system. To get successful operation, the position and heading angle measurements are necessary. Positioning with GPS or dead reckoning with does not guarantee successful operation. GPS and dead reckoning both have error elements. GPS measurements are sensitive to environment conditions. Dead reckoning produces error that increases with time due to sensor errors.

For successful operation of navigation system, a Kalman filtering of positioning sensor measurements is suggested in this paper. Positioning with Kalman filter is more accurate than that using GPS or IMU dead reckoning. GPS can compensate the error accumulation of dead reckoning. Test results indicate good performances with the Kalman filter.

At 30km/h of unmanned driving, the Kalman filtering method reduces the error by 20% compared to the existing GPS method. Based on this study, unmanned drive testing at 50km/h has been successful in the test area (Hyundai Kia Motors Namyang Institute, Jangdeok-dong, Hwaseong-si, Gyeonggi-do, Korea) and is now being tested around downtown in the Busan area.

Abstract: This paper presents studies on the Kalman filtering of yaw angle and vehicle position in the integration of an inertial measurement unit(IMU) with a new accurate real-time ultrasonic distance measurement system on a unmanned container transporter(UCT). Experimental tests conducted with a very low grade IMU and pseudolite ultrasonic system(PUS) measurement system showed that a moving vehicle's position can be estimated with a few centimeters accuracy. The test results confirmed that angular motions and vehicle positions improve the estimates of yaw angle and angular velocity, respectively.

Keywords: Kalman filtering, unmanned container transporter (UCT), pseudolite ultrasonic system (PUS), angular motions, ve hicle positions

1 INTRODUCTION

Research on the issue of the position acquisition of moving vehicles has been actively progressing in the field of navigation of which global positioning system(GPS) and inertial navigation system(INS) are widely known [1]. INS provides accurate positional information during brief periods, however, the fault of accumulating errors during prolonged periods still needs to be resolved. On the other hand, GPS gives greater errors during short time periods and has location limitations depending on the use but provides more stable positional information during longer periods of time. Since the two systems complement each other's faults, the combination of the two systems will lead to more accurate positioning information. Active research is being done to combine the two systems. Pseudolite(pseudo satellite) Ultrasonic System(PUS), which can operate indoors where GPS can't and are adaptable in ports, are also being studied for location positioning and control of moving vehicles and for calculating distance. Recently, studies to apply accurate estimated positioning into mobile robots and/or unmanned vehicles have increased [2].

In general, ultrasonic waves are used in mobile robots to detect objects and measure distances, in vehicle rear sensing, in vehicle traffic detection, in speed systems, in invasion detecting security systems, in accurate processing and measurements.

In the distance measurement systems using ultrasonic waves, there are two types of transmitter-receiver systems. The integrated type uses reflecting waves while the separated type uses direct waves. The integrated type is simple and easy to operate but precision target is difficult due to the wide angle. The separated type does not have this problem, but the transmitter and receiver require wireless synchronization. The basic method of distance measurement of the two types is measuring the time of flight it takes for the transmitted ultrasonic frequency to be received.

The threshold method is the most commonly used method to measure the flight time. However, the threshold method is affected by temperature, distance, the absorption of the ultrasonic waves by the object, the medium change in the air, and noise. To supplement these drawbacks, methods to control the various threshold levels are applied. Various calculation methods, such as measuring the initial point of the reception wave from the maximum amplitude point of the sound wave envelope, the time of flight acquired using the maximum time in the cross correlation of signals, or using the topology of the reception waves from the converted transmission waves [3]. Also, the topology difference of a wave using discrete fourier transform is used with the threshold method [4].

Another purpose of the study is to evaluate estimator performance in the integrated system of a pseudolite ultrasonic system(PUS) and low-grade inertial measurement unit(IMU). The experiments were conducted for the estimation of errors in the integrated system of PUS and IMU. A PUS receiver for position estimation and IMU were mounted on a plate so that the relative position between the ultrasonic receiver and IMU could be accurately measured.

2 IMPLEMENTATION OF THE PSEUDOLITE ULTRASONIC SYSTEM(PUS)

2.1 Period detecting method

2.1.1 Basic time of flight detecting method

The time it takes for the transmitted ultrasonic frequency to reach the receiver is defined by the difference of the transmitted time T_t and the received time T_r. The distance d between the transmitter and receiver using direct frequencies of the separated transmitter and receiver are shown in Eq. (1).

$$d = c \times T_f + d_0 \quad (1)$$

Here, $T_f = T_r - T_t = TOF$ (Time of Flight), d_0 is the offset distance due to the position error of the diaphragm, and c is the speed of the ultrasonic frequency according to the air temperature in Celsius (T).

$$c = 331.5 + 0.60714 \times T \quad (2)$$

The precision ultrasonic distance measurement is directly influenced by the precision measurement of flight time, that is the recognition accuracy of the transmitted ultrasonic frequency time T_r .

2.2 Accurate ultrasonic distance measuring system via the PUS

2.2.1 The organization of the accurate ultrasonic distance measuring system

The ultrasonic sensor 40kHz MA40BR/S was used in the accurate ultrasonic distance measuring system. This sensor is widely used to detect obstacles. The sensor sensitivity is highest around 40 kHz and the direction angle is about 70 degrees. The long distance accurate ultrasonic distance measuring system is shown in Fig. 1. The transmitter and receiver are separated and synchronized using RF to transmit the initial transmission point to the receiver. The time delay of RF is minute and so ignored. The transmitter transmits the ultrasonic frequency in certain cycles and the receiver receives the ultrasonic frequency and RF signal. The receiver measures the flight time using the period detection method and with this the final distance information is calculated. The calculated distance information is sent via wireless communication at 115200bps to a PC for confirmation.

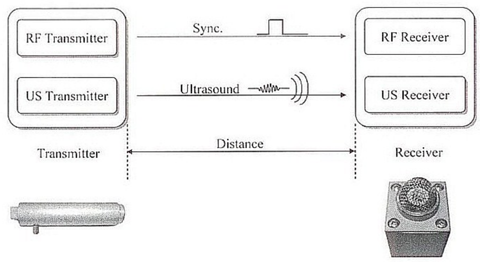

Fig. 1. Configuration of ultrasonic distance measurement system

2.2.2 Ultrasonic distance measurement test

The proposed ultrasonic distance measurement test was done with one transmitter and one receiver. The transmission distance was from 1m to 30m. The experiment started with the transmitter and receiver facing each other at 0m. The distance offset d_0 due to the diaphragm position error of the transmitter and receiver was measured and applied to the distance information.

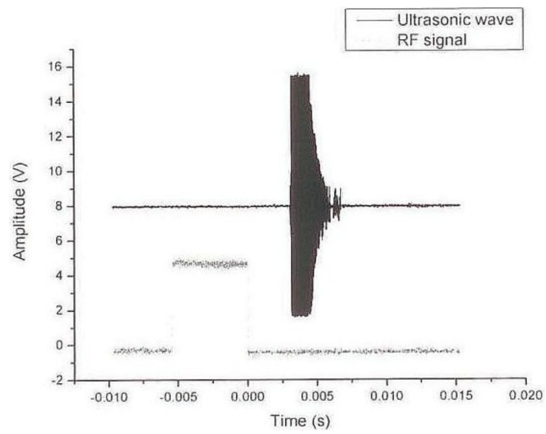

Fig. 2. Received ultrasonic waves at 1m

Fig. 2 show the measured reception frequency and RF synchronized signal at 1m and 20m, respectively. The wave form at the upper part of the figure is unprocessed signal while the lower part of the square wave form is the synchronized RF signal. The declining edge section corresponds to the ultrasonic transmission point.

The main reason of the distance error in the period detection method was examined. The ultrasound can react sensitively to the external environment. The velocity changes depending on the temperature and the frequency is stronger at close range so external disturbances matter less. However, in long distances, external disturbances greatly affected the results even in indoors testing. To determine the reception point of the ultrasonic frequency, repeating cycles were examined and the initial point was located.

Table 1. Distance errors by using threshold method and period detecting method

Distance (mm)	Threshold method (mm)		Period detecting method (mm)	
	mean	STD	mean	STD
1000	9.959	1.011	3.584	0.459
3000	12.698	1.455	5.611	0.681
5000	13.655	1.713	4.113	0.905
10000	11.180	3.589	4.879	1.280
15000	10.377	6.684	3.600	1.981
20000	10.241	9.139	6.715	5.417
25000	45.808	10.982	5.291	7.138
30000	97.166	24.853	14.602	16.559

2.3 Precision position sensing system using the PUS

The ultrasonic position sensing system uses the trilateration to calculate the position of the measuring object and the distance between three or more standard points. This method is the basis of GPS which recognizes the object's position by measuring the reception time of the signal from the satellite.

The ultrasonic positioning system is largely divided into two types according to the position of the transmitter and receiver [3]. The first type is the infrastructure transmitting type where the transmitter is positioned as the basis on the measurement object. Cricket [3] and global ultrasonic sensing system are the applied examples. The second type is the infrastructure receiving type where the receiver is the basis and the transmitter is located on the measurement object. Applied examples are Active Bat and similar method using infrared light is Active Badge.

The infrastructure transmitting type calculates the position information from the moving object, so it is more favorable in mobile robots during position prognosis. The infrastructure receiving type calculates the position information from the infrastructure so used to track moving objects.

Cricket transmitted RF that includes transmitter coordinates at the same time as the transmitting signals. The difference of the arrival time was obtained with the envelope detection method and the distance and location was calculated. The advantage is that the cover range expansion is simple. However, the disadvantages are the inference among the numerous transmitters is unavoidable so the position cannot be obtained in constant time intervals and the inference evaluation algorithm is very complicated. The restrictions of the direction angle range are difficult to overcome so the transmitters are placed within 5m range intervals.

3. Navigation Experiment of UCT

3.1 Location Positioning System and Navigation Algorithm

Four 40kHz ultrasonic transmitters are placed at high locations or indoor ceilings and synchronized to receive one RF signal. A built-in timer transmits the ultrasound every specific time(0.4 sec). The time of flight(TOF) value is calculated and the distance between the transmitter and receiver is estimated. Generally, it can consist of one or two receivers. In the case of one receiver, the local coordinates x, y, z are acquired. When two receivers are used, the direction angle can also be measured. In unmanned navigation, the absolute position and the direction angle of the UCT are needed and so two receivers were used in our experiment.

3.2 Unmanned Driving Test and Performance Evaluation of Model Car on UCT

The UCT speed of 0.36m/s, the control cycle of 0.4 sec when the Kalman filtering was not applied and the control cycle of 0.1 sec when Kalman filtering was applied were tested, respectively.

The dotted line represents without Kalman filtering and the solid line shows the data after it has been filtered through every 0.1 sec and measurement noise is (0.16)

3.3 Implementation to PUS of North Harbor in Busan, Korea

Fig. 3 shows the position recognition system of the vehicle using PUS in the harbor yard. Under the assumption that the height of the vehicle is constant, only two distances of the PUS transmitter needs to be measured for accurate x, y value. Therefore, placing the PUS transmitters in a row as shown in Fig. 4, and successively transmitting 300ms three times from the 1st transmitter to minimize the interference of the transmitters. The overall positions are shown in Fig. 21. ①, ②, ③ transmit the same identification signals successively and different identification signals are transmitted in different areas according to color. Each ultrasonic signal includes a different identification signal. Based on this, the receiver calculates position from the identification signal and distance from the transmitter.

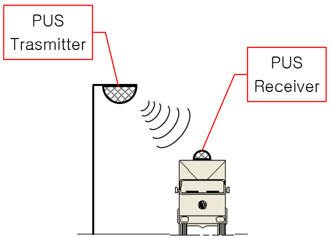

Fig. 3. The distance calculation of PUS transmitter and receiver

Fig. 4 shows the actual installation positions of the PUS transmitters, and Fig. 5 shows the ①, ②, ③ array of the transmitter groupings installed for the experiment. The experimental results of a vehicle installed with Kalman filter verifies accurate position recognition is possible even when applied in the real environment. During 10km/h forward and backward movements, ±100mm of error occurred. However, the efficiency can be increased with the accurate compensation of the ultrasonic transmitter. And also with the use of multiple transmitters, the efficiency will increase.

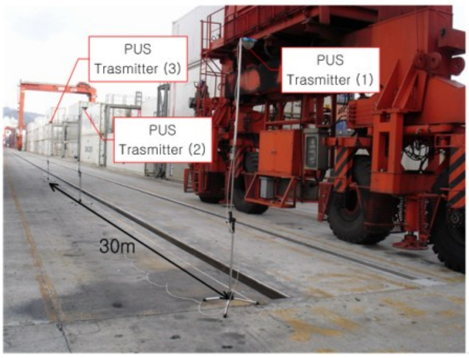

Fig. 4. The calculation of the receiver's coordinates using two PUS transmitters

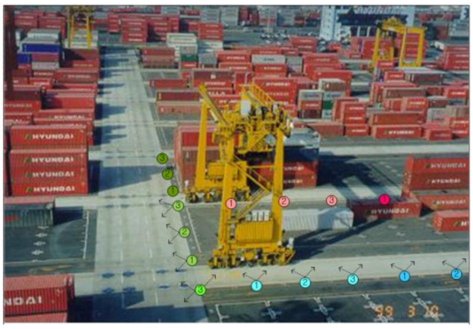

Fig. 5. The position of PUS in the yard

4. Conclusion

A precision position detecting system for indoors and/or designated areas was proposed, its practicality was demonstrated, and the following was concluded.

To satisfy the recognition range and the measurement precision at the same time, period detection method was proposed and test results confirmed its performance efficiency to be outstanding.

Pseudolite Ultrasonic Satellite (PUS) was proposed to enable position detection of multiple moving objects. The system demonstrated superior performance efficiency in precision and recognition. The proposed 3D ultrasonic position detecting system uses a low cost 8 bit microprocessor and is practical in design, power, and weight.

For application in mobile robots or ports that require precise positioning systems, Kalman filtering position estimation algorithm was applied and analyzed.

Test results show that this system can be applied in various ways such as position recognition of mobile robots, in production lines, or in large distribution centers. And also in AGV autonomous driving position detection, motion detection, and 3D precise coordination detection.

The Kalman Filtering method was adopted into the PUS to improve the vehicle's various operation performances. Especially, the proposed PUS was built into the real vehicle and basic experiments showed that the control of the vehicle was possible in centimeters error range. With these results, we confirmed that this system can be applied to actual port UCT.

Actual testing was applied to two transporter cranes at the Hutchison Terminal, Jasungdae Port, Busan Harbor.

Hyper-gourd theory: solving simultaneously the mysteries in particle physics, biology, oncology, neurology, economics, and cosmology.

Abstract: The inevitability of various particle masses for hadrons, quarks, leptons, atoms, biological molecules, droplets of fossil fuel and water, living cells including microorganisms and cancers, multi-cellar systems such as organs, neural systems, and the brain, stars, galaxies, and the cosmos is synthetically revealed. This is possible because each flexible particle is commonly generated by a mode in which a larger particle breaks up into two smaller ones through a gourd shape with two lumps. These masses, sizes, frequencies, and diversity dominated by super-magic numbers including the silver ratio, in fractal nature can be derived by the fusion of the quasi-stability principle defined between absolute instability and neutral stability, the indeterminacy principle extended for quantum, statistical, and continuum mechanics, and the spherical Lie group theory. The analyses also result in a new mathematical definition of living beings and non-living systems and further explain the standard network patterns of various particles and also the relation between information, structure, and function, because the proposed theory based on gourds posits a new hyper-interdisciplinary physics that explains a very wide range of scales, while the Newton, Schrodinger, and Boltzmann equations describe only a narrow range of scales.

Keywords: Biological, cosmic, hyper-interdisciplinary, subatomic, quark.

1. INTRODUCTION

There are still so many mysteries about non-living and living systems from subatomic to cosmic scales, which are related to the masses of subatomic particles, quantum entanglement, the magic numbers, morphogenetic processes, the standard circuit pattern of the neural network in the brain, overall mechanism of cancer, fusion of left-right symmetric and asymmetric organs, the definition of life, side effects, functions of introns and junk, economic systems generated by the human brain, dark matter, and super-cosmos outside our universe.

The reason why so many mysteries have not been explained is related to the fact that the traditional Newton, Schrodinger, and Boltzmann equations can reveal only a narrow range of scales, although each equation describes several classes of conservation of mass, momentum, moment, and energy. Super- interdisciplinary and supermulti-scale physics, which synthesizes the whole span from the pico- to the peta-scale, is necessary to go further.

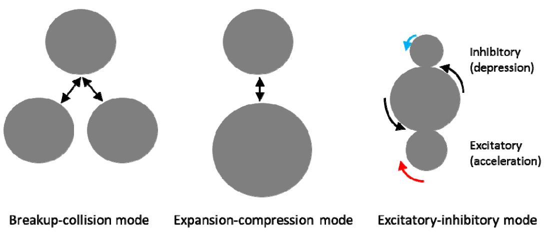

Fig. 1 Three modes.

Fig. 2 Gourd shapes.

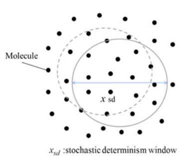

Fig.3 Window for averaging

Our previous researches [1, 2] offered some hypotheses and predictions regarding these mysteries. Later, some experimental researches done by other people verified our hypotheses and predictions [3, 4]. One concerns the function of introns and junk. Another concerns the left-right asymmetric part inside the brain system, which brings feelings of comfort.

Here, we will reveal the mysteries above more intensively and extensively. First, we will classify the natural processes into three modes: breakup-collision, expansion-compression, and excitatory-inhibitory process (acceleration-depression). (Fig.1) We name the modes of breakup-collision, expansion-compression, and excitatory-inhibitory process (acceleration-depression), as Gourds I, II, and III, respectively. This is because each one of the three modes has shape of gourd. (Fig. 2) Nature is dominated by gourds, rather than by strings or spheres. In short, we propose here a physical theory that explains the fractal nature in the gourds of the three models, although the fractal concept has only been used in mathematics so far.

2.METHODOLOGY

2.1 Quasi-stability principle [2, 5-7]

Natural systems are essentially discontinuous in three-dimensional space but relatively continuous in time, because from the subatomic to the cosmic scale they consist of particles such as quarks, hadrons, atoms, molecules, fluid particles, cells, and stars. Accordingly, various natural processes for non-living and living systems can approximately be described by the following momentum equation systems:

$$\frac{d^{(n)}}{dt^{(n)}} y_i(t) = \sum_j f_{ij}(y_i, y_j) + \varphi_i \text{ or } \frac{\partial^{(n)}}{\partial t^{(n)}} y_i(t, x_k) = \sum_j f_{ij}(y_i, y_j) + \varphi_i \quad (1)$$

where y_i, x_k, t, n, f_{ij}, and φ_i denote physical quantities such as velocity, particle deformation rate, and pressure, spatial coordinates, time, order of derivative, function of y_i and y_j, and random disturbance related to indeterminacy coming from the small number of particles, respectively. [2, 5-7] Quasi-stability is defined as a principle in which one part on the right-hand side of Eq. 1 is zero, when disturbance of φ_i enters the system. When at least one of the various terms of i or j for f_{ij} is zero, the system is quasi-stable against the disturbance. Quasi-stability as it is used here lies between neutral stability and an absolutely unstable condition. The quasi-stability is different from meta-stability denoted in thermo-physics, because this quasi-stability for momentum is weaker than the meta-stability for energy conservation. [One example of evidence is that the elimination of only one term among various numerical error ones in a finite difference equation derived with the Taylor series yields an approximate solution for a physical phenomenon such as the transition to turbulence [8].]

It is emphasized here that traditional stability analyses based on a mathematical variable transformation for matrix diagonalization is meaningless for revealing the nature of living beings, because life is not in mathematical space.

2.2 Indeterminacy level:

As shown above, various natural phenomena consist of particles, i.e., discontinuity in space. This discontinuity of particles leads to indeterminacy (stochasticity) for several stages of phenomena, such as electron particles described by the Schrodinger equation. An important point is that the level of indeterminacy, i.e., degree of variation, varies according to length scales and the number of particles. As an example, when the system being analyzed consists of a smaller number of particles, the level of indeterminacy increases. (Fig. 3)

Statistical mechanics based on the Liouville and Boltzmann equations tells us that a very large window for averaging the aggregation of a huge number of particles brings deterministic continuum mechanics, whereas a small window for a small number of particles leads to a stochastic differential equation. When a small window for averaging is used, physical quantities such as mass, size, and velocity are defined with indeterminacy, i.e., vagueness. [9]

The baryons and mesons are constructed of only three and two quarks, respectively. There are only two electrons inside the smallest orbit around an atom. The number of carbon, oxygen, and nitrogen particles inside a nitrogenous base is not enough for continuum, because of the order of ten. These small numbers of particles lead indeterminacy in the governing equations. On the other hand, a biological cell or a liquid droplet of over one millimeter in size includes a lot of molecular particles that result in deterministic governing equations. The most important point is that a system of only one particle is deterministic, although such systems are of an infinitely small number.

3. BREAKUP PHENOMENA (Gourd Ia)

3.1 Size and weight

The breakup phenomena on various spatial scales commonly show the shape of a gourd having two lumps at the time of breakup (Fig. 2). Thus, we can model the gourd having two lumps using two flexible spheroids connected as an approximation. [2, 5] Here, we define a parcel as a flexible spheroid (lump) having two long and short radii *a(t)* and *b(t)* dependent on time *t*, for the aggregation of some quarks or leptons generated by a high energy experiment, the aggregation of neutrons and protons in each child atom resulting from the fission of a large atom such as a uranium 235, a nitrogenous base in biological base pairs of nucleic acids hydrated with a lot of water molecules, a biological cell just before division, a liquid droplet at breakup, and a star (or dark matter) at breakup in the cosmos. The parcel becomes a sphere of the radius r_d ($=[ab^2]^{2/3}$) under an equilibrium condition. The deformation rate γ (t) is defined as *a(t)/b(t)*, while a sphere without deformation corresponds to $\gamma = 1$. Next, we derive a theory for describing the deformation and motions of the two connected spheroid parcels having two radii of r_{d1} and r_{d2} under equilibrium conditions and two deformation rates of $\gamma_k\ [k=1,2]$, while the size ratio of the two parcels is defined by $\varepsilon = r_{d1}/r_{d2}$.

We model the relative motion between the two parcels, nonlinear convections inside the parcels, and the interfacial force at the parcel surface. The interfacial force is evaluated in the form of σ / r^m where *m* and σ are constants and *r* is the curvature of the parcel surface. Several types of forces such as nuclear force, van der Waals force, surface tension, coulomb force, and the force of gravity can be explained by varying *m*. The relation *m* = 1 implies the surface tension of liquid. Mean density of the parcels is ρ_L.

We assume that the convection flow inside a flexible parcel is irrotational, i.e., potentially one. This potential flow is applicable, because fluctuations entering the parcels such as bases, cells, and atoms will be those of thermal fluctuations with very high speeds, which are less dissipative (fluctuation dissipation theorem). The potential assumption is also valid for star breakups, because of their large size and high speed. Moreover, we must consider that a parcel is not often a continuum, because the number of nucleons and water molecules inside the parcels of atom and nitrogenous bases will be fewer than 1,000. Thus, this leads to a weak indeterminacy of physical quantities such as deformation and density.

Here, we derive the relation between the dimensionless deformation rate $\gamma_k (\equiv a_k / b_k\ [k=1,2])$ of each parcel dependent on dimensionless time $\bar{t}$ and the size ratio of two parcels of $\varepsilon = r_{d1}/r_{d2}$.

The stochastic governing equation having indeterminacy can be written for momentum as

$$\frac{d^2}{d\bar{t}_i^{\,2}}\gamma_i = \{m_{ci}(\frac{d}{d\bar{t}_i}\gamma_i)^2 + m_{cj}(\frac{d}{d\bar{t}_j}\gamma_j)^2 + m_{si}\ \gamma_i^{\frac{5}{3}-\frac{2}{3}m} + m_{sj}\ \gamma_j^{\frac{5}{3}-\frac{2}{3}m}\} / Det + \delta_{st}$$
$$[\text{for } i = 1, 2.\ j = 1, 2.\ i \neq j] \qquad (2)$$

with $m_{ci}, m_{cj}, m_{si}, m_{sj}\ Det,\ B_{0k}\ , C_{0k}$, and E_{0k} [for $k = 1, 2$] defined in Refs. 2,5,6, and 7,

where the parameter δ_{st} denotes random fluctuation.

Next, we also define $y_i = \gamma_i - 1$ as deviation from a sphere.

The momentum equation is

$$\frac{d^2 y_i}{d\bar{t}_i^{\,2}} = [-\frac{2}{3}(3-\varepsilon^3-2\varepsilon^{2+m})\left(\frac{dy_i}{d\bar{t}_i}\right)^2 + 3(3-\varepsilon^3)my_i - 4\varepsilon^{1+m}\left(\frac{dy_j}{d\bar{t}_j}\right)^2 + 12\varepsilon^{1+m}my_j]/[3(\varepsilon^3+1)]$$
$$+\delta'_{st}, \qquad (3)$$

which is approximated by the first order of the Taylor series [2, 5-7].

For each *m*, the quasi-stable size ratios of 1.0 and about 1.44 appear in Eq. 3, i.e., in the 1st-order term of the Taylor series. It is stressed that a deformation disturbance entering a particle, i.e., that for y_i, leads to an asymmetric size ratio around $\varepsilon = 1.44$, while a disturbance of deformation speed, $dy_i / d\bar{t}_i$, brings a symmetric ratio of 1.0.

The higher-order of the Taylor series for parcel 1 results in

$$\frac{d^2 y_1}{d\tau_1^2} = \left(\sum_{k=1}^{\infty} b_k(\varepsilon,m) y_1^{k-1}\right)\left(\frac{dy_1}{d\tau_1}\right)^2 + \sum_{k=1}^{\infty} a_k(\varepsilon,m) y_1^k + \zeta \qquad (4)$$

where the third term on the right-hand side includes influences from parcel 2.

The higher order of terms of the Taylor series obtained with the statistical fluid dynamics model also reveals the various super-magic numbers for the size ratios of (Table 1). It is stressed that the ratios are desultory or discontinuous. We should recall that various values of *m* bring the same quasi-stable ratios of 1.0 and about 1.44 for the first order of the Taylor series, whereas the higher-order terms lead to various other ratios.

Table 1 Super-magic numbers

m=-3	m= -1	m=1	m=1.04	m= 1.3	m= 1.5	m=2	m=3
conv.							
1	1	1	1	1	1	1	1
1.23	1.34	1.27	1.27	1.26	1.25	1.24	1.21

4.53			1.95×10^{34}	37325	553.6	23.5	4.25
			1.43	1.43	1.43	1.42	1.4
surface							
1.44	1.44	1.44	1.44	1.44	1.44	1.44	1.44
	1.8	3.58	4.57				3.14
	1.7	2.47	1.99				
	1.63	2.1	1.84				
	1.59	1.79	1.74				
	6.11	1.71	4.42				
		4.54	1.68				
			2.97				

The size and weight ratios of purines and pyrimidines in DNA are around 1.45, which is close to 1.44 in Table 1, while the size ratios of identical bases in RNA is 1.0. Heavy chains in immune globulins (IgX) have size ratios of about 1.5, while the frequency ratio of small and large types of IgXs is also 1.5: two types of large immune globulines (IgM and IgE) and three small ones (IgG, IgD, and IgA).
The largest amino acid is about three times larger than the smallest one, which corresponds to 3.58 in the higher order of the Taylor series for m=1. The ratios of chromosomes in human beings are about six times at maximum, which may be seen as 4.54 in the higher order of the Taylor series for m=1 or 6.11 in the higher order of the Taylor series for m=-1. [This is because the values of m may be 1.0 or less for van der Waals and coulomb forces.]
Equations 2-4 and Table 1 may also explain the mysterious electron orbits such as 4f, because quasi-stable ratios do not increase monotonously according to increasing of the orders of the Taylor series related to the energy levels of orbits. For examples, the 3rd and 8th orders of terms bring the relatively large quasi-stable size ratios of about 3.58 and 4.54, whereas the 4th and 5th orders lead to the relatively small ones of about 2.47 and 2.10.
The constant m will often have values larger than 1.0 or 1.0 for nuclear force. Table 1 also reveals the magic numbers appearing in the weight ratios in various atoms generated by cold fusion: about 3.9, 2.1, and1.8 [5, 10].
When m has a value between 1.3 and 3.0, the ratios of ε are between 1.0 and about 105, which may correspond to the mass ratios in small particles including quarks and leptons or those in the hadron classes of baryons and mesons. [It is stressed that a weight ratio of about 2:3 is also observed in dark matter [10]. The fractional Taylor series also show quasi-stable ratios including about 1.44 and 1.0 in Table 1.]

3.2 Permanent and tentative components inside parcels

Parcels can essentially include two types of components, which are permanent and tentative ones. The permanent part exists both before and after the breakup process, while the tentative part appears and shows important features only at the time of breakup. In several cases of natural phenomena, the permanent part is a one-dimensional string or ring, having a mass proportional to the parcel size ε. Parcels including both tentative and permanent parts have a mass proportional to ε^3. Some natural phenomena have no tentative part, in which case only the permanent part is proportional to ε^3.
Let us examine the following examples. In biological systems, these magic numbers of ε explain those for biological molecules of one-dimensional strings and rings such as nitrogenous bases, amino acids, and proteins, whereas the values of ε^3.correspond to biological molecules hydrated by water molecules. In subatomic processes, the aggregation of baryons is one-dimensional, while the total mass including baryons, gluons, and the quark condensation effect is three-dimensional. The tentative part is similar to the immersed mass in fluid dynamics. Pure droplets of water or fuel and stars are three-dimensional because they only have the permanent part.
The group theory shows that one- and three-dimensional spheres are in a group. This may support the idea that ε and ε^3 repeatedly appear in various natural particles (parcels), while nature is relatively obviative to two-dimension, ε^2.

3.3 Discontinuity around m =1

Let us think about the reason why discontinuous jumps in size ratios can appear around m = 1. When the curvature is $1/r$, we define the surface force as one proportional to $1/r^m$. We can employ the simple form of $1/r^m$, because we consider only the breakup timing of the gourd having two lumps. Taking the r-integral of $1/r^m$ as the potential, the integral forms are discontinuous for m around 1.0. This is the reason why values of m a little larger than 1.0 discontinuously induce extremely large size ratios.
There are extremely large size ratios over 10^{30} in Table 1 for $1.0 < m < 1.1$. These very large ratios might possibly correspond to the size ratios of vapor molecules and water droplets produced at breakup and also to those of subatomic particles and stars, or the very large or infinite ratios for $1.0 < m < 1.1$ may explain interaction between particles at a infinite distance, i.e., the quantum entanglement.
The potential flow assumption, irrortaional flow one without viscosity, is applicable even for very small subatomic and molecular systems, because very high energy, ie., very high speed, is put for the particle. Actually, energy at the level of sound speed is put into the molecular system, while energy at the level of light speed is put into the subatomic experiment.

3.4 Number of particle types and frequencies

The size asymmetry of around 3:2 of the main rings in purines and pyrimidines naturally leads us to an asymmetric number of types, i.e., "two" types of purines and "three" types of pyrimidines, [6, 7] The multiplicative inverse of the asymmetric number of types is the size asymmetry. This can be easily understood from the mass conservation law, that is, from the fact that the main rings of purines have "nine" molecules of carbon and nitrogen, while "six" molecules of carbon and nitrogen form the main rings of pyrimidines. Accordingly, the number of base types is proportional to the frequency of bases inside RNA [6, 7]. In qualitative terms, the sizes and molecular weights of the twenty types of amino acids are also inversely proportional to the frequencies.

4. STRINGS AND RINGS PRODUCED BY COALESCENCE (Gourd Ib)

4.1 Clover structure

An extremely large frequency ratio for purines and pyrimdines in tRNA, say, far larger than 1.5, cannot produce the stem in tRNA, because purine and pyrimidine pairs do not easily form in the presence of only one type of base [6, 7]. It is also known that, as purines and pyrimidines in DNA have the same density, they form a pair at each locus due to hydrogen bonding. Thus, this frequency ratio of 1.0 for purines and pyrimidines cannot generate loops in tRNA [6, 7]. This is the reason why a frequency ratio between 1.0 and 1.5 for purines and pyrimidines promotes clover structures having stems and loops (Fig. 4). More complex structures such as rRNA can also be explained by the above-mentioned dynamical mechanism. [6, 7] Concavity and convexity, like thumbs in RNAs, play an important function for grasping objects, including nucleic acids and proteins.

During differentiation and proliferation of the morphogenetic process, repeats of symmetrical and asymmetrical cell sizes also induce the structures of concavity and convexity in multi-cellar systems, thereby leading to functional parts such as arms and legs.

Chromosomes in multi-cellar systems also have three-dimensional repeat structures of concavity and convexity. It is known that introns and junk are concave in shape, while exons having the clear function of producing proteins are convex in shape.

[Several sequence data in the world-wide databases show a tendency of purines richer than pyrimidines in RNA, which is contradict to the principle that smaller bases are more. Non-coding RNA reported recently solves this contradiction. There may also be other unknown RNAs which are rich with pyrimidines.]

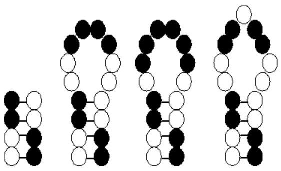

Fig. 4. Schematic diagram of symmetric and asymmetric density ratios in DNA and one leaf of tRNA

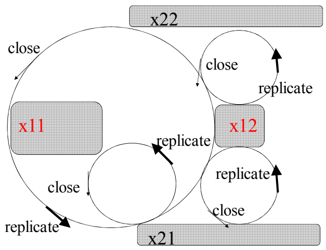

Fig. 5 Four-stroke molecular engine

4.2 Comfort

Human brain feels the golden and silver ratios of around 2:3 to be comfortable. Thus, our previous reports predicted that there will be about 2:3 ratios in the aggregations of neural cells of the brain. [2] Recently, some researchers found the left-right asymmetric part inside the habenular nucleus of the zebrafish brain, which has size ratios between 1:1 and 1:2 [4]. It is known that the habenular nucleus is related to fear, which is the opposite feeling of comfort. Thus, the asymmetric size ratios of neurons and networks inside the brain, which may be induced by some different neurons such as GnRH neurons and glia cells, also have sympathetic vibration with the asymmetric ratios in picture images entering from the outside into the eyes. The sympathetic vibration brings comfort.

Next, let us think about the musical scale inducing comfortable music. Musical scale Perfect 5 uses the ratio of 2:3 for the sound frequencies, while perfect 4 employs 3:4. Music also uses the magic numbers shown above. Then, perfect 5 consists of "seven" half tones, while perfect 4 is with "five" half tones. It is also stressed that the magic numbers of 2:3 (1.5) and 3:4 (1.33) mentioned above result in the ratio of 7:5 close to the silver ratio, which is the rhythm used for Japanese poems such as "haiku" and "tanka".

5. AGGREGATIONS GENERATED BY MORE COALESCENCES (Gourd Ic)

5.1 Inner-asymmetry in cells and morphogenesis

Symmetric and asymmetric size ratios are also observed at the cell level of microorganisms. [6, 7]

There are terminal cells and basal cells of different sizes in the morphogenetic processes. This difference in cell size also shows asymmetry [6, 7]. Embryo stem (ES) cells also show asymmetric cell divisions (differentiation) such as a division to glial cells and neurons.

The left-right symmetric distribution of arms and legs is observed in outward appearance, although the inner body, including the heart and liver, is asymmetric. Outer cells close to the surface move relatively easily in relation to the absolute origin on the earth, because one part of the cell is free without any connection to other cells. However, inner cells receive forces from many directions due to the presence of other cells in a homogeneous field, making it difficult for them to move relative to the origin on the earth. Therefore, inner cells deform relatively easily without any translational motion of the gravity center.

Equations 3 and 4 explain this important characteristic of the asymmetric division of inner cells and the symmetric division of outer cells. This is because the asymmetric size ratio of cells (the size ratio of about 1.45) is relatively quasi-stable against the disturbance of deformation that easily affects inner cells and also because the second term on the right-hand side of Eqs. 3 and 4 implies cell deformation. Outer cells divide into identical sizes of cells, because the first term corresponds to the translational motion of a cell.

5.2 Protons and neutrons in atoms

It is also well known that several atoms in nature have number ratios of protons and neutrons between 1:1 and 2:3. Here, let us examine the reason why larger atoms have larger number ratios close to 2:3.

As shown above, the inner and outer parcels of baryons determine whether the number ratio of neutrons and protons are asymmetric or symmetric, respectively [5, 6].

Larger aggregations of parcels such as thorium (Th), which contains more baryons than helium (He), have more inner baryons, because the surface/volume ratio of the aggregation becomes smaller as the size increases. More inner baryons for larger atoms bring more asymmetric number ratios of protons and neutrons.

Mysteriously, the masses of stable protons and neutrons are almost the same, while child atoms generated by fission of uranium 235 and nitrogenous bases (pyrimidines and purines) have a different weight ratio around 2:3. Some reasons are shown [5, 6]. There is the other analogical evidence supporting the inevitability of the ratio close to 1:1 for proton and neutron, that the Watson-Crick pair of nitrogenous bases has the asymmetric weight ratio of about 2:3, whereas the weight ratio of the pair including sugars inside DNA and RNA is close to 1:1 because of addition of sugar for each base.

6. REPEATS OF BREAKUP AND COALESCENCE (Gourd Id)

As shown above, one particle alone is deterministic without indeterminacy, whereas systems of two particles interacting can have indeterminacy, because the continuum assumption is impossible when there are only two flexible particles. Of course, systems having a number of particles from three to several hundred can also be indeterminant. Systems having more particles may be approximated as a continuum, i.e., deterministic, if the representative scale in space for averaging is very large. Aggregation of a lot of small particles results in a large particle at the next scale, which is close to a sphere or a spheroid. The new large particle is deterministic again, because it is only one.

As an example, let us look at the biological system. Only one DNA existing inside a cell is deterministic, because DNA must accurately determine the structures and functions of living beings. Two male and female DNAs for mating can produce diversity with indeterminacy by crossing over. There are extremely large numbers of genes, proteins, and water molecules inside a cell, which leads to a continuum, i.e., the next deterministic behaviors and sustainability during the cell's life time. Compartment due

to cell membrane leads to the determinacy as sustainability. The loss of many molecules during the aging process results in indeterminacy and also instability or death. Therefore, further thought experiments based on the indeterminacy level mentioned above may reveal the total numbers and groups of bio-molecules inside human beings, including presently unknown ones. The death rate of children will be between 10% and 0.1%, although the rate depends on economical situation of each country. This may imply that the total number of molecular groups inside healthy human beings is between 10 and 1,000.
Moreover, if the total numbers and types of molecules (or molecular groups) are revealed, the probability of survival after developing cancer can also be clarified by the indeterminacy level analysis. [It is known that a few electron orbits around atomic cores are indeterminant. Stars are nearly deterministic, because weak gravity forces lead to individual motion for each star.]

7. EXPANSION AND COMPRESSION (Gourd II)

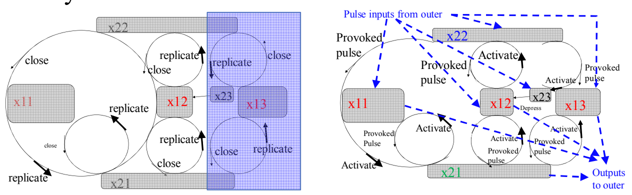
Other natural phenomena such as the morphogenetic and aging process are in the topological mode of expansion and compression. This mode is like a gourd expanding, which has two spherical parts and a duct for suction.
Our three-dimensional unsteady flow simulations obtained by solving the stochastic Navier-Stokes equation revealed the three-dimensional structure of the morphogenetic processes of human beings, including organs and the brain [11]. The morphogenetic process of the main blood vessels inside the brain was also simulated [12]. The computational simulations demonstrate left-right asymmetric organs in the inner region of the body, while symmetric organs and parts are relatively outside the body. The simulation results showing the principle of inner asymmetry and outer symmetry also correspond to the analytical results obtained in the foregoing sections by the quasi-stability principle (Eq. 3). Moreover, the simulation results also show another principle of early symmetry and later asymmetry [10]. [Compression will correspond to death, because compression process is very unstable as seen in turbulence increase during the compression stage of piston engine.]
Our universe may also be expanding. If there are no super-universes outside our universe, our one is symmetric.

8. EXCITATORY AND INHIBITORY MODE (Gourd III)

8.1 Self-replication
Our previous reports clarified the minimum excitatory network of chemical reactions necessary for self-replication. [7] The minimum system has four types of molecules (molecular groups): two information groups x11 and x12 and two functional molecular groups x21 and x22. (Fig. 5) [7] This four-cycle system in Fig. 5 works as a closed loop. Microorganisms including bacteria and archaea and cancer cells basically employ this network of the four molecular groups, because of a monotonic increase without any depression. Emphasis is placed on the fact that Fig. 5 shows a new, concrete, mathematical definition of life at a higher level. We can topologically see the symmetric and asymmetric circles of reaction networks in Fig.5, which also have gourd shapes connected with symmetric and asymmetric lumps. These gourds commonly appear because both parcels in a base-pair and those in network have connection at the rate-determining stage.
It is also clear that the fusion of asymmetric and symmetric size ratios of molecules (bipolarity of sizes) also naturally results in the fusion of asymmetrical and symmetrical network patterns (bipolarity of topology).
Complementary pairs of RNA such as double-strand RNA (dsRNA) may form the simplest cycle. However, information and a catalytic function are undetached in this type of system, because each strand of dsRNA has both of them. This leads to the fact that the dsRNA and DNA suitable for stabilizing information is not conducive to the production of various functions for inducing multi-cellar systems having complex geometries. Thus, living beings select the detachment of information and function.
8.2 Morphogenetic and economic processes
The main temporal mystery is the basic molecular instrument regulating the biological rhythm common to the cell cycle, proliferation and differentiation induced by the stem cell cycle, neural pulse, neural network, and circadian clock. At least two more inhibitory molecules (molecular groups) of information and function should be added to depress a monotonous increase in DNA. [13].
Here, we define x13 and x23 as the other molecular groups for inhibitory factors repressing reactions. These two groups are incorporated in the four groups of x11, x12, x21, and x22, because today's cells and the morphogenetic processes of multi-cellar systems use negative controllers such as Oct-4 and SOX2 for producing tissues and organs [14]. This leads to a macroscopic model having six types of molecular groups, or in other words, a six-stroke engine (Fig. 6a). We can describe the densities of the six groups at generation N after the mother cell generation by the following equations.

$$x_{1i}^{N+1} - x_{1i}^{N} = \alpha_{i1} x_{1i}^{N} \otimes x_{21}^{N} \quad ,(i = 1,2,3)$$
$$x_{2i}^{N+1} - x_{2i}^{N} = \alpha_{i2} \delta(x_{1i}^{N} - \xi_i x_{23}^{N}) \otimes x_{22}^{N} \quad ,(i = 1,2,3) \tag{5}$$

where $x_{ij} \otimes x_{km}$ denotes the smaller value among x_{ij} and x_{km} and also where $\delta(x)$ denotes the larger value of x or 0, i.e., max (x, 0). [13] Statistical mechanics inevitably leads to the mathematical form on the right-hand side in Eq. 5, because of collision probability.
Numerical solutions for Eq. 5 show about a sevenfold beat cycle of densities for molecular groups on average, while varying the parameters in Eq. 5 results in four- to ten- fold beat cycles.



(a) (b)

Fig. 6 Six-stroke engines for morphogenetic process and neural systems.

An important point is that the actual morphogenetic processes show about seven-beat cycles of molecular densities [13, 15]. Another example is that, in the morphogenetic processes, both human beings and giraffes have "seven" neck bones. These facts provide substantiating evidence for Eq. 5.
8.3 Neural network
Equation 5 also reveals the standard topology of the cortical neural circuit (network), the integration mechanism of brain functions, the neural system for muscle control, and the chemical reaction network inside a neuron [15].
Figure 6b shows the standard pattern for neural networks, which includes inputs and outputs. For the network, six variables of xij (i=1-2, j=1-3) are redefined as the activation level of neurons, related to the density of molecules and amount of total energy inside the neurons.
There are two sides in Fig. 6b, one for inputs and one for outputs, which correspond to information and functional molecules in Eq. 5 and Fig. 6a. The upside-down topology of inputs and outputs in Fig. 6b is also possible.
The most important point is that the present equation (Eq. 5) and Fig. 6 describe the essential physics underlying the

network of neural cells and the molecular network inside a neuron, whereas the Hodgkin-Huxley (H-H) model describes only the outer electrical quantities such as electron flow and voltage for a single neuron. It should be added that some variations modified from the network pattern in Fig. 6 and Eq. 5 are also possible, by varying the arbitrary constants and also by adding more molecular types except for x13 and x23.

It is stressed that the equation generated by the six groups for describing the seven-beat cycle on average (Eq. 5) also shows a quasi-stable feature for healthy conditions, whereas an unstable condition will be for sickness.

Equation 5 is an ordinary differential one that eliminates spatial variations of quantities, because the spatial diffusion of molecules and cells is relatively fast in comparison with temporal oscillations and also because a lot of molecules move between cells. However, spatial variations of quantities should be included for a detailed analysis.

Circadian clock of about 24-25 hours are also seven times the fundamental temperature oscillation of about 3.5 hours. [13, 15]It is interesting that these beat cycles from four to ten include those of five and seven for musical scales of Perfects 4 and 5, which are shown in the foregoing section.

Moreover, emphasis is placed on the fact that the cycles of boom and bust appearing in economic and social systems are also the seven-beat on average, because economic systems are produced by human brains. Flux and reflux of companies and capital can also be clarified by the present analysis.

[For standard neural network systems, the initial conditions or inputs may be inputs from outside networks. The initial inputs can be included on the right-hand side of Eqs. 5 and 6 by the Delta function.]

8.4 Total energy limit

The model (Eq. 5) in the previous sections was derived under the assumption of an infinite energy supply. However, energy supplied for molecular networks, cell colonies, organs, neural networks, or economic systems is limited, because the surface-to-volume ratio of each system decreases according to an increase in the number of molecules, cells, neurons, or populations, leading to a condition of insufficient energy. Thus, a new energy restriction term should be added to Eq. 5, which results in Eq. 6 [15].

$$x_{ij}^{\;N+1} - x_{ij}^{\;N} = \alpha_{ij}\,(x_{1j}^{\;N} - \beta_{ij}\,x_{23}^{\;N}) \otimes x_{2i}^{\;N} - \varepsilon_{ij}\,[x_{ij}^{\;N}]^{q},$$

$$x_{ij} \ge 0, \quad x_{1j}^{\;N} - \beta_{ij}\,x_{23}^{\;N} \ge 0. \; (i = 1-2, j = 1,-3) \qquad (6)$$

If the symbol $\otimes$ implies product, q > 2. If the symbol $\otimes$ means smaller value among two, q > 1

Numerical solutions for the equation extended with total energy limit show a transition to sick situation such as cancer in the aging process of the human beings including the brain, i.e., a mysterious transition from chaotic oscillation at 2nd stage to periodic one at 3rd stage, while the vibration amplitude keeps a constant level. (Fig. 7)

This limitation on the total mass and energy is also evident in today's economic systems, because a huge amount of information travels at the very high speed of light through the worldwide internet, whereas the speed of cargo shipment is still at the sonic level. This supply unbalance between information and objects may induce very complex oscillations and economic crisis, which do not have the sevenfold beat mentioned above.

8.5 Higher pressure for evolution and self-organization

The scenario described above for a universal network pattern in fractal nature can reveal the reason why living beings from the pre-biotic process to multi-cellar systems can be induced stably in a self-organizing manner. Random processes cannot generate the present living system having complex chemical reaction processes.

9. CONCLUSION

This approach solves mysterious problems concerning the origin of life, evolution, molecular biology, microbiology, system biology, morphogenesis, economics, medicine, brain science, subatomic theories, and cosmology.

Equation 5 may indicate that countries with excessive use of alcohol as depression factor now result in strong economic oscillations and low economic growth. Then, Eq. 6 shows that countries with less domestic and oversea transport lead to stop of economic growth in earlier time, while weak compartments such as national border and different current money are necessary.

Abstract: Living beings meta-stable between unstable and neutral-stable conditions use only five types of nitrogenous bases and twenty amino acids selected naturally. The quasi-stability principle derived for spheroid particles [Naitoh, JJIAM 2001, Artificial Life Robotics 2010, Naitoh et al. Artificial Life Robotics 2011] reveals the reason why the molecular weight of purines and pyrimidines among nitrogenous bases varies by only about 1.5 times, whereas the threefold variation for the molecular weights of amino acids. Here, the theoretical model extended for the various levels of van der Waals force, surface tension, and coulomb force reveals the inevitability of proteins having the size ratios over 3.0. Moreover, we will also show the theoretical considerations for the other shapes of particles except for spheroids.

***Keywords*: Asymmetry, Size, Cyto-fluid dynamic theory, Nitrogenous base, Amino acids, Inevitability**

I. INTRODUCTION

Lots of types of amino acids and bases are possible in the artificial pools of molecules, but living beings use only five types of nitrogenous bases and twenty amino acids selected naturally. [1-5]

Meta-stable living systems can exist only when fully surrounded by water molecules. Thus, the quasi-stability of biological molecules such as nitrogenous bases, nucleic acids, amino acids, and proteins in living beings should be analyzed by considering the flows of water molecules.

Our previous model based on statistical fluid dynamic [6-10] has revealed the reason why living beings employ only five nitrogenous bases, i.e., two purines of A and G and three pyrimidines of T, C, and U, and also why purines and pyrimidines have a size ratio of about 1.5. In addition, the model has revealed the reason why the molecular weights of the twenty types of amino acids show a threefold variation between 240 of cysteine as the maximum and 75 of glycine as the minimum by taking a higher order of the Taylor series for the unified momentum equation describing the deformation motions of biological molecules. Then, the model extended [10, 14] also reveal the inevitability of proteins having the size ratios over 3.0.

In this report, we will show that the momentum theory extended for the various levels of van der Waals force, surface tension, and coulomb force qualitatively [10, 14] reveals the inevitability of proteins having the size ratios over 3.0 in details. Moreover, we also show the theoretical considerations for the other shapes of particles except for spheroids.

II.CYTO-FLUID DYNAMIC THEORY BASED ON the γ-ε EQUATION[6-11]

First, we define a parcel as a flexible spheroid having two long and short radii of $a(t)$ and $b(t)$ dependent on time t and constructed of a bio-molecule such as a base, an amino acid or a protein that is surrounded by water molecules. (A parcel consists of a bio-molecule such as nitrogenous base, amino acid, or protein, water molecules hydrated with the bio-molecule, and the immerse mass due to adding mass effect while impulsive start and stop of deformations occur [8, 9].) It is assumed that the parcel size is proportional to that of biological molecules such as nitrogenous base, amino acid, or protein.

The parcel becomes a sphere of the radius $r_d(=[ab^2]^{1/3})$ under an equilibrium condition. The deformation rate $\gamma(t)$ is defined as $a(t)/b(t)$, while a sphere without deformation corresponds to $\gamma = 1$. We assume that the flow field inside the parcel is the potential flow.

We derive a theory for describing the deformation and motions of two connected spheroid parcels having two equilibrium radii of r_{d1} and r_{d2} and two deformation rates of γ_k $[k = 1, 2]$, while the size ratio of the two parcels is defined by $\varepsilon = r_{d1}/r_{d2}$.(Fig. 1) We model the one-dimensional relative motion between the two parcels, nonlinear convections inside the parcels, the interfacial force at the parcel surface due to forces interacting between molecules, and collisions with water molecules outside the parcels. The interfacial force is evaluated in the form of σ / r^m where m and σ are constants and r is the curvature of parcel surface. Several types of forces such as van der Waals force, coulomb force, and surface tension can be explained by varying m. Here, the relation m = 1 implies the surface tension of liquid. The mean density of the parcels is ρ_L.

Moreover, the scale for averaging, i.e., the minimum scale representing the phenomenon, will be smaller than that in continuum mechanics and will be between the atomic scale and the size of the bio-molecule. Thus, this small averaging window applied to the Boltzmann equation leads to a weak indeterminacy of physical quantities such as deformation and density because of molecular discontinuity. [9, 10, 11]

Next, we derive the momentum equation describing the relation between a dimensionless deformation rate $\gamma_k (\equiv a_k / b_k\ [k=1,2])$ of each parcel dependent on dimensionless time $\bar{t}_k = \sqrt{\dfrac{8\sigma}{\rho_L r_{dk}^{2+m}}}t \quad [k=1,2]$ and the size ratio of the two parcels of $\varepsilon = r_{d1}/r_{d2}$. The stochastic governing equation having indeterminacy can be described as

$$
\begin{aligned}
\frac{d^2}{d\bar{t}_i^{\,2}}\gamma_i = \{ & [(-\varepsilon-\varepsilon^4+\frac{2}{3}\varepsilon E_{0j}\gamma_j^{-1/3})B_{0i}+\frac{2}{9}\varepsilon^{2+m}E_{0i}\varepsilon\gamma_i^{-4/3}](\frac{d}{d\bar{t}_i}\gamma_i)^2 \\
& +[\frac{2}{3}\varepsilon^{2+m}E_{0i}\gamma_j^{-1/3}B_{0j}-\frac{2}{9}\varepsilon^{2+m}E_{0i}\gamma_j^{-4/3}](\frac{d}{d\bar{t}_j}\gamma_j)^2 \\
& +(-\varepsilon-\varepsilon^4+\frac{2}{3}\varepsilon E_{0j}\gamma_j^{-1/3})C_{0i}\,\gamma_i^{\frac{5}{3}-\frac{2}{3}m}+\frac{2}{3}\varepsilon^{2+m}E_{0i}\gamma_j^{-1/3}C_{0j}\,\gamma_j^{\frac{5}{3}-\frac{2}{3}m}\}/Det \\
& +\delta_{st}
\end{aligned}
$$

$$[\text{for } i=1,2.\ j=1,2.\ i\neq j] \tag{1}$$

with

$$Det=-\varepsilon-\varepsilon^4+\frac{2}{3}\varepsilon^4 E_{0i}\gamma_i^{-1/3}+\frac{2}{3}\varepsilon\ E_{0j}\gamma_j^{-1/3},\ B_{0k}=\frac{1}{3\gamma_k}\frac{\gamma_k^{\,2}-2}{\gamma_k^{\,2}-1/2},$$

$$C_{0k}=\frac{3}{8}\frac{2\gamma_k^{\,2m}-1/\gamma_k^{\,m}-\gamma_k^{\,m}}{\gamma_k^{\,2}-1/2},\ \text{and } E_{0k}=3\frac{\gamma_k^{\,7/3}}{\gamma_k^{\,2}-1/2}[\text{for } k=1,2]$$

where the parameter δ_{st} denotes random fluctuation.

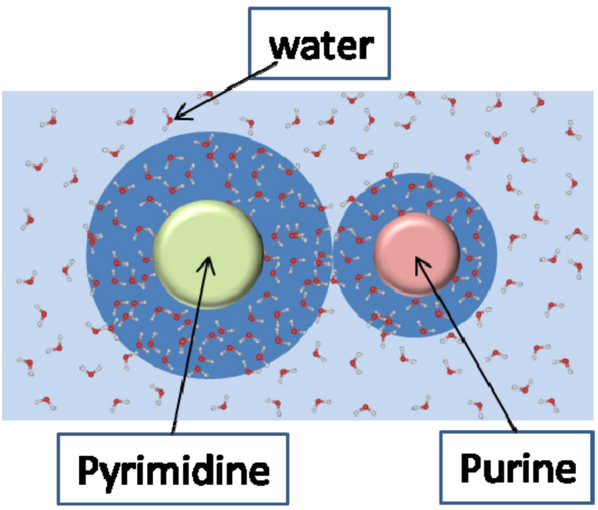

Fig.1. Two parcels connecting

III. FIRST ORDER OF ANALYSIS [6-9]

We then define the deviation from a sphere as y_i, which is equal to $\gamma_i - 1$. Taking the first order of approximation in the Taylor series leads to

$$
\begin{aligned}
\frac{d^2 y_i}{d\bar{t}_i^{\,2}} = [& -\frac{2}{3}(3-\varepsilon^3-2\varepsilon^{2+m})\left(\frac{dy_i}{d\bar{t}_i}\right)^2+3(3-\varepsilon^3)my_i \\
& -4\varepsilon^{1+m}\left(\frac{dy_j}{d\bar{t}_j}\right)^2+12\varepsilon^{1+m}my_j]/[3(\varepsilon^3+1)] \\
& +\delta'_{st},
\end{aligned} \tag{2}
$$

where the parameter δ'_{st} denotes random fluctuation.

A symmetric ratio of 1.0 (ε=1) makes the first term on the right-hand side of the equation zero, while an asymmetric ratio of $\sqrt[3]{3}$ around 1.44 (ε^3=3) makes the second term zero. The size ratios of 1.00 and approximately 1.44 can be described by the unified number of the n-th root of n.

We define a system as being quasi-stable when only one term on the right-hand side of the differential equation system governing the phenomenon (Eq. (2)) is zero. Life is relatively quasi-stable because d^2y_i/dt^2 becomes smaller when the size ratio of connected parcels takes the values of ε=1 or ε^3=3. An important clue for clarifying the inevitability and variety of biological molecules is the concept of quasi-stability (meta-stability) weaker than neutral stability. This is because biological systems are essentially neither neutrally stable nor absolutely stable owing to the potential for a brush with death and also since people can live over 50 years while maintaining the mysterious shape of the body. Thus, a new stability concept between the neutrally stable and unstable conditions is necessary for a meta-stable system of life, i.e., quasi-stability. [6-9]

Free nitrogenous bases in water often seem to be a column of two identical bases such as adenine-adenine, which are not in a two-dimensional plane. There are also multimeric complexes such as that of guanines. Then, it is well known that identical base pairs of $\varepsilon=1$ are often in RNA, while asymmetric base pairs such as the Watson-Crick type of about $\varepsilon^3=1$ are used in DNA.

IV. HIGHER-ORDER OF ANALYSIS [10, 11]

Higher order of the Taylor series

$$
\begin{aligned}
f(y) = & f(0)+\frac{f^{(1)}(0)}{1!}y+\frac{f^{(2)}(0)}{2!}y^2+\frac{f^{(3)}(0)}{3!}y^3 \\
& +.\frac{f^{(4)}(0)}{4!}y^4+\frac{f^{(5)}(0)}{5!}y^5+\frac{f^{(6)}(0)}{6!}y^6+\frac{f^{(7)}(0)}{7!}y^7 \\
& +\frac{f^{(8)}(0)}{8!}y^8+\frac{f^{(9)}(0)}{9!}y^9+......
\end{aligned} \tag{3}
$$

can be applied to Eq. (1).The ninth order of the Taylor series for parcel 1 brings

$$\frac{d^2y_1}{d\tau_1^2}=\left\{\begin{array}{l}\displaystyle\sum_{k=1}^{9}a_{9k}y_1^k+\sum_{k=0}^{8}\sum_{l=1}^{9-k}a'_{9\left\{l+k(19-k)/2\right\}}y_1^k y_2^l\\ \displaystyle+\left(\sum_{k=1}^{9}b_{9k}y_1^{k-1}+\sum_{k=0}^{7}\sum_{l=1}^{8-k}b'_{9\left\{l+k(19-k)/2\right\}}y_1^k y_2^l\right)\left(\frac{dy_1}{d\tau_1}\right)^2\\ \displaystyle+\left(\sum_{k=1}^{9}c_{9k}y_1^{k-1}+\sum_{k=0}^{7}\sum_{l=1}^{8-k}c'_{9\left\{l+k(19-k)/2\right\}}y_1^k y_2^l\right)\left(\frac{dy_2}{d\tau_2}\right)^2\end{array}\right\} \tag{4}$$

with

$\sum_{k=1}^{9}a_{9k}$, $\sum_{k=0}^{8}\sum_{l=1}^{9-k}a'_{9\{l+k(19-k)/2\}}$, $\sum_{k=1}^{9}b_{9k}$, $\sum_{k=0}^{7}\sum_{l=1}^{8-k}b'_{9\{l+k(19-k)/2\}}$, $\sum_{k=1}^{9}c_{9k}$, $\sum_{k=0}^{7}\sum_{l=1}^{8-k}c'_{9\{l+k(19-k)/2\}}$

are coefficients which include ε .

V. QUASI-STABILITY EXTENDED [7, 10, 11]

We can consider only the disturbance for parcel1, because the system of two parcels is mathematically symmetric. Then, we get

$$\frac{d^2y_1}{d\tau_1^2}=\left\{\sum_{k=1}^{9}a_{9k}y_1^k+\left(\sum_{k=1}^{9}b_{9k}y_1^{k-1}\right)\left(\frac{dy_1}{d\tau_1}\right)^2\right\} \tag{5}$$

as the ninth order of approximation, when the terms related to parcels 2 are eliminated.

The nine terms of $a_{91}y_1, a_{92}y_1^2, \cdots, a_{99}y_1^9$ come from interfacial force such as van der Waals force, coulomb force, and surface tension, whereas the later terms of $b_{91}, b_{92}y_1, \cdots, b_{99}y$ come from convection.

Here, we define

$a_{91}=0\ or\ b_{91}=0$

as the quasi-stable condition, while

$a_{92}=0,\ a_{93}=0,\ a_{94}=0,\ a_{95}=0,\ a_{96}=0,\ a_{97}=0,\ a_{98}=0,\ a_{99}=0,$
$b_{92}=0,\ b_{93}=0,\ b_{94}=0,\ b_{95}=0,\ b_{96}=0,\ b_{97}=0,\ b_{98}=0,\ or\ b_{99}=0$

is semi quasi-stable.

Table 1 shows the size ratios of parcels, which bring quasi-stable and semi quasi-stable conditions.

An important point is the numbers such as 4.25, 4.36, 4.54, 6.11, 8.02, 8.33, 10.4, 16.1, and 23.5. These numbers over 3.0 for size ratio will correspond to those of proteins.

VI. QUASI-STABILITY FOR THE OTHER SHAPES OF PARTICLES

We define a parcel as a spheroid shape in the cyto-fluid dynamic theory shown above, but biological molecules have various shapes. Thus, we redefine a parcel as that of a rice ball shape axi-symmetric for the x, which is formed by using spherical surface harmonics (Fig.2).

Assumptions different from the cyto-fluid dynamic theory are three. We first redefine $a(t)$ and $b(t)$ as lengths on the x axis, although $\gamma=(a/b)$ is same as that for the cyto-fluid dynamic theory. Secondly, the parcel becomes a sphere of the constant radius $r_d(=(a+b)/2)$ under equilibrium. Thirdly, the volume is shown by

$V=(\beta^3+4\pi/3)r_d^3$.

where β is defined as follows.

The rice ball shape axi-symmetric for the x axis is shown by

$$R(\theta,\varphi)=r_d\{1+\beta\cdot Y(\theta,\varphi)\} \tag{6}$$

With

$$Y(\theta,\varphi)=1/4\sqrt{7/\pi}\left(5Cos^3[\theta]-3Cos[\theta]\right)$$
$$\beta=2\sqrt{\pi/7}(\gamma-1)/(\gamma+1)$$

where the parameters θ and ϕ denote angle between *R* and the x axis and arbitrary rotation angle around the x axis, respectively.

In the case of m=1 the stochastic governing equation having indeterminacy can be described as

$$\begin{aligned}d^2\gamma_1/d\bar{t}_1^2=&-\Big[E_1F_1(1+\gamma_1)^2(1+\gamma_2)^2\Big(\big(-4H_1\varepsilon^3/(1+\gamma_1)^3\\&+B_1\big((-2E_2F_2+(1+\gamma_2)^2)H_2+(1+\gamma_2)^2H_1\varepsilon^3\big)\big/E_1(1+\gamma_2)^2\big)(d\gamma_1/d\bar{t}_1)^2\\&+\Big((1+\gamma_2)\big(-2C_2E_1F_2\gamma_2H_2\varepsilon^2+C_1\gamma_1\big((-2E_2F_2+(1+\gamma_2)^2)H_2+(1+\gamma_2)^2H_1\varepsilon^3\big)\big)\\&-2E_1(-2+B_2F_2(1+\gamma_2))H_2\varepsilon^2(d\gamma_2/d\bar{t}_2)^2\Big)\Big/E_1(1+\gamma_2)^3\Big)\Big]\Big/Det+\delta''_{st}\end{aligned} \tag{7}$$

With

$$Det=(1+\gamma_1)^2\left(2E_2F_2-(1+\gamma_2)^2\right)H_2+\left(2E_1F_1-(1+\gamma_1)^2\right)(1+\gamma_2)^2H_1\varepsilon^3,$$
$$B_k=-5\gamma_k^{-1}+8+\gamma_k^2,\ C_k=15/4(\gamma_k-1)(\gamma_k+1),\ E_k=3\gamma_k(1+\gamma_k)^2,$$
$$F_k=\left[2(-1+4\gamma_k-\gamma_k^2)\right]^{-1}$$
and $H_k=\left(49+6\sqrt{7\pi}(-1+\gamma_k)^3\right)/(1+\gamma_k)^3$ [for $k=1,2$]

where the parameter δ''_{st} denotes random fluctuation. Taking the first order of approximation in the Taylor series leads to

$$\frac{d^2y_1}{d\bar{t}_1^2}=\left[(1+\varepsilon^3)\left(\frac{dy_1}{d\bar{t}_1}\right)^2+\frac{15}{4}\left(\frac{1}{2}-\varepsilon^3\right)y_1+\frac{45\varepsilon^2}{8}y_2\right]/(\varepsilon^3+1)+\delta'''_{st,} \tag{8}$$

where the parameter δ'''_{st} denotes random fluctuation. A new ratio of about 1.26 makes the second term zero. This quasi-stability may correspond to base pairs of A-T.

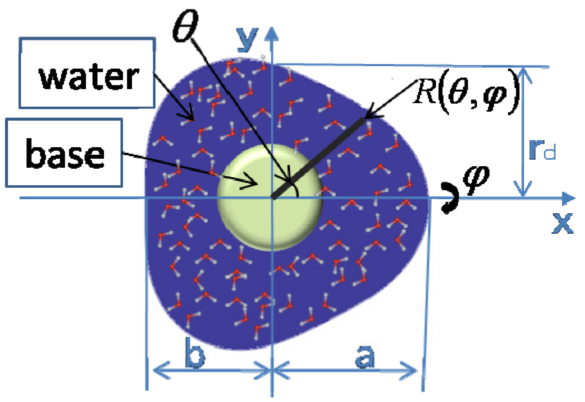

Fig.2. parcel of rice ball shape

Ⅶ. CONCLUSION

The theoretical model extended for the various levels of van der Waals force, surface tension, and coulomb force qualitatively reveals the inevitability of proteins having the size ratios over 3.0. Moreover, analysis based on a rice ball shape for parcel reveals the new quasi-stable ratio, which may correspond to base pairs of A-T.

Abstract: The object of this study is to fabricate three Dimensional cell structures utilizing PELID (Patterning with ELectrostatically-Injected Droplet) method. Because it is preferable to perform laboratory experiments with 3D cell structures in tissue engineering and artificial organ. However, it is difficult to fabricate 3D cell structures because own weight of cell is above the bonding force between cells. In this paper, we printed MDCK cells and collagen as scaffolds utilizing the PELID method. We investigated growth of printed cells. Number of printed cells was increased day by day. We investigated fundamental characteristics on patterning collagen. The printed collagen was thick when the time to print was increased. These results indicated that it is possible to fabricate 3D cell structure.

Keywords: Inkjet, PELID, Scaffolds, Cell

1 INTRODUCTION

The goal of this study is to fabricate precision 3-Dimensional cell structures utilizing PELID (Patterning with ELectrostatically-Injected Droplet) method. It is preferable to perform laboratory experiments with 3D cell structures in tissue engineering and artificial organ. However it is difficult to fabricate 3D cell structures because own weight of cell is above the bonding force between cells. Commercial piezo inkjet technology was applied for 3D positioning of calcium alginate which contained living cells [1, 2]. Calcium alginate was used as scaffolds instead of gelatin liquid or collagen liquid because these were difficult to eject due to high viscosity. Because calcium alginate was easy to stick each other, 3D positioning of cells was succeeded. However cells could not contact each other by the wall of the calcium alginate. To clear this problem, inkjet technology should be more developed to eject highly viscous liquid. Our inkjet technology, PELID method, had two merits; those were high resolution and ability to eject highly viscous liquid. These merits were suitable to print cells precisely and eject highly viscous scaffolds. We reported that living cells were printed and 3D structures which contained living cells were fabricated utilizing the PELID method [3] with born stem cells. In this paper, we print MDCK cells because we are now applying the PELID method for fabrication of 3D cell structures.

2 EXPERIMENTAL SET-UP

Merits of the PELID method were suitable to print living cells and to fabricate 3D cell structures because cell structures should be precise and liquid with scaffolds was relatively highly viscous. However, voltage of the PELID method is about several kV. Sometimes people are killed by electric shock through consent. Household voltage is about several hundred V. We should investigate effect on the cells ejected by the PELID method.

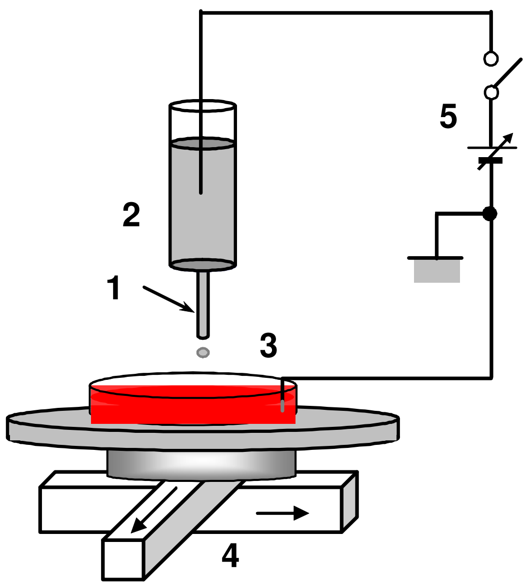

Figure 1 Experimental set-up of cell patterning utilizi ng PELID method. (1: water pin electrode, insulative c apillary tube was mounted at tip of syringe, 2: tank, fi lled with liquid of cells, 3: dish, filled with medium, 4: xyz linear stages, 5: DC high voltage power supply)

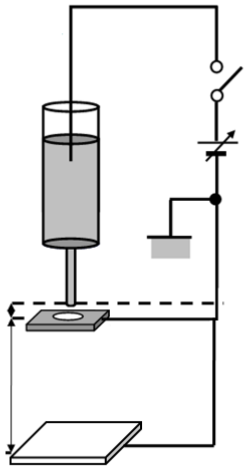

Figure 2: Experimental set-up to pattern collagen utilizing PELID. (plate electrode with hole is installed between nozzle and target)

An experimental set-up shown in Fig.1 was constructed to investigate characteristics to print living cells utilizing the PELID method. MDCK cells were used in this experiment. The tube filled with the liquid which contained the cells was hanged down perpendicular to a dish filled with medium. Voltage was applied between the syringes and the dish by a power supply (voltage range: -5kV ~ +5kV, Matsusada Precision Inc, Tokyo, HVR-10P). The air gap was adjusted by a z-stage and the dish was moved in x and y directions with two linear motors. Voltage application and motion of the linear stages were controlled by a PC.

In this paper, collagen was used as scaffolds between cells to fabricate 3D cell structures. An experimental set-up illustrated in Fig. 2 was constructed to investigate fundamental characteristics to print collagen. A tube filled with liquid that contained collagen was mounted perpendicular to a plate electrode made of stainless steel or dish that was filled with medium.

3 RESULTS

3.1 Cell ejection

Figure 3 and 4 show photos of printed cells when one day has passed after ejection of MDCK cells utilizing the ELID method. Figure 5 shows the enlarged view of living cells. Living cells were attached to the dish and spread. Dead cells were not attached to the dish and floating in the medium. Most cells were living in spite of high voltage application because current did not flow inside cells but around cells. Cells were living in case that the diameter of the tube was over 100 micron meters. In case that the diameter of the tube was less than 50 micron meters, it is difficult to eject continuously because cell attachment took place inside the tube. These results indicated that it was possible to print cells utilizing the PELID method.

3.2 Collagen patterning

Scaffolds are necessary to fabricate 3D cell structure because own weight of cell is above the bonding force between cells. In this paper, collagen is used as scaffolds. We investigate fundamental characteristics on patterning collagen. Figure 6 shows the line width in case that applied voltage is changed. When applied voltage is increased, line is fine. When applied voltage is further increased, line is wide. In case that applied voltage is the threshold of droplet mode

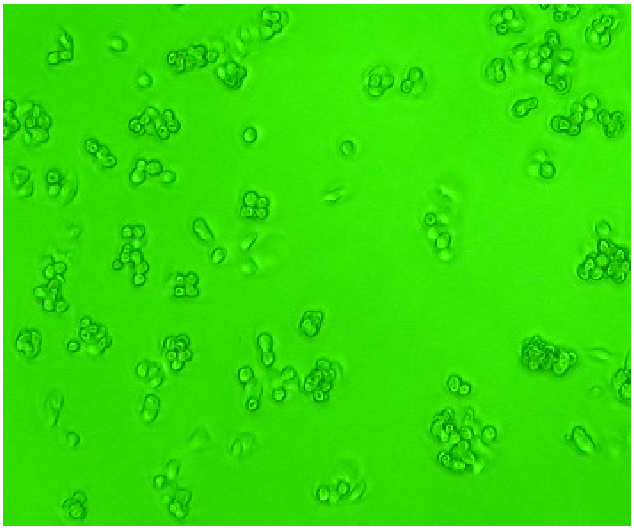

Figure 3 Picture of printed cells. (applied voltage: 2.9 kV)

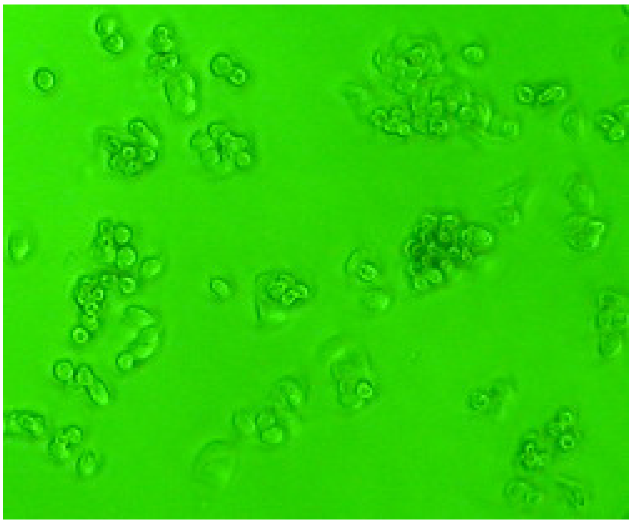

Figure 4 Picture of printed cells. (applied voltage: 3.9 kV)

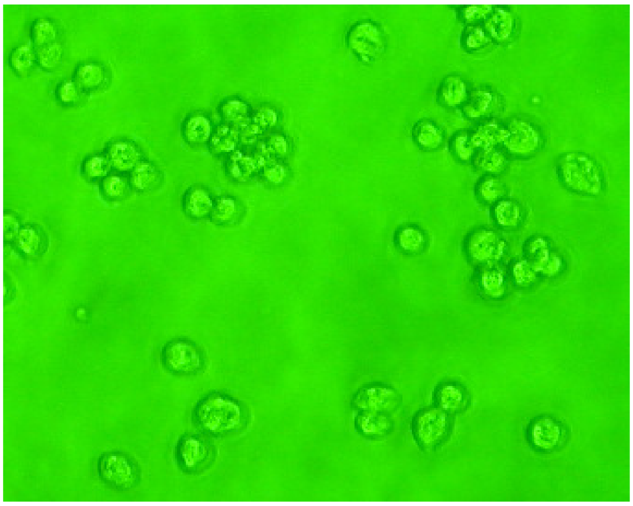

Figure 5 Enlarged view of printed cells.

[3], printed line is finest because ejected droplet is very small.

Figure 7 shows the thickness of printed collagen when the time to print is changed. Figure 8 shows photo of printed collagen. We measure height in center of printed collagen. The thickness is linearly increased when the time to print is increased. When the printed collagen is thick, the air gap is short. However, electric field around tip of nozzle is constant because plate electrode with hole is installed between the nozzle and target shown in Fig. 2. This result indicates that thickness of collagen is easy to control and it is possible to fabricate 3D cell structures.

Transportation of nutrient in 3D cell structure is most important issue. We fabricate 3D cell structure that collagen is printed on printed MDCK cells. This structure is fabricated in 96 well plates. Medium with nutrient is set on this structure. Figure 9 shows fabricated cell structures when 1 day has passed after print. Figure 10 shows fabricated cell structures when 2 days has passed after print. Figure 11 shows fabricated cell structures when 3 days has passed af-

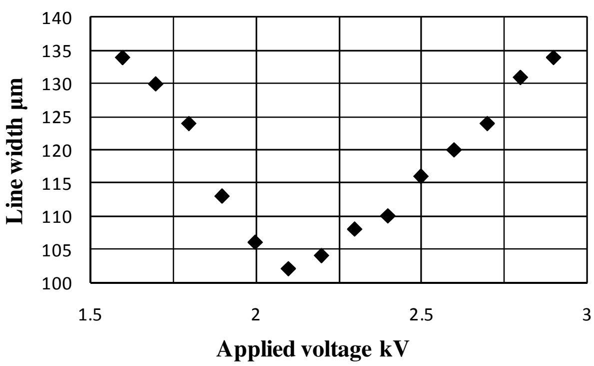

Figure 6 Line width of printed collagen.

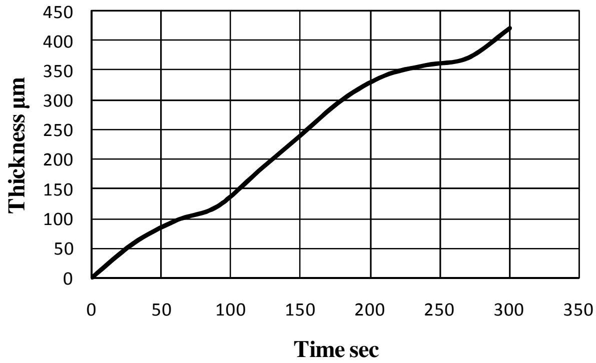

Figure 7 Thickness of printed collagen when the time to print was changed.

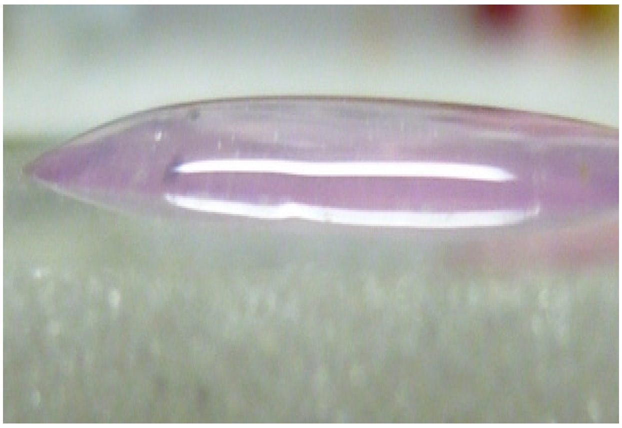

Figure 8 Photo of printed collagen.

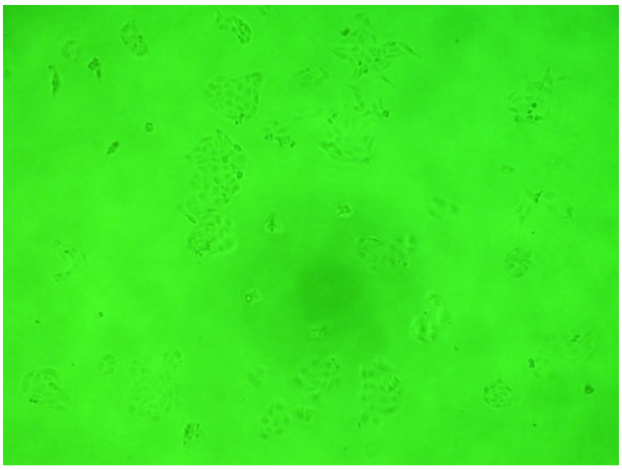

Figure 9 Photo of printed structure of collagen layer on MDCK cells when 1day has passed after print.

ter print. In spite that thickness of collagen is changed, nutrient reaches cells because collagen layer has cavit y. This result indicates that 3D cell structure is fabrica ted by PELID method and fabricated cell structure is l iving.

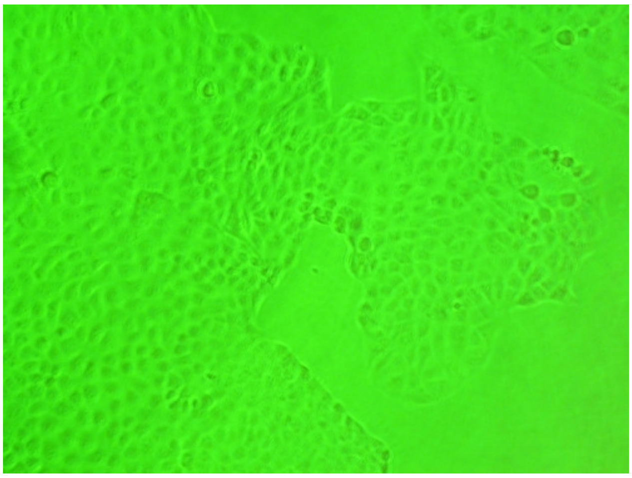

Figure 10 Photo of printed structure of collagen layer on MDCK cells when 2days has passed after print.

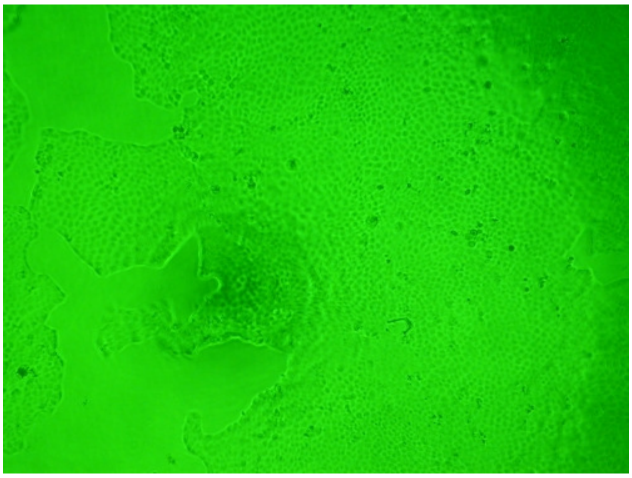

Figure 11 Photo of printed structure of collagen layer on MDCK cells when 3days has passed after print.

4 CONCLUSION

We fabricate 3D cell structure by using PELID method. The fabricated 3D cell is living and number of cells is increased day by day.

Abstract: We discuss a new take on an old mathematical problem of chase and escape. We consider one group chases another, called "group chase and escape", by presenting simple models. We have found that even a simple model can exhibit rich and complex behavior. The model has been extended to investigate the effects of (1) fluctuations in chasing and escaping movements, (2) reaction delays when chasing, and (3) the conversion of caught escapees to new chasers. We show that these effects can add further complexity and result in unexpected behaviors.

Keywords: Collective Motion, Chase and Escape, Delay, fluctuation

1 INTRODUCTION

"Chases and Escapes" (or "Pursuit and Evasion") is a traditional mathematical problem[1]. Typical questions include "How much time is needed for a chaser to catch a target?" and "What is the best escaping strategy?" There has been much mathematical interest in obtaining analytical results, so the majority of the questions have dealt with cases in which one chaser is pursuing a single escapee.

We recently proposed a simple extended model called "Group Chase and Escape"[2] in which one group chases another group. This extension connects the traditional problem of "Chases and Escapes" with current interest in the collective motions of self-driven particles such as animals, insects, cars, etc[3, 4, 5].

In this paper, we briefly present our basic model and its rather complex behaviors. Each chaser approaches its nearest escapee while each escapee moves away from its nearest chaser. Although there is no communications within groups, aggregate formations are observed both for both chasers and escapees. How these behaviors appear as a function of parameters, such as densities will be discussed.

In addition, we have extended our models in three main ways. First, we introduced a fluctuation. Players now make errors in which direction they step with some probability. It turns out that some levels of fluctuations work better for more effective capturing. Second, we introduced a reaction delay in a chaser who is pursuing an escapee that is moving with a uniform speed in a circular path. We did not observe a complex chaser's trajectory with constant reaction delay, but distance–dependent reaction delays can cause quite complex behaviors. Finally, we report briefly on the effect of the probabilistic conversion of the captured escapees into new chasers.

2 BASIC MODEL OF "GROUP CHASE AND ESCAPE"

Here, we describe our basic "Group Chase and Escape" model[2]. Essentially, it is a chase and escape problem in which one group chases another. In order to keep our extension simple, we made each chaser in a chasing group take one step toward its nearest escapee, while each escapee takes one step away from its nearest chaser. They do this independently of each other, meaning there is no communication or direct interaction among members within either the chasing or the escaping groups. We also decreed that a caught escapees be removed from the field, so that gradually the number of escapees decreases. The chase and escape finishes when all the escapees are caught and removed from the field ("complete capture").

There are various possible implementations of this conceptual model. To start with, we considered a square lattice with a periodic boundary condition and discrete step and time movements of the players. We also introduced an exclusion volume property: they cannot move if another of the same type (chaser or escapee) occupies the next location of intended motion. Also, when there are multiple choices (typically only two, due to the square lattice) for the next step, one of them is chosen with equal probability.

We have simulated the above model under various conditions[2, 6]. One of the interesting qualitative behaviors observed is a formation of aggregates by both chasers and escapees in spite of the fact that there is no direct interaction among the members of each group. In a related matter, given the initial size of the number of escapees, there exists an optimal number of chasers for effective capture. This can be seen by increasing the number of chasers with a given number of escapee, and noting the time taken to finish capturing all of the escapees. This complete capture time will decrease at a rather fast pace until it reaches the optimal number of chasers, after which it changes at a much slower rate. One of the reasons for this is the excluding volume effect (mentioned above): chasers get in each other's way. However, this is not the only cause – the very act of chasing and escaping is also a crucial factor, as such an effect is not seen if we set both chasers and escapees as groups of random walkers.

3 EFFECTS OF FLUCTUATION

We have extended our study to examine the effects of fluctuation in the above basic model[2, 7, 8, 9]. Specifically, we introduced errors in taking steps by players of both sides. With some probability, a chaser now takes a step in the wrong direction, thus increasing its distance from the nearest escapee. This error probability, which is also introduced in the steps of the escapees, is designed so that with the maximal error both sides become groups of random walkers, while with zero errors the model is reduced to the basic model described in the previous section.

We simulated the model with the above fluctuation error with varying probabilities and different ratios of the numbers of chasers and escapees. Increasing the error rate naturally led to a longer time for complete capture, and this is what happened when the number of chasers was relatively large. However, a rather interesting situation was observed when there were small number of chasers and escapees compared to the size of the square grid field. In this case, there exists the optimal level of fluctuation with which the time for complete capture became minimal – indeed less than not only the case in which both sides were randomly walking, but also in the case of the basic model mentioned above.

Cases that exhibit an appropriate level of fluctuation leading to "better" effects are being studied in various fields, including biology, material science, engineering and so on, under the name of "stochastic resonance"[10, 11, 12]. Our observation here can be considered as one of such examples.

4 EFFECTS OF DELAY

Next, we consider the effects of delayed reaction time on the part of the chasers[13, 14]. To examine this, we go back to one of the original one-to-one chase and escape problems in which the escapee moves in a circular path at a constant speed while the chaser moves with its velocity vector pointing to the current position of the escapee. We know that if the speed of the chaser is not as fast as the escapee, the capture is not possible, and the path of the chaser will approach to a "limit circle". The center of the two circles is the same and the ratio of the radii is the same as the ratio of the speeds of the chaser and the escapee.

Now let us consider a case in which the speeds of the chaser and escapee are the same. In this case, the chaser moves behind the escapee with the same uniform distance on the same circle. We now introduce a delay to the reaction time of the chaser. Specifically, the velocity vector of the chaser points to the past position of the escapee. We can immediately see that if we introduce this reaction time as fixed constant (fixed delay), the qualitative behavior of the chaser's motion does not change: the effect is merely an increase of the distance between the chaser and the escapee on the same circle.

However, if we set the reaction time to be proportional to the distance between the chaser and the escapee (distant dependent delay: the longer the distance, the longer the delay), the path of the chaser deviates from the circle. As we increase the rate of this proportionality, the path will become quite complex.

Delay–induced complex behaviors have been studied in various contexts. The most notable examples are the dynamical trajectories given by delay differential equations, such as the MacKay – Glass model[15]. In this model, a very simple first order differential equation with an external force term, which is a function of the delayed past state of the dynamical variable, can show various dynamics from a stable fixed point, limit cycles, and further create complex chaotic trajectories as we increase the value of the delay. Our observation here can be considered another example of delay–induced complexities.

5 EFFECTS OF CONVERSION

Finally, we briefly discuss the effect of conversions[16]. We extend the basic model in such a way that the caught escapee becomes a new chaser with a certain probability, while escapees can proliferate with some probability as well. The balance between these two factors again produces a non-monotonic change in the time it takes for complete capture with varying parameters. For example, if we fix the number of chasers and escapees and change the proliferation probability, there exists an optimal value to have the longest time for complete capture for a smaller value range of conversion probabilities. This finding has also been reported in a separate publication[16].

Using our model with this extension has potential for application to studies on the spread of certain epidemics such as rabies.

6 DISCUSSION

We have described our recent proposal and investigation of group–based chases and escapes and are faced with the following tasks. First, we should make our model more realistically by including communication within groups or more complex chasing and escaping strategies. They reflect such cases of one group of animals chasing another, e.g., wolves hunting deer[17]. Second, we need to consider a possible application to distributed robotics or other engineering systems. For example, the human immune system includes neutrophil granulocytes that chase foreign external viruses or chemicals. Could we implement such a defense system against attacks in cyberspace by adapting the concept of chase and escape included? Finally, this type of chase and escape interactions among the constituents in groups has not been addressed in studies of physical theories. Extension of many-body theories of statistical physics for the purpose of adapting them to chase and escape–type interactions will likely pose interesting challenges in the future.

The author would like to thank A. Kamimura, S. Matsumoto, and R. Nishi for their collaborative works. Thanks also go to T. Nogawa, N. Ito, K. Nishinari and J. Milton for their fruitful discussions.

Abstract: Arterial casts from animal brain, kidney, and ear as well as chorioallantonic arteries of chick embryo were subjected to the microscopic measurement of arterial geometry. According to the optimization principle known as Murray's law, the blood vessel geometry at a bifurcation satisfies the relation $D_0^m = D_1^m + D_2^m$ $(m=3)$, where D_0, D_1, and D_2 are the diameters of the parent and two daughter vessels, respectively. The values of diameter exponent m were found to be 2.59 for brain, 2.54 for kidney, 2.58 for earlobe, and 2.49 for chick embryo, showing significant deviation from the Murray's law. Physiological implication of m values is discussed.

Keywords: Arterial geometry, Blood flow, Murray's law, Optimal theory,

1 INTRODUCTION

Understanding the physiological significance of organization and structure of the vascular system has been the major subject of vascular physiology. Murray [1] has applied minimum work concept to a theoretical analysis of blood flow through cylindrical segment of blood vessel. This principle, which stipulates that the total energy required to drive and maintain the blood to be minimal, predicts an expression that the diameters D of blood vessels are proportional to the cube root of the flow Q which they convey,

$$D \sim Q^{1/m}, \quad \text{or} \quad Q \sim D^m \quad (m=3). \qquad (1)$$

With similar consideration, the angle of vascular branching has been predicted to be a function of relative sizes of the parent trunk and its branch vessels [2]. Considering the mass flow continuity at arterial bifurcation, we obtain the relation among vessel diameters at a bifurcation ,

$$D_0^m = D_1^m + D_2^m, \qquad (2)$$

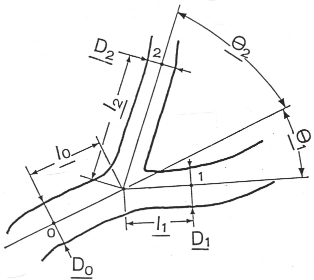

Fig. 1. Scheme of arterial bufurcation

where Do, D_1 , and D_2 are the respective lumen diameters of the parent vessel and the two daughter vessels (Fig. 1.).

Murray's law has been tested in the cardiovascular systems of several different animals including man [3][4]. It has been generally accepted that the arterial bifurcation geometries are understandable in terms of optimization with respect to the energy expenditure required for the fluid conducting system. However, some authors, who measured arterial geometries, reported significant deviation from the Murray's law. For example, Suwa et el. [5] reported that the diameter exponent m is different in organ to organ, and average value for various organs in human body is to be 2.7.

In this study, we made arterial casts from several parts of animal body such as brain, kidney and ear, and measured parent and branch vessel diameters and branching angles at arterial bifurcations. We also measured geometries of living arteries growing around chick embryo. Based on the geometrical data of arteries, we derived m values and compared them with those from the theory and other experiments.

2. METHOD

2.1 Preparation of arterial casts

Arteries in the cat brain, kidney and earlobe were visualized by casting procedure using a silicone compound or a aclilic resin. For the casting procedure, after death of animals due to excess dose of an anesthetic, a cannula was inserted into the ascending aorta through the left ventricle of the heart. Then the animal was perfused with a normal saline solution, and then a fixative solution under physiological pressure. After that, the casting medium was injected through the cannula. After few hours of medium polymerization, the organs were removed, and subsequently immersed in a glycerin solution to clear the tissue. Then, the photographs of the cleared organs were taken using a photomicroscope. Finally, the tissue surrounding the cast was corroded away by using a KOH solution. Microscopic examination readily allowed three dimensional visualization of the vascular bed. The present animal experiment has been approved by the Tokyo Medical and Dental University Institutional Review Board.

2.2 Visualization of arteries in chick embryo

Chick eggs incubated at a temperature of 311 K to 5-12 days of a 21-day incubation period were used for the present measurement. The shell and inner membrane were removed carefully and the avian chorioallantonic membrane (CAM) were exposed, which were subjected to the present measurement. The chorioallantonic artery is the largest extra embryonic and the major respiratory organ in the chick embryo.

(A)

(B)

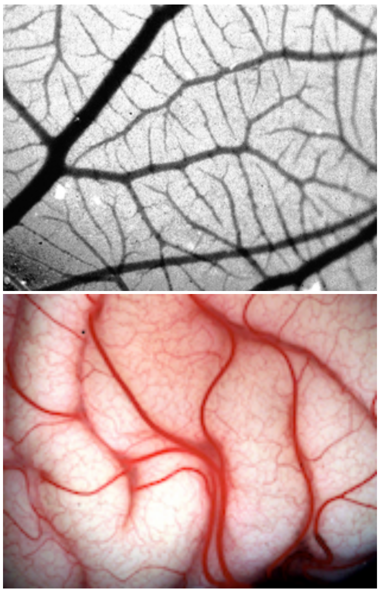

Fig.2 (A) Blood vessels (arteries and veins) in the CAM of chick embryo. (B) Arteries distributing on the cortical surface of the brain.

2.3 Measurement of vessel geometry

The vessel patterns obtained were magnified and recorded with a disecting microscope coupled with a video imaging system and a digital camera. Measurements were made manually on frame-grabbed images using an image analysis software.

Figure 2 (A) shows an example of the photograph of blood vessels in the CAM, and (B) arteries distributing on the cortical surface of the cat brain. Arteries in the CAM grow in a topologically two-dimensional and both arteries and veins show comparatively simple layered structure with little overlapping among them. The patterns are clear and the geometric measurements could be dome easily. We classified the vessels as arteries, if the blood flowed from the parent to the daughter vessels, otherwise, classified them as veins.

The diameter was measured at three locations near the bifurcation (see Fig. 1). Then, the average diameters D_0, D_1 and D_2 were computed for the parent the larger daughter, and the smaller daughter vessel, respectively.

3. RESULTS

3.1 Determination of diameter exponent

In order to obtain diameter exponent m from measured lumen diameters of the parent vessel and the two daughter vessels at arterial bifurcation, we rearrange equation (2) into following equations [6];

$$\frac{D_1}{D_0} = \left[1 + \left(\frac{D_2}{D_1}\right)^m\right]^{-1/m} , \quad (3)$$

and

$$\frac{D_2}{D_0} = \frac{D_2}{D_1}\left[1 + \left(\frac{D_2}{D_1}\right)^m\right]^{-1/m} . \quad (4)$$

We obtained diameter exponent m by nonlinear regression analysis of measured diameter ratios.

3.2 Measured diameter exponent

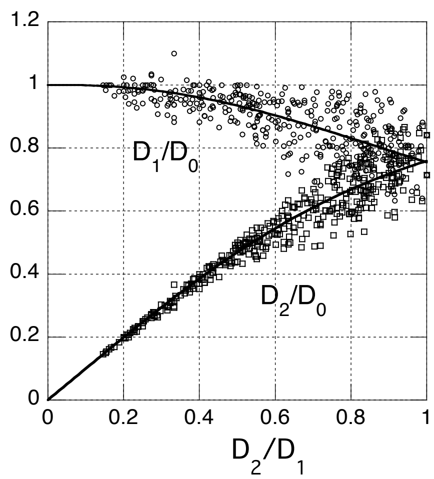

Fig.3. CAM arteries

In Fig. 3, normalized diameters of larger and smaller daughter branches (D_1/D_0 and D_2/D_0, respectively) are plotted as functions of the diameter ratio of the daughter branches (D_2/D_1) in the CAM arteries of chick embryo. In Fig. 3, also plotted are nonlinear regression fits to Eqs. (3) and (4) with *m* taken as the regression parameter. The regression analysis resulted in *m*= 2.46 for (D_1/D_0) and 2.51 for (D_2/D_0).

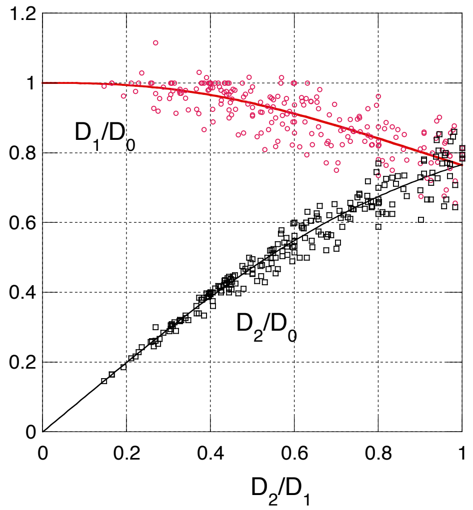

Fig. 4. Cortical surface of the brain

Figure 4 shows normalized diameters (D_1/D_0 and D_2/D_0, respectively) as functions of the diameter ratio (D_2/D_1) in the arteries distributed over the cortical surface of the cat brain. The regression analysis yielded *m*= 2.58 for (D_1/D_0) and 2.60 for (D_2/D_0).

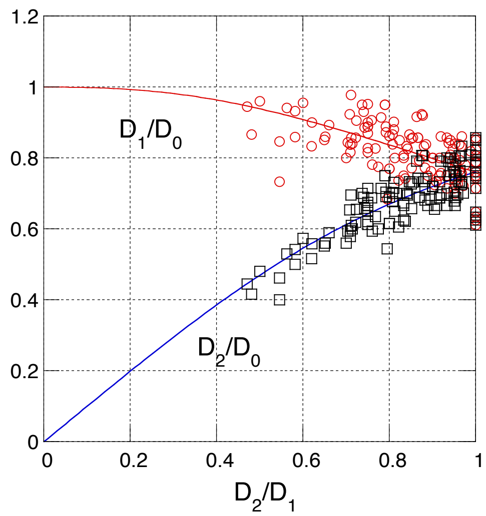

Fig. 5. Kidney

Figure 5 shows the results for arteries in the kidney. The regression analysis showed *m*= 2.53 for (D_1/D_0) and 2.54 for (D_2/D_0)in this case.

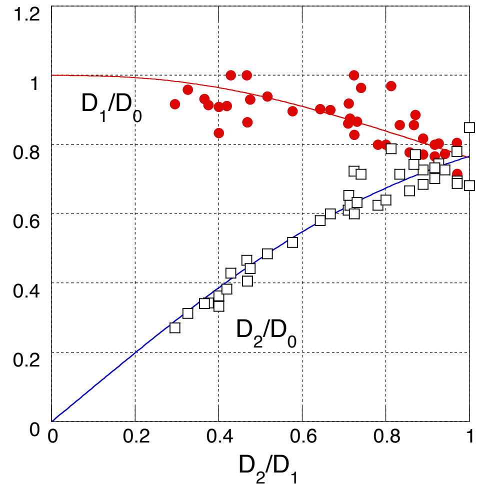

Fig. 6. Earlobe

Figure 6 shows the results for arteries in the earlobe. The regression analysis showed *m*= 2.56 for (D_1/D_0) and 2.61 for (D_2/D_0).

4. DISCUSSION

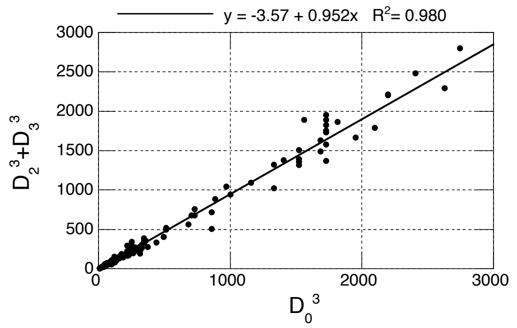
4.1 Statistical error

As can be noted in Figs. 3-6, the relationships between diameter ratios show considerable scattering. The degree of scatter is similar to that found by other researchers [6]. Human error is considered to be the main source of error in the present study. Selection of vessels to be measured was highly subjective, and choosing the proper locations of diameter measurements required some judgment. We tried to minimize such errors by averaging measurements at three positions for one artery. Moreover, the reliability of the data is supported by the fact that four people participated in the measurement at different times obtained similar results. The scattering of the geometry data is ascribable to the essential nature of blood vessels.

4.2 Determination of diameter exponent

In several reports [6][7], the validity of Murray's law was confirmed based on the regression analysis for α (= $(D_1^m + D_2^m)/ D_0^m$) with assuming *m*=3 a priori. This way assuming *m*=3 a priori could, however, yield misleading results. In Figs. 7 (a)(b), are plotted the present $(D_1^m + D_2^m)$ versus D_0^m relationships in CAM arteries with linear regression analysis; panel (a) : *m*=3 and panel (b) : *m*=2. In both cases, the slopes of regression lines are around unity with correlation coefficient R of nearly 1. These indicate that the linear regression analysis for ($D_1^3 + D_2^3$) versus D_0^3 relationships is not satisfactory for determination of diameter exponent m. This is because we calculated m values using equations (3) and (4).

(a)



(b)

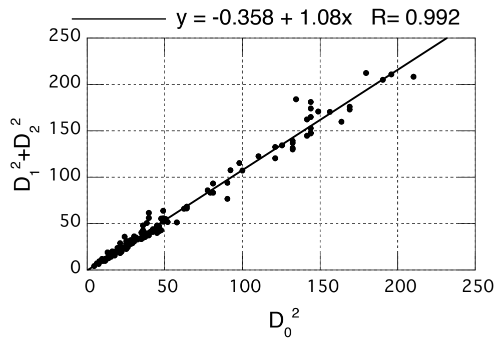


Fig.7. Relationships between ($D_1^{\mathrm{m}} + D_2^{\mathrm{m}}$) and D_0^{m}

4.3 Comparison of diameter exponent

Taber et al. [6] have reported diameter exponent for living organisms. They measured vessel diameters in yolk arteries of chick embryo, and reported the diameter exponent to be 2.88, which is markedly larger than the present m=2.49 for CAM arteries. The difference is significant, and in part ascribed to the difference of tissues, to which the arteries are belonging. In the present study, yolk arteries around chick embryo were visualized as well as CAM arteries. However, we exclude yolk arteries from the measurement, since they were frequently overlapped by yolk veins and tended to subduct in the yolk, and thereby geometric measurement for them were rather difficult. In fact, Taber et al. obtained m values using data from both arteries and veins. This can be another reason for the difference in m.

4.4 Physiological implication of diameter exponent

From equation (1), the averaged velocity (over cross sectional area) Va of blood flow through a vessel of diameter D is given by:

$$Va \sim D^{m-2}. \qquad (5)$$

Diameter exponent m=3 means that the velocity Va is linearly proportional to D. When m=2, Va is constant irrespective of diameter. Differences in m in different organs indicate that diameter-velocity relationships are different in organ to organ and connected to the function of organ.

It is remarkable that in the animal body, m could take a value smaller than 2, where the blood velocity increases as vessel diameter decreases. Bennett et al. [8] have found that m values for the perinatal pulmonary arteries were 1.74-1.82. They concluded that compared with an adult, the increased velocity is necessary to yield a very high flow resistance that serves to shunt blood flow away from the lung to other organs prior to birth. Thus, the diameter exponent m is considered to be an important index characterizing the blood circulation of organ.

5. CONCLUSION

The presently measured values for diameter exponent were considerably smaller than 3, which Murray' law predicts. It should be noted that the Murray' low was derived from several assumptions; Poiseuille flow for blood flow and simplified assumption for energy expenditure of blood. The physiological importance of diameter exponent is that it is closely related to blood flow properties in organs. In this sense, more sophisticated measurements of m for various organs would be necessary.

Abstract: We have analyzed the synchrony of neurons using the effective input theory. First, the dependence of intra-regional synchrony on the strength of synaptic connections is clarified. When the synaptic connections are weaker than thresholds of neurons, spontaneous firings do not exist. Second, we have studied the inter-regional synchrony of two regions connected by modulatory common noises. As a result, under the appropriate modulatory-effects there exist nontrivial sets of synchronized states of regions. Furthermore, at least one of these two regions satisfies the condition of intra-regional synchrony. When both regions do not satisfy the condition of intra-regional synchrony, these two regions should have the same structure of synaptic connections in order to synchronize inter-regionally.

Keywords: Populations of neurons, Effective input theory, Synchronized firing, Synchrony between regions, Analytical approach

1 INTRODUCTION

Up to now, the input trains to a neuron are mainly described as stochastic processes in such as Ricciardi[1], Stein[2], and others. Because the properties of the stochastic processes with random Langevin forces are well known (Uhlenbeck and Ornstein[3]), we can easily obtain a lot of essential properties of neurons with applying the stochastic theories. However, methods of stochastic theories approximate the neurons to a single neuron framework which corresponds to the mean-field theory or the phenomenological theory. Essentially these approximations do not include synaptic connections directly. On the other hand, Chen and Jasnow[4] formulate the "effective input theory", which includes one or more synaptic connections using "effective inputs". Here, the "effective inputs" denote the mean value of inputs to populations of several neurons, namely "cluster", from outside neurons through the synaptic connections. Thus the effective input theory is useful to clarify the effects of synaptic connections on synchronies of neurons.

Using the effective input theory, we have studied the conditions of the synchrony in two typical cases as follows:

(1) When neurons are firing spontaneously (and periodically) without external inputs from outside the system, there assumes to exist only effective inputs. First, we obtain the frequency of synchronous firing of neurons under effective inputs. Then we require the condition that the effective inputs corresponds to the frequency of synchronous firings. From this condition, namely "self-consistency", we obtain the frequency of the synchronous firing. If the self-consistency is not fulfilled by any frequency, the synchronous firing does not occur. From the above discussion, we have shown that high frequency is obtained for strong synaptic connections, while low frequency is obtained for weak synaptic connections.

(2) When the neurons additionally receive modulatory effects, we have examined the effects on synchronies of neurons. We have introduced two independent clusters of neurons and obtained the self-consistency using the effective input theory. Here the synaptic connections and external inputs have changed under the modulatory effects. If we assume that modulatory effects are global, two independent clusters receiving the same modulatory effects correlate each other. Then we analyzed the condition of synchrony between the independent areas.

In section 2, we make a brief review of the effective input theory and discuss synchronized firings of neurons in a cluster. Then we obtain the conditions between synaptic connections and thresholds for the spontaneous synchronized firings. In Section 3, we apply the effective input theory for synchronization between different regions with modulatory common noises. In Section 4, we summarize the results of our studies.

2 EFFECTIVE INPUT THEORY

In this section, we make a brief review of the effective input theory[4] for discussing a periodic synchronized firing of neurons located in the same cortex region, namely "spontaneous firings", using our formulation.

At first, we approximate the neuron connections as shown in Fig.1. Because the neurons are connected very complexly, we approximate the cluster neurons i and j whose membrane potentials are denoted as $V_i(t)$ and $V_j(t)$, respectively, with the effective input $I_{\rm eff}$. The effective input $I_{\rm eff}$ includes large numbers of inputs from outside of the cluster.

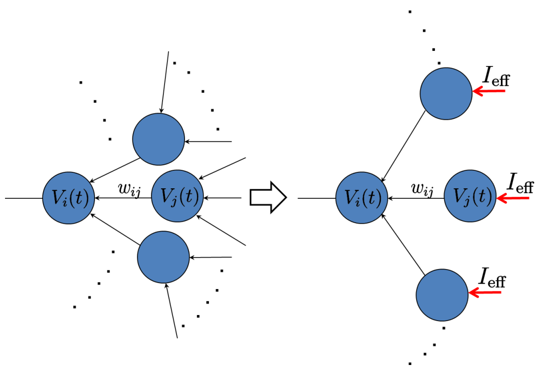

Fig. 1. Approximation of the cluster neurons: The neurons are connected each other as shown in the left-side figure. We approximate the neuron connections to the cluster including the neurons i and j and the effective input as shown in the right-side figure.

Then we obtain the effective equations of motion about the membrane potentials $V_i(t)$ and $V_j(t)$ as follows:

$$\tau\frac{d}{dt}V_j(t) = -V_j(t) + I_{\rm eff} \tag{1}$$

and

$$\tau\frac{d}{dt}V_i(t) = -V_i(t) + \sum_{j=1}^{c}\tau w_{ij}\sum_{k}\delta(t - t_j^k), \tag{2}$$

where the parameters τ, w_{ij}, c, and t_j^k denote time-constants, synaptic weights, connection numbers, and the k-th firing time of neuron j, respectively.

From Eq.(1), the membrane potential $V_j(t)$ is obtained as

$$V_j(t) = I_{\rm eff}(1 - e^{-t/\tau}). \tag{3}$$

Then we obtain the firing time $t_j^k = kT_j$ using the effective input $I_{\rm eff}$ as

$$T_j = -\tau\log\frac{I_{\rm eff} - \theta}{I_{\rm eff}} \tag{4}$$

with the threshold potential θ. Here, for convenience of calculations, we use a simple condition that the resting potential and the reset potential after firing take the same value of 0.

The time dependence of $V_i(t)$ is derived from Eq.(2) under the firing of j-neuron satisfying Eq.(4) as follows:

$$\begin{aligned} V_i(t) &= \frac{1}{\tau}e^{-t/\tau}\int_0^t ds e^{s/\tau}\sum_{j=1}^{c}\tau w_{ij}\sum_{k}\delta(s - t_j^k) \\ &= W\frac{1 - e^{-t/\tau}}{1 - e^{-T_j/\tau}}, \end{aligned} \tag{5}$$

where the parameter $W = \sum_j w_{ij}$ means the total synaptic weight. Then, we obtain the cycle-time T_i of i-neuron's firings as

$$T_i = -\tau\log\left[1 - \frac{\theta}{W}(1 - e^{-T_j/\tau})\right]. \tag{6}$$

Now, we consider the self-consistency

$$\begin{aligned} I_{\rm eff} &= \frac{1}{T}\int_0^T ds\sum_{j=1}^{c}\tau w_{ij}\sum_{k(<t)}\delta(s - t_i^k) \\ &\simeq \frac{\tau}{T}\sum_{j=1}^{c}w_{ij}\sum_{k=1}^{T/T_i}\int_0^T ds\delta(s - kT_i) \\ &= \frac{\tau}{T_i}W. \end{aligned} \tag{7}$$

This consistency means a periodic synchronized firing of neurons what we call "spontaneous firing". Then, from Eqs.(4), (6), and (7), we obtain the self-consistent equation as

$$\frac{\tau}{T}(1 - e^{-T/\tau}) = \left(\frac{\theta}{W}\right)^2, \tag{8}$$

where we have redefined $T = T_i$. The cycle-time T of spontaneous firing of the cluster neurons is given as a solution of Eq.(8). The function $f(T/\tau)$ defined as the left-side of Eq(8), namely $f(T/\tau) = (\tau/T)(1 - e^{-T/\tau})$, is plotted in Fig.2. As is shown in Fig.2, the function $f(T/\tau)$ has the asymptotic value 1 in the case of $T \to 0$ (namely the frequency $\nu = 1/T \to \infty$). Consequently, in the case of $\theta > W$, there does not exist the spontaneous firing. On the other hand, in the case of $\theta < W$, there exists the spontaneous firing. This result is supported by the following physical phenomena, that is, the firing frequency of neurons are enhanced by effective inputs (from neighbor neurons) exceeding the threshold potential. Meanwhile the spontaneous firing does not occur under the weak effective inputs.

3 SYNCHRONY OF DIFFERENT REGIONS

We apply the above effective input theory to analyze the modulatory effects for synchronization between different regions. Membrane potentials of neurons are modulated by diffuse modulatory systems, for example, norepinephrine, 5-hydroxytryptamine, dopamine, and others. These transmitters cause diffusive effects to neurons, and modulate the neuron's behaviors (especially the acceptance of noise effect). Thus we introduce a model which has two neural clusters and the common random input trains from modulators, as shown in Fig.3.

At first, we analyze the membrane potentials $V_i(t)$ and $V_j(t)$ in the region R1. The equations of motion of neurons in the region R1 are defined as follows:

$$\tau\frac{d}{dt}V_j(t) = -V_j(t) + I_{\rm eff} + \eta(t) \tag{9}$$

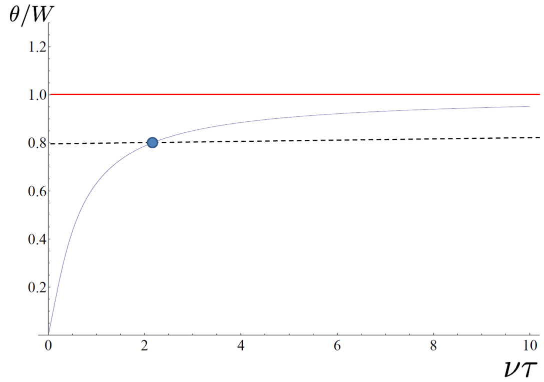

Fig. 2. Condition of spontaneous firings: The vertical axis expresses the rate θ/W while the horizontal axis expresses the firing frequency. The condition has the asymptotic value 1 with respect to θ/W. Then, in the case of $\theta > W$, spontaneous firing never occurs.

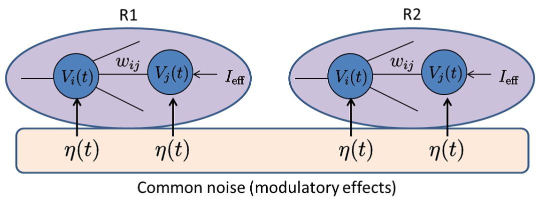

Fig. 3. Modulating effects for populations of neurons: Neurons in the two different regions (R1 and R2) receive the common noise from the diffuse modulatory systems. The regions R1 and R2 synchronize through the common noise.

and

$$\tau \frac{d}{dt} V_i(t) = -V_i(t) + \sum_{j=1}^{c} \tau w_{ij} \sum_{k(<t)} \delta(t - t_j^k) + \eta(t), \quad (10)$$

using the effective input $I_{\rm eff}$ and the common random input $\eta(t)$. Here the random input assumes to be a stochastic input train with the average $\langle \eta(t) \rangle = \lambda$.

From Eq.(9), the average potential $\langle V_j(t) \rangle$ is obtained as

$$\langle V_j(t) \rangle = (I_{\rm eff} + \lambda)(1 - e^{-t/\tau}). \quad (11)$$

Then, the condition $\langle V_j(T_j) \rangle = \theta$ yields the cycle-time T_j as

$$T_j = -\tau \log \frac{I_{\rm eff} + \lambda - \theta}{I_{\rm eff} + \lambda}. \quad (12)$$

Similarly to the derivation of Eq.(5), we obtain the time dependence of $V_i(t)$ from Eq.(10) as

$$\begin{aligned} V_i(t) &= \frac{1}{\tau} e^{-t/\tau} \int_0^t ds e^{s/\tau} \left[\sum_{j=1}^{c} \tau w_{ij} \sum_{k(<t)} \delta(s - kT_j) + \eta(s) \right] \\ &= W e^{-t/\tau} \frac{e^{T_j/\tau}(e^{t/\tau} - 1)}{e^{T_j/\tau} - 1} + \frac{1}{\tau} e^{-t/\tau} \int_0^t e^{s/\tau} \eta(s) ds. \end{aligned} \quad (13)$$

Then, the random average of Eq.(13) yields

$$\langle V_i(t) \rangle = \sum_{j=1}^{c} w_{ij} e^{-t/\tau} \frac{e^{T_j/\tau}(e^{t/\tau} - 1)}{e^{T_j/\tau} - 1} + \lambda(1 - e^{-T_i/\tau}). \quad (14)$$

From Eq.(14), we obtain the mean value of cycle-time T_i as the solution of the following equation:

$$\theta = e^{-T_i/\tau} \sum_{j=1}^{c} w_{ij} \frac{e^{T_j/\tau}(e^{T_i/\tau} - 1)}{e^{T_j/\tau} - 1} + \lambda(1 - e^{-T_i/\tau}). \quad (15)$$

Using the self-consistency Eq.(7), and Eqs.(12) and (15), we obtain the self-consistent condition

$$1 = \left[\alpha \left(\frac{\alpha}{x} + \bar{\lambda} \right) + \bar{\lambda} \right] (1 - e^{-x}), \quad (16)$$

with the dimensionless parameters $\bar{\lambda} = \lambda/\theta$, $\alpha = W/\theta$, and $x = T/\tau$, where we redefine the cycle-time as $T = T_i$.

The self-consistent condition in the region R2 is obtained similarly as

$$1 = \left[\alpha' \left(\frac{\alpha'}{x} + \bar{\lambda} \right) + \bar{\lambda} \right] (1 - e^{-x}), \quad (17)$$

where the parameter α' reflects the construction of synaptic connections $\{w'_{ij}\}$ in R2, namely $\alpha' = \sum_j w'_{ij}/\theta$.

When the synchronized firing occurs between the regions R1 and R2, the firing cycle T takes the same value in each region. Consequently, we obtain the relation between α and α' under synchrony as

$$\bar{\lambda} = \frac{x - \alpha^2(1 - e^{-x})}{x(1 - e^{-x})(\alpha + 1)} = \frac{x - \alpha'^2(1 - e^{-x})}{x(1 - e^{-x})(\alpha' + 1)} \quad (18)$$

The second equation of Eq.(18) has nontrivial solution

$$\alpha' = \frac{\alpha - e^x(\alpha + x)}{(e^x - 1)(\alpha + 1)}. \quad (19)$$

The solutions $\alpha = \alpha'$ and Eq.(19) are shown in Fig.4. From the discussion in Section 2, in the case of $|\alpha| > 1$, R1 shows the spontaneous firing, while, in the case of $|\alpha| < 1$, R1 does not show the spontaneous firing. Similar relation is shown in R2 with respect to $|\alpha'|$. Then, from Fig.4, it is necessary to lead the nontrivial synchrony that the parameters $|\alpha|$ and $|\alpha'|$ take $(|\alpha| > 1, |\alpha'| > 1), (|\alpha| > 1, |\alpha'| < 1)$ or $(|\alpha| < 1, |\alpha'| > 1)$. That is, there exists nontrivial synchrony of two regions only in such cases that at least one region takes conditions of spontaneous firings.

The strength of modulating effects $\bar{\lambda}$ is shown in Fig.5 using Eq.(18). Especially, when the parameters α and α' take the value $|\alpha| < 1$ and $|\alpha'| < 1$ (namely both R1 and R2 do not show the spontaneous firing), there exists only trivial relation $\alpha = \alpha'$ for synchrony. Then, from Eq.(18), the limiting behavior of $\bar{\lambda}$ for $x \to \infty$ and $x \to 0$ is obtained as

$$\bar{\lambda}_\infty \equiv \lim_{x \to \infty} \bar{\lambda} = \frac{1}{1 + \alpha} \quad (20)$$

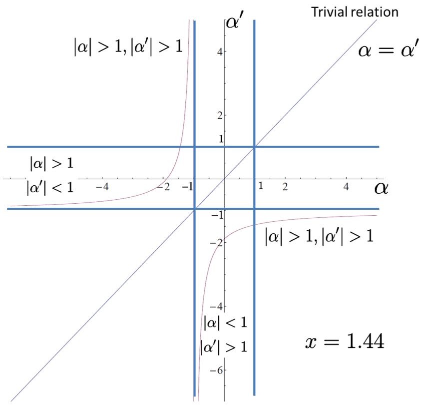

Fig. 4. Relation of α and α' where $x = 1.44$: The vertical axis express the parameter α' while the horizontal axis expresses α. Parameters α and α' means W/θ and W'/θ, respectively. These parameters mean the characters of each region (R1 (α) or R2 (α')). Of course, this graph has a symmetry between α and α'. We find the non-trivial relation as shown in Eq.(19) only in the cases of $(|\alpha| > 1, |\alpha'| > 1), (|\alpha| > 1, |\alpha'| < 1)$ and $(|\alpha| < 1, |\alpha'| > 1)$.

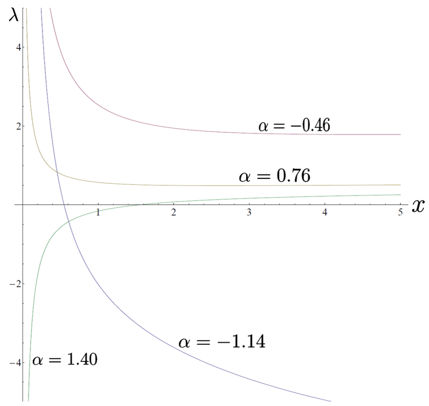

Fig. 5. Dependence of common noise on the synchrony frequency: The vertical axis expresses the parameter $\bar{\lambda}$ while the horizontal axis expresses the parameter x. The parameter $\bar{\lambda}$ means the strength of common noises, and the parameter x means the cycle-time of a synchrony. We chose the parameters $\alpha = -1.14, -0.46, 0.76$ and 1.40. These cases are corresponds to each region of Fig.4.

and

$$\bar{\lambda}_0 \equiv \lim_{x \to 0} \bar{\lambda} \sim \frac{1-\alpha}{x}. \tag{21}$$

Consequently, under the condition $|\alpha|, |\alpha'| < 1$, $\bar{\lambda}$ satisfies the conditions $\bar{\lambda}_\infty > 0$ and $\bar{\lambda}_0 \to +\infty$, that is, the parameter $\bar{\lambda}(x)$ takes positive value for all x. This result shows the following plausible physics: The modulatory effects should enhance the firings of neurons in both regions when the spontaneous firing does not occur in each regions R1 and R2 (Fig.5). Additionally, the R1 and R2 should be constructed by the same configuration (Fig.4). Conditions for synchrony between the regions which do not show the spontaneous firing are very strict.

4 CONCLUSION

We have studied the synchrony firings of neurons in typical two cases.

First, using the effective input theory, we have analyzed the inner region synchrony of neurons (spontaneous firing) using the effective input theory within the region. We have clarified that the inner region synchrony depend on the strength of synaptic connections. When the synaptic connections are weaker than thresholds of neurons, there do not exist spontaneous firings.

Second, we consider the synchrony between two regions connected by modulatory common noises. The synchrony of different regions through the modulators occurs in two typical cases as follows:

(1) At least one of two regions takes the state for spontaneous firings and receiving appropriate modulation.

(2) When both two regions do not take the state for spontaneous firings, these two regions should be constructed by the same synaptic connections for synchrony. Additionally, modulatory effects enhance the firing of neurons in both regions.

The second condition is very strict, and may be very rare.

We have considered the two regions for inter region synchrony. If these regions assumed to be two of many regions in brain, the parameters α and α' can be treated as continuous parameters. Then this model of synchrony may change depending on the region of the brain.

This method is generally applicable to other complicated dynamical systems. Although we have used the integrate-and-fire neuron model in this study, any other neuron models can be analyzed generally in the same way.

Abstract: Klaes et al. showed that multiple potential actions could be generated only single spatial cue according to task rule. Also they reported that population activities of the PPC neurons which represent two different motor goals might be biased. The motivation of this paper is to make a computational model which can reproduce Klaes's experimental results. We have proposed a decision making model which has the PFC layers encoding the rule informations and showed that the potential action for the inferred goal was observed in the PPC layer, and the balance of the potential actions in the PPC layer varied depending on the connection strength from PFC to PMd. These results suggest that the observed biased potential actions during the memory periods were the result of "trade-off" for achieving the balanced multiple potential actions while the spatial cue was presented.

Keywords: action choice, computational model, parietal cortex, potential actions, premotor cortex, rule selection task

1 INTRODUCTION

Recent studies have demonstrated that when animals are presented multiple action goals, they compute multiple potential goals (multiple potential actions) based on visual inputs simultaneously and choice an action from them [1][2][3]. These studies have also reported that frontparietal cortex, specifically PPC (Posterior Parietal Cortex), PMd (Premotor Dosal), and PFC (Prefrontal Cortex) relate to information processing on generating potential actions[1][3].

Cisek et al. [1] observed neural responses corresponding to potential actions in primate motor area. In this experiment, two reaching goals (spatial cues) were presented to monkeys and successive cue (color cue) indicated the correct goal which monkeys had to select. Although the spatial cues generated two potential actions in PMd, one of the potential actions was specified by color cue presentation. [1]. Cisek and his colleagues also demonstrated that a computational model composed of frontoparietal stream simulated the process of generation and selection of potential actions as short term memory of visual inputs [2].

On the other hand, Klaes et al. showed that multiple potential actions could be generated even when only single spatial cue was visually presented. In this experiment, monkeys were trained to reach in the same or opposite direction to the presented spatial cue depending on the rule cue which are successively presented. Neurons in the primate PPC simultaneously represented two distinct potential actions corresponding to direct and opposite (inferred) movement goals[3]. This result means that the potential actions are not only the short term memory of the presented spatial cues, but the representation of the movement goals internally generated by the neural processes using information of the presented cues.

In the Klaes's rule-selection task, it is also reported that the population tuned activities of the PPC neurons which represent two different motor goals might be biased. Interestingly, trained monkeys showed a preference to reach the opposite direction of the spatial cue, and neural activities correspond to the inferred direction in the PPC become strong during the spatial cue period. This biased neural activity was balanced only if the probabilities of the rewards were adjusted to reinforce balanced choice behavior.

In this paper, we propose a computational model which generates multiple potential actions and decides appropriate one according to the task rules in the

Klaes's task. We also show that this model also exhibits the biased or balanced potential actions depending on parameter values and consider the mechanisms of the biased potential actions observed in the Klaes's task.

2 METHODS

2.1 Process of the Psychological Experiment

First, we show the potential motor-goal task[3] (Fig.1) which we simulate in this study. This paradigm is the fundamental framework of Klaes's experiments.

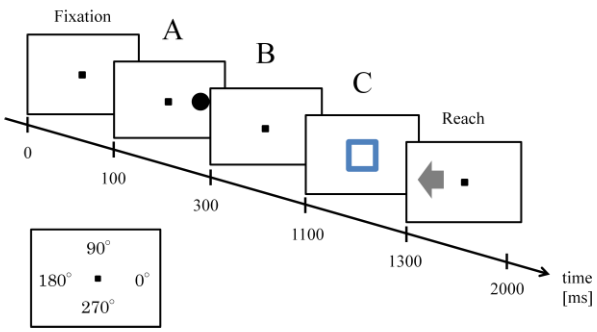

Fig. 1. Rule selection task. The inset shows directions of the spatial cue.

At stage A in Fig.1, a spatial cue (one of the four positions: 0, 90, 180, 270 degree) is provided for 200ms. Then, the subject should keep this memory at least for 800ms. At stage C, after the rule cue (direct or inferred rule) is provided, the subject is required to the same direction as the spatial cue (direct rule) or the opposite direction (inferred rule) alternatively. The direct (or the inferred) rule is instructed by a green (or blue) square on the fix point.

2.2 Framework of Model

In this study, we expand the Cisek's computational model to go through with the potential motor-goal task. Our model neurons, neural connections within layers and inter-layers, and the basic structure of the network are almost the same as Cisek's model. Two main differences are as follows: (1) We introduced two prefrontal layers that are responsive to direct and inferred rules (PFC_D and PFC_I), (2) There are synaptic connections from PFC_D and PFC_I to corresponding neurons in the first PMd layer.

Visual inputs include spatial cues and rule cues (Fig.2). The information of position of a spatial cue is provided to PPC, PFC_D and PFC_I neurons. In case of a rule cue, rule information is given to PFC_D or PFC_I alternatively. Each neuron in PPC, PMd, and M1 has directional preference to reach, and its neighboring neurons represent close directions. The arrow in Fig.2 shows the direction of each projection of synaptic connection. To generate two neural activities representing potential plans from a spatial cue, the PFC_I neuron should excite PMd layer neurons which represent the direction opposite from the spatial cue.

On the other hand, within each of the frontparietal layers except PFC, neurons with similar directional preferences excite each other, whereas neurons with different preference mutually inhibit each other.

Since some neurons are excited and others are suppressed in this competitive neural field, some groups of activated neurons usually appear. We regard the activated group represents a potential action (potential action plan). Neural activities generated in PPC, PFC_D, PFC_I layers are integrated in PMd1 layer.

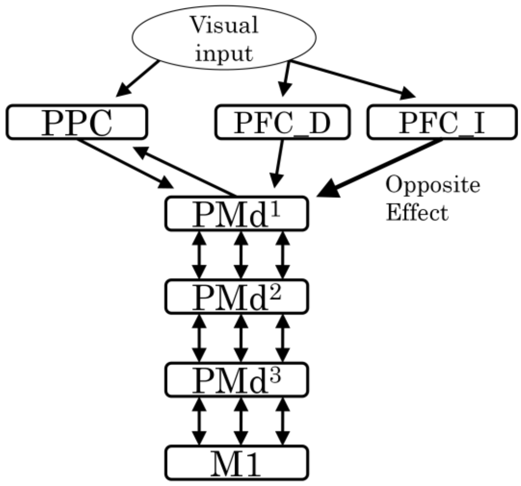

Fig. 2. Framework of this model [2]

2.3 Neuron Model

We use the "mean-rate leaky-integrator" neurons model. The mean firing rate of *i* th neuron at layer N follows this differential equation [2]:

$$\frac{dx_i^N}{dt} = -\alpha X_i^N + (\beta - X_i^N)\cdot\gamma\cdot E_i^N - X_i^N \cdot I_i^N + \Theta, \quad (1)$$

where X_i^N is the activity of the *i* th neuron in layer *N*, E_i^N is the excitatory input to the neuron, I_i^N is the inhibitory input to the neuron, α is the decay rate, β is the neuron's maximum activity, and γ is the excitatory gain. Θ is a Gaussian noise. Each parameter value follows Cisek's numerical experiments[2].

2.4 Neural Connections between Layers

To excite two neurons in different layers each other if they insist similar directions, the synaptic weight from *j* th neuron in layer N to *i* th neuron in layer M depends on the difference of neuron index (*i* – *j*) as follows:

$$\begin{cases} W_{ji}^{N\to M} = 0.4 - 0.2(i-j) & \text{if} \quad i-j \geq 0 \\ W_{ji}^{N\to M} = 0.4 + 0.2(i-j) & \text{if} \quad i-j < 0 \end{cases} \quad (2)$$

The synaptic weights from PFC_I to PMd1, however, should be relatively so strong that the neural activity representing direct direction supported by PPC and PFC_D competes with that of inferred direction by PFC_I only. Otherwise, the potential action in an inferred direction will be suppressed away. Thus we introduced an amplitude parameter κ to examine the effects of synaptic weights from PFC as follows:

$$\begin{cases} W_{ji}^{PFC\to PMd1} = \kappa\cdot\{0.15 - 0.015(i-j)\} & \text{if } d \geq 0 \\ W_{ji}^{PFC\to PMd1} = \kappa\cdot\{0.15 + 0.015(i-j)\} & \text{if } d < 0 \end{cases} \quad (3)$$

When we think of PFC_D (PFC_I), we regard κ as κ_D (κ_I).

3 RESULTS

3.1. Balanced Potential actions in Memory Period

Figure 3 shows activity of the model network at $\kappa_D = \kappa_I = 1.0$.

The cue direction neurons in the PFC_D and the inferred direction neurons in the PFC_I were activated by the visual input. During the cue period, neural populations encoding the cue direction in the PPC and PMd layers were strongly activated.

The potential actions in the PPC were balanced during the memory period (Fig.1 B) because the connection strength from the PFC_D and the PFC_I were same value. On the other hand, PPC neurons showed biased potential actions during the cue period because of the additional visual input to the PPC population tuning to the cue direction.

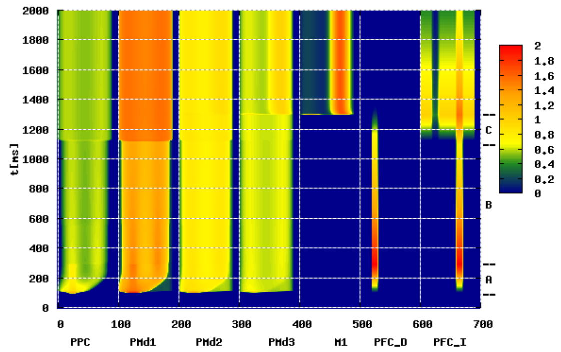

Fig. 3. Population result for the balanced data set (0 degree cue, Inferred rule, $\kappa_D = \kappa_I = 1.0$). A is the spatial cue period, B is the memory period, and C is the rule cue period.

3.2 Biased Potential actions in Memory Period

Figure 4 shows activity of the model network at $\kappa_D = 1.0$, $\kappa_I = 5.3$. In the situation of larger KI, the projections from PFC_I to PMd excites the neural population to encode opposite goal more than direct goal in PPC. Simulated biased potential actions during the memory periods require at least a condition that $\kappa_D < \kappa_I$. This means that the connections from the PFC_I to the PMd is stronger than that from the PFC_D.

In the PPC layer, neural population encoding the direct cue direction was strongly activated during the spatial cue period. In contrast, neural population encoding the opposite cue direction was strongly activated during the memory period. The cause of inversion in active groups is due to the disappearance of the spatial cue during the memory period. Therefore, "direct" population became weaker, and "inferred" population became stronger relatively.

However, despite biased activities in PPC, this model chose appropriate an action according to the displayed rule, on the rule cue period. As a result, under the conform to the biased data set and choose the action comfortable to rule cue which are consistent with the experimental data[3].

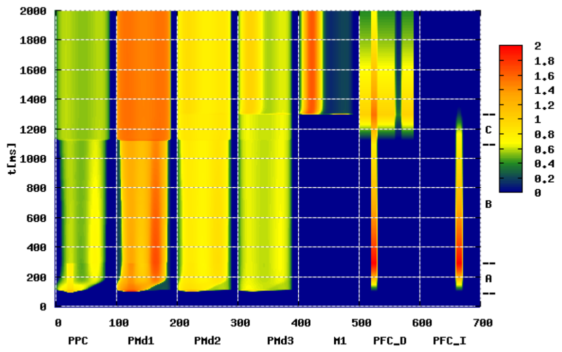

Fig. 4. Population result for the biased data set (0 degree cue, Direct rule, κ_D =1.0, κ_I =5.3).

3.3 Mechanism for bias of potential actions

Klaes et al. reported that, for the well trained monkeys, the potential actions in the PPC were biased during the memory periods. Two types of the rule cue (indicating the direct motor goal and the inferred motor goal) were equally presented in their experiment. So the biases of the potential actions may not be reasonable.

Figure 5 shows a population activities when the spatial cue was presented for a prolonged time (κ_D =1.0, κ_I =5.3). In this situation, the potential actions during the prolonged cue period seemed balanced. The time lag of the potential actions for the direct and the inferred goal is caused by the parameters β and γ which are different between PFC and PPC neurons. This time lag was responsible for the switching of the potential actions in the PPC for the short-lasting cue presentation (200-400 ms in Fig.4).

This result implied that the balance of the cue period may make it inevitable that the potential actions during the memory periods become biased. That is, although the bias of the potential actions (and the behavioral performance) of the trained monkeys is apparently unreasonable, this bias can be reasonably interpreted as the "trade-off" for the balanced activities of the potential actions when the spatial cue is continuously presented. We also insist that this hypothesis will be confirmable by the physiological experiment that the cue stimulus will be continuously presented to the monkeys while this hypothesis is a matter of speculation at the current moment.

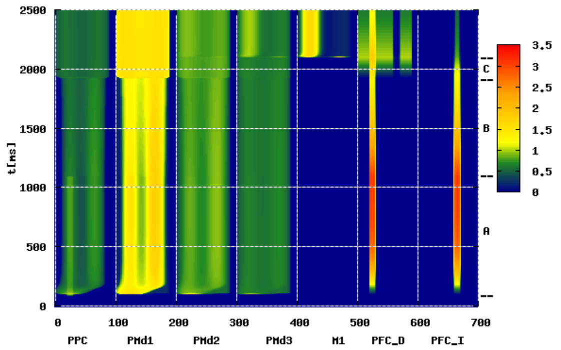

Fig. 5. Population result with longer spatial cue (0 degree cue, Direct rule, κ_D =1.0, κ_I =5.3).

4 CONCLUSION

In this paper, we proposed a decision making model with PFC layers which encodes the rule information of the task. This model generates the multiple potential actions which correspond to the candidates of the movement goals even when the single spatial cue was presented in the task.

We also demonstrated that the proposed model shows both the biased and balanced potential actions. This result suggests that the observed biased potential actions (and biased behaviors) during the memory periods were the results of "trade-off"s for achieving the balanced multiple potential actions while the spatial cue was presented.

Abstract: To make an action plan, it is thought that the brain uses memory systems. Thus, we propose an action plan model, which deals with the physiological experiments to push buttons in the correct order. In the model, there are two independent action-planning systems of long-term memory and working memory. When the stimulus set is input, they propose action plans, and the selection is decided in a competitive way via the value of estimation parameters. As a result, the model reproduces similar behaviors to the biological data. Especially our model make errors at first but it gradually learns correct responses by trial and error utilizing the memory systems as the monkey did in the physiological experiment. The results suggest that SMA and pre-SMA may have close relationships to the entries to long-term memory and working memory systems in the brain.

Keywords: action plan, long-term memory, Pre-SMA, sequential procedure, short-term memory, SMA

1. INTRODUCTION

In the physiological experiments of Hikosaka et al., 2 of 16 (4 by 4 matrix) buttons were illuminated (this matrix is called a "set") simultaneously and the monkey had to push them in a predetermined order. The monkey was required to push the buttons in 5 consecutive sets (called a "hyperset") [1]. When a hyperset which the subject has already learned is the stimulus, the task is called a "learned task". And when a hyperset consists of only novel sets, it is called a "new task". It is reported that SMA and pre-SMA are specifically activated by the case of the learned task and new task, respectively [1][3][4]. When a hyperset of which a few sets in a learned hyperset are replaced by novel sets, the task is called "modified task". Although monkey made mistakes in the early trials in the modified task, it gradually became to push the buttons correctly. Intriguingly, in the early trials, the monkey sometimes pushes unilluminated buttons in response to a novel set [1]. We think that this is because it may associate the previous stimulus sets with an action to be done next from the learned memory of a series of actions even if it actually encounters a novel stimulus.

Additionally, in the modified task, the neurons in pre-SMA become activated in response to the learned sets as well as the novel sets [1]. This implies that the activation in pre-SMA in response to the learned sets increases while the monkey is learning the modified task.

On the other hand, Nakahara et al. reproduced the behaviors and neural activities using a neural network model of the basal ganglia and the cortices in the reinforcement learning framework [2]. But the model does not attend the kinds of monkey's errors, where all of them are treated as learning errors. Thus, we pay attention to the error that is sometimes observed in the modified task, which makes the monkey to push an unilluminated buttons. From a new viewpoint to explain this error behavior, the

purpose of this study is to propose the simple functional model, which reproduces this error as well as the other behaviors observed in the previous experiments.

2. OUTLINE OF THE MODEL

2.1 Task for computer simulations

According to the previous experiments, we assume a task as follows: the subject is required to push the buttons in the correct order in 5 sets, treated as a sequential procedure, in a trial. Since 2 of 16 (4 × 4 matrix) square buttons are illuminated evenly on a set, the subject has to learn the order from the visual pattern of illuminated positions by trial and error. If it makes a mistake, the trial returns back to the first stage, but the pattern of five stimuli do not change within the same task. Thus five consecutive sets (hyperset) are presented in a fixed order. The task is repeated until the subject completed the hyperset successfully for a total of 10 trials.

2.2 Structure of the model

Fig.1 shows the outline of our proposed model. The model mainly consists of three systems as follows: short-term memory system (STMS), long-term memory system (LTMS), and decision system of strategy (DSS). STMS proposes an action plan based on the short-term memory especially dealing with stimuli in the current task, while LTMS tries to retrieve an action sequence in the long-term memory over tasks. These systems work in parallel and independently. Actually only one action plan should be selected to execute in DSS. For each stimulus set, DSS stochastically and alternatively selects one of LTMS or STMS. The probability of the selection is updated depending on the estimate of decisions and their results in response to the stimulus sets.

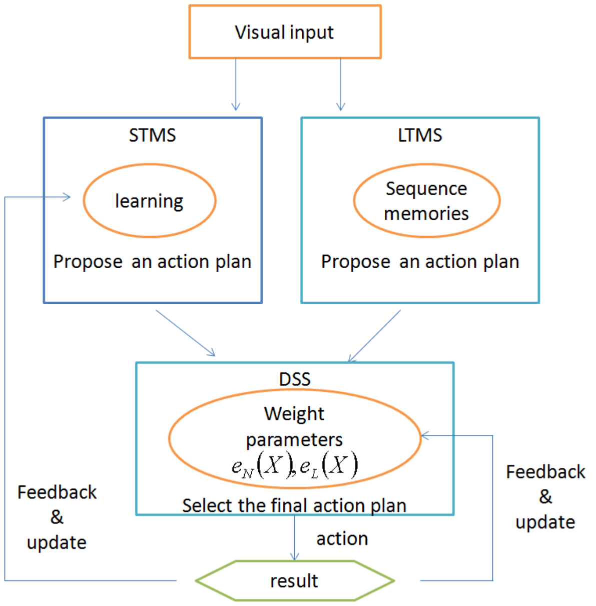

Fig.1. Outline of the model

2.3 Short-term memory system

STMS proposes one action plan from two options of action orders based on the short-term memory for the current stimulus (illuminated two buttons). In response to a novel stimulus, the probability of selection is even. As the monkey learns stimulus-response relationships, the probability to press the buttons correctly becomes higher. The probability will be influenced by how many times it has received the stimulus so far. Thus, we assume that the probability of proposal of the correct action plan for a set in STMS is updated by the short-term experience as follow

$$p_{\text{set}}(n+1) = p_{\text{set}}(n) + \gamma \ (\alpha_{\text{MAX}} - p_{\text{set}}(n)) \qquad (1)$$

where n is the number of input of the stimulus sets, α_{MAX} is the maximum value of the probability, and γ is a learning rate.

2.4 long-term memory system

LTMS also proposes one action plan from the two options based on the long-term sequential memory. When the model recognizes that the first set is a learned stimulus, we assume that this memory system recalls 5 series of actions responsive to current and succeeded stimuli. Therefore, LTMS is completely different from the STMS in that LTMS suggests plans for supposed stimuli in the near future.

Additionally, this memory has been constructed for a long time such as a year or two years. Thus, the probability to suggest the correct order for the learned hyperset is assumed to be very high rate. Thus, we let this higher probability be P_l. When the hyperset of stimuli includes a few new sets after the first set (i.e. modified task), however, LTMS at first proposes to push an unilluminated button and the panel does not respond. For this error, LTMS is temporarily suspended and STMS is driven to deal with this stimulus.

2.5 decision system of strategy

DSS selected the final action plan to execute from the plans proposed by STMS and LTMS. We assume two weight parameters $e_S(X)$ and $e_L(X)$ to represent the reliability of STMS and LTMS, respectively. The strategy with a large value of this parameter assumes to be more reliable. If the stimulus is a learned one and the result of LTMS strategy is correct, $e_L(X+1) = e_L(X) + u_1$. But, if it was wrong, $e_L(X+1) = e_L(X) - u_2$. If LTMS is suspended in case of modified hyperset as shown above, $e_L(X+1) = e_L(X) - u_3$.If STMS strategy is selected and the result is correct, $e_S(X+1) = e_S(X) + u_4$, otherwise $e_S(X+1) = e_S(X) - u_5$.

Initially, $e_S(0) = e_L(0) = 0$. u_1, u_2, u_3, u_4,and u_5 are positive constant parameters. According to the physiological experiment [1][3], the monkey seemed to infer whether the current task is a new or learned one when it watched the first stimulus set. We think that this influence strongly biases the monkey's behavior to coming stimuli. Thus, we assume that $e_L(1) = e_L(0) - b$ if the first set is new, and $e_L(1) = e_L(0) + b$ if it is already learned.

The larger the value of $e_S(X)$ or $e_L(X)$ is, the more the probability of selection of corresponding plan is. Because of sigmoidal shape and the range, we assume that the probability to adopt one from two systems depends on the sine of difference of $e_S(X)$ and $e_L(X)$ as follows :

$$p_L(X) = 0.5\{\sin(e_L(X) - e_S(X)) + 1\}, \qquad (2)$$

$$p_S(X) = 0.5\{1 - \sin(e_L(X) - e_S(X))\}. \qquad (3)$$

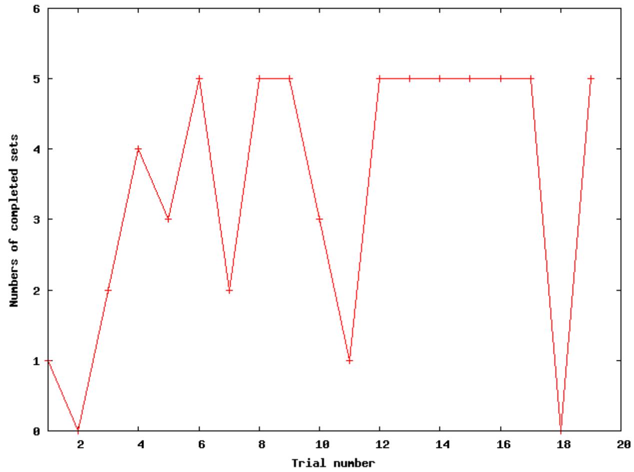
The difference of $e_L(X)$ and $e_S(X)$ is limited to the range [$-\pi/2, \pi/2$]. These values are updated within this range.

3. COMPUTER SIMULATIONS

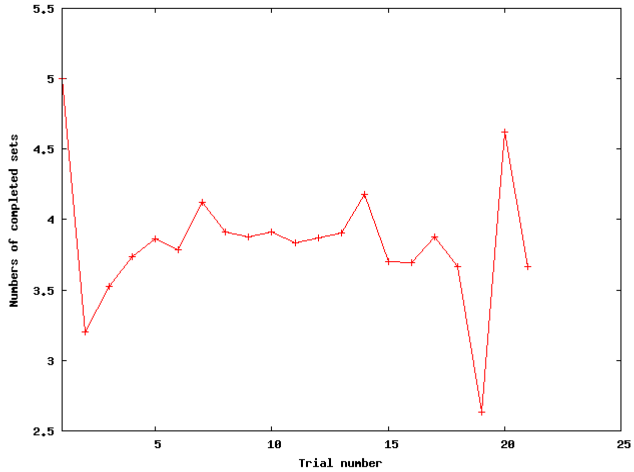
We show the results of computer simulations of the model in the new task, the learned task, and the modified task, respectively. The parameter values are selected to field results correspondent to physiological data as follow: $p_{\text{set}}(0) = 0.5$, $\gamma = 0.4$, $\alpha_{\text{MAX}} = 0.91$, $P_l = 0.99$, $u_1 = 0.01$, $u_2 = 0.1$, $u_3 = 0.5$, $u_4 = 0.1$, $u_5 = 0.01$, $b = \dfrac{\pi}{2}$.

3.1 New task

During this task, no stimulus set is assumed to be memorized in LTMS. As the learning proceeds, it gradually becomes to act correctly because of the role of STMS. **Fig.2** shows a typical example of temporal change of the number of successful sets. The average number of mistakes until 10 trials successful is 10.2±6.0 (which is close to 10.3±5.9 from experimental data [1]). In this task, STMS was almost selected in DSS because novelty of the first stimulus decreases e_L . This activated STMS may correspond to higher activities in Pre-SMA in this task of experimental data [1][4][5].



(a)



(b)

Fig.2. Simulation results in the new task: (a): Numbers of completed sets. (b): Numbers of completed sets from the first successful trial averaged over 100 tasks.

3.2. Learned task

In this task, the familiar stimulus in the first set increases e_L greatly and immediately. The probability of selection of STMS has been kept small, because the probability for success by STMS is much lower than that by LTMS. Fig.3 shows the examples of numbers of successful sets in the learned task. It is shown that the model performed perfectly for already learned hyperset. The average number of mistakes until 10 trials successful is 0.48±0.72, (which is close to 0.5±1.2 from experimental data [1]). In this task, almost all plans proposed by LTMS were adopted by DSS.

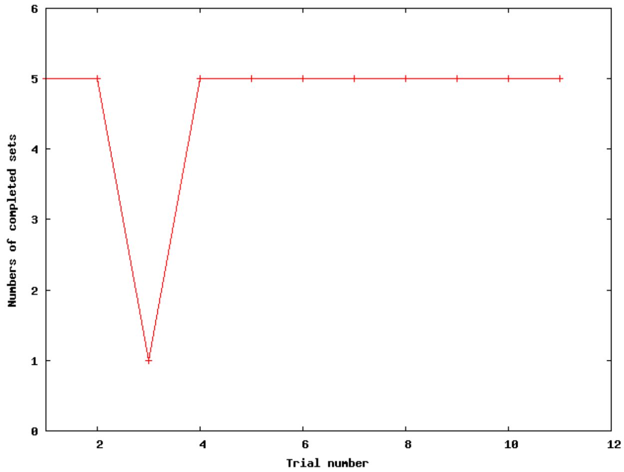


Fig.3. Simulation results in the learned task: Numbers of completed sets.

3.3. Modified task

In this task, second and third stimulus sets in hyperset are modified. Table2. shows the actions and results for each stimulus set. The meaning of abbreviations in table2. are as follows. SC: correct result by STMS plan, SW: wrong result by STMS plan, LC: correct result by LTMS, and rC/rW: correct or wrong result by retried STMS plan after ineffective LTMS action. In the early trials of the task, DSS selected the plan from LTMS because the first set is a learned one. In table2., trial #1 and set #2, trial #3 and set #2, and trial # 4 and set #2 indicate the case, when the subject pushed an unilluminated button in vain and retry another strategy of STMS. When the errors in response to the modified sets occur, the selected plan in DSS will be replaced by STMS with decreased e_L . At the same time, the correct rate of the plan from STMS gradually increases following eq.(1) from 50% as the learning proceeds. If the correct probability increases, its estimate increases e_S . Fig.4 shows temporal change of the values of e_L and e_S . Finally the performance was improved with high accuracy rate adopting the STMS plan for all of the sets.

4. CONCLUSIONS

We propose a simple action selection model in the brain, which deals with pushing two illuminated buttons in the correct order. In this model, there are two independent action-planning systems using either of long-term memory or short-term memory (working memory), respectively. When the stimulus set is input, they propose action plans, and the selection is decided in a competitive way via the value of estimation parameters. The results show that our model could make a few errors to push an unilluminated buttons following long-term memory at first but it gradually learns correct responses by trial and error using working memory in the modified task, as the monkey did in the physiological experiment. In addition, the model also reproduces similar behaviors to the biological data in the new and learned task.

On the other hand, the value of the reliability parameter e_L and e_S show common tendencies with the neuronal activities of SMA or pre-SMA in the previous experiments [1][3], in that some neurons in the SMA are relatively activated in the learned task and some pre-SMA neurons are activated in the modified task, respectively. In the modified task, the value of e_S increases not only for the novel stimulus but also for the learned stimulus as the observed pre-SMA neurons. If the distinctive memory system in our model actually works in the brain, SMA and pre-SMA may have close relations to the entries to long-term memory and working memory systems in the brain, respectively.

To confirm this hypothesis, more refinements of the model plausible to biological data and computer experiments are needed in our future works. Other issues include how to implement interactions between decision system of strategy and memory systems, and memory consolidation from the short-term memory to long-term memory.

Abstract: Phase synchronization is a mechanism that plays a crucial role for information processing in the brain, and coherence is one of methods that are used to evaluate pairwise degree of phase synchronization. Coherence is also an important measure for examining brain functions because it can indicate communication and cooperation among neurons. In this work, we study the coherence patterns of spontaneous activity in the neural field model at criticality, which is a region where a second order phase transition occurs. The results are summarized as follows. First, at high frequency bands, the system outside the critical regime cannot communicate via phase synchronization at all. Second, the dynamical coherence patterns in the critical regime show switching between high and low coherent states. Finally, we found that in a very brief period of time, there is the high broadband coherence between some pairs of spatial points. This phenomenon can be observed only in the critical regime.

Keywords: criticality, neural fields, coherence, synchronization, brain spontaneous activity

1 INTRODUCTION

Critical phenomena occur at a second order or continuous phase transition (a critical point). This point is at the boundary between a stable and ordered state and a disordered state. Critical phenomena can be found frequently in various natural systems, such as earthquakes and avalanches. This kind of systems is characterized by scale invariance, which is a power-law distribution of some variables, and by the divergence of both spatial and temporal correlation scales.

Recently, there is a proposal by many authors suggesting that neuronal networks probably operate on the critical regime [1]. Some researches also show that at the critical point, the dynamic range [2], memory capacity [3], and computational power [4] are optimal in neural network simulations. The critical neural network also provides important factors for learning, such as flexible response and adaptation to input [5]. Furthermore, there are some evidences from experimental data pointing that criticality might underlie neural network behaviour, such as neuronal avalanches *in vitro* [6], $1/f$ type power spectrum of local field potential in visual neocortex [7] implying long-range correlations, and $1/f^{\beta}$ power spectrum of electroencephalograms (EEG) [8] and functional magnetic resonance imaging (fMRI) [9]. In addition, functional brain networks exhibit a power-law degree distribution [10].

Even when someone receives no explicit sensory stimulus and does not perform any task, which is called a resting state, his brain is still active. This activity is brain spontaneous activity or so-called ongoing activity. In the most brain experiments, spontaneous activity is filtered or averaged out and treated as a baseline activity or noise because experimenters are interested only activity induced by performing tasks or given stimuli. However, it was found that this spontaneous activity is not random noise but specifically organized [11]. Until now, the function which spontaneous activity in the brain serves for is still unclear. After all, the importance of spontaneous activity is stressed by the fact that most of the energy consumed by the brain is accounted for this activity, and task-induced activity increases only a small portion ($< 5\%$) of brain energy consumption [11].

Phase synchronization plays a crucial role for brain information processing. It is one of the methods the brain uses to code information and to allow distributed neural populations to communicate. Phase synchronization occurs not only when external stimuli are presented but can also occur in spontaneous activity of the brain during the resting state [12]. Coherence is one of methods that are used to evaluate pairwise degree of phase synchronization and is an important measure for examining brain functions and structures. It can indicate communication and cooperation between neurons.

Here, we use the neural field model tuned to the critical region and regions outside to simulate the brain spontaneous activity and studied some dynamical aspects of coherence by adopting the analysis using a moving time window. The results from the field at criticality are compared with those from the fields far from critical point.

2 METHODS

2.1 Neural field model

Neural fields are the mesoscopic models used to describe spatio-temporal dynamics of neural activity in the brain at a tissue level, where there are many neural populations interacting with each other. Because a brain cortex tissue is composed of a large number of neurons, we can take the continuum limit and characterize activity of neural populations as a field [13]. Here, we use this model to describe activity in the brain's cortex tissue.

In neural field models, the dynamics of each point in a field depends on its internal dynamics, activity of other points, and an external stimulus. A common form of neural field equation [14] is the integro-differential equation

$$\frac{1}{\ }\frac{\partial u(x,t)}{\partial t} = -u(x,t) + \int_{-\infty}^{\infty} w(x-y) f(u(y,t))dy, \quad (1)$$

where $u(x,t)$ is the neural activity at point x and time t. It corresponds to the local potential in this work.   is the decay rate of activity. $w(x)$ is the weight function, which describes the strength of connections between points in the field. $f(x)$ is the firing rate function, which determines firing rate output transmitted to postsynaptic neurons. The first term in the right-hand side of equation (1) represents neurons' internal dynamics, while the second term is a convolution between $w(x)$ and $f(x)$ representing influence of output from other neurons weighted by synaptic efficacy between points.

There are many choices of proper $w(x)$ and $f(x)$. In this research, we choose

$$w(x) = (2-|x|)\frac{e^{-|x|}}{2}. \quad (2)$$

It is called a Mexican hat function because its shape looks like a Mexican hat. The lateral-inhibition connectivity used by Amari [14] is the function of this type, too. The shape of this weight function displays local (short-range) excitation and distant (long-range) inhibition, which are typical cortical connections. It is also assumed that this neural field is homogeneous and isotropic, i.e., the weight function is identical for all neurons and depends only on distance between interacting neurons. For the firing rate function $f(x)$, we use a half sigmoidal function,

$$f(x) = \frac{2}{1+e^{-ax\Theta(x)}} - 1, \quad (3)$$

where $\Theta(x)$ is the Heaviside step function. The negative input cannot send out the output at all. Here, a is a parameter controlling steepness of the function when $x > 0$.

The real brain tissue is noisy and also has spontaneous activity, so we add a noise term ξ and small external field h representing spontaneous activity to the equation (1). Now, we have a neural field model of the form

$$\begin{aligned} \frac{1}{\ }\frac{\partial u(x,t)}{\partial t} &= -u(x,t) + \int_{-\infty}^{\infty} w(x-y) f(u(y,t))dy \\ &\quad +h(x,t) + \xi(x,t). \quad (4) \end{aligned}$$

ξ is a multiplicative white noise with $\langle \xi(x,t)\xi(x',t')\rangle = \ u(x,t)\delta(x-x')\delta(t-t')$, and   is noise intensity. For the spontaneous activity, we use a constant $h(x,t) = h$.

2.2 Critical point

Our neural field model (equation (1), (2), and (3)) can feature second order phase transition and a critical point. The steepness variable a in equation (3) works as a control parameter. To identify a critical point, we want to know at which value of a, a uniform stationary solution $u(x) = 0$ for all x begins to be unstable, or the order parameter $\langle u\rangle = \frac{1}{2L}\int_{-L}^{L} u(x)dx$, where L is a half size of the neural field, becomes nonzero.

Then, we did simulations of one dimensional neural field and consider the model's bifurcation graph between the order parameter $\langle u\rangle$ versus the control parameter a (Fig. 1.). According to the diagram, we can see that many possible neural activity patterns can emerge. However, the point that a non-uniform stationary solution begins to appear is $a_c \approx 1.782$, which is the position of a critical point. From now, we will call the left side of the critical point ($a < a_c$) a subcritical region and the right side of the critical point ($a > a_c$) a supercritical region, while a critical region is placed in the vicinity of a_c.

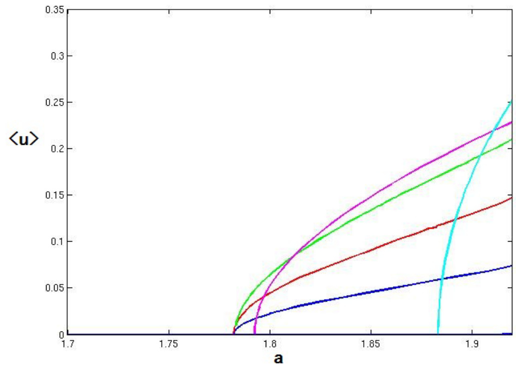

Fig. 1. A bifurcation diagram of the neural field model. A blue, red, green, pink, and light blue lines represent a pattern of 1, 2, 3, 4, and no bump, respectively.

In our simulation, we used $a = 1.782$, 1.982, and 1.582 to represent critical, supercritical, and subcritical region, respectively. We used $L = 20$ and applied periodic boundary condition to the field. Other parameters were set as follows: decay rate, $= 0.2$; noise intensity, $= 1$; and spontaneous activity, $h = 0.00001$.

2.3 Dynamical coherence

The coherence or magnitude-squared coherence is used in spectral analysis for measuring of the phase consistency and one of methods to determine a degree of phase synchronization between a pair of signals. It does not only determine the dependency between simultaneous values of two time series but also considers leading and lagging relationships. The coherence between signals $x(t)$ and $y(t)$ at given frequency f

is defined by

$$C_{xy}(f) = \frac{|P_{xy}(f)|^2}{P_{xx}(f)P_{yy}(f)}, \tag{5}$$

where P_{xy} is the cross power spectral density (CPSD) between $x(t)$ and $y(t)$, which is the Fourier transform of cross correlation, and P_{xx} and P_{yy} are power spectral densities of $x(t)$ and $y(t)$, which are the Fourier transform of autocorrelation. Also, note that the coherence is a function of frequency f, and signals are regarded as the superposition of each frequency component.

The coherence value ranges from 0 to 1. The coherence value of 1 or perfectly coherent signals indicate that the phase difference between two signals is fixed with time, while the value of 0 means that the two signals are completely unrelated. However, noise in the systems can contribute to the coherence greater than zero.

We were interested in dynamical coherence patterns, which mean that coherence values can change in time. We begin with defining the time window Δt as a length of time series at each time step (here, $\Delta t = 2000$). Then, move this frame forward by 1 step in each time step until it reaches the terminal time point. Consequently, dynamical time window is constructed, and we obtain a set of time series at each time step in which we can measure dynamical quantities of our interest, coherence in this case.

3 RESULTS

The spatial averages of dynamical coherence between the point $x = 0$ and all other points in the field for four frequency bands (f_0, $2f_0$, $3f_0$, and $4f_0$) from one sample of simulations are shown in Fig. 2 (Here, $f_0 = 5$ Hz, and the sampling rate determined from the time constant (decay rate) is 2000 points). The dynamical coherence of random noise is also shown for being a reference of insignificant coherence level. It is apparent that the highest coherence appears in the critical region at all frequency bands. In the other regions, the coherence is very low, particularly in higher frequency bands. Actually, at higher frequencies ($\geq 2f_0$), only coherence values in the critical region are significantly higher than the coherence level of noise, though, sometimes the coherence level in supercritical region can be little higher than noise's but still lower than the critical region's. However, there are some periods of time where the coherence in the critical region drops to the same level with or lower than noise's.

Another interesting phenomenon observed only in the critical region is broadband coherence. For the coherence of some pairs of spatial points, there are some short periods of time where high coherence appears in many frequency bands. For example, Fig. 3. shows dynamical coherence in all frequencies between the point $x = 0$ and $x = -20$ at the critical region in the same simulation of Fig. 2.

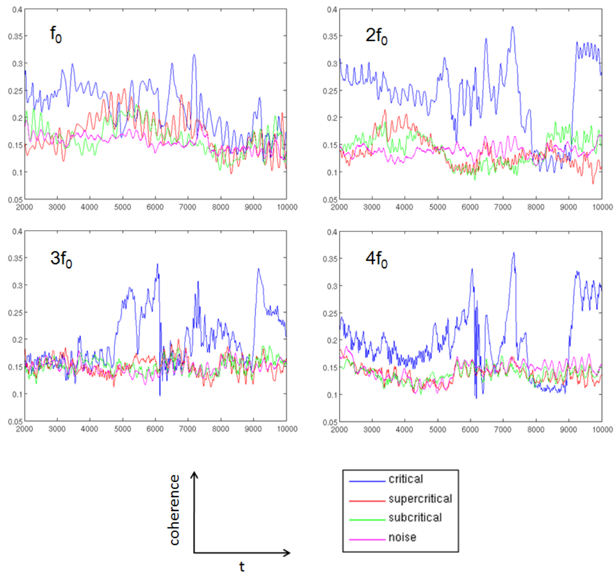

Fig. 2. Spatially average values of dynamical coherence between the point $x = 0$ and the others of the three regions in f_0, $2f_0$, $3f_0$, and $4f_0$ frequency bands including that of random noise.

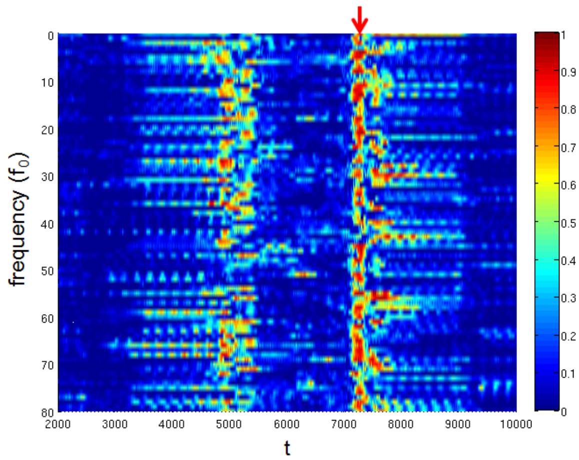

Fig. 3. The pairwise dynamical coherence between points $x = 0$ and $x = -20$. The arrow points the brief periods of high broadband coherence.

4 DISCUSSION & CONCLUSION

The dynamical coherence is highest in the critical region. Actually, at frequencies higher than $2f_0$, only coherence in the critical region is significantly higher than coherence of noise. This result shows that outside the critical region, neurons in the field communicate to each other by high frequency bands much less efficiently than those at criticality. Also, it is at criticality that neurons can communicate most efficiently by any frequency, although there are some periods that the coherence level drops to a value of a non-coherent state. The rise and drop of coherence can be regarded as coherence switching. Archerman and Borbély demonstrated the similar switching in human EEG during NREM-REM (non-rapid eye movement and rapid eye movement) sleep cycles [15].

Furthermore, we found that only at criticality, there are some periods in time that the coherence of some pairs become broadband, i.e., coherence occurs in almost all frequencies at the same time. One reason for this phenomenon is that power spectral density and squared CPSD's cross-frequency correlations are very high in the critical region (the results are not shown). However, its origination and functions still need further investigation. Gervasoni and his colleagues found the high transient broadband coherence occurring at global brain state transitions in rats' LFP (local field potential) [16]. They also suggested that this transient coherence may construct distributed structures of functional connectivity and allow information flow between neurons.

In summary, we used the neural field model to simulate spatio-temporal evolution of spontaneous neural activity in the critical regime, namely, the region around a critical point. Then, dynamical coherence patterns were studied in the critical region compared with regions outside. Our study suggests that communication between neurons in the field is optimized in the critical region. Also, in this region, we observed many phenomena that are consistent with the empirical experiments of the brain.

Abstract: We propose a one-step prediction method by using a simple network consisting phase adjusting units. The network is for learning a continuous time series. Each unit have a function of amplitude and phase adjusting. We tried to predict a point for nonlinear time series like as a logistic map by using the lasso algorithm.

Keywords: Network, Phase, Chaos, time series

1 INTRODUCTION

It is important to make a mathematical model for an observed time series which is complicated such as a deterministic chaos. Although some methods are proposed[1, 2, 3], it is still difficult problem to make a mathematical model for the deterministic chaos yet. As a preliminary step, we propose a method to predict the next point of a given time series by using the lasso algorithm[4]. Our method will be very fast for one-step prediction of complicated time series.

2 PROPOSAL METHOD

First, we prepare k units each of which outputs d dimensional polynomial equation $f(x) = \sum_{j=0}^{d} a_j x^j$. The given parameter k corresponds to the dimension of delay coordinates. This scheme can express many types of complicated time series including chaos.

The dimension of given time series is usually estimated by false nearest neighbor method. In future, we will consider about some types of networks consisted of these units. However in this report, we put the units linearly as shown in Fig. 1.

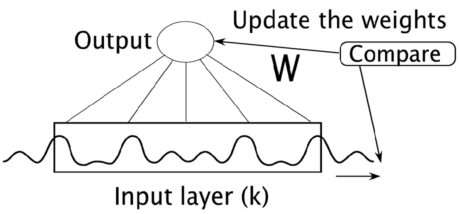

Fig. 1: Schematic diagram of inputs and output.

Next, we minimize the following error value E in Eq. (1) for an applicable prediction. We consider a decaying weight for using late x values.

$$E = \mathrm{E}_t \left(x_{t+1} - \sum_{i=0}^{k} \sum_{j=0}^{d} a_{ij} {x_{t-i}}^j \right)^2 + \lambda \sum_{i=0}^{k} \sum_{j=0}^{d} w_{ij} |a_{ij}|, \quad (1)$$

where x_i is i th data point of given time series, λ is the regularization parameter for the lasso, the weights w_{ij} means $\exp(\gamma_i)$ representing decaying weight, and γ is given value from 1.01 to 1.1. By using the lasso, we expect to get a sparse representation of the polynomial equation which is useful for checking a behavior of the dynamics.

Actually, we split the given time series by k th, and pack up into the following matrix X in Eq. (2).

$$\begin{cases} X = \begin{pmatrix} x_1, ..., x_k, x_1^2, ..., x_k^2, x_1^d, ..., x_k^d \\ x_2, ..., x_{k+1}, x_2^2, ..., x_{k+1}^2, x_2^d, ..., x_{k+1}^d \\ \vdots \\ x_{z-k}, ..., x_{z-1}, x_{z-k}^2, ..., x_{z-1}^2, x_{z-k}^d, ..., x_{z-1}^d \end{pmatrix} \\ Y = (x_{k+1} \cdots x_z)^T \end{cases} \quad (2)$$

We obtain the parameter sets satisfied the map $X \mapsto Y$ by using the lasso.

3 RESULTS

We used a logistic map which is generated a following equation (3) as a tested time series.

$$x_{n+1} = a x_n (1 - x_n), \quad (3)$$

where a characterized parameter a is fixed to 3.8, an initial value x_0 is set to 0.1, and the data size is 5000 points. The dimension of delay coordinates k is assumed to 2. The polynomial dimension of a model d is given to 2. We use the glmnet package[5] under the R system. A parameter in this package s corresponding to λ is set to 0.001. The results will be diverged when the parameter s is very small.

As the results, we obtained an estimated polynomial equation shown in Eq. (4). We completed the calculation within 1 sec.

$$x_{n+1} = 3.4911(x_n)^2 - 0.0160(x_{n-1}) - 3.5508(x_{n-1})^2 + 0.0881 \quad (4)$$

The convergence in a number of parameters and mean squared errors are shown in Figs. 2 and 3. We confirmed that the regularization parameter λ is an effective of the sparse representation. The results of one step prediction using obtained parameters are shown in Fig. 4. We confirmed that our method is effective for one step prediction of complicated time series. However, our method is inability for free-run with parameters fixed. The difference between given time series and obtained model are shown in Fig. 5.

We also checked the effects with an assumed dimension d and an assumed delay dimension k. The results in case of the dimension d assumed 3, are shown in Figs. 6, 7, and 8. The results in case of the delay k assumed 3, are shown in Figs. 9, 10, and 11.

4 CONCLUSION

We proposed a one-step prediction method for chaotic time series using the lasso. As the results, we got good predictions for the logistic map. In future we will try to make a mathematical model which is capable of free run, based on this method.

Abstract: In cellular systems, complicated intracellular reaction circuits implement various types of information processing in response to external stimuli such as decision-making. These processes involve stochastic fluctuations owing to low copy numbers of molecules per cell and uncertainty of environmental signals. Major mechanisms that can cope with such noise, known currently, are potential-induced bistability at the single-cell level, or mutual communication at the population level. Another mechanism, noise-induced bistability, is recently demonstrated to be connected to optimal noise-filtering dynamics from external stimuli. In this work, we focus on the difference of potential-induced and noise-induced dynamics in terms of their information processing ability. Furthermore, we investigate the effect of mutual communication to the noise-induced dynamics. To address these problems, we propose a mathematical model of an intracellular network that combines both bistablility. In addition, we also investigate the impact of intercellular communication.

Keywords: Cellular dynamics, Decision making, Stochastic process, Cell-cell communication

1 INTRODUCTION

Information processing in response to external stimuli is a fundamental function of all living systems. In cellular systems, for example, various types of information processing such as decision-making are implemented by complicated intracellular reaction circuits. However, all components of the circuits such as transcriptional control, alternative splicing, translation, diffusion and chemical modification reactions of transcriptional factors, involve stochastic fluctuations owing to low copy numbers of molecules per cell and uncertainty of an external environment. These intrinsic and extrinsic noise in the building components can inevitably disturb the cellular information processing [1].

Two mechanisms are mainly known that can cope with such noise: one is single-cell level, and the other is the population level. At the single-cell level, a cell may have intracellular circuits that can resist to noise. For example, a bistable potential system implemented by mutually inhibitory reactions can sustain its state against noise if the deterministic force exerted by the potential is sufficiently strong. At the population level, cells can also employ mutual communication to realize coordinated behavior out of noisy single-cell level behavior [2, 3, 4]. While these mechanisms are prevalently observed within intracellular circuits, they may be insufficient to explain all the biological phenomena because such strong deterministic potential or communication may reduce not only the noise but also the flexibility and variability of the cells to the external stimuli.

On this issue, one of the authors has recently demonstrated that intracellular networks that can optimally filter out noise in external stimuli have ability to show noise-induced bistability [5, 6], suggesting that noise-induced as well as deterministic potential-induced dynamics can also efficiently cope with noise. Furthermore, it is also suggested that such dynamics can optimally balance the suppression of noise and sensitivity to external stimuli. Nonetheless, the difference between potential-induced and noise-induced dynamics in terms of their information processing ability has not yet been clarified. Furthermore, even though mutual communication of potential-induced dynamics has been intensively investigated [3, 7, 8], almost nothing is known on the effect of mutual communication to the noise-induced dynamics.

In this study, we tackle this problem using a mathematical approach, and propose a model of an intracellular network that combines both potential-induced and noise-induced bistablility. First, we analyze deterministic and stochastic properties of this model by calculating null-clines and bifurcation diagram. Next, by numerical simulations, we confirm that this model exhibits bimodal histograms produced by the potential-induced and noise-induced bistability in case of constant external stimuli. We also examine the response of the model to a step-like external stimuli. Finally, we introduce intercellular communication that enables each cell to detect the state of the other cells and react together with them. We investigate the responses to external stimuli for different strength of communication to clarify the impact.

2 COMBINED MODEL OF POTENTIAL- AND NOISE-INDUCED BISTABILITY

2.1 Derivation of equation

In [5], it was demonstrated that the following autophosphorylation and autodephosphorylation reaction as an intracellular network is approximately equivalent to an optimal dynamics to infer the state of environment from noisy receptor signal. Its Gaussian approximation was derived subsequently in [6] to further clarify the noise-induced bistability in that cycle. We extend this model such that a new model can have potential-induced bistability as well as noise-induced bistability that the original model has.

The model is described as follows:

$$\frac{\mathrm{d}Z_i}{\mathrm{d}t} = \quad Z_i\tilde{Z}_i I(t) + r_{\mathrm{on}} H(\tilde{Z}_i)\tilde{Z}_i \quad r_{\mathrm{off}} H(Z_i) Z_i, \tag{1}$$

where $Z_i \in [0,1]$ and $\tilde{Z}_i := 1 \quad Z_i$ are the state of the system in i-th cell, such as ratios of phosphorylated and un-phosphorylated molecules in a cell. Under this interpretation, $r_{\mathrm{on}}H(\tilde{Z}_i)$ and $r_{\mathrm{off}}H(Z_i)$ are respectively the rate of input-independent phosphorylation and dephosphorylation reactions that occur spontaneously where $H(Z) := p + 2(1 \quad p)/(K_0^n + Z^n)$. When $p = 1$, Eq. (1) is equivalent to the model derived in [6]. When $p = 0$, $r_{\mathrm{on}}H(\tilde{Z}_i)\tilde{Z}_i \quad r_{\mathrm{off}}H(Z_i)Z_i$ has a bistable potential by the inhibition of state transition between Z_i and $\tilde{Z}_i$ introduced by the Hill's kinetics. Thus, $p \in [0,1]$ controls the extent to override bistable potential onto the original model. The external input $I(t)$ with extrinsic noise is described as the following:

$$I(t) = \alpha(\ _0 U dt + \sigma \circ \mathrm{d}W_t), \tag{2}$$

where $\circ$ represents Stratonovich interpretation [9]. $\ _0U$ is the signal that the cell have to detect. $\sigma W_t$is the noise that cell receives. $\ _0$ is introduced to control the strength of the signal with respect to noise. The signal noise ratio (SNR) $\ _0/\sigma$ determines the ambiguity of the signal. α is the amplification factor of both signal and noise that a cell can control. For notational simplicity, we define the following functions:

$$F(Z,U) = \alpha\ _0 U Z\tilde{Z} + r_{\mathrm{on}}H(\tilde{Z}) \quad r_{\mathrm{off}} Z H(Z),$$
$$G(Z) = \alpha\sigma Z\tilde{Z}.$$

2.2 Deterministic properties of Eq. (1)

Firstly, we analyze deterministic properties of our model. The equilibrium state of Eq. (1) satisfies $F(Z,U) = 0$. By solving this equation with respect to U, we obtain

$$U_{null}^{det}(Z) = \frac{1}{\alpha\ _0} \quad \frac{r_{\mathrm{on}}}{Z}H(\tilde{Z}) + \frac{r_{\mathrm{off}}}{\tilde{Z}}H(Z) \ ,$$

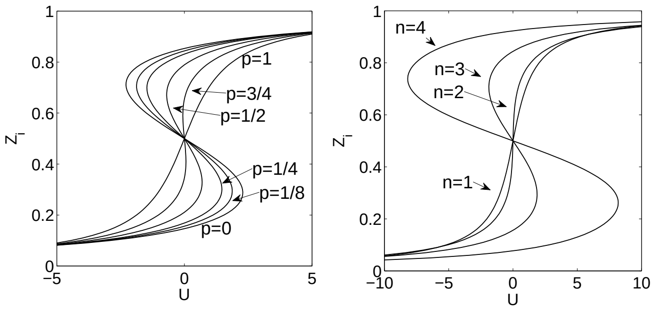
which is the analytic expression of the null-cline of Eq. (1). For a given U, the equilibrium state of Z may have more than one state. In other words, the system can have multi-stable states. While the condition for multi-stable state is not generally expressed analytically, we can derive it for a symmetric condition such that $K_0 = 1/2$, $r_{\mathrm{on}} = r_{\mathrm{off}} = r_0$. Fig. 1. (a) and (b) show the null-clines of this system with respect to the parameters n and p, respectively. Given these conditions, Eq. (1) becomes symmetric with respect to the exchange of Z and $\tilde{Z}$. Thus, when $U = 0$, $Z = 1/2$ is always one of the equilibrium state. Therefore, the derivative of $U_{null}^{det}(Z)$ with respect to Z can be used as the condition for the transition from monostable to bistable state. More specifically, $\left.\frac{\mathrm{d}U_{null}^{det}(Z)}{\mathrm{d}Z}\right|_{Z=1/2} = 0$ is the condition of changing the number of the equilibrium states. By rearranging this equation, we have

$$p = \frac{2^n(n \quad 2)}{2 \quad 2^{1+n} + 2^n n} \qquad (n \neq 1),$$

which is depicted by the solid line in Fig. 2.

2.3 Stochastic properties of Eq. (1)

Next we clarify the properties of Eq. (1) when noise is introduced. Let consider the situation such that U and σ are constant and that $\mathrm{d}W_t$ is the white Gaussian process. Then,



(a) Null-clines for different values of p (b) Null-clines for different values of n

Fig. 1. Null-clines of Eq. (1)

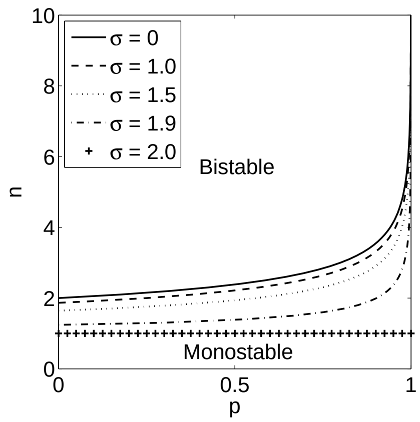


Fig. 2. Bifurcation Diagram. The upper (lower) side area of each curve correspond to bimodal (unimodal) distribution.

Eq. (1) can be described by a stochastic differential equation as

$$\mathrm{d}Z_i = F(Z,U)\mathrm{d}t + G(Z) \circ \mathrm{d}W_t. \tag{3}$$

We here use Stratonovich interpretation as the original work did[6].

The probability distribution $\mathbb{P}(t,Z)$ of Eq. (3) then satisfies the corresponding Fokker-Planck equation [9] as

$$\frac{\partial \mathbb{P}(t,Z)}{\partial t} = \quad \frac{\partial \left[F_{Ito}(Z,U)\mathbb{P}(t,Z)\right]}{\partial Z} + \frac{1}{2}\frac{\partial^2 \left[G(Z)^2\mathbb{P}(t,Z)\right]}{\partial Z^2},$$

where $F_{Ito}(Z,U) := F(Z,U) + \alpha\sigma G(Z)(1/2 \quad Z)$. The stationary state of Eq. (3) can be represented [9] as

$$\mathbb{P}_{st}(Z) = \frac{N}{G(Z)^2}\exp\left[2\int^Z \frac{F_{Ito}(Z',U)}{G(Z')^2}dZ'\right].$$

This equation can be solved analytically when $p = 1$ as

$$\mathbb{P}_{st}(Z) \propto \frac{1}{Z\tilde{Z}}\left(\frac{Z}{\tilde{Z}}\right)^{\bar{U}} \exp\left[\quad \frac{2}{(\alpha\sigma)^2\left(\frac{r_{\mathrm{on}}}{Z} + \frac{r_{\mathrm{off}}}{\tilde{Z}}\right)}\right],$$

where $\bar{U} = \frac{2(\alpha\mu_0 U + r_{\mathrm{on}} \quad r_{\mathrm{off}})}{(\alpha\sigma)^2}$.

For $p < 1$, this equation cannot be analytically solved. Nevertheless, some properties, especially stochastic bifurcation, can be analytically derived. Let identify the peak positions of stationary distribution of Eq. (3) with the deterministic equilibrium points considered in the previous section. Then, the change of the number of peaks can be regarded as the bifurcation of the stochastic system, which is known as phenomenological bifurcation [10]. The peak positions of $\mathbb{P}_{st}(Z)$ satisfies $\frac{\partial \mathbb{P}_{st}(Z)}{\partial Z} = 0$. This equation can be solved with respect to U as

$$U_{null}^{st}(Z) = U_{null}^{det}(Z) + \frac{(\alpha\sigma)^2}{\alpha \quad _0}(1/2 \quad Z).$$

Similarly to the deterministic case, $U_{null}^{st}(z)$ becomes symmetric around $Z = 1/2$ when $r_{\mathrm{on}} = r_{\mathrm{off}} = r_0$. In addition, $Z = 1/2$ and $U = 0$ is always the equilibrium state under the symmetric condition. Thus, the bifurcation points from unimodal to bimodal distribution satisfy

$$\left.\frac{\mathrm{d}U_{null}^{st}(Z)}{\mathrm{d}Z}\right|_{Z=1/2} = \left.\frac{\mathrm{d}U_{null}^{det}(Z)}{\mathrm{d}Z}\right|_{Z=1/2} \quad \frac{(\alpha\sigma)^2}{\alpha \quad _0} = 0,$$

which is also the condition for the change of the number of peaks when $\left.\frac{\mathrm{d}^2 U_{null}^{st}(Z)}{\mathrm{d}Z^2}\right|_{Z=1/2} \neq 0$. Then we have

$$\begin{cases} p = \frac{2^n(n \quad 2)}{2 \quad 2^{1+n}+2^n n} + \frac{(\alpha\sigma)^2/(4r_0)}{2 \quad 2^{1+n}+2^n n} & (n \neq 1) \\ \sigma = 2 & (n = 1), \end{cases}$$

which is depicted in Fig.2.

2.4 Simulation results

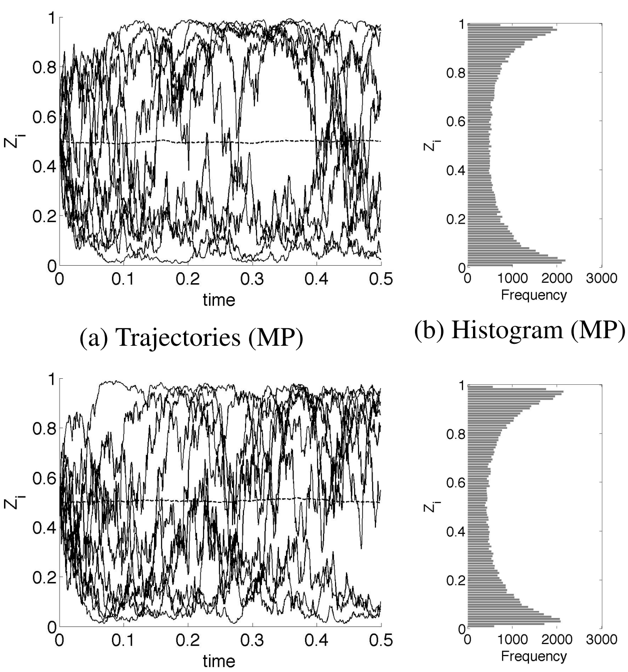
We compare monostable and bistable potential cases for external input signal $\quad = 0$. We choose $p = 1$ for monostable potential case and $p = 1/8$ for bistable potential case. We set parameter of Hill function $n = 3$ to have bistable potential for $p = 1/8$, and noise intensity $\sigma = 7$ to realize noise-induced bistability for $p = 1$. We simulate Eq. (1) for $\quad t = 0.001$ and $N = 2000$ by using Milstein scheme [9]. Fig. 3. (a) and (b) show the results of monostable potential case whereas Fig. 3. (c) and (d) show those of bistable potential case.

Then we simulate the response of cells to step-wise change of external signal $\quad _0U$ from $\quad$ to $+ \quad$. Now $\quad = 21$, and time of step-wise change is at $t = 0.1$. Fig. 4. (a) and (b) show responses of populations to the inputs. Both figures show similar Z_i trajectories and mean trajectory of Z_i.

3 CELL-CELL COMMUNICATION MODEL

We modify Eq. (3) to have cell-cell communication by adding the term for diffusive cell-cell communication. The equation is described as follows:

$$\begin{aligned} \mathrm{d}Z_i = {} & F(Z_i,U)\mathrm{d}t + G(Z_i) \circ \mathrm{d}W_t \\ & \frac{D}{N \quad 1}\sum_{j\neq i}(Z_i \quad Z_j)\mathrm{d}t, \end{aligned} \tag{4}$$



(a) Trajectories (MP) (b) Histogram (MP)

(c) Trajectories (BP) (d) Histogram (BP)

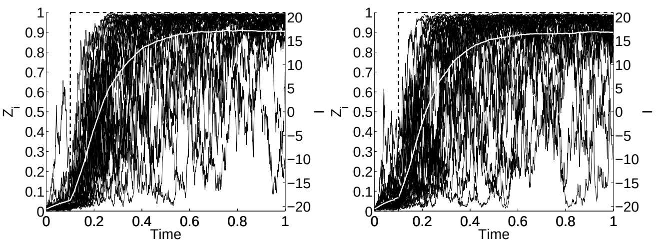
Fig. 3. Response to constant input. MP and BP represent monostable and bistable potentials, respectively. (a) and (c) show the trajectories of Z_i. Solid curves are the trajectories of Z_i (We plot trajectories of only 10 cells). Dashed curve is the trajectory of mean of Z_i. (b) and (d) are the histogram.

where D is the diffusion constant controlling the strength of communication, and N is the total number of cells.

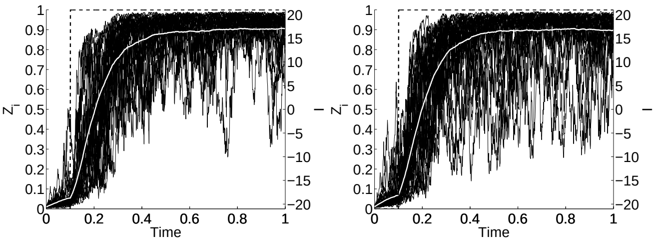
Fig. 4. (c) and (d) show the simulation results of the response of cells to step-wise change of external signal $_0U$ from to $+$. Now $= 21$, $D = 10$, rising time of step input is $t = 0.1$.

Comparison of Fig. 4. (a) (b) and Fig. 4. (c) (d) show that fluctuation of Z_i by noise is moderated by communication, which means that intercellular communication made the transitions of cellular populations more adequate.

To confirm the effect of diffusion constant D, we conduct simulation for various D. Fig. 5. (a) and (b) are the results of monostable and bistable potential cases, respectively. We plot the trajectories of mean of Z_i for various D. The larger D becomes, the faster the reaction of cellular population is in both monostable and bistable potential cases.



(a) Without coupling (MP) (b) Without coupling (BP)



(c) With coupling (MP) (d) With coupling (BP)

Fig. 4. (a) and (b) are the response to step-wise input without coupling. Solid curves are trajectories of Z_i (We plot trajectories of only 30 cells) and correspond to left axis. White curve is trajectory of mean of Z_i, correspond to left axis. Dashed curve is external signal and correspond to right axis. (c) and (d) are the response to step-wise input with coupling. The meaning of curves are the same as (a) and (b).

Fig. 5. Average Z_i in switching at various diffusion constant

4 DISCUSSION

In this study, we have examined the difference of potential-induced and noise-induced bistability with respect to their response to external stimuli with and without intercellular communication. However, their difference is not clearly observed. The reason of this small difference may be attributed to the property of our model; bistable potential is overridden onto the noise-induced bistability, indicating that two mechanisms are not clearly separated. In order to reach firm conclusion, we need further investigation and/or modification of our models.

Cholinergic top-down modulation based on the free-energy principle

Abstract: Acetylcholine (ACh) has a key role in the cortex in perception. Although cholinergic modulations have been revealed in recent experimental studies, it remains unclear what is the essential role of ACh. In order to clarify the crucial computational function of ACh in perceptual inference, we propose a model of cholinergic top-down modulation based on the free-energy principle in this paper. We made the only assumption that ACh modulates the magnitude of top-down processing. Then, dynamics of the ACh level is derived by the free-energy principle. Our model suggests that ACh reports uncertainty of top-down information and reduces noise of top-down input. Thus, ACh can contribute to precise perception.

Keywords: neuromodulation, acetylcholine, free-energy principle, perception

1 INTRODUCTION

Acetylcholine (ACh) is one of the neuromodulators such as dopamine, serotonin, and noradrenaline. ACh is synthesized in the basal forebrain including medial septum, diagonal band of Broca, and nucleus basalis. Then, it is delivered to large areas of the cortex. Delivered ACh acts various functions in the cortex [3], [4]. First, recurrent intracortical connections and top-down processing are suppressed via muscarinic receptors. Second, afferent input is facilitated via nicotinic receptors. These cholinergic modulations relate to perception.

In theoretical studies, Yu and Dayan have suggested that the ACh level represents the uncertainty associated with top-down information [6], [7]. They proposed an ACh model by means of hidden Markov model, showing that cholinergic modulation leads to efficient perceptual inference. On the other hand, Friston has recently suggested that perception is realized by the free-energy principle. The free-energy principle has strong impacts because we can uniformly deal with neuronal activity, synaptic plasticity, and neuromodulation.

Although cholinergic modulation is well studied in recent studies, the relationship between cholinergic modulation and the free-energy principle is not clear. Furthermore, the crucial computational role of ACh is poorly understood. Here, we propose a model of cholinergic modulation based on the free-energy principle in this paper. We assume that ACh modulates the efficacy of top-down processing, showing that the ACh level changes in response to uncertainty of top-down information and ACh yields better perceptual inference.

2 MODELING OF PERCEPTION

Before we introduce cholinergic modulation, we review the perception model derived by the free-energy principle proposed by Friston [1] in this section. See [1] and [2] for details.

2.1 Generative model

Consider the following state-space model,

$$\dot{x} = Ax + Bv + z_x, \tag{1}$$

$$y = Cx + z_y, \tag{2}$$

where $v, x,$ and y denote input, state, and output, respectively. State equation (1) demonstrates the transition of state x in terms of input v, state itself x, and noise z_x. Output equation (2) defines output y by state x and noise z_y. $A, B,$ and C are time-invariant matrices. This linear state-space model generates observable consequence y by causes x and v. In this sense, this state-space model is called a generative model.

Next, generalized coordinates are introduced under the smoothness assumptions. We assume that all variables are smooth enough to differentiate infinitely. We use the notations, tildes, in the sense of generalized coordinates, e.g., $\tilde{x} := [x^T, \dot{x}^T, \ddot{x}^T, \dots]^T$. Then, the state-space model can be written by

$$D\tilde{x} = \tilde{A}\tilde{x} + \tilde{B}\tilde{v} + \tilde{z}_x, \tag{3}$$

$$\tilde{y} = \tilde{C}\tilde{x} + \tilde{z}_y, \tag{4}$$

$$\tilde{A} := I \otimes A,\ \tilde{B} := I \otimes B,\ \tilde{C} := I \otimes C, \tag{5}$$

$$D := \begin{bmatrix} 0 & 1 & 0 & \cdots \\ 0 & 0 & 1 & \cdots \\ \vdots & \vdots & & \ddots \end{bmatrix} \otimes I, \tag{6}$$

where I is the identity matrix and $\otimes$ is Kronecker product.

Moreover, if we assume that noises $\tilde{z}_x$ and $\tilde{z}_y$ obey Gaussian distributions $\mathcal{N}(0, \Sigma_x)$ and $\mathcal{N}(0, \Sigma_y)$, we can rewrite the state-space model to the probabilistic model as follows

$$p(\tilde{y}, \tilde{x}, \tilde{v}) = p(\tilde{y}|\tilde{x}, \tilde{v})p(\tilde{x}|\tilde{v})p(\tilde{v}), \quad (7)$$

$$p(\tilde{y}|\tilde{x}, \tilde{v}) = \mathcal{N}(\tilde{y} : \tilde{C}\tilde{x}, \Sigma_y), \quad (8)$$

$$p(\tilde{x}|\tilde{v}) = \mathcal{N}(D\tilde{x} : \tilde{A}\tilde{x} + \tilde{B}\tilde{v}, \Sigma_x). \quad (9)$$

We solve the inversion of this generative model in the following section.

2.2 Perception model

In the perception model, the brain estimates states $\tilde{x}$ and $\tilde{v}$ by observing $\tilde{y}$ and using prior knowledge $\tilde{v}_{\mathrm{pr}}$. Under the ergodic assumptions, given model m, the entropy of sensory state is

$$H(\tilde{y}|m) = -\int p(\tilde{y}|m) \ln p(\tilde{y}|m) d\tilde{y} \quad (10)$$

$$= -\int \ln p(\tilde{y}|m) dt \quad (11)$$

$$\leq \int \left(-\ln p(\tilde{y}|m) + D_{\mathrm{KL}}(q(\vartheta)||p(\vartheta|\tilde{y}, m))\right) dt \quad (12)$$

$$= \int \left(\langle -\ln p(\tilde{y}, \vartheta|m)\rangle_q - \langle -\ln q(\vartheta)\rangle_q\right) dt, \quad (13)$$

where ϑ is internal parameter including causes $\tilde{x}$ and $\tilde{v}$. Distribution q is (arbitrary) recognition density. Here, we define the free-energy $\mathcal{F}$ as

$$\mathcal{F} := -\ln p(\tilde{y}|m) + D_{\mathrm{KL}}(q(\vartheta)||p(\vartheta|\tilde{y}, m)) \quad (14)$$

$$= \langle -\ln p(\tilde{y}, \vartheta|m)\rangle_q - \langle -\ln q(\vartheta)\rangle_q. \quad (15)$$

The free-energy is an upper bound of sensory entropy. The free-energy principle says that recognition is realized by minimizing this free-energy.

Here, we assume that the recognition density $q(\tilde{x}, \tilde{v})$ can be factorized into $q(\tilde{x})$ and $q(\tilde{v})$ (mean field approximation), and has a Gaussian form with means $\tilde{\mu}_x$ and $\tilde{\mu}_v$ (Laplace assumption). We also assume that noise $\tilde{z}_v$ obeys $\mathcal{N}(0, \Sigma_v)$, where $\tilde{\mu}_v = \tilde{v}_{\mathrm{pr}} + \tilde{z}_v$. Then, the free-energy can be written by (ignoring constant)

$$\mathcal{F} = \frac{1}{2}\varepsilon_y^T \Pi_y \varepsilon_y + \frac{1}{2}\varepsilon_x^T \Pi_x \varepsilon_x + \frac{1}{2}\varepsilon_v^T \Pi_v \varepsilon_v - \frac{1}{2}\ln|\Pi_y| - \frac{1}{2}\ln|\Pi_x| - \frac{1}{2}\ln|\Pi_v|, \quad (16)$$

$$\varepsilon_y = \tilde{y} - \tilde{C}\tilde{\mu}_x, \quad (17)$$

$$\varepsilon_x = D\tilde{\mu}_x - \tilde{A}\tilde{\mu}_x - \tilde{B}\tilde{\mu}_v, \quad (18)$$

$$\varepsilon_v = \tilde{\mu}_v - \tilde{v}_{\mathrm{pr}}, \quad (19)$$

where precision matrices Π_y, Π_x, and Π_v are defined as the inverse of covariance matrices Σ_y, Σ_x, and Σ_v.

Thus, we can obtain the inversion (perception) model by gradient descent of minimizing free-energy as follows

$$\dot{\tilde{\mu}}_x = D\tilde{\mu}_x - k_1(-\tilde{C}\Pi_y\varepsilon_y + (D - \tilde{A})\Pi_x\varepsilon_x), \quad (20)$$

$$\dot{\tilde{\mu}}_v = D\tilde{\mu}_v - k_1(-\tilde{B}\Pi_x\varepsilon_x + \Pi_v\varepsilon_v). \quad (21)$$

Note that $\tilde{\mu}_x$ and $\tilde{\mu}_v$ are estimated values of $\tilde{x}$ and $\tilde{v}$.

One of the advantages of this perception model is that the equations (20) and (21) reflect cortical circuitry as shown in Fig. 1. It consists of thalamus, lower cortex, and higher cortex. Sensory input enters from environment through thalamus to the lower cortex, while prior knowledge enters from the higher cortex to the lower cortex. The cortical circuit estimates states in deep layers and conveys estimation to the lower area, while it also calculates estimation errors in superficial layers and conveys errors to the higher area.

3 MODELING OF ACETYLCHOLINE

In this section, we introduce ACh effects in the above perception model proposed by Friston [1]. Then, ACh dynamics is derived by the free-energy principle.

3.1 Introduction of acetylcholine effects

Yu and Dayan have proposed ACh model in a framework of hidden Markov model, suggesting that ACh represents uncertainty of top-down information, and controls the balance between bottom-up and top-down input [6], [7]. So, we also start with the following assumption.

Assumption: Let α denote the ACh level. Then, ACh controls the magnitude of top-down input as follows

$$\Pi_v = \pi_v \exp(-\lambda_v \alpha), \quad (22)$$

where π_v is prior precision matrix, and λ_v is positive constant.

The high ACh level decreases the magnitude of precision matrix Π_v, resulting in decreasing the contribution of ε_v to estimation in (21). In other words, ACh suppresses top-down processing. It corresponds to muscarinic feedback suppression by ACh released from the basal forebrain as shown in Fig. 1.

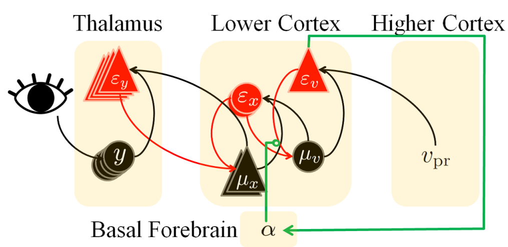

Fig. 1. Neuronal implementation of perception model with cholinergic modulation

3.2 Derivation of acetylcholine dynamics

Since we defined cholinergic modulation, we next derive dynamics of ACh level by the free-energy principle. Assuming that α obeys prior distribution $\mathcal{N}(\alpha_{\mathrm{pr}}, \Pi_\alpha)$, the free-energy is given by

$$\mathcal{F} = \frac{1}{2}\varepsilon_y^T \Pi_y \varepsilon_y + \frac{1}{2}\varepsilon_x^T \Pi_x \varepsilon_x + \frac{1}{2}\varepsilon_v^T \pi_v \varepsilon_v \exp(-\lambda_v \alpha) - \frac{1}{2}\ln|\Pi_y| - \frac{1}{2}\ln|\Pi_x| - \frac{1}{2}\ln|\pi_v| + \frac{1}{2}\lambda_v \alpha + \frac{1}{2}\varepsilon_\alpha^T \Pi_\alpha \varepsilon_\alpha - \frac{1}{2}\ln|\Pi_\alpha|, \tag{23}$$

where $\varepsilon_\alpha = \alpha - \alpha_{pr}$. Because the ACh level changes slower than state estimation, ACh minimizes the time integral of the free-energy by gradient descent as follows

$$\dot{\alpha} = -k_2 \partial_\alpha \int \mathcal{F} dt \tag{24}$$

$$= -k_2 \int (\frac{1}{2}\lambda_v - \frac{1}{2}\lambda_v \varepsilon_v^T \pi_v \varepsilon_v \exp(-\lambda_v \alpha) + \Pi_\alpha \varepsilon_\alpha) dt. \tag{25}$$

By time differentiating of both sides, we obtain ACh dynamics.

Derived dynamics: ACh level changes according to

$$\ddot{\alpha} = -k_2(\frac{1}{2}\lambda_v - \frac{1}{2}\lambda_v \varepsilon_v^T \pi_v \varepsilon_v \exp(-\lambda_v \alpha) + \Pi_\alpha \varepsilon_\alpha). \tag{26}$$

Instead of using gradient descent, the optimal ACh level that minimizes the free-energy at each time can be written analytically by solving $\partial_\alpha \mathcal{F} = 0$ and assuming that Π_α is close to zero. The optimal ACh level can be written by

$$\alpha = \frac{1}{\lambda_v} \ln \varepsilon_v \pi_v \varepsilon_v. \tag{27}$$

This equation shows that the ACh level varies proportional to the square of the estimation error ε_v. In other words, the ACh level represents the magnitude of estimation errors associated with top-down information in perception. Released ACh affects the efficacy of top-down modulation.

4 SIMULATION

We first simulate the generative model to create observed data, and then simulate the perception model with cholinergic modulation using sensory data given by the generative model. We use time step $\Delta t = 0.01$ in both the generative and perception model.

4.1 Generative model

In our simulation, the generative model creates 2 dimensional state x and 4 dimensional output y according to the equations (3) and (4) with scholar input v, given by

$$v(t) = \tanh(t-70) - \tanh(t-130) + \tanh(t-270) - \tanh(t-330) + \tanh(t-470) - \tanh(t-530) + z_v. \tag{28}$$

Embedded order of generalized coordinates is $n = 3$. We used the following constant parameters

$$A = \begin{bmatrix} -0.25 & 1.00 \\ -0.50 & -0.25 \end{bmatrix}, B = \begin{bmatrix} 1 \\ 0 \end{bmatrix}, \quad C = \begin{bmatrix} 0.1250 & 0.1633 \\ 0.1250 & 0.0676 \\ 0.1250 & -0.0676 \\ 0.1250 & -0.1633 \end{bmatrix}, \tag{29}$$

and precision matrices

$$\Pi_y = S \otimes I_4 \exp(10), \quad \Pi_x = S \otimes I_2 \exp(4), \quad \Pi_v = S \exp(6), \quad S = \begin{bmatrix} 1 & 0 & -\frac{1}{2}\gamma & \cdots \\ 0 & \frac{1}{2}\gamma & 0 & \\ -\frac{1}{2}\gamma & 0 & \frac{3}{4}\gamma^2 & \\ \vdots & & & \ddots \end{bmatrix}^{-1}, \tag{30}$$

with a roughness parameter $\gamma = 4$. These parameterizations are similar to [1].

Simulation results of the generative model are shown in Fig. 2. Input v becomes high at time $t = 70\sim130$, $270\sim330$, and $470\sim530$. State x and output y vary depending on the input v. In our simulation, we raise the noise level to $\Pi_y = S \otimes I_4 \exp(8)$ at time $t = 200\sim400$.

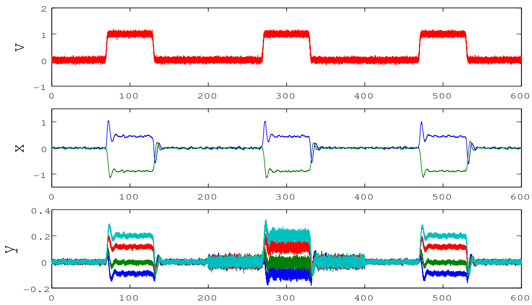

Fig. 2. Generative model

4.2 Perception model with cholinergic modulation

Next, we simulate the perception model (20) and (21) with ACh effects (22) and (26). We used parameters

$$\Pi_\alpha = 1, \alpha_{pr} = 0, \tag{31}$$

$$\pi_v = S \exp(6). \tag{32}$$

A, B, C, Π_y, and Π_x are the same as those of the generative model. Afferent input y is noisy at time $t = 200 \sim 400$, while prior knowledge v_{pr} is noisy at time $t = 400 \sim 600$.

Simulation results are shown in Fig. 3. Cortical circuitry estimates states μ_x and μ_v, changing the ACh level α in response to estimation errors at the same time. Estimated states μ_x and μ_v are similar to true dynamics in the generative model in Fig. 2. The ACh level α has oscillatory behavior after afferent input comes in. When prior knowledge is noisy, the ACh level becomes high. This means that ACh reports uncertainty of top-down information. The lower two figures show the free-energy $\mathcal{F}$ in the case of proper cholinergic modulation (above) and cholinergic deficit in which α is always zero (bottom). Although the free-energy level increases when afferent input as well as prior knowledge is noisy regardless of cholinergic modulation, ACh suppresses the rise of the free-energy in the case of noisy prior knowledge. As a result, ACh yields better perception.

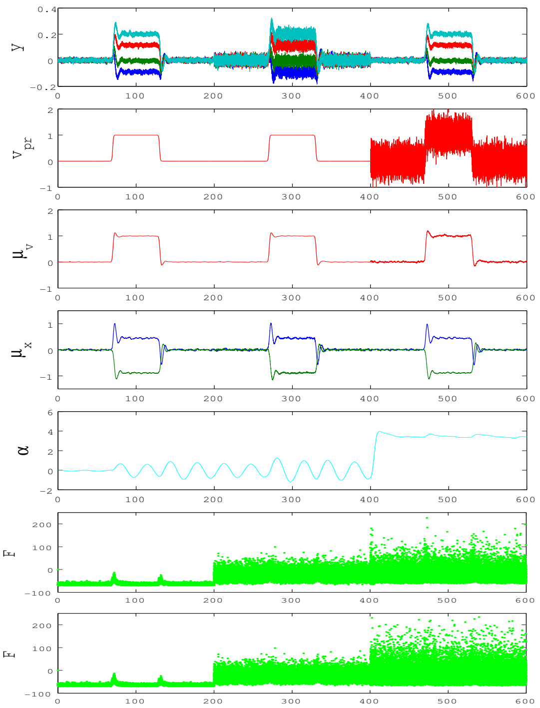

Fig. 3. Perception model with cholinergic modulation (above) and without cholinergic modulation (the lowest)

5 DISCUSSION

The role of ACh in this study is similar to that of [6] and [7], which is based on hidden Markov model, because both suggest that ACh reports uncertainty associated with top-down information. The biggest difference is that ACh contributes to efficient calculation in [6] and [7], whereas it contributes to estimation precision in our model, which is thought to be more realistic.

In addition to changing the ACh level depending on the noise level, ACh has oscillatory behavior. This is because the ACh level is defined by the "time integral" of the free-energy and thus its dynamics is written by quadratic differential equation. This fact indicates the possibility that oscillations in the brain can occur by minimizing the time integral of the free-energy.

Besides inserting cholinergic modulation effects in Σ_v, we can also introduce ACh effects in Σ_y and Σ_x [5]. These effects correspond to nicotinic thalamo-cortical facilitation and muscarinic intracortical suppression [3], [4]. We consider that the effects on Σ_v, Σ_y, and Σ_x result in noise reduction of prior knowledge, noise reduction of afferent input, and detection of mismatch of prior knowledge and afferent input, respectively.

6 CONCLUSION

In this paper, we introduce cholinergic modulation effects in a perception model based on the free-energy principle. The effects correspond to muscarinic top-down suppression. Then, we derive ACh dynamics by the free-energy principle. Our model suggests that the ACh level increases when top-down input is noisy, that is, ACh represents uncertainty of top-down information. Precise perception can be realized by cholinergic top-down modulation.

Abstract: We investigate an associative memory model consisting of both self-oscillatory and non-self-oscillatory oscillators that store temporal patterns on relative phase differences between the oscillators. We numerically simulate this model and show that the speed of memory retrieval is enhanced with increase in the proportion of number of non-self-oscillatory elements. These results imply, from a viewpoint of neuroscience, that the presence of resting or down state of neurons facilitates an ability of memory retrieval.

Keywords: associative memory, aging transition, coupled oscillators, up-down state transition.

1 INTRODUCTION

There have been many associative memory models composed of various elements that store various types of patterns. Aoyagi proposed an associative memory network, each element of which is an oscillator, and represents patterns in their relative phase difference [1]. In this model, the Stuart-Landau equation is used as the model of oscillator. The oscillators are connected with Hopfield-like weight matrix [2].

Dynamics of coupled oscillators are well studied independently of the associative memory models. Daido and Nakanishi studied globally coupled oscillators which are composed of two types of oscillators: namely, active and inactive oscillators [3, 4]. The active oscillator shows oscillation without an external driving force (self oscillatory) and its underlying mechanism is characterized by a stable limit cycle. The inactive oscillator requires external driving forces to oscillate (non-self oscillatory) and is characterized by a stable equilibrium point. If the proportion of number of inactive oscillators in the coupled oscillator system is sufficiently small, all the oscillators show synchronous oscillation; the active oscillators oscillate around the limit cycle and the inactive ones oscillate around the stable equilibrium with small amplitude. If the proportion of number of inactive oscillators becomes large, on the other hand, the system shows a phase transition and stops the oscillation. This phase transition is called an aging transition [3, 4].

In the present study, we investigate an associative network model which stores phase information and is composed of both active and inactive oscillators. We first model the associative network model. Then, we analyze the dynamics of the system while the system retrieves stored pattern, i.e., how the increase in the proportion of number of inactive oscillators contributes to the initial quickness of retrieving the stored patterns. Finally, we discuss the underlying mechanism of this initial quick memory retrieval and an interpretation of the model from a viewpoint of neuroscience.

2 MODEL

Our model is based on the associative memory model proposed by Aoyagi [1], which is a coupled oscillator system that stores phase patterns in the coupling connections.

The coupled oscillator system is described by

$$\frac{\mathrm{d}z_i}{\mathrm{d}t} = f_i(z_i) + K(\sum_{j=1}^{N} C_{ij}z_j - z_i), \tag{1}$$

where z_i is the complex state variable of the ith element. The interactions between the elements are represented by the complex weight matrix C_{ij} and the coupling strength $K \geq 0$. As for the oscillation dynamics f_i, we follow Aoyagi [1] and use the Stuart-Landau equation as follows:

$$f_i(z_i) = (\alpha_i + \mathrm{i}\Omega - |z_i^2|)z_i, \tag{2}$$

where the parameter α_i determines the dynamical characteristics of the ith element; the ith oscillator is active if $\alpha_i > 0$ and inactive if $\alpha_i < 0$.

This coupled oscillator system is an associative memory model that stores relative phase differences between the elements. The μth phase pattern is represented by a complex vector $Z^\mu = (Z_1^\mu, \dots, Z_N^\mu)$, where each element Z_i^μ with $|Z_i^\mu| = 1$ represents the phase of the ith element in the pattern. Note that multiplying by $e^{\mathrm{i}\theta}$ does not alter the embedded pattern, since only the phase differences are stored. Here, we assume the phase patterns $Z^1, \dots, Z^P$ are orthogonal. The complex weight matrix C is determined from the

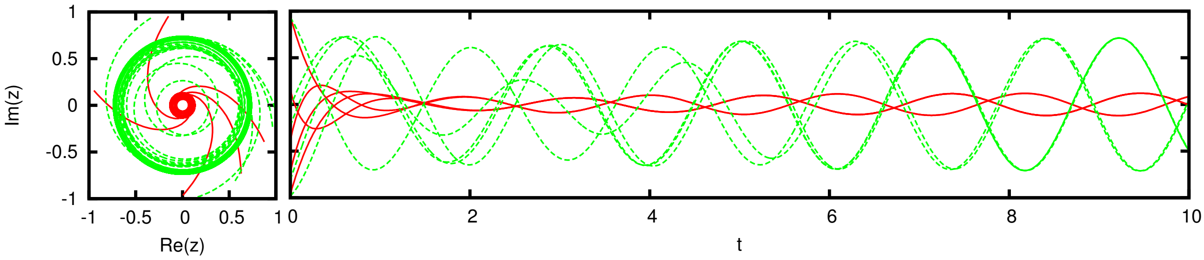

Fig. 1. Dynamics of the coupled oscillator system with $p = 0.6$. The trajectries of z_i in the complex plane (left) and the time evolutions of the imaginary part $\mathrm{Im} z_i$ (right) of five active oscillators (dashed lines) and five inactive oscillators (solid lines) are shown.

phase patterns $Z^1, \ldots, Z^P$ as follows:

$$C_{ij} = \frac{1}{N} \sum_{\mu} Z_i^{\mu} \cdot \overline{Z_j^{\mu}}. \tag{3}$$

Using the model whose all the elements are identical ($\alpha_i = 1$), Aoyagi [1] showed that the coupled oscillator system recalls the embedded phase patterns.

In this paper, we consider a network consisting of both active ($\alpha_i = 1$) and inactive ($\alpha_i = -2$) oscillators. This kind of network with active and inactive oscillators has been investigated by Daido and Nakanishi [3, 4], though their model is not for associative memory. Specifically, they studied the system with uniform connection weights $C_{ij} = 1/N$ as follows:

$$\frac{\mathrm{d}z_i}{\mathrm{d}t} = f_i(z_i) + K\left(\frac{1}{N} \sum_{j=1}^{N} z_j - z_i\right). \tag{4}$$

If the proportion of inactive oscillator p is small, inactive elements oscillate by effect of oscillation of active elements. If p is increased, the oscillation stops at the critical value $p = p_c$, which is given by

$$p_c = \frac{K+2}{3K}. \tag{5}$$

This phase transition is called an aging transition.

Retrieval of the μth pattern embedded in the system is evaluated by the overlap M_μ with pattern Z^μ defined by

$$M_\mu = \frac{1}{N} \left| \sum_i \overline{Z_i^{\mu}} \cdot \frac{z_i}{|z_i|} \right|. \tag{6}$$

This value shows a concordance rate between the state of the system and the stored pattern Z_μ. The larger M is, the more accurately the pattern is retrieved.

3 SIMULATION RESULTS

We performed numerical simulations of the associative memory model composed of $N = 100$ elements with $\Omega = 3$. For simplicity, the number $P = 3$ of orthogonal patterns are chosen from $\{\pm 1\}^N$ and embedded in the weight matrix C_{ij}. The coupling strength is set to $K = 1$.

From N elements, pN elements are randomly chosen as inactive elements, and the rest $(1-p)N$ elements are set as active elements.

We set initial states close to a certain embedded pattern $Z^\mu \in \{\pm 1\}^N$. Specifically, we obtained initial phases from the chosen pattern by adding perturbations $\Delta\theta$ that follow the von Mises distribution, whose probability density function is given by

$$\mathrm{P}(\Delta\theta|\kappa) = \frac{1}{2\pi \mathrm{I}_0(\kappa)} \exp(\kappa \cos \Delta\theta), \tag{7}$$

with the measure of concentration $\kappa = 1$

Figure 1 shows the dynamics of the system with $p = 0.6$ in the simulation. Active oscillators and inactive oscillators show oscillations with large and small amplitude, respectively. Inactive oscillators converge to the corresponding limit cycle more quickly than active oscillators.

In the following, we calculate the overlap M_μ with the chosen pattern Z^μ averaged over 3000 realizations.

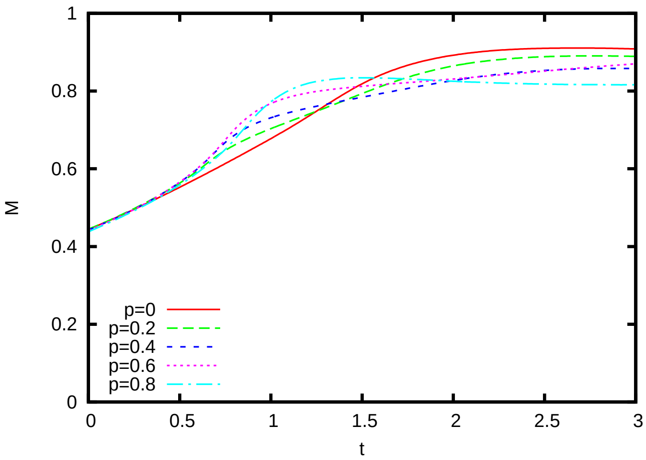

Fig. 2. The overlap M as a function of time t.

Figure 2 shows the overlap M as functions of time t for each value of p. We find that M is an increasing function in most of the time region. While the value of M for $p = 0$

is the smallest at time $t = 1$, it becomes the largest at time $t = 2$.

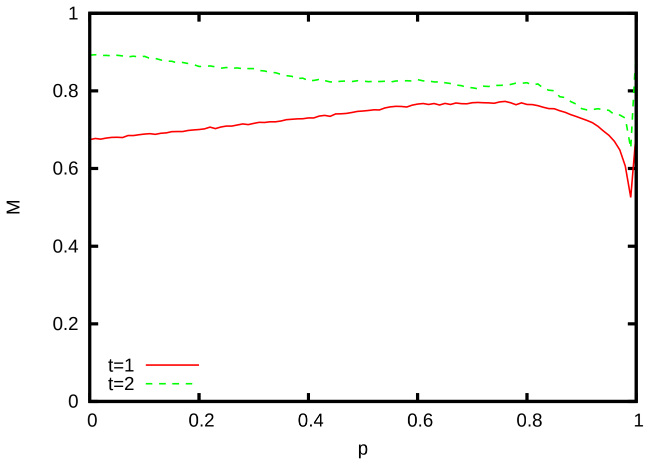

Fig. 3. The overlap M as a function of p at $t = 1$ and 2. In the range $0 \leq p \leq 0.8$, it is almost increasing for $t = 1$ (solid line) and almost decreasing for $t = 2$ (dashed line).

The dependence of the overlap on p is shown in Fig. 3. The solid and dashed lines correspond to $t = 1$ and $t = 2$, respectively. At $t = 1$, M is an almost increasing function in the range between $p = 0$ and $p = 0.8$. At $t = 2$, M is an almost decreasing function in the range.

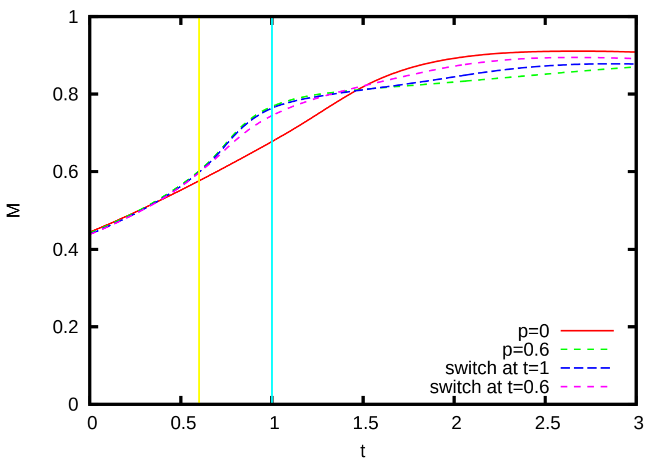

Fig. 4. The overlap M as a function of time t. The value of p is changed from 0.6 to 0 at time $t = 0.6$ and $t = 1$. The cases of $p = 0$ and $p = 0.6$ without the change are also shown.

These result show that small p enhances speed of retrieving and decrease the value M after certain period of time. We investigate the case in which the value of p is changed at a certain time. Figure 4 shows the overlap M as functions of t when the value of p changes from 0.6 to 0 at $t = 0.6, 1$. The value of M at time $t = 2$ in the cases with the change are larger than the case of $p = 0.6$ without the change. While the value of M at $t = 1$ in the case with the change at $t = 0.6$ is smaller than the case without the change, it becomes larger at $t = 2$.

4 DISCUSSION

In the previous section, we observed that the system with inactive oscillators shows quicker initial responses than without inactive oscillators. This can be intuitively explained as follows. Let r_i and θ_i be the amplitude and the phase of the state z_i of the ith element, respectively; i.e., $z_i = r_i \exp \mathrm{i}\theta_i$. Then the dynamics of θ_i is given by

$$\frac{\mathrm{d}\theta_i}{\mathrm{d}t} = \Omega + K\frac{r_i^\star}{r_i}\sin(\theta_i^\star - \theta_i), \tag{8}$$

where $r_i^\star$ and $\theta_i^\star$ are the amplitude and the phase of the input to the ith element through C_{ij}, respectively, as follows:

$$\sum_j C_{ij} z_j = r_i^\star \exp \mathrm{i}\theta_i^\star. \tag{9}$$

The second term of Eq. (8) describes the effect that attracts θ_i to $\theta_i^\star$. Thus its strength is inversely proportional to r_i. Since the amplitude r_i is large for active elements and small for inactive elements, the phases of inactive elements move more quickly to an embedded pattern than active elements.

In the context of neuroscience, temporal aspects of neural activities have been considered to be important [6]. In a neural network, spikes (action potentials) are responsible for the mutual interaction and communication between neurons. Multi-channel recording of neural activities often shows a repetition of certain temporal patterns of spike train, which may be caused by interactions among neurons. Such temporal aspects of neural activities are often modeled with coupled oscillators as shown in the present paper. In Aoyagi's model, temporal patterns are represented as the phase differences among oscillators and embedded in the complex weight matrix.

Another intriguing observation of neural activities is about the two-state dynamics [7], which is a characteristic switching of the membrane potential between two preferred levels, namely the more polarized level (down state) and the more depolarized level (up state). Similarly, the transition between the resting state and the sustained oscillatory state is observed and is modeled as a bistable system with a stable equilibrium and a stable limit cycle [8]. Such a model is closely related to Daido's model in the sense that active and inactive element coexist.

In the present study, to elucidate the contribution of coexistence of active and inactive elements in the associative network, we consider non-uniformity of the elements instead of the bistability. We found that the proportion of inactive oscillator is important for speed of retrieving a temporal pattern. This indicates that the increase in proportion of neurons in resting state facilitates retrieval process of memories. Although the proportion of inactive oscillators is fixed or time-invariant in the present network model, real neurons dynamically switch their state between up and down state. Contribution of this dynamical aspect of switching to the ability of memory retrieval should be evaluated in future.

5 CONCLUSION

We investigated the dynamics of pattern embedded oscillatory networks which include non-self-oscillatory elements. The property of non-self-oscillatory element determines the speed of retrieving stored patterns. This mechanism may play some functional role in neural networks of the brain.

Abstract: We experimented for the purpose of development of the objective evaluation technology of emotions. Persons requiring care will also increase in number with the increase in this population. In the case of the person requiring care who lost the function to convey an intention especially, the objective judgment to a physical and mental pain is required. Specifically, we gave subjects stimulus of a comfortable or an uncomfortable sound and measured concentration of the oxygenated hemoglobin of a frontal lobe part by Near-Infared Spectroscopy. Based on the experimental result, a comfortable state or an uncomfortable state was distinguished concentration of the oxygenated hemoglobin using the bayesian network. As a result, we were able to estimate the subject's psychological condition.

Keywords: objective evaluation, Near-Infared Spectroscopy, bayesian network, emotion.

1 INTRODUCTION

In Japan, low birthrate and longevity are progressing quickly. According to National Institute of Population and Social Security Research, the rate of population aged 65 and over will reach to 35.7% in 2050. Persons requiring care will also increase in number with the increase in this population. In the case of the person requiring care who lost the function to convey an intention especially, the objective judgment to a physical and mental pain is required. In the past, the objective evaluation of the intention by brain waves (the sensitivity-spectrum analyzing method and the sensitivity fractal dimension analyzing method) has been proposed. Moreover, the machine which operates an electronic device using brain waves is developed. The interface which applies cerebral activity to control or support is called Brain Machine Interface. BMI is expected as a machine which supports transfer of a human intention [1][2].

By the way, functional Magnetic Resonance Imaging (fMRI) and Near-Infared Spectroscopy (NIRS) are the methods of measuring cerebral activity. When oxygenated hemoglobin changes to deoxygenated hemoglobin, the method of measuring brain activity indirectly using the increase in a magnetic resonance signal is fMRI [3][4]. Generally restriction by the environment and the conditions of measurement is strong. Moreover, the influence of the motion with the body is strong. On the other hand, NIRS is equipment which measures the amount of change of oxyHb and deoxyHb in blood using near-infrared light. In process of cerebral information processing, the system of the communication of information which nerve activity bears and the system of the energy supply supporting nerve activity are related [5]. If nerve activity takes place, the blood vessel in the circumference will be extended. The mechanism of the adjustment for supplying the arterial blood containing oxygen and glucose occurs [6]. The quantity of a blood flow increases in the tissue of a nearby nerve. The oxidation state (ratio of oxyHb and deoxyHb) of blood changes. Based on assumption that the relation between nerve activity and a blood flow exists, NIRS measures the oxygenated hemoglobin within a brain. In short, this index is not the nerve activity which is actually processing information. However, it is an index of an indirect brain function. Moreover, the measurement by NIRS uses the two characteristics [7]. The 1st is the high permeability of the organism in near-infrared light (700-900 nm). The 2nd is the permeability of the light from which oxyHb and deoxyHb in blood differ. When the head is irradiated with near-infrared light, the ingredient of the light is diffused in cerebral tissue by high permeability. And the cerebral cortex which is in a depth of about 20-30 mm flatly is reached. When light is measured in about 3-cm distance from a glaring point, the optic element which has returned by diffused reflection can be detected [8]. NIRS calculates change of oxyHb and deoxyHb of the cerebral cortex using this detection light. NIRS is inferior to fMRI in the point of visualization of structure and the range of measurement. However, the restriction to a motion of the body is small. Moreover, it can experiment in the more natural state. Therefore, NIRS has high practicality as a means for transmitting an intention.

We experimented for the purpose of development of the objective evaluation technology of emotions. There are some researches on the emotions using NIRS. For example, there is research on change of a cerebral blood flow when a vision stimulus and a sense-of-smell stimulus are given. But, there are still few examples. Moreover, there is almost no example studied about objective evaluation of a comfortable sound or an uncomfortable sound. A sound stimulus is one of the important stimuli which evoke the emotions of those dependent on care. A sound stimulus is one of the important stimuli which evoke the emotions of a person requiring care [9]. Therefore, we set up the sound stimulus as a candidate for evaluation. Specifically, we gave subjects stimulus of a comfortable or an uncomfortable sound and measured concentration change (⊿oxyHb) of the oxygenated hemoglobin of a frontal lobe part by NIRS. Be based on the measured data, we evaluated quantitatively the difference in brain activity. By developing the technology of objective evaluation, it may be applicable to evaluation of the brain activity under various environments. It is shown that the result of an experiment has relation nature between the psychological amount by a comfortable or an uncomfortable sound and ⊿oxyHb in a part of frontal lobe. Based on the experimental result, a comfortable state or an uncomfortable state was distinguished ⊿oxyHb using the bayesian network (BN). As a result, we were able to distinguish the subject's psychological condition.

2 EXPERIMENT METHOD

2.1 Experimental environment

It experimented within electromagnetism shield room. Room temperature was 22.0±1.0 [℃]. Illumination was about 200 [lx]. The interior of a room was calm. Fig.1 showed the counting system. The shimadzu FOIRE-3000 was installed next to the subject and we measured ⊿oxyHb. Fig.2 shows the position of the measured channel and measurement. The position of measurement serves as the middle point of the position of irradiation, and the position of detection. First of all, the channel 9 of the holder for measurement was united with Fpz. In the next step, the subject was equipped with the holder using the fixed belt. The interval of the probe for irradiation and the probe for detection was set to about 30 [mm].The number of the measured channels was 32. Sampling time was 175 [ms].

2.2 Experimental conditions

The number of subjects was 5 (21-25 age, healthy subjects). We experimented after the subject rose and 4 hours or more had passed. The subject's previous day sleeping hours were about 8 hours. 2 hours before beginning an experiment, ingestion of a meal, smoking and a caffeine was forbidden. Excessive movement on the day was forbidden. This experiment was conducted by ethical consideration based on Declaration of Helsinki (1964). The subject's human rights were considered in the experiment. We fully explained and got consent by signature. Fig. 3 shows a measurement schedule. The subject which hears sound was performed in Task. The subject was made to hear white noise within a rest time. The comfortable sound used the album (music gentle to autonomic nerves). The uncomfortable sound used scratch sound. It is clear that these tasks give a subject comfortable or uncomfortable emotions in a preliminary experiment. Time to hear these tasks was set to 60 [sec]. Moreover, Visual Analogue Scale questionnaire was written 20 seconds after the start of rest time.

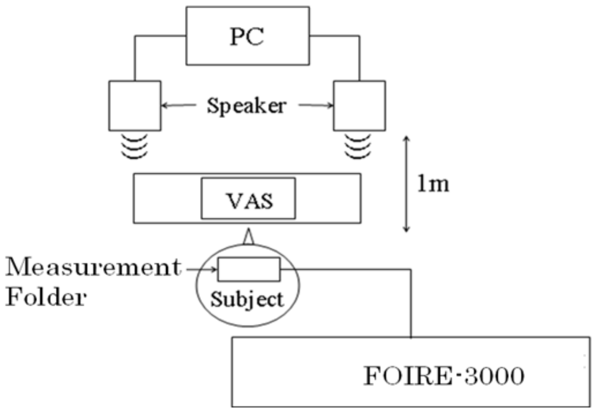

Fig.1. Measurement System

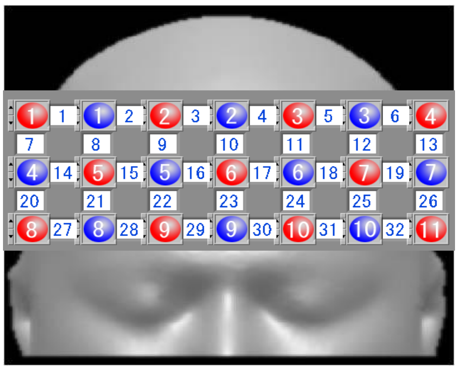

Fig.2. Measurement position

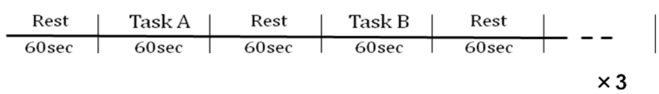

Fig.3. Measurement Schedule

3 EVALUATION METHOD

3.1 Psychological index

The Visual Analogue Scale questionnaire was used for the psychological index [10]. Fig.3 shows an example about how to write a Visual Analog Scale questionnaire. Visual Analog Scale is a tool used to help a person rate the intensity of certain sensations and feelings. The rate (0% - 100%) of the length from a left end to a check position was measured to the length of a line segment. This experiment estimated uncomfortable (0%) - comfortable (100%).

3.2 Physiological index

⊿oxyHb in a frontal lobe part was measured. Baseline compensation was performed in order to extract only a changed part to a stimulus (Fig.4). Task for 3 times was added and averaged. The following is the method of compensation. ⊿oxyHb of the channel measured at the TASK time T and the REST time R is made into the following.

$$h(t),(-R<t<T+R) \qquad (1)$$

Compensation data is hC(t). The data at the time of a Task start is h(0).

$$h_C(t)=h(t)-h(0) \qquad (2)$$

Moreover, the average amount of change of oxygenated hemoglobin concentration is defined as ⊿oxyHbave. It is considered as a physiological index.

$$\Delta oxyHb-abe=\frac{1}{T}\sum_{t=0}^{T}h_C(t) \qquad (3)$$

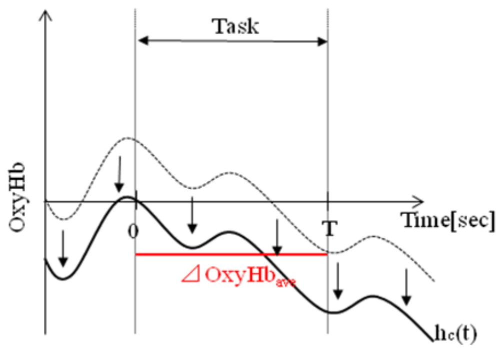

Fig.4. Baseline compensation

4 EVALUATION METHOD

When a comfortable stimulus was given, ⊿oxyHb decreased in a part of measured part (Fig.5). On the other hand, when an uncomfortable stimulus was given, ⊿oxyHb decreased slightly (Fig.6). However, the parts which reacted to each stimulus differed. Comfortable and uncomfortable emotions are related to a limbic system. It is closely related to especially an amygdaloid body. Control and rise of frontal lobe activity are affected. In short, reduction of ⊿oxyHb is considered that rise of activity of a limbic system has influenced. Under the influence through which blood flowed into the nearby part, it is thought that reduction of ⊿oxyHb occurred in a part of frontal lobe part. Based on the result of Fig.5 and Fig.6, the difference in ⊿oxyHb in two stimuli was evaluated. T test was performed for every Channel using ⊿oxyHbave. As a result, there was a significant difference in Channel 2 and Channel 28 (Fig.7). Fig.8 is a time change of ⊿oxyHb in Channel 2. ⊿oxyHb at the time of giving a comfortable stimulus showed the tendency higher than ⊿oxyHb at the time of giving an uncomfortable stimulus. The relation between ⊿oxyHbave of channel and VAS was considered. Fig.9 is a relation of ⊿oxyHbave and VAS in Channel 2. In the case of Channel 2, the correlation coefficient of VAS and ⊿oxyHbave was 0.55. In the case of Channel 28, it was 0.66. Both of channels were positive correlation. It inquired in the similar way also to other subjects. Channels which were a significant difference and positive correlation were examined. It was a result as shown in Table 1. These results show a possibility that NIRS can estimate emotions objective.

Subject D	2	4	9	15	18

5 ESTIMATION MODEL

Based on the experimental result, we built the estimation model of emotions using BN. A figure is the estimation model of emotions. Visual Analog Scale performed t official approval by each channel. The data used for the construction was data of the channel which had a significant difference in ⊿oxyHb. A physiological quantity used the average value (⊿oxyHb-ave) of ⊿oxyHb of task. A psychological quantity classified the value of Visual Analog Scale into three states. Three states were "uncomfortable (0-33%)", "normal (34-66%)", and "comfortable (67-100%)." The frequency of each state was computed from reference data. Graph structure and the conditional probability in each state were calculated. BN was built using the data. The following is a formula of graph structure. The following is a formula of graph structure. The amount-of-information standard AIC was used for the judgment of the dependency between nodes. The number of times of trial was performed 10 times per person. The amount of seven trials was the reference data for model construction. The amount of three trials was the data for evaluation for presumption.

6 RESULT AND CONSIDERATION

Bayesian estimation was performed from the built model to the data for evaluation. The presumed result was compared with actually measured VAS and the presumed rate was calculated from the number of coincidence. Fig.10 is presumed accuracy. The presumed rate became 67% on the average as a result of the experiment. This result shows a possibility that emotions can be presumed by BN.

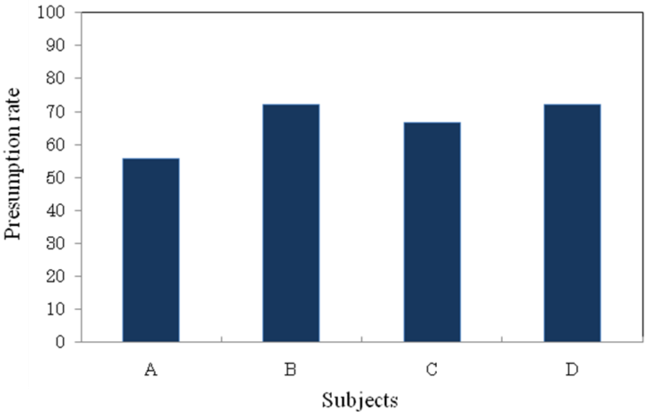

Fig.10. Estimation rate

7 CONCLUSION

We proposed the technique of objective evaluation of the emotions by NIRS. If this research develops, we may be able to develop the system by which a care worker can understand the emotions of a person requiring care easily. Specifically, we gave subjects stimulus of a comfortable or an uncomfortable sound and ⊿oxyHb of a frontal lobe part by NIRS. Be based on the measured data, we evaluated objectively the difference in brain activity. It is shown that the result of an experiment has relation nature between the psychological amount by a comfortable or an uncomfortable sound and ⊿oxyHb in a part of frontal lobe. Based on the experimental result, a comfortable state or an uncomfortable state was distinguished ⊿oxyHb using BN. The presumed rate became 67% on the average as a result of the experiment. This result shows a possibility that emotions can be presumed by BN. As a result, we were able to estimate the subject's psychological condition by BN.

Abstract: Reinforcement learning is a machine learning method that does not require a detailed teaching signal by a human, which is expected to be applied to real robots. In its application to real robots, the learning processes are required to be finished in a short learning period of time. A reinforcement learning method of non-bootstrap type has fast convergence speeds in the tasks such as Sutton's maze problem that aim to reach the target state in a minimum time. However, these methods are difficult to learn either task to keep a stable state as long as possible. In this study, we improve the reward allocation method for stabilizing control tasks. The validity of our method is demonstrated through simulation for stabilizing control of an inverted pendulum. Our proposed method can acquire a policy in order to keep a stable state within a short learning period of time.

Keywords: Reinforcement Learning, Stabilizing Control Tasks, Profit Sharing, SMDP

1 INTRODUCTION

The machine learning methods have attracted a lot of attention by a characteristic that robot's adaptive actions are able to get from action results of itself. Reinforcement learning is a method of machine learning, which does not require a detailed teaching signals by a human. Reinforcement learning can be divided into two types of bootstrap and non-bootstrap. As well-known non-bootstrap methods, there are Profit sharing [1] , Adaptive immunity - based reinforcement learning [2] and so on. Those types of learning methods are faster than famous reinforcement learning methods such as Q-learning [3] in learning convergence speeds, when applying to the problem of minimizing the amount of time to achieve the goal (e.g., maze searching, swing-up control for an invert pendulum and so on). Those methods are not able to get the optimal policy, but they can get the policy that achieves to the goal state by satisfying the rationality theorem proposed by Miyazaki et al [4].

However, when applying that method to stabilizing control tasks, we cannot acquire a policy to achieve the goals. The bootstrap methods can acquire the policy of the stabilizing control by giving a negative reward at a change from a stable state to an unstable state [5]. On the other hand, since the non-bootstrap learning method cannot deal with negative a reward value, the reward value has to take a positive value [6]. In this case, there is a great risk of learning an undesirable behavior of changing from a stable state to an unstable state according to reward values.

In this study, we improve the reward allocation method for the stabilizing control tasks. In the stabilizing control tasks, we need to model an environment by Semi-Markov decision process (SMDP) because a time of doing actions is not constant by each state. The validity of our method is demonstrated through simulation for stabilizing control of an inverted pendulum.

2 PROFIT SHARING

Reinforcement learning method is for learning by updating to the Q-value that is an estimated value of action in a state. The reinforcement learning method of non-bootstrap type does not require Q-values of other states in Q-value updating process. The following equation shows how to update the Q-values of the Profit Sharing.

$$Q(s_t, a_t) \leftarrow Q(s_t, a_t) + \alpha\left[r(t) - Q(s_t, a_t)\right] \tag{1}$$

where t is the time, s_t is the state in time t, a_t is the selected action in time t, $\alpha(0 < \alpha < 1)$ is the learning rate and $r(t)$ is the reward function. The Q-value is updated based on the reward function of the actions that has been selected before receiving a reward. Following equation is generally to use as a reward function that satisfied the rational theorem [4], when applying to the problem of minimizing the amount of time to achieve the goal.

$$r(t) = R\left(\frac{1}{S}\right)^{T-t} \tag{2}$$

where, $S(\geq L+1)$ is the constant value, L is the number of selectable actions, T is the episode time and R is received reward.

In many cases, action selection methods in Profit Sharing use the roulette selection, which is based on the probability

$P(s,a)$ with weight of the Q-values.

$$P(s,a) = \frac{Q(s,a)}{\sum_{a \in A} Q(s,a)} \tag{3}$$

Here, since Eq. (3) cannot take zero or negative Q-values, the Q-values must be greater than zero in updating process.

3 REWARD FUNCTIONS IN STABILIZING CONTROL TASKS

In this section, we discuss about the method of non-bootstrap reinforcement learning for applying it to the stabilizing control tasks. We considered about conditions of the reward allocations for obtaining the policy of the stabilizing control tasks. In addition, we propose a reward allocation method by use of those conditions.

3.1 Semi-Markov Decision Process

The problem of minimizing amount of time to achieve the goal dose not need to deal with the actions of keeping same state. On the other hand, there are no problems that deal with actions of keeping the same state in the stabilizing control tasks. However, Markov decision process (MDP) must to select an action at the each time of the constant control cycles. If the state is divided roughly, each action selection may include multiple effective action or illegal actions in the same state. It can be resolved by dividing the state into smaller pieces, but it requires longer time to learning.

In this study, we model an environment by SMDP. SMDP selects an action after the state transition has occurred. It cannot completely resolve the trade-off for the state space division, but there is no need to handle the autoregressive action to the same state. Therefore, it is possible to make a relatively rough state division.

3.2 Reward allocation

The non-bootstrap method updates all estimate values of state and action when receive a reward. Therefore, we can use the duration of actions in the episode unlike bootstrap methods such as Q-learning. However, if using the duration of episode as the reward, we have a very large reward. Overflow may occur when performing the actual calculation, or if the estimated value has a very small initial one, there is a risk that state solution search is not performed sufficiently. Therefore, we give the reward of constant value (R=1), which is allocated from duration time of action. In addition, we assume that each episode starts from the stable region, and discuss about a reward allocation method in stabilizing control tasks by using an example shown in Fig. 1.

First of all, we give an example of the state transition in Fig. 1.

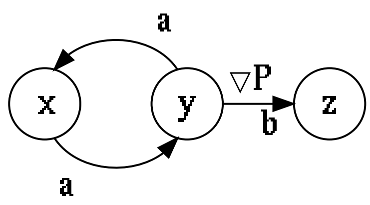

Fig. 1. An example of state transition

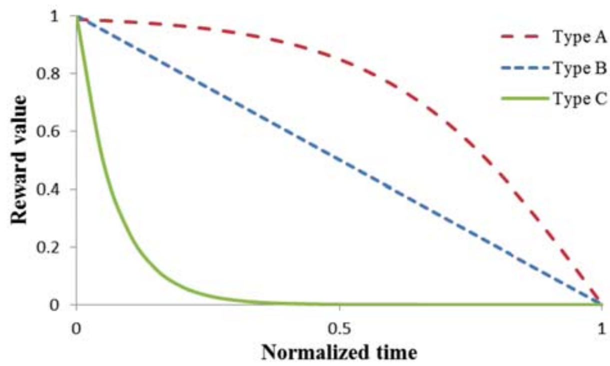

Fig. 2. An example of reward allocation

State transition example(1)

$x_a \rightarrow y_b \rightarrow z$

State transition example(2)

$x_a \rightarrow y_a \rightarrow x_a \rightarrow y_b \rightarrow z$

where x and y are the stable states, and z is the unstable state their subscripts is show selected actions. The above example means to suppress the action b of under going a transition from the state y to the state z. For the stabilizing control tasks, the reward allocation value should be zero or small value because action taken just before receiving the reward should not be selected. On the other hand, the reward allocation value may be higher values because actions taken long before receiving the reward one useful for stabilization. Therefore, the reward of actions allocates higher value around the initial time (t_a), and does lower values around the episode end time (t_b).

$$r(t_a) > r(t_b)$$

Figure 2 shows three types of functions. The horizontal axis in this figure shows the normalized time duration episode, the vertical axis does the value of reward allocation. In initial learning is short, it is better to reduce the action selections for changing to unstable state as soon as possible. We want to assign a small reward for it. The type C function is not suitable from the above view. And also, the episode duration time becomes longer on the way of learning. In this case, since it may also contribute on the way of learning, it is better allocate the reward equivalent to that in the initial episode. The type A functions allocates a small reward to actions just before Stabilization state end, and dose a small discounted reward to actions in the initial-middle stage of the episode. The following equation is an example of the type A functions shown in Fig. 2.

$$r(t) = 2\left(0.5 - \frac{1}{1+\exp(-(t-1)/T_a)}\right) \quad (4)$$

where t is the normalized time by episode time and T_a is the constant value for decide to functions gradient.

As the duration of episode becomes to be longer with learning, action selection is to be performed multiple times in the same state. However, the type A function cannot make an evaluation of difference between actions for moving to unstable state and others. Because each evaluation is decided by normalized time of action, and each value has only small difference. Here, we consider about the number of selected actions when transitions among some states are undergone periodically. We set that the action for keeping stable state is a_{loop}, and the action for moving to unstable state is a_{open}. It is clear that the number of action selection for keeping stable state is longer than that of the action for moving to unstable state ($Num(a_{loop}) \geq Num(a_{open})$, $Num()$ is action selected numbers). And also, the actions for keeping stable state are made earlier than the actions for moving to unstable state. From those considerations, we can make a difference in the update process by use of the sum of the reward. Therefore, the update formula of Profit Sharing method for stabilizing control task is shown as.

$$Q(s_i,a_i) \leftarrow Q(s_i,a_i) + \alpha\left[\sum_t r(t|s_i,a_i) - Q(s_i,a_i)\right] \quad (5)$$

The reward function $r(t)$ is defined in the range $[0,1)$, the initial Q-values have to set 1 and more. This provides a searching in the environments is performed well by Boltzmann and roulette selection.

4 SIMULATION

This section shows a simulation result of our proposed method applying to stabilizing control of the inverted pendulum (Fig. 3). The motion equation of the inverted pendulum is expressed as

$$(M+m)\ddot{x} + ml\cos\theta\ddot{\theta} + D_x\dot{x} + ml\sin\theta\dot{\theta} = a \quad (6)$$

$$-ml\cos\theta\ddot{x} + I\ddot{\theta} + D_\theta\dot{\theta} - mgl\sin\theta = 0 \quad (7)$$

where, M is the mass of the cart, m is the weight of the pendulum, l is the length of the pendulum to the gravity center,

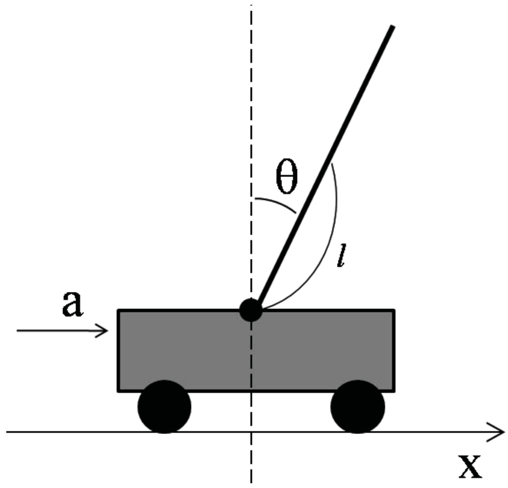

Fig. 3. Inverted pendulum

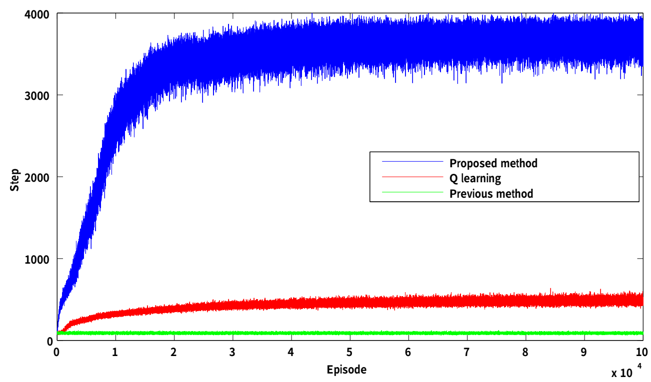

Fig. 4. Results of convergence speeds

D_x is the frictional coefficient on the cart, D_θ is the friction of the pendulum rotation, I is the moment of inertia of the pendulum. The states $x, \dot{x}, \theta$ and $\dot{\theta}$ are inputted to the learning module, whose values are observed with the normalized random values ($N(\mu,\sigma^2), \mu = 0, \sigma = 0.0001$) added. And also, we divide the states as 10 for x, 10 for $\dot{x}$, 50 for θ and 50 for $\dot{\theta}$. In this simulation, we perform a learning of the stabilizing control of the inverted pendulum according to action list $\boldsymbol{A} = [-10, -1, -0.1, 0, -0.1, 1, 10]$. If the pendulum is not around the upright position ($|\theta| > 0.1$[rad]), or the cart position is out of the range ($|x| > 3$[m]), we give the reward, and restart and proceed to the next episode. Also, if we can reach to 4,000 simulation steps, we deemed that it was possible to get the stabilizing control policy; we give the reward and end the episode.

Figure 4 shows the results of convergence speeds in learning by using our proposed reward allocation method, the previous reward allocation method (Eq. (2)) and the Q-learning method. In the case of the Q-learning, we give the penalty reward ($R = -10$), when the pendulum is not around upright position, or the cart position is out of the range. The previous reward allocation method was not able to give the policy of the stabilizing control. It was able to give the policy that the pendulum fall down as soon as possible instead. On the other hand, the Q-learning was able to give the stabilizing control policy, but only in a short time this success was made. Our method was able to produce the stabilizing control policy with a shorter convergence time than other methods.

5 CONCLUSION

In this paper, we improved the reward allocation method in the non-bootstrap reinforcement learning through the stabilizing control tasks. We showed the conditions of reward allocation for the stabilizing control tasks, and introduced an example of reward allocate function for it. Since the reward is allocated only from the duration time of action, we do not need to change the reward value according to environments.

In our future works, we are to build a learning method that can deal with combined problems such as swing-up and stabilizing controls of the inverted pendulum. And also, we have studied on the reinforcement learning method imitating the human adaptive immunity [2][7]. Those methods have fast convergence speed in the problems of minimizing the amount of time to achieve the goal with a very few configuration parameters. It is possible to construct a learning method with fast convergence speed by integrating those methods.

Abstract: This paper presents a solution for the problems of state representation as well as a variety of optimal solutions in multiagent systems. These problems cannot be solved by traditional reinforcement learning methods such as Sarsa(λ). We apply a method of Multiagent Enforced SubPopulations to the task of stationary behavior acquisition. The stationary behavior acquisition task means that the agents continue to select behavior in order to keep the stationary state. The behaviors of acquired agents are not uniquely determined in those tasks. In addition, there is a state representation problem in multiagent systems due to the complexity of the system. Furthermore, there is no example of the Multiagent Enforced SubPopulations applied to these types of tasks, in which the design policy of the fitness function is unclear. We demonstrate the validity of our proposed method through comparison with a Keepaway task in RoboCup Soccer as a stationary behavior acquisition task.

1 INTRODUCTION

The researches on multiagent systems aim to solve more complex problems with the cooperation of multi-robots. However, the multiagent systems are difficult to control agents by top-down methods which enumerate all behaviors, because it is necessary for us to consider mutual behaviors between agents. Therefore, bottom-up methods teaching with fitness in each behavior should be proposed.

There are unsupervised reinforcement learning methods, for example, Q-learning [6], Sarsa(λ) [7] as bottom-up methods. These methods achieve the desired state by selecting a behavior to maximize an expected reward which will be received in each decision. The Q-learning guarantees convergence to an optimal value in the Markov decision process, and there are many examples in its application. However, these applications need to properly divide the state to satisfy the Markov property. In general, the amount of state divisions increases exponentially because the number of states in multiagent systems increases over that of single-agent systems. There are traditional research studies about state division methods such as tile-coding, but they cannot fundamentally resolve the problems. In addition, the optimal solution is not uniquely determined in multiagent systems, and these methods do not consider about a variety of optimal solutions.

There is the Multiagent Enforced SubPopulations (ESP) method as an evolutionary neural network method which is different from Q-learning or Sarsa(λ). The Multiagent ESP method is expected to solve the problems of state representation and of a variety of solutions which cannot be solved by traditional reinforcement learning methods, due to a combined advantage of neural networks and genetic algorithms. However, the Multiagent ESP is applied only to a prey catch task scheme, and also there is no discussion about the design of fitness functions.

In this research, the Multiagent ESP apply to a Keepaway task which is a sub-task of the RoboCup Soccer Simulation League. The aim of this task is to keep a ball as long as possible against 2 "Takers" by cooperating with 3 "Keepers". The existing research uses traditional reinforcement learning methods such as Sarsa(λ). So, the methods and accuracy of state division influence learned behavior. In addition, this task continues to select behavior in order to keep a stationary state while controlling the ball. We call these behaviors as stationary behavior. It is natural that there are more than one solution in the achieved stationary behavior. Therefore it is difficult to get a unique solution. We demonstrate the validity of our proposed method by applying the Multiagent ESP to the Keepaway task. Our proposed method is better than traditional reinforcement learning methods in multiagent tasks beyond the prey catch task. Lastly, we summarize an experimental consideration on fitness function design in the case where the Multiagent ESP is applied to the acquisition of a stationary behavior as in the case of Keepaway task.

2 BACKGROUND AND RELATED WORKS

We describe Multiagent ESP method underlies bases for our proposed method, and describe Keepaway task which is an application of our proposed method.

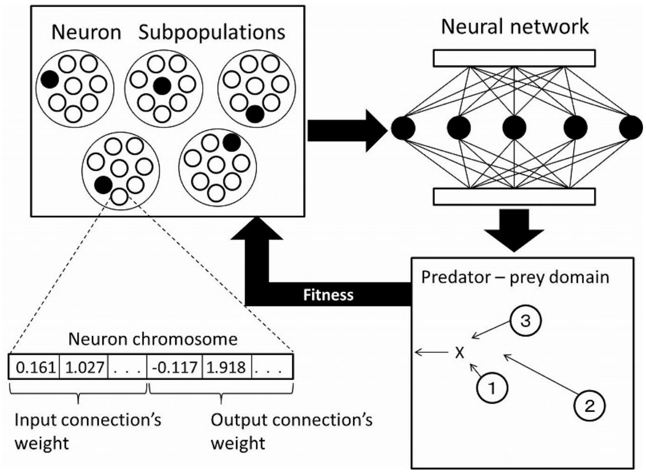

Fig. 1. ESP method applying to prey catch task

2.1 Multiagent ESP method in prey catch task

Multiagent ESP method is a coevolution method in multiagent systems, which is proposed by C. H. Yong, R. Miikkulainen [3]. Next, Multiagent ESP method is of ESP method expanded to multiagent systems. ESP method is proposed by F. Gomes, R. Miikulaiinen [4], [5]. So, we explain ESP method and Multiagent ESP method through the prey catch task [3].

The prey catch task is a task that “Takers” chase and catch the “Prey”. One task is finished when Takers catch a Prey, or time is over. The symbols ①, ②, ③ are Takers, and X is Prey in Fig. 1 showing ESP method's framework. One of Taker's policy is coordinated with learning in ESP method. The controller for learning Taker is 3 layered neural network. The input of this neural network is a difference between my current position and Prey. The output is moving direction for Taker. Hidden layer neuron has a weight of network. We define neuron subpopulations which have some different connection weights in each hidden neuron. The agent controller is constructed by random-selected neuron from neuron subpopulations in each task. If the agents catch a Prey in limited time by using this controller, it gets a constant fitness. In contrast, if the agents miss catch a Prey by using this controller, it gets more lower fitness based on average distance between Takers and a Prey. The fitness is accumulated in neuron subpopulations by repeating this task. As a result, high fitness neurons are selected by genetic algorithm, then neuron subpopulations are constructed by high fitness neuron. Lastly, we can get the controller to solve the task.

Next, we explain Multiagent ESP method which is one expansion of ESP method. All takers learn at one time to solve the task in Multiagent ESP method. Figure 2 shows a structure in which Multiagent ESP is applied to the prey catch task. The controller of each agent is of the same structure with ESP method, and is prepared with the same number as learning agents. Each controller is coordinated independently by ESP method. The calculation of fitness is same as ESP method, and there are no difference between agents.

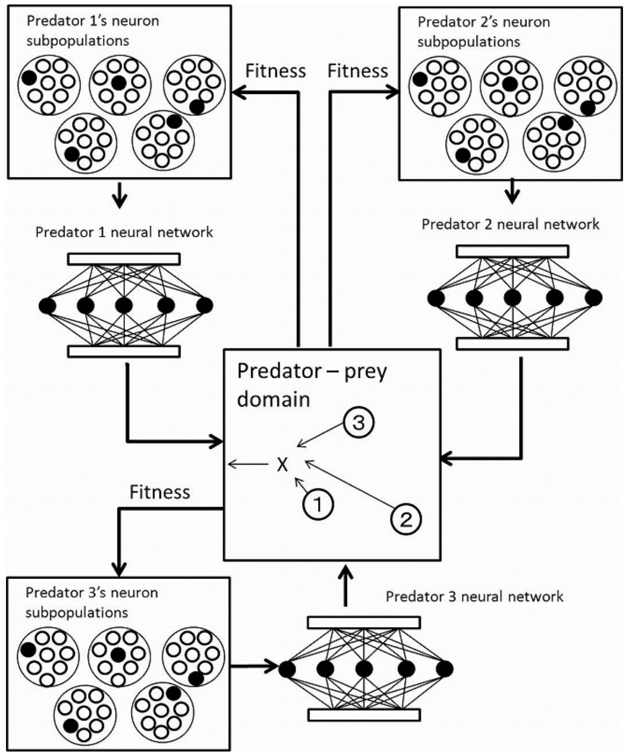

Fig. 2. Multiagent ESP method applying to prey catch task

As a property of ESP method, the input of controller can take continuous value. It is different from Q-learning or Sarsa(λ) which need state division. So, it can be expected to solve the state representation problems essentially. And also, ESP method has more than one optimal solutions in the form of neuron subpopulations after learning. As a result, it can be expected to get a class of optimal solutions in the task that the optimal solution cannot be determined.

In the existing researches which apply to prey catch task, the aim of all Takers is to go around the Prey as quickly as in order to achieve the task. This task easily determines the aim of each agent to achieve the task. And also, it is proper to hypothesize that there are a unique optimal solution. However, there are some tasks which cannot determine clearly the aim of each agent for achieving the task, and cannot determine a unique optimal solution in multiagent systems. In this research, multiagent ESP method will be applied to Keepaway task as an example of a task that cannot determine the aim of each agent and a unique optimal policy. So, we discuss about the design of fitness function.

Table 1. Agent selectable macro behaviors

Agent Role	**Selectable Macro Behavior**
Passer	Hold Ball, Pass Ball K_2, Pass Ball K_3
Receivers	Get Open, Go To Ball
Takers	Go To Ball, Block Pass K_2, Block Pass K_3

2.2 Keepaway task

Keepaway task is a testbed of reinforcement learning which is used in RoboCup Soccer Simulation League. This task is proposed by P. Stone, R. S. Sutton, G. Kuhlmann [1]. The aim of this task is that 3 Keepers keep a ball against 2 Takers as long as possible. Keepers are numbered K_1, K_2, K_3 in order of the distance to ball. Takers are numbered T_1, T_2 in order of the distance to K_1. And each agent have a specific ID such as K^1, K^2, K^3, T^1, T^2. K_1 is called "Passer", and he can actively control a ball. The other Keepers are called "Receiver". Task start position of Passer is top-left, and the positions of Receivers are top-right and bottom-right, and the positions of Takers are bottom-left. The task continues until fail in ball keeping. One task called one episode.

Keepers and Takers select a macro behavior once every 100 milliseconds. Here, we summarize macro behavior which each agents can select as shown in Table 1. Hold Ball behavior means to keep a ball at the current position. Pass Ball behavior means to pass a ball to a Receiver. Get Open behavior means to go to an open space. Go To Ball behavior means to go near to the ball. Block Pass behavior means to cut a pass course of the target (Keepers).

Learning objects in this task is Passer's policy. Passer is one of the Keepers who nearest to the ball, and is changed off in this task. Each Keeper has a controller learning independently, so he needs a coevolution with the others. The policies of agents without Passer are designed by human. First, Fig. 3 shows a Receiver's policy. Receivers select Get Open when friends have a ball, or friends is nearer to ball than me. They select Go To Ball in the other state. We prepare two types of Taker's policies. The first type policy is that all Takers select Go To Ball. This policy is often used in many existing researches. The second policy is that one agent selects Go To Ball, the other agent selects Block Pass. There are few researches on the second policy, which is more difficult than the first.

The lines in Fig. 4 shows a state variable which Passer can know during the episode.

Existing researches on Keepaway task uses traditional reinforcement learning method such as Sarsa(λ) [1], [2]. Sarsa(λ) algorithm needs to divide environment, but it cannot get enough state representation due to the limit of methods

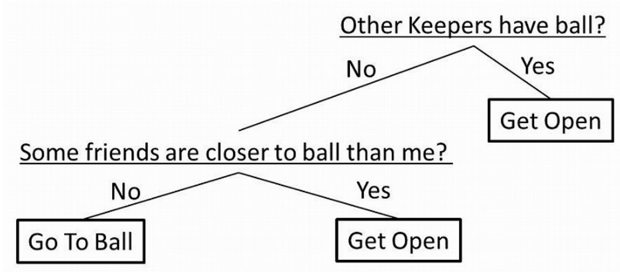

Fig. 3. Receiver's policy

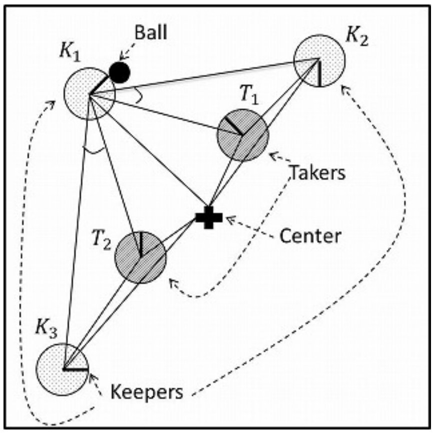

Fig. 4. State variable in Keepaway task

and accuracy of discretization in multiagent systems. The optimal solution is unique according to Sarsa(λ), but it is natural that there are more than one optimal solutions in the task which needs to continue to select stationary behavior such as this task. We think that these problems are occurred by Sarsa(λ) algorithm. In this research, Multiagent ESP method is applied to Keepaway task to improve the episode duration time.

3 MULTIAGENT ESP APPLY TO KEEPAWAY TASK

In this section, we explain how to apply the Multiagent ESP method to a Keepaway task. First, we explain configuration of our system, and next explain the design of fitness function in the Keepaway task. Finally, we explain about process of generation change in the Multiagent ESP method.

3.1 Multiagent ESP method in Keepaway task

Figure 5 shows a configuration of the Multiagent ESP method applying to the Keepaway task. Each Keeper have an independent controller, and they independently evolve according to received fitness value.

Each agent controller is in the form of three layered neural network. Its input takes 13 state values, the output does 3

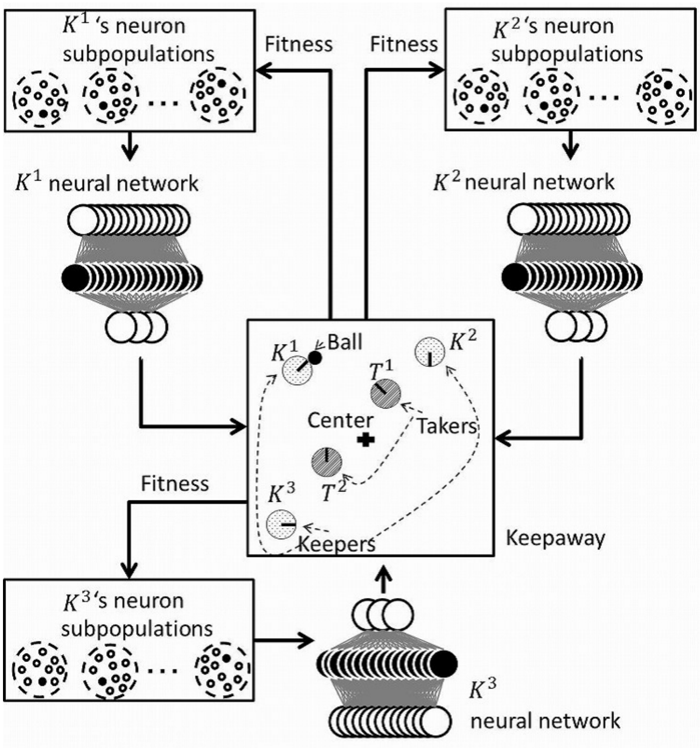

Fig. 5. Multiagent ESP method applying to Keepaway task

macro behaviors, and the number of hidden layer's neuron is 16. The calculation of activation of hidden and output neurons is made by use of the sigmoid function. Passer chooses the behavior of the highest activating neuron. The number of neuron belonging to neuron subpopulations in each agent is 100. These neurons are received fitness values calculated by the fitness function as shown in 3.2. The connection weights of controller are renewed to fit the task through the process of generation change as shown in 3.3.

3.2 Design of fitness function

In this section, we describe the design of fitness functions in the Multiagent ESP method applied to a Keepaway task. The fitness function shows how much the controller constructed by selected neurons in each episode fit to the aim of the task. Existing researches such as Sarsa(λ) give reward when Passer decides his own behavior. However, Passer's strategy can evaluate correctly at the end of task in the endless task such as the Keepaway task. The reward on the way of task is sub goal. But, it is difficult to correctly decide sub goals to achieve the aim of task. Furthermore, the research by Arai et al. shows that it is effective to combine reward and penalty to achieve the aim of task [2]. That is concluded that appropriate setting of some sub goals is effective to achieve the aim of the task. But this approach is reduced to a multipurpose optimal problem, and sometimes shows the inferior performance based on the combination of sub goals due to mutual actions.

Table 2. Sub goals and fitness functions

No.	Sub goal	Fitness
1	The purpose of making a ball to each agent as long as possible time to pass	Eq. (1)
2	The purpose of not relating with task failure	Eq. (2)
3	Our purpose to keep 5m distance from Passer to the nearest Taker	Eq. (3)

First of all, this research shows the difficulty to set some sub goals. Table 2 shows sub goals and fitness functions in own interests. Sub goal 1 is proposed by Stone et al. and has the purpose of making a ball to each agent as long as possible time to pass [1]. Sub goal 2 is proposed by Arai et al. and has the purpose of not relating with task failure [2]. Arai et al. shows the validity to combine sub goal 1 and 2 through experiments. Sub goal 3 is introduced to show the difficulty to set the sub goal by us. It is our purpose to keep 5m distance from Passer to the nearest Taker.

$$fitness = T_C - T_A \tag{1}$$

$$fitness = \begin{cases} -\frac{1}{T_E - T_A} & \text{(failure)} \\ 0 & \text{(otherwise)} \end{cases} \tag{2}$$

$$fitness = \begin{cases} \frac{dist}{5} & (0 \leq dist \leq 5) \\ \frac{4}{3} - \frac{dist}{15} & \text{(oherwise)} \end{cases} \tag{3}$$

Here, T_C is the current time, T_A is the last time for action selection, T_E is task end time, $dist$ is a distance to the nearest Takers. Figures 6, 7 show the result of preliminary experiment which shows the difficulty to set some sub goals. These experiments are made by Multiagent ESP method. Figure 6 shows the Taker's policy is Go To Ball, and Figure 7 shows the Taker's policy is Go To Ball and Pass Cut. The broken line shows the result of the combination of sub goals 1 and 2, the solid line shows the result of the combination of sub goals 2 and 3, the 1-dot dashed line shows the result of sub goal 3. Each pattern is simulated three-times. The combination of sub goals 2 and 3 shows a bad result from these figures. This fact demonstrates the difficulty in a sub goal design.

It is possible to give the rewards based on episode duration time in Multiagent ESP method, but not in Sarsa(λ) algorithm. So, our method gives fitness based on episode duration time(T_D) given by Eq. (4). Existing methods need a design of sub goals to achieve the aim of the task, but our proposed method does not need a sub goal design.

$$fitness = T_D \tag{4}$$

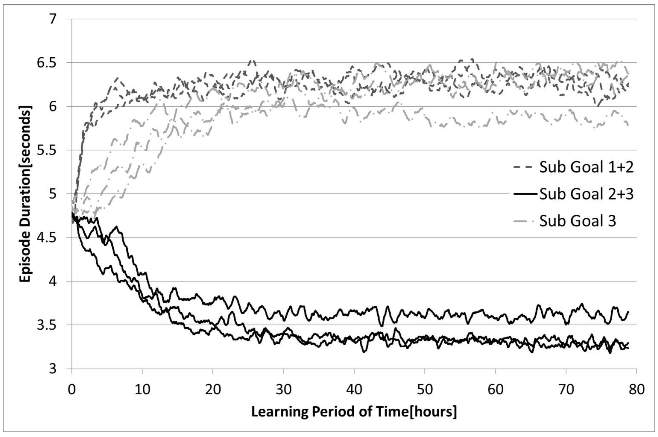

Fig. 6. Taker's policy: Go To Ball

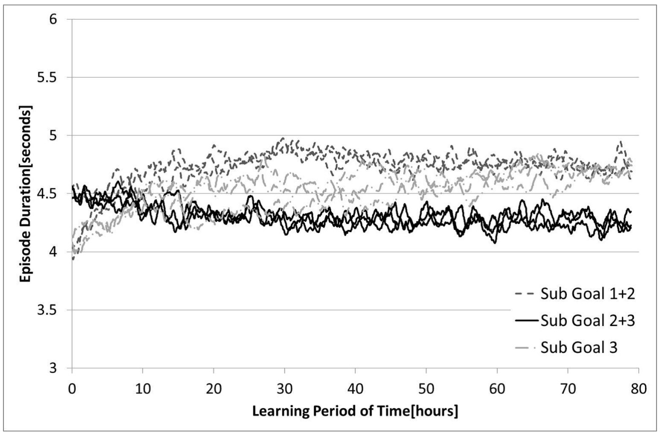

Fig. 7. Taker's policy: Go To Ball and Pass Cut

3.3 Process of generation change

In this section, we describe about the process of generation change in the Multiagent ESP method. The generation changing process is performed through three steps, which is selection, crossover, and mutation. The first selection is a process to bring down high fitness neurons to the next generation, and in our method roulette selection is used. The fitness is updated by windowing which subtract a minimum fitness value in neuron subpopulation from the fitness, and is performed by the power-law scaling which raises the fitness. The second step is one point crossover whose probability is 60 %. The third step is mutation whose probability is 10 % .

This process has to be performed just when all the neurons in neuron subpopulations have been evaluated enough. In this research, the process of generation change are performed every 1000 episodes. That is, one neuron is evaluated 10 times because there are 100 neurons in each neuron subpopulations. Finally, Fig. 8 summarized the process of generation change under these conditions.

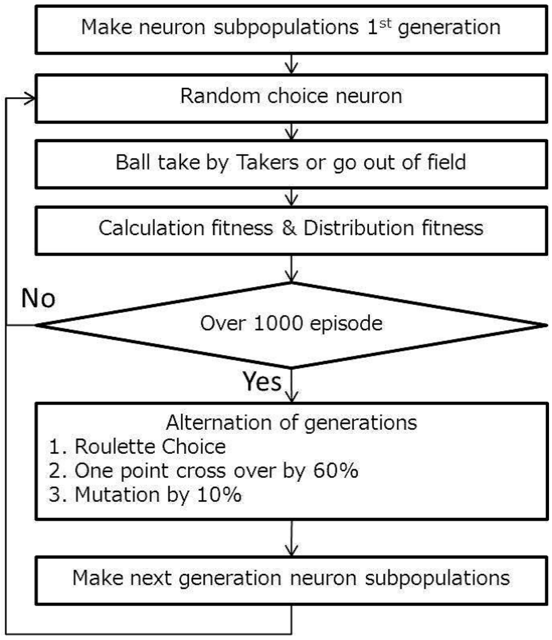

Fig. 8. Process of generation change in Multiagent ESP

4 SIMULATION RESULT

To demonstrate the validity of our proposed method, Figs. 9, 10 show the results of three-times learning of 80 hours in the Keepaway task. Our proposed method which uses the episode duration time as a fitness value is compared with the Sarsa(λ) method proposed by Stone et al. [1], and with the Multiagent ESP method which uses sub goal combination as the fitness value proposed by Arai et al. [2]. Figure 9 shows that the Taker's policy is Go To Ball. Figure 10 shows that the Taker's policy is Go To Ball and Pass Cut. The solid line shows the result of our proposed method, the 1-dot dashed line shows the result of the Sarsa(λ), the broken line shows the result of the Multiagent ESP by Arai's sub goal. The horizontal axis is the learning period of time, and the vertical axis is the episode duration time.

In both of Taker's policies, our proposed method using the episode duration time as a fitness value can give the longest episode duration time. This is because the aim of the task reflect clearly the fitness by using the Multiagent ESP. And, if Taker's policy becomes more difficult, our method can get a better solution than the existing researches by advantages of that it can take continuous state values and can have a set of the optimal solutions. We concluded that the problems in traditional reinforcement learning methods' (such as Sarsa(λ)) : the state representation problem and a variety of the optimal solutions can be solved by using our proposed Multiagent ESP method.

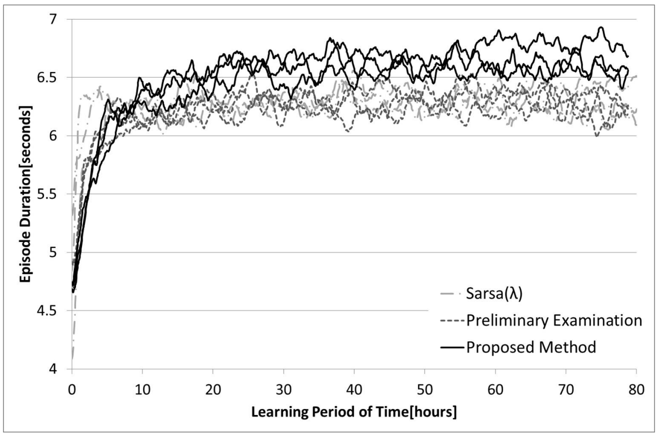

Fig. 9. Taker's policy: Go To Ball

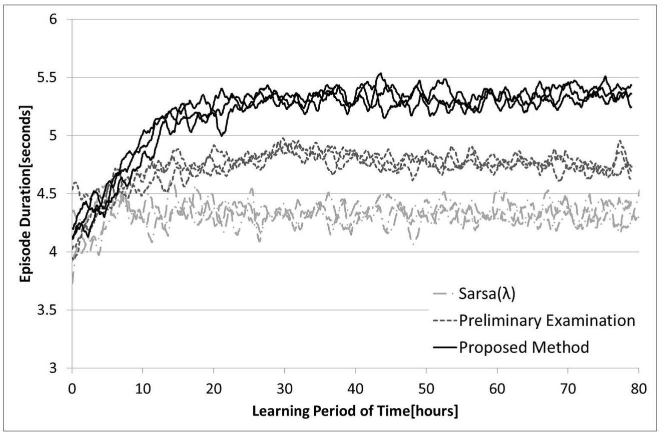

Fig. 10. Taker's policy: Go To Ball and Pass Cut

5 CONCLUSION

In this research, we proposed that the problems of state representation and a variety of optimal solutions can be solved by using our proposed Multiagent ESP method through Keepaway task. And also, we demonstrated that it produced a good learning result to calculate the fitness based on the task duration time at the end of task in order to apply the Multiagent ESP to acquisition of stationary behavior task.

Abstract: Robust DC-DC converter which can covers extensive load change and also input voltage changes with one controller is needed. Then demand to suppress output voltage change becomes still severer, We propose an approximate 2 DOF digital controller which realized the startup response and dynamic load response independently. Controller make the control bandwidth wider, and at the same time make variations of the output voltage small at sudden changes of load and input voltage. In this paper a new approximate 2DOF digital control system with additional zeros is proposed. Using additional zeros second-order differential transfer characteristics between equivalent disturbances and output voltage are realized. Therefore the new controller makes variations of the output voltage smaller and sudden changes of load and input voltage. These controller is actually implement on a DSP and is connected to DC-DC converter. Experimental results demonstrate that this type of digital controller can satisfy given severe specifications with low frequensy sampling.

Keywords: DC-DC converter, Approximate 2DOF, Second-order differential, Digital Robust control

1 INTRODUCTION

In many applications of DC-DC converters, loads cannot be specified in advance, i.e., their amplitudes are suddenly changed from the zeros to the maximum rating. Generally, design conditions are changed for each load and then each controller is re-designed. Then, a so-called robust DC-DC converter which can cover such extensive load changes and also input voltage changes with one controller is needed. Analog control IC is used usually for control of DC-DC converter. Simple integral control etc. are performed with the analog control IC. Moreover, the application of the digital controller to DC-DC converters designed by the PID or root locus method etc. has been recently considered [1]. However, it is difficult to retain sufficient robustness of DC-DC converter by these techniques. Various robust control methods [2] for improving start-up characteristics and load sudden changes characteristics of DC-DC converters. However, they take tens [ms] for the rising time of the startup response, and hundreds [mV] output voltage regulations, have arisen in the load sudden changes. The demand for suppressing output voltage changes becomes still severer, and the further improvements to startup characteristics and load sudden changes characteristics are required. In this paper, we propose a new approximate 2DOF digital controller which realizes second-order differential transfer characteristics. These characteristics are realized by introducing additional zeros into transfer functions between equivalent disturbances and the output. The new controller make the variations of the output voltage the almost same as the former controller [3] at sudden changes of resistive loads and input voltages with low sampling frequensy. A new DC-DC converter equipped with the proposed controller in DSP is actually manufactured. Some simulations and experiments show that this new DC-DC converter can satisfy given severe specifications.

2 DESIGN METHOD

2.1 DC-DC converter

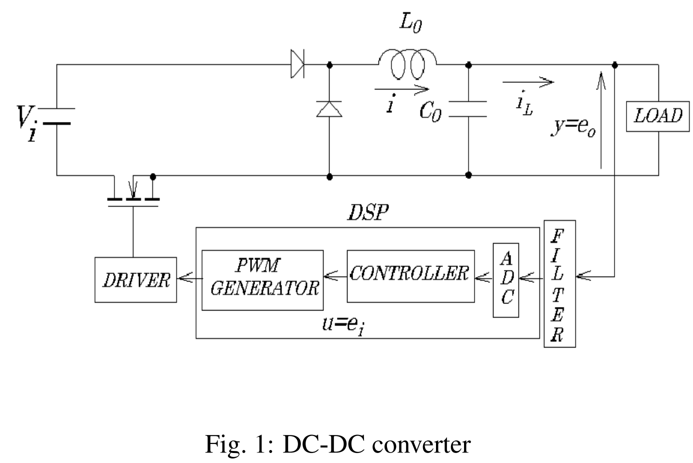

Fig. 1: DC-DC converter

The DC-DC converter are shown in Fig.1 has been manufactured. In order to realize the approximate 2DOF digital controller which satisfies given specifications, we use the DSP (TMS320F28335). This DSP has a builtin AD converter and a PWM switching signal generating part. The triangular wave carrier is adopted for the PWM switching signal. The switching frequency is set at 100[KHz]. The LC circuit is a filter for removing carrier and switching noises. Where Co is 235[μF] and Lo is 0.55[μH]. If the frequency of control signal u is smaller enough than that of the carrier, the state equation of the DC-DC converter at a resistive load in Fig.1 except for the controller in DSP can be expressed from the state equalizing method as follows:

$$\begin{cases} \dot{x} = A_c x + B_c u + B_{cq} u \\ y = C_x + q_y \end{cases} \tag{1}$$

where

$$x = \begin{bmatrix} e_0 \\ i \end{bmatrix} A_c = \begin{bmatrix} -\frac{1}{C_0 R_L} & \frac{1}{C_0} \\ -\frac{1}{L_0} & \frac{R_L}{L_0} \end{bmatrix} B_c = \begin{bmatrix} 0 \\ \frac{k_p}{L_0} \end{bmatrix} c = \begin{bmatrix} 1 & 0 \end{bmatrix}$$

$$u = e_i, y = e_o, k_p = -\frac{V_i}{C_m L_0}, G_p = \frac{R_L}{R_0 + R_L} \times \frac{V_{in}}{TBPRD}$$

and R_0 the total resistance of coil and ON resistance of FET, etc., whose value is 0.015[Ω]. Then the discrete-time state equation of the system eq.(1) with a zero-order hold is express as

$$\begin{cases} x(k+1) = A_d x(k) + B_d u(k) + B_{dq} u(k) \\ y(k) = Cx(k) + q_y(k) \end{cases} \tag{2}$$

where

$$A_c = \begin{bmatrix} a_{11} & a_{12} \\ a_{21} & a_{22} \end{bmatrix} = e^{A_c T}$$

$$B_c = \begin{bmatrix} b_{11} \\ b_{21} \end{bmatrix} = \int_0^T e^{A_c T} B_c d_t$$

2.2 Additional zeros method

The following equation is obtained by repeating the difference of the output of eq.(2):

$$Y = O^* xd(k) + U\bar{u}(k) + U\bar{q_u} + \bar{q_y} \tag{3}$$

where

$$Y = \begin{bmatrix} y(k) \\ y(k+1) \\ y(k+2) \end{bmatrix} O^* = \begin{bmatrix} C \\ CA_d \\ CA_d^2 \end{bmatrix} U = \begin{bmatrix} 0 & 0 \\ CB_d & 0 \\ CA_d B_d & CB_d \end{bmatrix}$$

$$\bar{u} = \begin{bmatrix} u(k) \\ u(k+1) \end{bmatrix} \bar{q_u} = \begin{bmatrix} q_u(k) \\ q_u(k+1) \end{bmatrix} \bar{q_y} = \begin{bmatrix} q_y(k) \\ q_y(k+1) \\ q_y(k+1) \end{bmatrix}$$

If both sides of eq.(3) are multiplied by $\bar{I}_2$from the left, x_d is obtained by the following equation:

$$\begin{aligned} x_d(k) &= (\bar{I}_2 O^*)^{-1} \bar{I}_2 Y - (\bar{I}_2 O^*)^{-1} \bar{I}_2 U \bar{u}(k) \\ &- (\bar{I}_2 O^*)^{-1} \bar{I}_2 U \bar{q_u} - (\bar{I}_2 O^*)^{-1} \bar{I}_2 \bar{q_y} \end{aligned} \tag{4}$$

where

$$\bar{I_2} = \begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \end{bmatrix}$$

By substituting the above equation into eq.(3), the following equation is obtained:

$$(I_3 - (\bar{I}_2 O^*)^{-1} \bar{I}_2) U \bar{q_u} + (I_3 - (\bar{I}_2 O^*)^{-1} \bar{I}_2) \tag{5}$$

where I3 is a 3 $\times$ 3 unit matrix. That is, $\bar{q_u}$ and $\bar{q_y}$ can bbe replaceed to Y and $\bar{u}(k)$. Eq.(5) is transformed as

$$\begin{aligned} &- \quad (l_2 z + l_1) q_u(k) + (z^2 + m_2 z + m_1) q_y(k) \\ &= \quad (l_2 z + l_1) u(k) + (z^2 + m_2 z + m_1) y(k) \end{aligned} \tag{6}$$

where

$$\begin{bmatrix} l_1 & l_2 \end{bmatrix} = -(I_3 - O^*(\bar{I}_2 O^*)^{-1} \bar{I}_2) U$$

$$\begin{bmatrix} m_1 & m_2 & m_3 \end{bmatrix} = (I_3 - O^*(\bar{I}_2 O^*)^{-1} \bar{I}_2) \tag{7}$$

The delay time for AD convertion time etc., replacing current feedback and zeros addition are connected to input of system(2). The state equation of a new controlled object connecting can be expressed as

$$\begin{aligned} &x_{dw}(k+1) = A_{dw} x_{dw}(k) + B_{dw} v(k) \\ &y(k) = C_{dw} x_{dw}(k) \end{aligned} \tag{8}$$

where

$$x_{dw}(k) = \begin{bmatrix} x_d(k) \\ \xi_1(k) \\ \xi_2(k) \\ \xi_3(k) \end{bmatrix} \quad A_{dw} = \begin{bmatrix} A_d & B_d & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \\ 0 & 0 & 0 & 0 \end{bmatrix}$$

$$B_{dw} = \begin{bmatrix} 0 \\ 0 \\ 0 \\ 1 \end{bmatrix} \quad C_{dw} = \begin{bmatrix} C & 0 & 0 & 0 \end{bmatrix} \; \xi_1(k) = u(k)$$

Applying the following feedforwards from q_u, q_y and r, and state feedback from x_{dw} for model matching to the system in eq.(8), the system shown in Fig.2 is obtained. From Fig.2.

$$\begin{aligned} v(k) = &-k_q(l_2 z + l_1) q_u(k) + k_q(z^2 + m_2 z + m_1) q_y(k) \\ &+(z^2 + g_2 z + g_1) r(k) + [f_1 \; f_2 \; f_3 \; f_4 \; f_5] x_{dw}(k) \end{aligned} \tag{9}$$

In Fig.2, the parts surrounded by dotted lines are the feedforward coefficients from q_u and q_y and the part surrounded by a chain line is the estimated part of current. From eq.(6), the feedforwards of eq.(9) are changed as

$$\begin{aligned} &v(k) = k_q(l_2 z + l_1) u(k) + k_q(z^2 + m_2 z + m_1) y(k) + \\ &(z^2 + g_2 z + g_1) r(k) + [f_1 \; f_2 \; f_3 \; f_4 \; f_5] x_{dw}(k) \end{aligned} \tag{10}$$

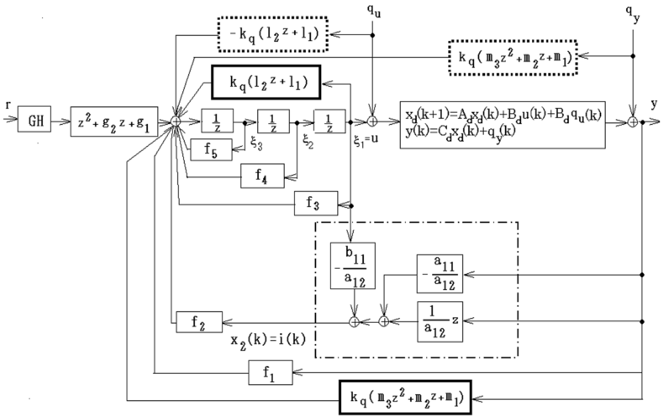

Fig. 2: Feedforword from equivalent disturbances q_u and q_y, and model matching with state feedback

That is, the parts surrounded by the dotted lines are replaced by the parts surrounded by solid lines from u and y. The system expect for the parts surrounded by the dotted lines in Fig.2 can be transformed equivalently as shown in Fig.3. In Fig.3,

$$\begin{aligned}
ff_1 &= f_1 - f_2(a_{11}/a_{12}) + k_q m_1 + f_5(k_q m_2 + f_2/a_{12}) \\
&+ f_5^2 k_q m_3 + (f_4 + k_q l_2) k_q m_3 \\
ff_2 &= k_q m_2 + f_2/a_{12} + f_5 k_q m_3 \\
ff_3 &= f_3 - f_2(b_{11}/a_{12}) + k_q l_1 \\
ff_4 &= f_4 + k_q l_2 \\
ff_5 &= f_5 \\
ff_6 &= k_q m_3 \\
gg_1 &= f_5^2 + f_5 g_2 + k_q l_2 + f_4 + g_1 \\
gg_2 &= f_5 + g_2 \qquad (11)
\end{aligned}$$

The transfer function between r and y, q_u and y, and q_y and

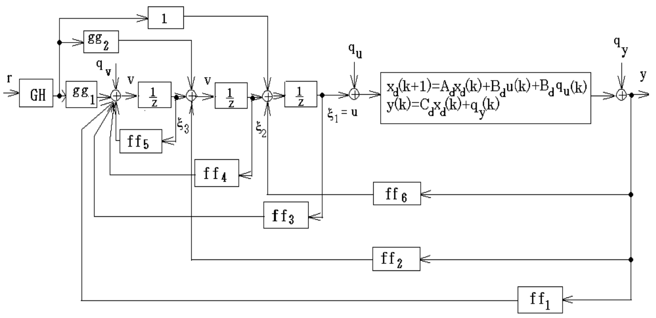

Fig. 3: Model matching system using only voltage (output) feedback

y in Fig.3 are descrived as

$$\begin{aligned}
W_{ry}(z) &= N_{ry}(z)/D(z) \qquad (12) \\
W_{q_u y}(z) &= N_{q_u y}(z)/D(z) \qquad (13) \\
W_{q_y y}(z) &= N_{q_y y}(z)/D(z) \qquad (14)
\end{aligned}$$

where

$$\begin{aligned}
N_{ry}(z) &= GH(z^2 + g_1 z + g_0)(b_{11}z + b_{21}a_{12} - a_{22}b_{11}) \\
N_{q_u y}(z) &= N_{qz} N_p \\
N_{q_y y}(z) &= N_{qz} D_p \\
N_{qz} &= (a_{12}z^3 - a_{12}f_5 z^2 + (a_{12}b_{11}k_q - a_{12}f_4)z \\
&- f_3 a_{12} + f_2 b_{11} - a_{12}a_{22}b_{11}k_q + a_{12}^2 b_{21} k_q) \\
D(z) &= z^5 + (-f_5 - a_{22} - a_{11})z^4 + (a_{11}f_5 \\
&+ a_{11}a_{22} - a_{21}a_{12} + a_{22}f_5 - f_4)z^3 \\
&+ (a_{21}a_{12}f_5 - f_3 + a_{11}f_4 - a_{11}a_{22}f_5 \\
&+ a_{22}^2 2f_4)z^2 + (a_{22}f_3 + a_{21}a_{12}f_4 + a_{11}f_3 \\
&- b_{11}f_1 - f_2 b_{21} - a_{11}a_{22}f_4)z + f_2 a_{11} b_{21} \\
&- a_{21}f_2 b_{11} + a_{21}a_{12}f_3 + f_1 a_{22} b_{11} \\
&- f_1 a_{12} b_{21} - a_{11}a_{22}f_3
\end{aligned}$$

From $D(z)$, the poles of the overall system can be arranged arbirarily by f_1, f_2, f_3, f_4 and f_5. From $N_{ry}(z)$, two zeros of r-y can be arranged arbitrarily by g_0 and g_1. Moreover, from common N_{qz} in $N_{qz}(s)$ and $N_{q_y y}(s)$, one zeros of $q_u - y$ and $q_y - y$ can be arranged arbitrarily at the same place by k_q. That is, one zeros can be added arbitrarily to W_q.

2.3 Design of the model matching system

We consider transfer function between the reference input r and the output y specified as below.

$$W_{ry}(z) = \frac{(1+H_1)(1+H_2)(1+H_3)(z-n_1)(z+n_2)(z+n_4)(z+n_5)}{(1-n_1)(1-n_2)(1+H_1)(z+H_2)(z+H_3)(z+H_4)(z+H_5)} \qquad (15)$$

This transfer function is realized by the model matching system shown in Fig.5. The robust system is constructed as shown in Fig.4. The transfer function r to y and q of Fig.5 are as follows

$$y \approx \frac{1+H_2}{z+H_2} \quad y \approx \frac{(z-1)^2}{z-1+k_z}\bar{W_{Qy}}Q \qquad (16)$$

From eqs. (16) it turn out that the characteristics from r to y can be specified with H_2, and the characteristics from qu and q_y to y can be independently specified with k_z. That is, the system in Fig.4 is an approximate 2DOF, and its sensitivity against disturbances becomes lower with the increase of k_z. If an equivalent conversion of the controller in Fig.4 is carried out, the approximate 2DOF digital integral-type control system will be obtained as shown in Fig.5.

3 SIMULATION AND EXPERIMENTAL RESULTS

The sampling period T are set 10[μs].The nominal value of R_L is 0.33[Ω]. We design a control system so that H_1,

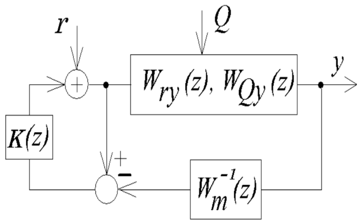

Fig. 4: System reconstituted with inverse system and filter

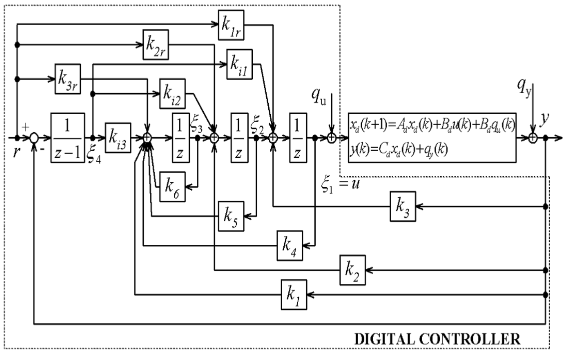

Fig. 5: Approximate 2DOF digital integral-type control system

H_2, H_3, H_4, and H_5 are specified as

$$H_1 = -0.2 + 0.2i \qquad H_2 = -0.9 \qquad H_3 = -0.2 - 0.2i$$
$$H_4 = -0.4 + 0.3i \quad H_5 = -0.4 - 0.3i$$

The simulations results of the dynamic load responses is smaller than 50[mV] as shown in Fig.6 Experimental results are shown in Fig.7,8. Experimental results of dynamic load response by the first order differentiation with sampling frequency 300[KHz] is shown in Fig.8. The output voltage change is suppressed within about 50[mV]. This is almost the same results by the second order differentiation with sampling frequency 100[KHz] as shown in Fig.7. We can get almost the same performance with low sampling fregeuncy.

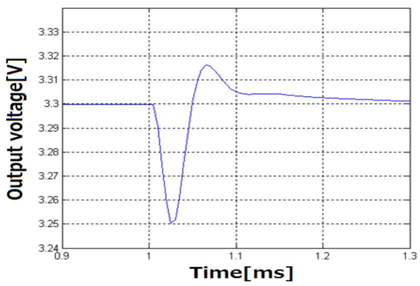

Fig. 6: Dynamic load response

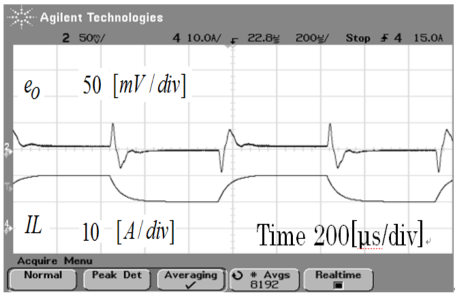

Fig. 7: Experimental results of using the second order differential characteristic with Fs = 100[kHz]

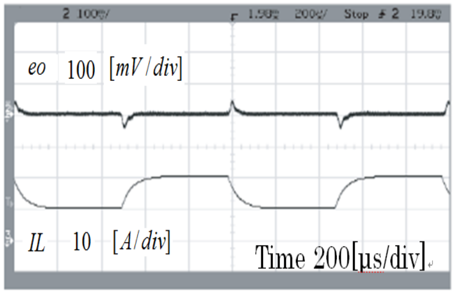

Fig. 8: Experimental results of the first order differential with Fs = 300[kHz]

4 CONCLUSION

In this paper, the concept of controller of DC-DC converter to attain good robustness against extensive load changes and input voltage changes was given. The proposed digital controller was implemented on the DSP. It was shown from experiment that the sufficiently robust digital controller is realizable. The characteristics of dynamic load response and output response were improved by using low sampling frequency approximate 2DOF digital controller with additional zeros.

Abstract: Tactile apparent movement recognition is normally considered as a subjective sense of human. Applying the tactile apparent movement to an engineering system, a quantitative evaluation study becomes necessary. In previous studies, finding the body-sway caused by the tactile apparent movement in a fixed experimental condition became possible. However, characteristic of the body-sway was not thoroughly investigated. In this study, investigating the body-sway caused by tactile apparent movement in a fixed experimental condition was aimed. Therefore, we focused on biological information, the body-sway and the comparison between the apparent movement recognized trials and the non-recognized trials. The findings of this research will be conducive to optimize the performance of the systems that are using the tactile apparent movement.

Keywords: Tactile Apparent Movement, EMG (Electromyography), Discrete Wavelet Packet Transforms

I) INTRODUCTION

Tactile sense as one of the five senses of human body has always been considered as an efficient substitution for the other senses of body such as sight and hearing. For example, a tactile interface system is able to transfer the required information by using the tactile sense instead of visual sense. Today we can see the various applications of this substitution in different interface and display systems that are helping people specially the physically challenged persons to perform many tasks despite of a loss in one of their sensory organs. [1]

In this study, the term *apparent movement* (AM) refers to the illusory perception of a movement on skin that is created by the discrete stimulations of a number of points on skin of a part of body that are appropriately separated in space and time. [2]

In previous studies the evaluation of the apparent movement recognition was particularly based on the statistical techniques instead of the quantitative evaluations. As a result of our previous studies, the sway of the subjects' arm during a tactile apparent movement experiment under a specified experimental condition was reported. [3] It has been expected that the quantitative evaluation of the body-sway that in our study refers to the sway of the testing arm, will make the tactile apparent movement evaluation possible.

The characteristics of the body-sway were analyzed by studying the EMG (electromyography) waveforms recorded during the apparent movement recognition time. The analysis was performed by using the various frequency analysis methods and tools such as the Wavelet packet transform. [4]

II) MEASURMENT AND EXPERIMENT

The experiments of our study take place on two different days. Figure 1 shows the experiment system of the first day. By using a PC different stimulations can be applied to the 4 skin stimulators (vibrators) randomly through a D/A convertor and an Op-amp amplifier.

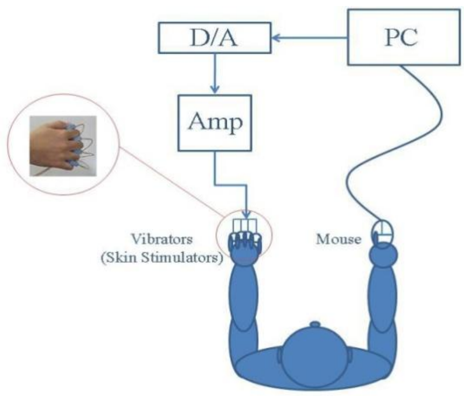

Figure 1: AM recognition experiment system.

During the measurement, the subject (in this report, three 23 years old male student) sits on a chair while the arm (which the vibrators are between its fingers) is open and making a 90 degree angle with upper body. The eyes will be closed and ears will be covered by a voice proof cover. The mouse clicks will be recorded as the subjects' reaction when recognizing the apparent movement.

Figure 2 shows the experiment system that has been used on the second day's experiment. There are two PCs in the experiment system that the first one (PC1) is responsible for applying the stimulations to the stimulators and also recording the real-time tracing data (CCD camera). The second PC (PC2), after amplification and A/D conversion, records the EMG data and the signals from a three-axis acceleration sensor attached to the wrist of the subject`s testing arm. In this experiment, EMG waveforms will be recorded by means of 12 electrodes and 18 channels resulting from the electrode combination.

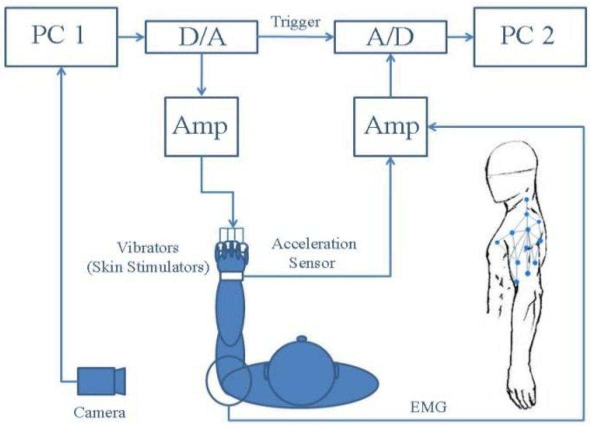

Figure 2: EMG measurement system and electrode combination.

The stimuli are controlled by the two parameters of T and τ that will be applied to the stimulators randomly in 10 cycles (repetitions). The period of applying the stimulation is represented by T and τ is for the interval between the starting (trigger) points of the stimulation in the 4 vibrators (see Figure 3).

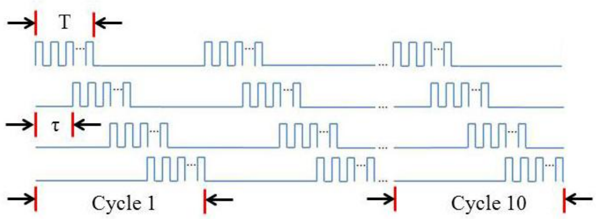

Figure 3: T and τ.

Table 1 shows the of T and τ values which will be selected randomly to make the different types of stimulations.

Table 1: Values of T and τ.

Parameter	[ms.]					
T	300	500	700	900	1100	1300
τ	100	200	300	400	500	600

III) DATA ANALYSIS AND RESULTS

Figure 4 shows the result of the first day`s experiment on one of the subjects. The area with higher values shows the AM recognition area, where the subject has reacted to the stimuli by a mouse click. The center of gravity of the recognition area is named as the (TM, τM) point. In this stage, the experiment will be repeated with the constant value of the T=TM in order to see the precise values (thresholds) of τ at the recognition area which the lower threshold will be represented by τL and the higher threshold will be represented by τH (see Figure 5).

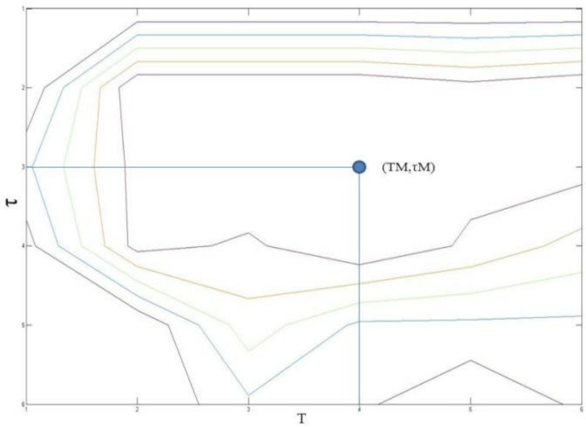

Figure 4: Results of the AM recognition experiment

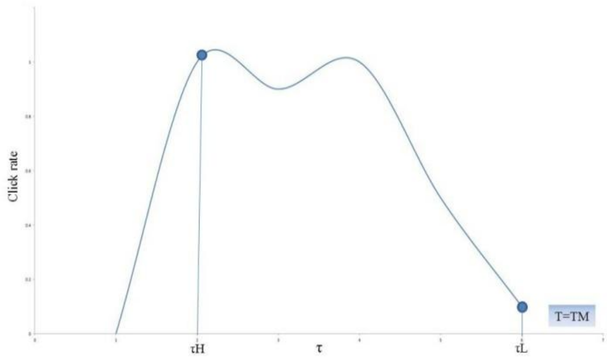

Figure 5: Results of the AM recognition experiment with the constant value of T=TM.

The obtain values of TM, τ0 (the lowest τ value in the first experiment's result), τL, τM, τH will be used as the variables of the second day's (EMG) experiment.

In our study, two periods of the EMG data are in the center of attention: the period before applying the stimulations (pre-stimulation data) and the period after applying the stimulations (post-stimulation data).

In order to study the frequency characteristics of the EMG data (since it has a vast frequency range from 50Hz to 200Hz) discrete Wavelet packet transform was tried. The Wavelet packet transformation is performed in 8 levels by using the Doubachese-3 mother wavelet. As a result of wavelet packet decomposition in 8 levels, 256 packets appeared. Additionally, in order to compare the data of wavelet packets of different channels and different subjects *Fisher`s ratio* is used. Fisher's ratio (FR) is a measure for (linear) discriminating power of some variable that is defined as below: [5]

$$FR = \frac{\sum_{i=1}^{c} \frac{n_i}{n} \left\| \bar{x}_i - \bar{x} \right\|^2}{\sum_{i=1}^{c} \frac{n_i}{n} \bar{\bar{x}}_i} \tag{2}$$

when:

$$\bar{\bar{x}}_i = \frac{1}{n_i} \sum_{i=1}^{c} \left\| x_i - \bar{x}_i \right\|^2 \tag{3}$$

The EMG results recorded with (TM,τ0) parameters will be considered as class 1 and the EMG results recorded with (TM,τL) or (TM, τM) or (TM,τH) parameters will be considered as class 2. In these equations *i* is the index of wavelet packets, $\bar{x}$ is the average values and $\bar{\bar{x}}$ represents the variance values.

Since the EMG data recorded before applying the stimulations can be considered as the default behavior of the subject, the results of data analysis will be presented as the variance between the post-stimulation data and pre-stimulation EMG data (*V*) as:

$$V = (Post\ Stimulation - Pre\ Stimulation) \tag{4}$$

The calculated FR of the 12^{th} EMG recording channel of all subjects owns the maximum value of FR among the other 18 channels. Thus, the 12^{th} channel`s results will be presented as the final results for each subject.

After obtaining Fisher`s ratio in the mentioned 3 types of class selection (τ0-τL, τ0-τM andτ0-τH), we tried to find the packets (frequency ranges) which Fisher`s ratio is maximum when the selected 2 classes, regarding to the definition of τM, are τ0 and τM .

Different ranges of Fisher`s ratio were tried and compared. In order to find the range that owns the maximum FR values, variance between the 3 types of FR class selection was calculated. Figures 6 and 7 show the variance between the summations of FR values that have been calculated in 3 different types of class selection. In figure 6 variances between FR summations of two different class selection groups (τ0-τM and τ0-τL) for 3 subjects is depicted. Figure 7 depicts the variances of FR summations in two different class selection groups of τ0-τM and τ0-τH (3 Subjects).

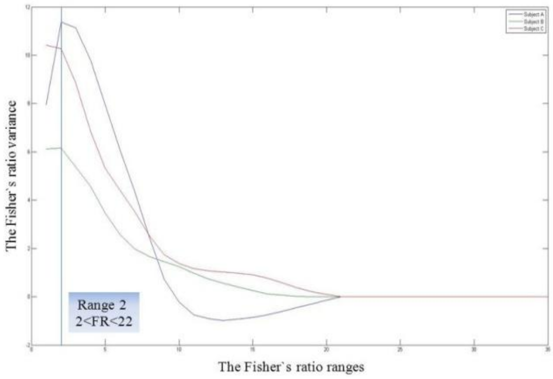

Figure 6: Subject A

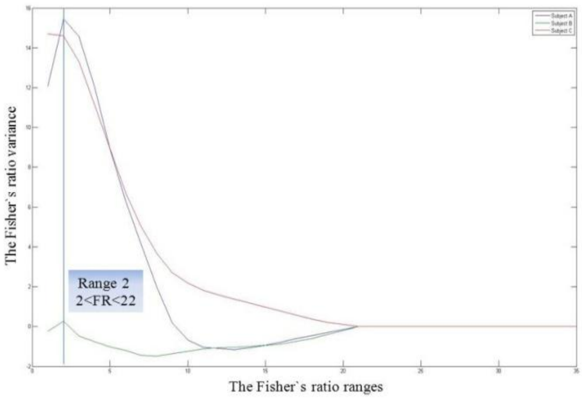

Figure 7: Subject B

Comparing the different FR ranges, we came to this conclusion that Fisher`s ratio is maximum in the $2^{nd}$ range that belongs to the range between FR=2 and FR=22. Figures 8, 9 and 10 show the Fisher`s ratio values (calculated with the two classes of τ0/τM) in the mentioned range of 2~22 for all the 256 packets of the 8^{th} level of DWPT.

In order to present the most results in the most understandable form, the results of the figures 8, 9 and 10 are depicted after applying a low-pass filtration in frequency domain. In these figures, the higher areas show the bigger values of FRs that has been calculated between the two classes of data recorded with τ0 and τM.

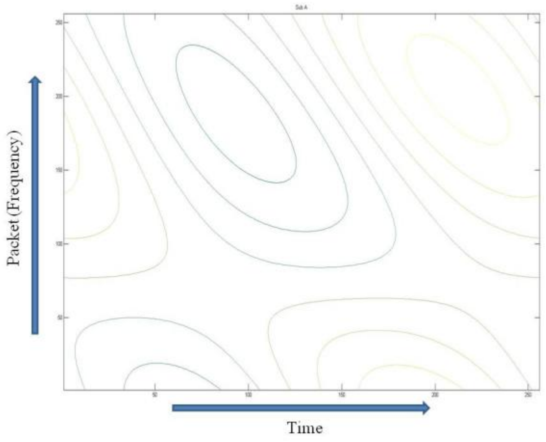

Figure 8: Subject A

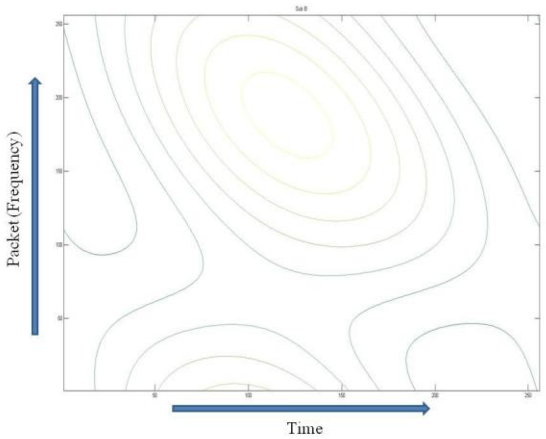

Figure 9: Subject B

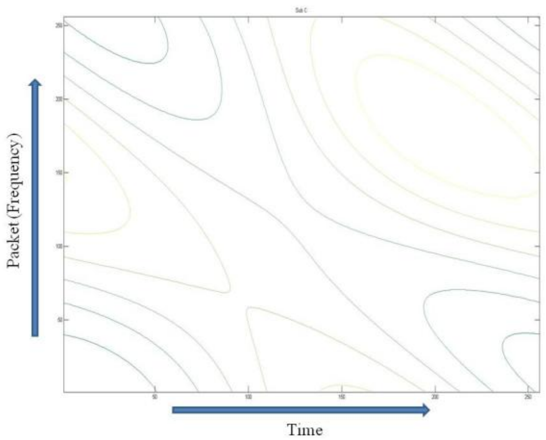

Figure 10: Subject C

Comparing the results of the recorded EMG data analysis for the 3 subjects of A, B and C, basically, two significant areas own the maximum ranges of FR with a similar shape and formation. It can be understood that the results of the subjects A and C are quite similar from the formation of the maximum areas point of view while the result of subject B is still obeying the same form with a down-ward shifting.

IV) CONCLUSION

In this study, the sway of the subjects' arm caused by individual tactile stimulations and tactile apparent movement recognition as its result was investigated. By focusing more on the frequency characteristics of the body-sway, the expected quantitative evaluation of the body-sway became possible. The results of this study show the possibility of the periodic movements of the testing part of the body which occur during the apparent movement recognition.

Abstract: Unmanned Aerial Vehicle (UAV) is becoming useful tool for the surveillance of the area where man can't go in. Ideally, UAV should fly fully automatically and some of them are becoming to be able to do this. Autonomous flying UAV can use large amount of data for posture control and navigation during its flight. This paper proposes the method which recycles these data for the purpose of environment recognition. In order to achieve this, we adopt machine learning techniques. Support Vector Machine (SVM) is chosen because it is faster and lighter than other machine learning technique. We demonstrate the method using the UAV made by Hitachi Ltd. and Kawada Industries, Inc. It can fly autonomously using GPS, motion sensor, magnetic sensor. From the flight log obtained by these sensors, SVM can not only classify the space into safe and dangerous area, but also predict undiscovered dangerous area. These areas coincident with the impression of operator who flied the radio control airplane in the same airspace.

Keywords: UAV, Automatic Surveillance, Machine Learning, Data mining, Support Vector Machine

1 INTRODUCTION

There is a growing demands for surveillance using UAV (Unmanned Aerial Vehicle) in disaster area[1][2][3]. For example, at the early stage of the nuclear crisis in Fukushima Daiichi Nuclear Power Station which is caused by Tsunami of 2011 Tohoku earthquake, US military's global hawk flied around and collected valuable data[4].

Ideally, the UAV should fly autonomously, but there are many difficulties for autonomous flight. Compared with the automatic flight of large passenger plane, the status of the flight airspace of UAV is usually unknown because when it is expected to fly above disaster area, the previous information wii be useless.

This paper proposes a method that enables the UAV to recognize the environment using machine learning technique. This method recycles the information from GPS, motion sensor, and so on which is observed originally for flight control.

The following is the contents of this paper. Section 2 introduce the UAV which is used in this research. Section 3 explains our proposed method environment recognition. Section 4 show the results of the recognition from real data. Section 5 concludes this paper.

2 EXPERIMENTAL APPARATUS

The UAV used in this study is made by Hitachi Ltd. and Kawada Industries, Inc. Fig. 1 shows the appearance of the UAV and Table 1 show the specs of the UAV.

The significant feature of the UAV is that it can fly fully autonomously using the hybrid navigation of GPS and INS. In order to achieve that, the UAV equipped various sensors. The following is the information that can be observed.

Table 1. The specs of the UAV used in this research

size	600 x 503 x 163 (mm)
weight	720g
air speed	45 – 70 km/h
duration of flight	15 min
propulsion	propeller propulsion
power	lithium polymer battery
control of flight	autonomous / radio control
camera	1280 x 1024
record	flight data and photo data
takeoff / landing	hand throw / belly-landing

- GPS (position, time)
- acceleration sensor (3-axis acceleration)
- angular velocity sensor (3-axis angular velocity)
- magnetic sensor (direction)
- anemometer (air speed)
- digital camera (photo)

The UAV can send the status to and receive the com-

Fig. 1. The micro UAV used in this research.

mand from the ground station with wireless communication. The flight plan consist of the sequence of waypoints. Hand thrown take off and belly landing enable us to operate the UAV without a runway. It can fly about 15 minutes by the power of lithium-polymer batteries. In autonomous flight, the UAV can't recognize obstacle. Therefore human operator can override the control by radio-control.

3 THE RECOGNITION OF ENVIRONMENT

This section proposes the environment recognition method using support vector machine[6]. SVM is one of the supervised learning method and is used for binary classification.

3.1 Support Vector Machine

SVM has linear separator but the separation is done in the feature space which is produced by kernel function. SVM shows a good performance in non-linear separation problem.

Let the mapping to feature space $\Phi : X \rightarrow H$. Kernel function k can be represented by the inner product of them as $< \Phi(x), \Phi(x') >$.

$$k(x, x') =< \Phi(x), \Phi(x') > \tag{1}$$

In classification problem, SVM divide the hyperplane into two class by

$$< \mathbf{w}, \Phi(x) > +b = 0. \tag{2}$$

Decision function f is

$$f(x) = \mathrm{sign}(< \mathbf{w}, \Phi(x) > +b). \tag{3}$$

The performance of separation is maximum when the margin which is made by hyperplane is maximum.

This problem result in solving constrained quadratic programming. For many kernel functions, the weight can be written as $\mathbf{w} = \sum_i \alpha_i \Phi(x_i)$.

This classification only depends on the data on the margin. These data are called support vectors.

In an attempt to meet the overlapped data, soft margin term ξ can be introduced:

$$\begin{aligned} \text{minimize} \quad & t(\mathbf{w}, \xi) = \tfrac{1}{2}||\mathbf{w}||^2 + \tfrac{C}{m} \textstyle\sum_{i=1}^{m} \xi_i \\ \text{subject to} \quad & y_i(< \Phi(x_i), \mathbf{w} > +b) \geq 1 - \xi_i \\ & \xi_i \geq 0 \;\; (i = 1, \ldots, m) \end{aligned} \tag{4}$$

Here, m is a number of training data and $y_i = \pm 1$.

Solution of SVM $\mathbf{w}$ can be represented as follows:

$$\mathbf{w} = \sum_{i=1}^{m} \alpha_i y_i \Phi(x_i) \tag{5}$$

α_i can be obtained by solving the following duality problem.

$$\begin{aligned} \text{maximize} \quad & W(\alpha) = \textstyle\sum_{i=1}^{m} \alpha_i \\ & -\tfrac{1}{2} \textstyle\sum_{i,j=1}^{m} \alpha_i \alpha_j y_i y_j k(x_i, x_j) \\ \text{subject to} \quad & 0 \leq \alpha_i \leq \tfrac{C}{m} \\ & \textstyle\sum_{i}^{m} \alpha_i y_i = 0 \\ & \xi_i \geq 0 \;\; (i = 1, \ldots, m) \end{aligned} \tag{6}$$

Using duality theorem $\mathbf{w}$ and b can be disappeared and the problem becomes to the maximization problem only for α.

3.2 Data to be Classified

During the flight of our UAV, various kinds of data which is explained in Section 2 is observed and stored in the form of CSV file. The sampling rate is 0.1 sec.

4 EXPERIMENTS

In order to demonstrate our method, some experimental flights have been done. The flight area is the above of the baseball ground in our campus (Fig. 2).

The purpose of this experiment is to find dangerous airspace to flight. Knowing the dangerous airspace is very important for this UAV because it flies fully autonomous.

We set the criteria of dangerous airspace as follows:

- The airspace where large acceleration is observed.
- The airspace where the difference between ground speed and air speed is large.

As we explained in Section 3.2, the UAV gathers a data every 100 msec. Each sampling point checked and marked as "danger" when the above criteria is hold. SVM learned and classify the airspace from these data. Table 2 is a summary of the parameters and results.

The results of estimation are shown from Fig. 3 to Fig. 6. In these figures, each point shows the observation point. Circle is judged as "normal" airspace and triangle is judges as "danger." Black circles and triangles are support vectors.

From the top view (Fig. 3 and Fig. 5), we can see the dangerous airspace is slightly different. This means acceleration based dangerous airspace and speed difference based dangerous airspace is not the same, however the overlapping zone is quite dangerous.

From the side view (Fig. 4 and Fig. 6), we can see the middle of the height is more dangerous than other heights. This result coincidents with the impression of human pilot of radio controlled airplane which flied just before the experiments. This can be thought that there are some air flow around the middle height above the ground. This wind comes from the sea and make a turbulence above the ground because the ground is located on the top of the hill very near from the sea. You can see the location from Fig. 2.

Table 2. Setting parameters and results of support vector machine

experiment	cost parameter	hyperplane parameter	number of support vector	error
Fig. 3	4	4.69	1431	0.336
Fig. 4	8	16.31	1400	0.320
Fig. 5	7	8.96	482	0.059
Fig. 6	7	11.65	424	0.065

5 CONCLUSION

This study proposes a machine learning based method of environment recognition for small UAV in disaster area. This method recycles the information that is obtained originally for autonomous flight into the environment recognition. This method estimates air status of whole airspace from the very little airspace where the UAV fly. As a demonstration, we flied the UAV above the ground of our campus and made the hazard map of the air. The results coincident with the human expert impression. For future works, we need an extension of this method to the realtime estimation (on-flight estimation) and to the coordinated estimation by multiple UAV.

Abstract: The Great East Japan Earthquake occurred at 14:46 on Friday, 11 March 2011. It was the most powerful known earthquake to have hit Japan, and one of the five most powerful earthquakes in the world overall since modern record-keeping began in 1900. The earthquake triggered extremely destructive tsunami waves of up to 40.5 meters in Miyako, Iwate. Over 20,000 people dead and the missed.

International Research Center for Marine Policy is think tank of Japan Coast Guard and is belong to Japan Coast Guard Academy. Research unit was organized to survey and research of The Great East Japan Earthquake in particular about ocean. This unit collects the information about it and analyzes and synthesizes collected information from a professional viewpoint respectively. Then, the unit study about damage by TSUNAMI, damage of ships, urgent refuge and search rescue to pick new actual explication and various lessons out.

Keywords: the Great East Japan Earthquake, TSUNAMI, evacuation, multi-agent simulation.

1 INTRODUCTION

The earthquake off the Pacific coast of Tohoku, also known as the 2011 Tohoku earthquake, or the Great East Japan Earthquake, was a magnitude 9.0 undersea megathrust earthquake off the coast of Japan that occurred at 14:46 on Friday, 11 March 2011. It was the most powerful known earthquake to have hit Japan, and one of the five most powerful earthquakes in the world overall since modern record-keeping began in 1900. The earthquake triggered extremely destructive tsunami waves of up to 40.5 meters in Miyako, Iwate. In some cases it traveled up to 10 km inland. In addition to loss of life and destruction of infrastructure, the tsunami caused a number of nuclear accidents in the Fukushima I Nuclear Power Plant complex.

Over 20,000 people dead and the missed and over 125,000 buildings damaged or destroyed by the earthquake. The earthquake and tsunami caused extensive and severe structural damage in Japan, including heavy damage to roads and railways as well as fires in many areas, and a dam collapse. Around 4.4 million households in northeastern Japan were left without electricity and 1.5 million without water. Many electrical generators were taken down, and at least three nuclear reactors suffered explosions due to hydrogen gas that had built up within their outer containment buildings after cooling system failure.

International Research Center for Marine Policy is think tank of Japan Coast Guard and is belong to Japan Coast Guard Academy. Research unit was organized to survey and research of Tohoku - Pacific Ocean Earthquake in particular about ocean. This unit collects the information about it and analyzes and synthesizes collected information from a professional viewpoint respectively. Then, the unit study about damage by TSUNAMI, damage of ships, urgent refuge and search rescue to pick new actual explication and various lessons out.

In our viewpoint, we focus on the evacuation from TSUNAMI. Then, we analyze about ships evacuation from TSUNAMI using multi-agent simulation and we want to prepare for a coming earthquake. When considering evacuation, we often stick to only refuge to a hill and a shelter to get it. But, as seen on TV news, some ships run aground on land by TSUNAMI. And staffs of local public bodies lead refuge or staffs of peace or rescue organization go to the office urgently. Then, there occur very traffic jam and it is difficult to reach the destination. We investigate the evacuation to shelter from TSUNAMI of refugees and perform the own mission of staffs.

2 RESERCH UNIT

Research unit was organized to survey and research of the Great East Japan Earthquake in particular about ocean this summer. And they collect and the public or non-public information about the earthquake and analyzes and synthesizes collected information from a professional viewpoint respectively. Then, the unit study about damage by TSUNAMI, shipping damage, urgent refuge and search rescue to pick new actual explication and various lessons out.

The research unit is classified into six groups. The groups is for stering and perform a ship, traffic on the sea, estimation of floatage, rescue and disaster prevention, technique of search in the sea, and the engine of ship.

Our study belongs to group about traffic on the sea. We can deal with Automatic Identification System data what is called AIS [1] data, Marine Traffic Information service[2], what is called MARTIS radar data, record of communication by VHF, directions such as taking shelter of ships, ebb and flow data, tide data, and so on. The research group has three sub groups. First sub group is to analyze the actual taking shelter of ships when a seismic sea-wave warning alarmed and TSUNAMI came. Second sub group is to survey the control in the port and sea route control when a seismic sea-wave warning alarmed and TSUNAMI came. And last sub group is to study of simulation when ships take shelter, which is we belong to.

3 BEHAVIOR OF SHIPS AFTER EARTHQUAKE

Fig. 1 is plotting figure of the real AIS data of ships after the earthquake around port of Sendai-Shiogama.

With the AIS installed, vessels are able to monitor the movement of a multiple number of vessels simultaneously regardless of visibility, thereby dramatically reducing the danger of ship collision. Furthermore, ground facilities can obtain the ship-specific information necessary for automatic, real-time maritime traffic control. AIS will play an important role in ensuring navigational and operational efficiency in congested waterways [1].

In Japan, passenger ships of less than 300 tons of gross tonnage and all ships of more than 300 tons of gross tonnage for international sailing, and all ships of more than 500 tons of gross tonnage for non-international sailing have to be equipped AIS equipment[3].

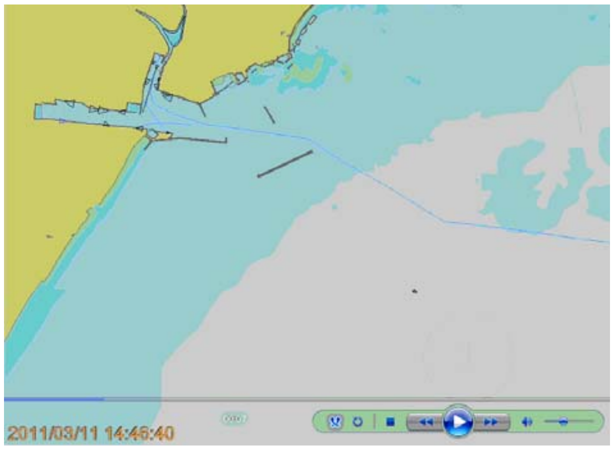
Because AIS data was recorded, we can review the behavior big ships by AIS data in Japan.

In Fig.1, there are several banks at offshore of port. And in Fig. 1(a), there were some ships with AIS in the bay at the time of earthquake. Ship is described by an isosceles triangle and the heading is shown by the top. Speed and the heading of the ship are described by a bar, that is, length of the bar means the speed and the direction of bar means the heading of ship. And light lines mean the traits of ships.

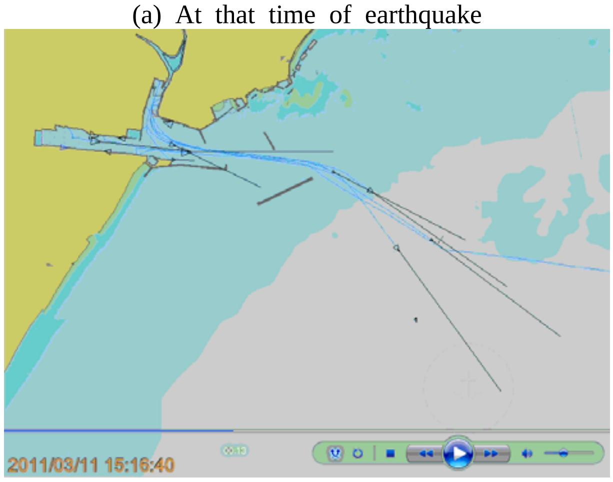
Then, from Fig. 1(b), we found that many ships started to go offshore to evacuate at 30 minutes after the earthquake. Fig.1 (c) shows the behavior of ships at one and half hour after earthquake, it looks like that many ships were push by TSUNAMI. It is reported that TSUMAMI reach to this area around 4 pm, which is about between 1 hour and 1.5 hours after earthquake. Then, many ships could escape TSUNAMI, but several ships, which started go offshore lately, could not evacuate and were repelled from TSUMANI to bay.

Fig.1 (d) shows the behavior of ships at three hours after earthquake. We found that several ship remain the bay because they fail to escape.

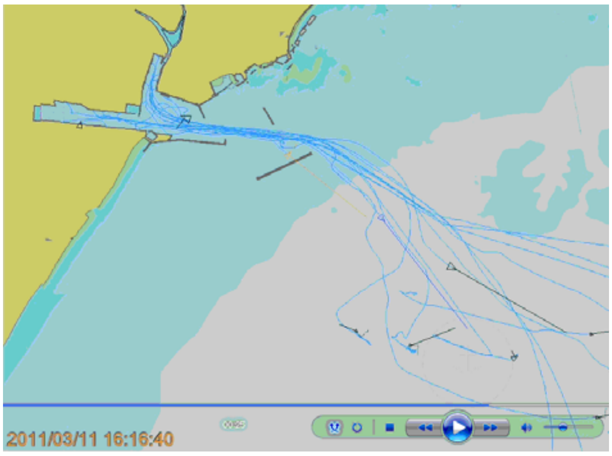
Then, we found that ship started go offshore early could escape the TSUNAMI. Japan Coast Guard also recommends going away off the port for safety of ships in case of TSUNAMI. And this is the cope with the TSUNAMI. But, sailors are not always on ship and many sailors are on the ground when the ship is anchoring. So, to go offshore the ship, the sailors must rerun the ship quickly. But, the roads to the port on the ground are crowded because many people evacuate from TSUNAMI for the hill. Then, it will be done to confront the crowded for the port.



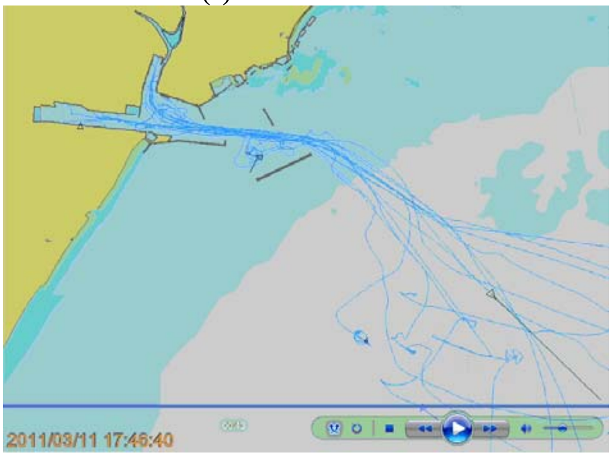
(a) At that time of earthquake



(b) after 30 minutes



(c) After 1.5 hour



(d) After 3 hours

Fig. 1. Traits of large big ships

After the earthquake, many people will move to get away. And staffs of local public bodies lead refuge or staffs of peace or rescue organization, such as policemen, firemen or coast guard staffs, go to the office urgently. Then, there occur very traffic jam and it is difficult to arrive at the destination. We investigate the evacuation to shelter from TSUNAMI of refugees and perform the own mission of staffs.

Indeed, staffs of local public bodies or city worker have to lead refuge or broadcast for going away to hills. Staffs of Japan Coast Guard have to go to work, that is, he has to go port after the big earthquake immediately. And some fire brigades have to go to shut the floodgate in case of TSUNAMI.

At the beginning, we thought about on the sea to escape the ships. But, the ships could not launch because the sailor could not gather the ship in time in many cases. So, we expand the research area not only on the sea but also on the land. Moreover, when we think about disaster prevention, we tend to focus on the refuge of people. On the other hands, there are many people to support the refugee. And they want to complete the mission, safety. But, there occur very traffic jam and it is difficult to arrive at the destination.

Then, we investigate the evacuation to shelter from TSUNAMI of refugees and action to perform the own mission using multi-agent simulation.

4 MODEL

We have an idea of simulation of earthquake and TSUNAMI. We denote briefly as follows.

4.1 Space

We deal with land and ocean. The sample is shown Fig.2 using Google Map (http://www.google.co.jp). In land, there are many roads and almost people move on the roads to get away. And people want to get away in time to survive. So, behaviors of people are restricted by space and time. But, there might be traffic jam or the road might cut by earthquake. Then, there need to control traffic. On the other hand, sailors gather to port to launch the ship to offshore. If sailor is in town, he will be done to confront the crowded for the port to go back to port.

Then, when the sailors gather to the ship, the ship will launch to offshore. On the sea, ship can move freely because there are not specified road. But, if ship move freely, ships can corrupt each other or ship can go aground. Then, it becomes difficult for ships to go away. Especially after earthquake, almost all are in hurry. Then, we design the sea route for simplify the simulation.

In fact, the performers on the sea is very few, comparing with on land because only few people have ship, such as fisher, ferry company, Japan Coast Guard. That is why multi-agent simulation on the sea is few and agent in the sea such as fish often moved freely on the sea. And agents move shortsightedly, such as fish go to the nearest plankton and eat it. So, if there is obstacles in front of the fish, it cannot eat the over the obstacle. But, ship is clever because sailors ride on. And they have a map and they know the land and the obstacles. To realize the ships as agent, it is simple to design the ocean route similar on land.

Fig. 2. Image of simulation

4.2 Agent

We define the agents as Table 1. Refugee agent evacuate from TSUNAMI shelter or hill immediately. City worker agent of local public bodies broadcasts the information about TSUNAMI and leads refuge or patrol the town immediately. And policeman agent goes to point of traffic jam or traffic accident immediately. Fireman agent leads refuge. Sailor agent in town goes to the port. If sailors of ship are gathered, the ship agent leaves the port t to offshore.

Table 1. Agents in simulation

	Behavior	Destination	Start time
Refugee	Move	Hills	Immediately
City worker	Stay building		Immediately
	patrol		Immediately
policeman	Move	Traffic jam point	Immediately
fireman	patrol		Immediately
Sailor	Move	Port	Immediately
ship	move	offshore	when sailors gather

4.3 Behavior of agent

4.3 Simulation

We are now programming using multi-agent simulator Artisoc [4]. Artisoc allows us to easily and quickly reproduced on a computer interactions between humans, is a multi-agent simulator to analyze social phenomena alive dynamically changing.

Artisoc, the five-year plan implemented in fiscal 2003 Scientific Creation Project "social order change research by the multi-agent simulator," which was developed as part of copyright, Ltd. Kozo Keikaku belong to both the Graduate School of Arts and Sciences, Professor, University of Tokyo Susumu Yamakage.

Using this simulator, some disaster or accident are dealt with such as TSUNAMI in Okushiri in 1993, accident on Akashi footbridge in 2001.

4 CONCLUSION

Now, we are discussing and programming the simulation. We analyze about ships evacuation from TSUNAMI using multi-agent simulation and we want to prepare for a coming earthquake. When considering evacuation, we often stick to only refuge to a hill and a shelter to get it. And staffs of local public bodies lead refuge or staffs of peace or rescue organization go to the office urgently. Then, there occur very traffic jam and it is difficult to reach the destination. We investigate the evacuation to shelter from TSUNAMI of refugees and perform the own mission of staffs.

Abstract: Target enclosure by autonomous robots is useful for many practical applications, for example, surveillance of disaster sites. Scalability is important for autonomous robots because a larger group is more robust against breakdown, accidents, and failure. However, it is more difficult to operate a larger group of robots because their individual capacity for recognizing teammates should be higher. In this paper, to achieve a highly scalable target enclosure model, we demonstrate a new condition for Takayama's enclosure model. The original model requires a static relationship between agents. However, robots can form an enclosure even under a dynamic topology on the basis of a nearest neighbor graph; hence, they do not require recognition capability. We confirm this by an analytical discussion of switched systems and a series of computer simulations.

Keywords: Collective Intelligence, Distributed robotics, Formation, Cyclic pursuit, robot swarm

1 INTRODUCTION

In this paper, we propose a new condition for Takayama's target enclosure model [10] that can allocate robots to an unspecified number of targets.

Target enclosure, which is useful for monitoring disaster sites and unknown vehicles, has recently become an important goal for multiple robots. Robots can operate in dangerous circumstances, replacing human presence.

Disaster sites are usually far from an operator. In this case, a group of robots examines the exact number of sites to be observed and their locations. Therefore, it is desirable that more robots than necessary are employed, which enables them to accept a larger number of targets . For this purpose, the tasks of target allocation and target enclosure must be performed simultaneously.

However, it seems difficult for most target enclosure models proposed so far to realize this requirement.

Several related studies deal with target enclosure[12][5][4][10]. Except for the study of Kobayashi et al.[5], all other studies require that a particular physical arrangement of the robots be maintained in order to build a target enclosure. For example, Yamaguchi[12] discussed a target capturing task in which the robots must maintain a chain structure. Kim et al.[4] discussed the target enclosure problem; in their solution, each robot needs information on the relative speed of one robot and relative geographical relation to its target to determine its behavior. If the relationship between a robot and its reference robot is considered as a link in graph theory, the graph of the group of robots must follow a Hamiltonian cycle.

When a robot changes the target to be enclosed, the following two events should be considered: withdrawal and accedence of the robot. In the former, the remaining robots in the group must maintain the constraint of the Hamiltonian cycle without the removed robot. In the latter, a group that satisfies the Hamiltonian cycle condition and the new member must form a new Hamiltonian cycle. As far as we know, discussion of these events is inadequate when there are no restrictions on the timing of withdrawal and accedence of robots.

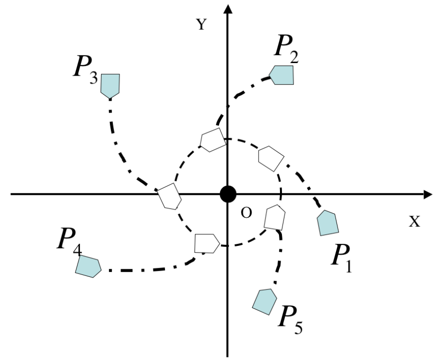

Fig. 1. Process of target enclosure using five robots.

Therefore, we investigated the relaxation of the condition of maintaining a Hamiltonian cycle to achieve target enclosure. In particular, we focused on the study of Takayama et al.[10]. In their model, each robot needs information of one neighbor and its target. As in other studies, this model also requires the Hamiltonian cycle constraint. However, in this paper, we show that this model can realize target enclosure without this constraint when each robot bases its behavior on information from its nearest neighboring robot. Therefore, in this model, robots can change targets without considering the above two events.

Note that the reference relationships among more than four robots in the proposed nearest neighbor model are often unconnected in the graph theory sense. Therefore, it is not

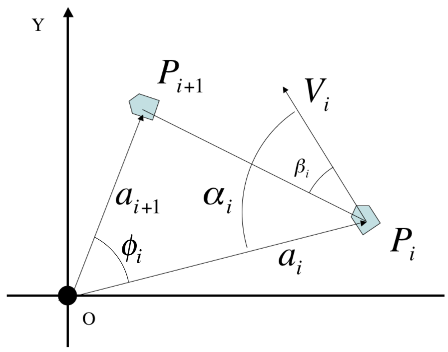

Fig. 2. Model of Takyama's target enclosure: α, β.

easy to discuss this issue using a graph Laplacian, which is the primary analytical approach used for multirobot systems. In this paper, the theory of switched systems[7] is adopted for analyzing groups of less than five robots. A series of computer simulations is used for larger groups.

This paper is organized as follows. First, Takayama's model is introduced. Next the proposed method based on using the nearest neighbor as a reference is presented, and the problems in verifying its ability to form a target enclosure are discussed. In section 4, the practical asymptotic stability of a small group is proven analytically. In addition, we use computer simulations to demonstrate the ability of a larger group to achieve target enclosure.

2 TAKAYAMA'S TARGET ENCLOSURE MODEL

Firstly, Takayama's target enclosure model is explained.

2.1 Takayama's target enclosure model

In this section, we assume that all robots choose the same target. We assume that on a two-dimensional (2D) plane, there is only one target O at the origin and n robots. Fig.1 illustrates the case of $n = 5$. Robots are numbered counterclockwise as $P_1, \ldots, P_n$, and r_i is the position vector of the robot P_i. In the target enclosure task, each robot moves to the corresponding white marker.

To achieve this task, Takayama et al.[10] proposed the following model. Each robot determines its control input, speed v_i, and angular velocity ω_i using two aspects of angular information: relative angles with respect to the target and an anterior neighboring robot,denoted as α_i and β_i, respectively. As a result, rotational movement occurs with a central focus on the target.

$$v_i = f\beta_i \tag{1}$$

$$\omega_i = v_i/\bar{r} \quad k\cos\alpha_i, \tag{2}$$

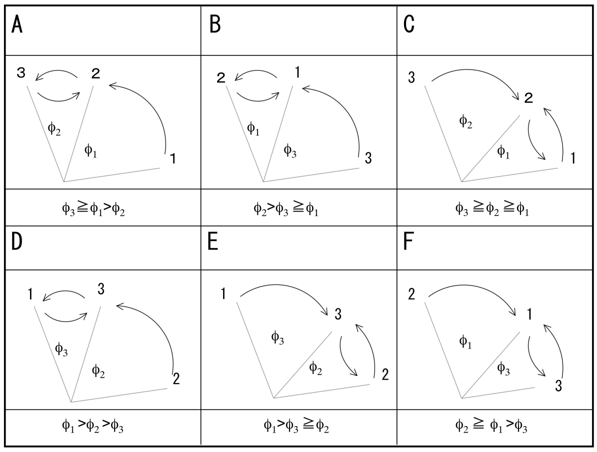

Fig. 3. Patterns of reference relationships among robots in a three-robot group.

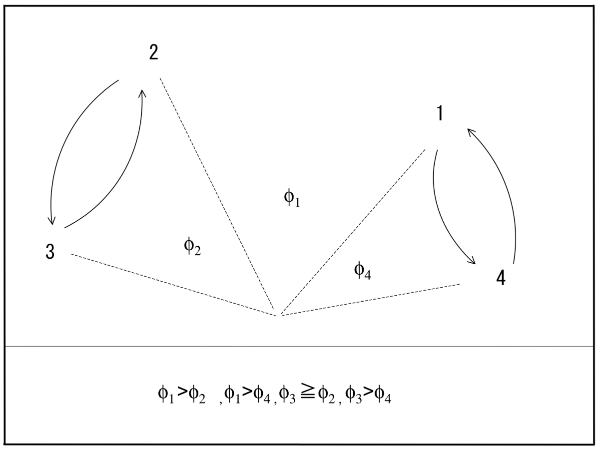

Fig. 4. Unconnected pattern of reference relationships in a four-robot group.

where the parameters $\bar{r}, k$, and $f > 0$ specified beforehand. P_{i+1} is the robot to which P_i refers, and $\bar{r}$ is the expected distance to the target. In Takayama's model, the i-th robot refers to the $i+1$-th robot, and the n-th robot refers to the first robot P_1. That is, if the relationship between a robot and its reference robot is considered as a link in graph theory, the graph of the group of robots must be a Hamiltonian cycle. The authors proved the convergence to the goal state of the target enclosure under this constraint.

Takayama et al. reported the following three characteristics of their model. (E1) The distance between the target and each robot converges to $\bar{r}$. (E2) The speed vector V_i and the vector $(O \quad P_i)$ are orthogonal. (E3) The gaps between a robot and its neighbors are equalized, i.e., $\ _i = \frac{2\pi}{n}$.

3 NEW REFERENCE RULE PROPOSAL OF TAKAYAMA'S MODEL

3.1 Takayama's model considering the nearest neighboring robot as the reference

In this paper, the robots observed by the i-th robot are considered to be its reference robots. In the original Takayama's model, the i-th robot P_i's reference robot is the $i+1$-th robot P_{i+1}. This relationship forms a Hamiltonian cycle. As mentioned above, this constraint makes target allocation behavior difficult. It also causes the scalability problem. Furthermore, each robot must identify its reference robot from the group of robots. This typically becomes difficult as the group size increases.

Therefore, we examine a new reference robot scheme in which each robot considers its anterior neighboring robot as its reference robot. Each robot controls itself as described in equations 1 and 2, but it chooses its nearest neighbor as its reference robot. If possible, the robots can change their target during the target allocation task. Such a system also has higher scalability because individual robots need not be identified to observe the nearest robot.

3.2 Problems in verification of the proposed reference model

In the work of Takayama et al.[10], the model was proven analytically by two approaches: convergence of the distance from the target and convergence of the distance between robots. The former convergence holds true for our proposed model.

In contrast, the result of the latter approach in which the angle between each adjacent robot converges to 2 $/n$ does not apply in our proposed model because Takayama's proof assumes that the relationship between the robot and its reference robot is static and robots are connected in the graph theory sense, as in references [8], [8], [9], and [10]. However, this assumption is inadequate for the following reasons.

1. The reference relationship in the proposed model changes dynamically. For example, there are six graphical patterns for the three-robot group (see Fig.3.).

2. The graph is not connected when $n > 3$. If $n \quad 3$, the graph is dynamic but connected (at least, it is weakly connected as a digraph). However, when $n > 3$, unconnected patterns appear, as shown in Fig.4.

Because of these two differences, alternative approaches of verifying the proposed model are required.

4 VERIFICATION OF THE PROPOSED NEAREST NEIGHBOR REFERENCE MODEL

In this section, switched systems theory is adopted to verify the convergence of the angle between a pair of neighboring robots in the three- and four-robot groups.

First, the target enclosure problem is defined.

4.1 Definition of enclosure task

In this paper, the target enclosure task for an n-robot group is defined as follows. The task consists of determining the distance to the target and equalizing the gap angle.

The distance task is

$$E_d = \sum_{i=1}^{n} (r_i \quad \bar{r})^2. \tag{3}$$

The angle equalization task is

$$E_a = \sum_{i=1}^{n} (\;_i \quad \frac{2}{n})^2. \tag{4}$$

Because of these two requirements, the robots are deployed evenly on a circle having a radius of $\bar{r}$.

4.2 Verification using switched system

The results of the switched system are used here. Instead of the graph Laplacian, the Poincaré-Bendixson theorem[3] can be used, but this theorem is generally applicable only to systems with two variables. In contrast, the results of the switched system adopted here can be used to examine the convergence property of a small group of robots.

4.3 Switched systems

A switched system is defined as[7, 11]

$$\dot{x} = f_s(x), \tag{5}$$

where $x \in R^n$ is a continuous state variable, and $\dot{x}$ is its derivative. Furthermore, S is a set of discrete values s, and s is static even if t and/or x change. In this case, reference [11] proves the sufficient condition for the practical asymptotic stability of the switched system. Let $V(x)$ be a continuous differentiable positive definite function. In addition, we assume that a set of positive values $\Omega_\rho = \{x \in R^n : V(x) \quad \rho\}$ is bounded. In this case, the switched system exhibits practical asymptotic stability for any $D \subset \Omega_\rho$ when the following conditions are satisfied.

$$a) \quad \min_{s \in S} \frac{\partial V}{\partial x} f_s(x) < 0, \;\; \forall x \in \Omega_\rho \quad \{0\} \tag{6}$$

$$b) \quad 0 \in Int(C), \tag{7}$$

where $Int(C)$ is the interior of (C). C is given as

$$\begin{aligned} C &= conv(\{f_s(0) : s \in S\}) \\ &= \{\sum_{s\in S} \lambda_s f_s(0) : \lambda s \quad 0, \sum_{s\in S} \lambda_s = 1\}. \end{aligned} \tag{8}$$

We assume that a sufficient time has passed so that all the robots are near their common target. Furthermore, we assume that the distance between the robots and the target is $\bar{r}$, and each robot determines its nearest neighbor using only the angle with respect to its neighbor. In this case, the angle $_i$ between the i-th robot and its reference robot is expressed as follows.

Case 1: $_{i+1} \quad _i, \; _i \quad _{i\ 1}$

$$\frac{d \ _i}{dt} = \frac{b}{2}(\quad _i + \ _{i\ 1}) \tag{9}$$

Case 2: $_{i+1} < \ _i, \; _i \quad _{i\ 1}$

$$\frac{d \ _i}{dt} = \frac{b}{2}(\ _{i+1} + \ _{i\ 1} \quad 2 \ ) \tag{10}$$

Case 3: $_{i+1} \quad _i, \; _i < \ _{i\ 1}$

$$\frac{d \ _i}{dt} = b(\quad _i) \tag{11}$$

Case 4: $_{i+1} < \ _i, \; _i < \ _{i\ 1}$

$$\frac{d \ _i}{dt} = \frac{b}{2}(\ _{i+1} \quad _i) \tag{12}$$

where $b = f/\bar{r}$. In this case, the dynamics of their angles is considered to represent a switched system according to each robot's three angles $_{i\ 1}, \ _i, and \ _{i+1}$.The heading direction d_i of the i-th robot can be described by $_{i\ 1}$ and $_i$ as follows.

$$d_i = \begin{cases} 1 & (\ _i \quad _{i\ 1}) \\ 0 & (otherwise) \end{cases} \tag{13}$$

where "0" and "1" indicate a counterclockwise and clockwise heading direction, respectively. By using equation 13, equations 9-ref(84) are written as follows.

$$\dot{} = A_s \quad + B_s \tag{14}$$

$$= [\ _1 \cdots \ _i \cdots \ _n]^T \tag{15}$$

$$A_{s,i,j} = \begin{cases} \frac{b}{2} d_i & (j = i \quad 1) \\ \frac{b}{2}(d_{i+1} \quad d_i + 1) & (j = i) \\ \frac{b}{2}(1 \quad d_{i+1}) & (j = i + 1) \\ 0 & (otherwise)) \end{cases} \tag{16}$$

$$B_i = \ (d_{i+1} \quad d_i) \tag{17}$$

$$s = \{d_1, \ldots, d_i, \ldots, d_n\} \in \{0, 1\}^n \tag{18}$$

where $_n = 2 \quad \sum_{i=1}^{n\ 1} \ _i$. For simplicity, let $b = 1$ in the remainder of this paper. In the next subsection, we prove the practical asymptotic stability of the system represented by equation 14.

4.4 A four-robot group

In this section, we discuss the practical asymptotic stability of a four-robot system. A four-robot group has 14 control inputs, $s = \{1, 0, 1, 0\}$, $\{1, 0, 0, 1\}$, $\{0, 1, 1, 0\}$, $\{0, 1, 0, 1\}$, $\{0, 0, 1, 1\}$,
$\{1, 1, 1, 0\}$, $\{1, 1, 0, 1\}$, $\{1, 0, 1, 1\}$, and $\{0, 1, 1, 1\}\}$.

When $s = \{1, 0, 0, 0\}$, the result of the left of equation 6 in this case by using equation 16 is $w(\ ) = \ 4 \ ^2 \quad 3 \ _1^2 \ 4 \ _1 \ _2 \quad 3 \ _2^2 + 6 \ (\ _1 + \ _2) + 8 \ _3 \quad 6 \ _1 \ _3 \quad 4 \ _2 \ _3 \ 4 \ _3^2$. Therefore, the maximum of $w(\ )$ in the given range is calculated by a Lagrange multiplier. We rewrite $z(\ ) = \ w(\ )$ as a minimization problem.

The set of constraints representing the control input $s = \{1, 0, 0, 0\}$ is $_1 > \ _4 \wedge \ _2 < \ _1 \wedge \ _3 < \ _2 \wedge \ _4 < \ _3 \wedge \ _1, \ _2, \ _3 > 0, \ _4 > 0$. We define the following functions from this condition by adding equal conditions for convenience.

$$\begin{aligned} g_1(\ ) = 2 \quad 2 \ _1 \quad _2 \quad _3 \quad 0 \\ g_2(\ ) = \ _2 \quad _1 \quad 0 \\ g_3(\ ) = \ _3 \quad _2 \quad 0 \\ g_4(\ ) = \ _1 \quad 0 \\ g_5(\ ) = \ _2 \quad 0 \\ g_6(\ ) = \ _3 \quad 0 \\ g_7(\ ) = \ 2 \ + \ _1 + \ _2 + \ _3 \quad 0 \end{aligned} \tag{19}$$

$$\begin{aligned} \nabla g_1 = [\ 2 \quad 1 \quad 1]^T, \nabla g_2 = [\ 1\ 1\ 0]^T \\ \nabla g_3 = [0 \quad 1\ 1]^T, \nabla g_4 = [\ 1\ 0\ 0]^T \\ \nabla g_5 = [0 \quad 1\ 0]^T, \nabla g_6 = [0\ 0 \quad 1]^T \\ \nabla g_7 = [1\ 1\ 1]^T \end{aligned} \tag{20}$$

Then, the following Karush-Kuhn-Tucker conditions are obtained from $\nabla z(\ ) + \sum_i^7 \nabla g_i(\ ) = 0$.

$$\begin{aligned} 6 \ _1 + 4 \ _2 \quad 6 \ + 6 \ _3 \quad 2u_1 \quad u_2 \quad u_4 + u_8 = 0 \\ 4 \ _1 + 6 \ _2 \quad 6 \ + 4 \ _3 \quad u_1 + u_2 \quad u_3 \quad u_5 + u_7 = 0 \\ 6 \ _1 + 4 \ _2 \quad 8 \ + 8 \ _3 \quad u_1 + u_3 \quad u_6 + u_7 = 0 \\ u_1(2 \quad 2 \ _1 \quad _2 \quad _3) = 0, \ u_1 \quad 0 \\ u_2(\ _2 \quad _1) = 0, \ u_2 \quad 0 \\ u_3(\ _3 \quad _2) = 0, \ u_3 \quad 0 \\ u_4(\quad _1) = 0, \ u_4 \quad 0 \\ u_5(\quad _2) = 0, \ u_5 \quad 0 \\ u_6(\quad _3) = 0, \ u_6 \quad 0 \\ u_7(\ 2 \ + \ _1 + \ _2 + \ _3) = 0, \ u_7 \quad 0 \end{aligned} \tag{21}$$

This equation reveals that the maximum of $w(\ )$ in the given range is $w(\ ) = 0$ at $_1 = \ _2 = \ _3 = \ _4 = \frac{\pi}{2}$.

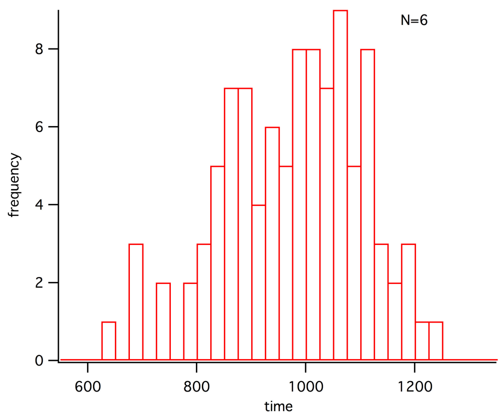

Fig. 5. Time to achieve enclosure task by 6 robots group

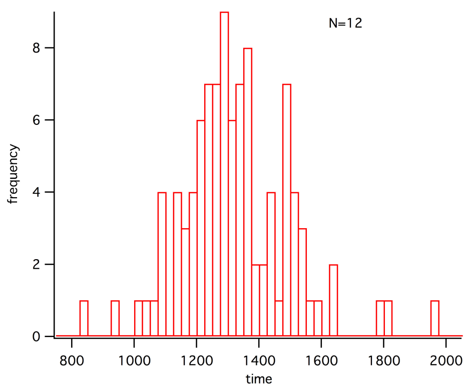

Fig. 6. Time to achieve enclosure for 12-robot group.

Therefore, equation 6 is satisfied when this control signal s is activated.

We verify the maximum of $w(\ )$ for all other s values in a similar manner.

When $s = \{0, 1, 0, 0\}$, $w(\ ) = \ \ 4 \ ^2 \ \ \ 4 \ ^2_1 \ \ \ \ ^2_2$ $2 \ _2 \ _3 \ \ \ 3 \ ^2_3 \ \ \ 2 \ _1(\ _2 + 2 \ _3) + 2 \ (4 \ _1 + \ _2 + 2 \ _3)$. The maximum of $w(\ )$ is 0 at $(\ _1, \ _2, \ _3) = (\frac{\pi}{2}, \frac{\pi}{2}, \frac{\pi}{2})$.

In the same manner as these cases, the maximum of $w(\ )$ in all of the remaining cases, is 0.

Therefore, equation 6 is satisfied for any control input s. Furthermore, $C = \{0\}$ satisfies $0 \in Int(C)$ because $\ _1 = \ _2 = \ _3 = \ _4 = \frac{\pi}{2}$ is a fixed point for which $f_s(\ ) = 0$ for all f_s. Therefore, equation 7 is satisfied.

4.5 Verification of target enclosure task for larger groups

The above discussion shows that the proposed model can achieve angle equalization for a small group. However, we did not provide the proof of the distance task represented by equation 3. In addition, we did not verify the performance for groups of more than four robots. Therefore, in this section, we discuss the ability to achieve target enclosure by using computer simulations.

We examined 3-, 4-, 6-, and 12-robot groups. There was only one target at the origin, and it was assumed that $\bar{r} = 20$. The initial position of a robot was specified inside a 100 100 rectangular region by a 2D uniform random number generator. We counted the time to achieve target enclosure as the time until $E_d + E_a < 0.5$ in equations 3 and 4. This simulation was repeated 100 times for each group size.

Fig.5,6 show the results for the 3-, 4-, 6-, and 12-robot groups, respectively. The x-axis of each graph indicates the time required to achieve enclosure, and the y-axis denotes the frequency. For the three-robot system, the average time required for enclosure is 813.123, and the standard deviation is 125.737. For the four-robot system, the average time is 813.123 and the standard deviation is 125.737. For the six-robot system, the average time is 874.143 and the standard deviation is 96.921. For the 12-robot system, the average time is 1044.371 and the standard deviation is 115.408.

Thus, as the number of robots increases, the time required to achieve target enclosure increases. However, in all the simulations, groups of any size can achieve this task. Therefore, we conclude that any group of fewer than 13 robots can achieve target enclosure.

5 CONCLUSION

In this paper, to achieve a highly scalable target enclosure model, we examined a new reference model based on that of Takayama et al., in which each robot determines its actions according to its nearest neighboring robot. We demonstrated the model's performance using an analytical discussion and a set of computer simulations. Conventional research on target enclosure assumes that a robot can recognize predefined team-mates from among many robots. However, this recognition becomes difficult as the group size increases. In the proposed model, a robot does not need this recognition capability. The results of switched systems theory were applied instead of the graph Laplacian to prove the convergence to an enclosure state because the connectivity of the reference relationship among robots is not maintained. We analytically proved that a group containing fewer than five robots can enclose a target. Computer simulations with n = 3, 4, 6, and 12 suggest that a group of 12 or fewer robots can enclose a target.

Abstract: Optically reconfigurable gate arrays (ORGAs) consisting of a holographic memory, a laser diode array, and a programmable gate array were developed to realize an artificial brain system for robots. In the ORGA, much information or many reconfiguration contexts can be stored in a volume-type holographic memory and can be programmed dynamically onto a programmable gate array at nanosecond-order perfectly in parallel. Therefore, by exploiting the huge storage capacity of the holographic memory and large parallel operations on a programmable gate array, huge parallel brain operations can be executed quickly on an ORGA. This paper presents a proposal of a binary MEMS-interleaving reconfiguration operation on an optically reconfigurable gate array for an artificial brain system.

Keywords: Field programmable gate arrays, optically reconfigurable gate arrays, programmable logic devices.

1 INTRODUCTION

An adult human brain holds more than 100 billion neurons and more numerous synapses connecting them [1]–[3]. To realize an artificial neural network system that can provide performance similar to that of a human brain, a huge number of parallel operations must be executed on an embedded system. In this case, a three-dimensional very large scale integration (VLSI) technology is one candidate.

However, fortunately, the response time of each neuron of a human brain is about 1,000,000 times slower than that of the currently available VLSIs. Therefore, for emulation of a human brain, one neuron circuit can serve 1,000,000 neuron operations. Despite that rapid performance, since the storage capacity and bandwidth of synaptic connections of a human brain are extremely large and broad, respectively, the capabilities of current silicon memories remain insufficient to emulate synaptic weights.

Holographic storage systems are excellent candidates for such human brain systems since three-dimensional holographic memories can easily provide large storage capacity. The density potential reaches V/λ^3, where V denotes the recording volume and λ is the wavelength of the recording light source [4][5]. For example, photorefractive crystal holographic memories $LiNb0_3$ can store 100 bits/μm^2 [6] and can achieve 100 Gbit/in^2 [7]. The area densities are superior to even the latest 32 nm process dynamic random access memory (DRAM) cell with area of 0.039 μm^2 [8].

To date, optically reconfigurable gate arrays (ORGAs) have been developed to realize next-generation large-virtual gate count programmable VLSIs [9]–[12]. An ORGA typically comprises an ORGA-VLSI, a holographic memory, and a laser array. The ORGA-VLSI is a fine-grained gate array, as are field-programmable gate arrays (FPGAs)[13],[14]. Its function is the same as those of currently available FPGAs, but the ORGA-VLSI configuration procedure is executed optically. In an ORGA, many configuration contexts can be stored on a holographic memory that is addressed by a laser array, and which can be implemented dynamically onto the ORGA-VLSI in a very short time [11]. By virtue of those features, the ORGA can achieve numerous virtual gates along with a high-speed nanosecond-order context switching capability. Using these features, vastly numerous synaptic weight operations and neuron operations can be executed. However, although the ORGA architecture presents such advantages, an important issue is its future mass production. The salient cost problem is posed by the laser array. For example, to implement a million reconfiguration contexts onto an ORGA, a million lasers must be implemented onto the ORGA, but a laser array with numerous lasers is invariably expensive. In contrast, other components such as photopolymer holographic memory materials and a standard process ORGA-VLSI are cheap. Therefore, the number of lasers presents an important concern in developing ORGAs.

Recently, a useful microelectromechanical system (MEMS) technology, a digital micromirror device (DMD), was produced by Texas Instruments Inc. [15],[16]. The specifications of a DMD device are presented in Table 1. A photograph of the chip, which consists of 1,024 × 768 mirrors, is portrayed in Fig. 1. Potentially, it can address numerous reconfiguration contexts. Although the response time of the DMD device is slow, many interleaving methods have been proposed to increase the speed of slow response devices, particularly the speed of memory devices [17]–[20].

Therefore, this paper presents a proposal of a binary

MEMS optically reconfigurable gate array for use in an artificial brain system based on a binary MEMS-interleaving method.

2 BINARY MEMS-INTERLEAVING METHOD

2.1 MEMS device

As explained previously, the MEMS device described in Table 1 and presented in Fig. 1 has 1,024 × 768 tiny mirrors, each having a size of 10.8 × 10.8 μm^2. For example, if the DMD device is implemented and each mirror is used for addressing one configuration context, then 786,432 configuration contexts can be addressed. Therefore, the MEMS is useful for addressing numerous reconfiguration contexts. However, the microsecond-order switching of the MEMS device is not sufficiently fast. In artificial brain operations on an ORGA, the gate array must be reconfigured at nanosecond-order. Therefore, microsecond-order switching speed is insufficient for an artificial brain system.

2.2 Interleaving method

This paper therefore presents a proposal of a binary MEMS-interleaving ORGA designed to achieve a higher reconfiguration frequency than the MEMS switching speed. Up to now, many interleaving methods have been proposed in earlier reports of the literature [17]–[20]. Based on them, the MEMS - laser addressing interleaving method concept was produced. A block diagram of a novel concept of a MEMS-interleaving ORGA is depicted in Fig. 2. In this method, some MEMS mirrors and a laser are grouped to a module, as shown in Fig. 3. In addition, many modules are implemented onto a MEMS-interleaving ORGA. When a certain reconfiguration request arises, firstly, a MEMS mirror angle is changed and then a laser in the same module turns on so that the laser beam is reflected on the MEMS mirror and is incident to a holographic memory. Then, an optical configuration context is read out from the holographic memory and finally, the configuration context is programmed onto an ORGA-VLSI, as shown in Fig. 2. This is a normal reconfiguration procedure. Of course, if a second configuration procedure is executed inside the same module, then the procedure must wait until the first mirror angle is changed to an off state, another mirror angle is changed to an on-state, and the laser turns on again. In this case, the wait period becomes the summation of the MEMS response time and the laser switching period. Consequently, the period of this reconfiguration procedure is longer than the MEMS switching period: no acceleration can be achieved.

However, using the interleaving method, in such a case, a laser of another module, for which the angles of mirrors have already been adjusted and a configuration procedure has been readied, turns on. Furthermore, the lasers on the third module, the fourth module, and so on turn on in sequence. While the other modules function, modules which have completed one configuration procedure start to prepare the next-configuration mirror position. For example, it is assumed that if the respective switching speeds of a laser and MEMS are 10 ns and 10 μs, and 1001 modules which have 1000 mirrors are implemented onto the ORGA, then the ORGA has a million configuration contexts. Each reconfiguration can be executed within 10 ns constantly because mirrors of the idle module can be changed for 10,000 ns while another 1000 modules work for a period 1000 × 10 ns. Therefore, using this method, even a million configuration contexts can be switched by only 1001 lasers.

Up to now, a MEMS-interleaving read operation of a holo-

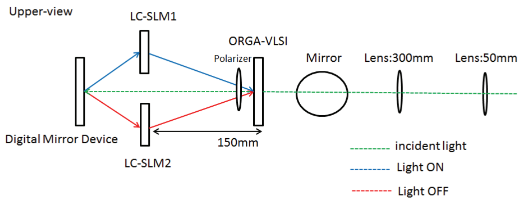

Fig. 4. Experimental system.

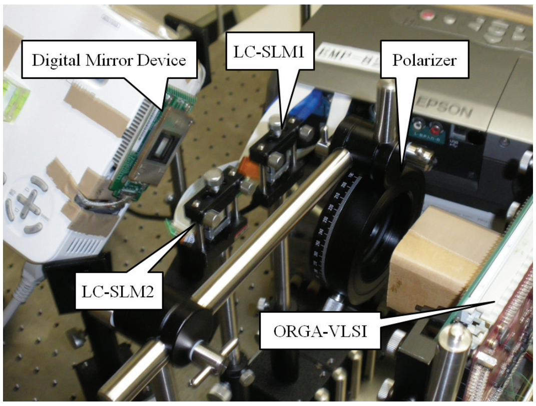

Fig. 5. Photograph of the experimental system.

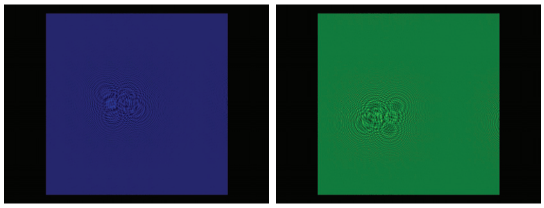
graphic memory, which can control a MEMS mirror as an ON/OFF switch, has been proposed [21]. In this method, 1000 mirrors could only address 1000 configuration contexts. However, if we can use both angles of ON state and OFF state of each mirror for configurations, the number of mirrors can also be decreased. Therefore, this paper proposes a binary MEMS-interleaving method. In this method, a mirror is used to generate two beams instead of ON/OFF states. Therefore, 1000 mirrors address 2000 reconfiguration contexts. Results show that this system uses fewer lasers and fewer MEMS mirrors.

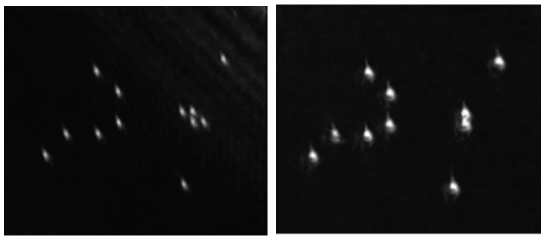
3 EXPERIMENTAL SYSTEM

For this study, a single-module implementation with two configuration contexts was conducted as the first step for binary MEMS-interleaving ORGA development. Figures 4 and 5 respectively portray a block diagram and a photograph of the binary MEMS-interleaving ORGA. The binary MEMS-interleaving ORGA was constructed by using a 532 nm, 300 mW laser (torus 532; Laser Quantum), a MEMS device, two liquid-crystal spatial light modulators (LC-SLMs), and an ORGA-VLSI. The 1.7-mm-diameter beam from the laser source was expanded six times to 10.2 mm using two lenses of 50 mm focal length and 300 mm focal length. The expanded beam is incident to a MEMS mirror device (Digital Mirror Device). In this case, the mirror state is controlled as with a binary state. If the MEMS mirror is +12°, then the reflected laser beam is incident to the LC-SLM1, which



(a) OR circuit (b) AND circuit

Fig. 6. Holographic memory patterns calculated using a personal computer.



(a) OR circuit (b) AND circuit

Fig. 7. CCD-captured images of configuration context patterns of an OR circuit and an AND circuit.

functions as a holographic memory. However, the reflected laser beam is incident to the LC-SLM2 if the MEMS mirror is -12°. Two holographic memory patterns respectively recording an OR circuit and an AND circuit were calculated as shown in Figs. 6(a) and 6(b) and were displayed on LC-SLM1 and LC-SLM2, respectively. Holographic memory patterns comprised 700 × 700 pixels. The LC-SLMs are a 90° twisted nematic device with a thin film transistor. Each pixel is 12 μm × 12 μm. The first holographic memory pattern shown in Fig. 6(a) is used for +12°-state of a MEMS mirror and the second holographic memory pattern shown in Fig. 6(b) is used for -12°-state of the MEMS mirror. For this implementation, an ORGA was placed 150 mm distant from the LC-SLM. The ORGA had been fabricated using a 0.35 μm triple-metal CMOS process. Photodiodes were constructed between the N-well layer and the P-substrate. The photodiode size and distance between photodiodes were designed as 25.5 × 25.5 μm^2 and as 90 μm to facilitate the optical alignment. The gate array structure is fundamentally identical to that of typical FPGAs. The ORGA-VLSI chip includes 4 logic blocks, 5 switching matrices, and 12 I/O bits. In all, 340 photodiodes were used to program the gate array.

4 EXPERIMENTAL RESULTS

Using the optical system explained above, the binary MEMS-interleaving operation has been confirmed. First, the MEMS mirror angle was adjusted to +12°. Then a laser source was turned on. In this case, the laser beam is reflected on the MEMS mirror. It is then incident to the LC-

SLM1 including a holographic memory pattern of an OR circuit. Finally, the configuration context pattern generated from the holographic memory, as shown in Fig. 7(a), was programmed correctly onto an ORGA-VLSI. For the next experiment, the MEMS mirror angle was adjusted to -12°. Then a laser source was turned on. In this case, the laser beam is reflected on the MEMS mirror. It is incident to the LC-SLM2, including a holographic memory pattern of an AND circuit. Finally, the configuration context pattern generated from the holographic memory pattern shown in Fig. 7(b) was programmed correctly onto an ORGA-VLSI. Therefore, we have demonstrated that one MEMS mirror can address two configuration contexts.

5 CONCLUSION

Optically reconfigurable gate arrays (ORGAs) have been developed to realize artificial brain systems for robots. Nevertheless, conventional ORGAs require many lasers to address the configuration contexts stored on a holographic memory. Such laser arrays with numerous lasers are invariably expensive, which presents an extremely important concern related to their development. Therefore, to address numerous configuration contexts with fewer lasers, this paper has proposed a novel method using a binary MEMS-interleaving ORGA. If a 4,000 $\times$ 4,000 mirror array with 10 μs response time can be used along with about 1,000 lasers that can generate a 10 ns light pulse, then 32 million reconfiguration contexts can be achieved along with 10 ns reconfiguration speed, since two configuration contexts can be addressed by a MEMS mirror. This method can be expected to provide an addressing capability of a billion configuration contexts along with nanosecond-order high-speed configuration capability which is very suitable for emulation of an artificial neural network.

Abstract: This paper presents the finding of the research we conducted to evaluate the variability of signal release probability at Hebb's presynaptic neuron under different firing frequencies in a dynamic stochastic neural network. According to our results, synaptic redistribution has improved the signal transmission for the first few signals in the signal train by continuously increasing and decreasing the number of postsynaptic 'active receptors' and presynaptic 'active-transmitters' within a short time period. In long-run at low-firing frequency it has increased the steady state efficacy of the synaptic connection between Hebbian presynaptic and postsynaptic neuron in terms of the signal release probability of 'active-transmitters' in the presynaptic neuron. However, this 'low-firing' frequency of the presynaptic neuron has been identified by the network when compared it to the ongoing frequency oscillation of the network.

Keywords: Dynamic stochastic network, Hebbian neurons, Synaptic redistribution, Release probability

1 INTRODUCTION

As per recent biological findings a synaptic connection between two neurons is strengthened by increasing the number of postsynaptic receptor channels or by increasing the probability of neurotransmitter release at presynaptic neuron. This functional behavior at synapses is varied if long-term plasticity interacts with the short-term depression, Abbott and Nelson [1]. Short-term depression is an activity dependent reduction of neurotransmitters from the readily releasable pool at presynaptic neurons, Zucker [2]. When long-term plasticity interacts with the short-term depression, the effect is called synaptic redistribution. This synaptic redistribution increases the probability of neurotransmitter release at presynaptically; and subsequently increases the efficiency of signal transmission between neurons and decreases presynaptic readily releasable pool size, Abbott and Nelson [1]. Therefore, the high-frequency dependent increase in synaptic response for the first few spikes in the spike-train is caused because of the redistribution of the available synaptic efficacy and not because of the increase of synaptic efficacy at the steady-state. However, at low-firing-frequencies of presynaptic neuron such as < 10 Hz, an increase of synaptic efficacy at steady state has been observed. This increase of synaptic efficacy depends on the short-term plasticity factors such as probability of neurotransmitter release and time constant of recovery, Markram and Tsodyks [3]. Conversely Okatan and Grossberg [4] suggest that pairing of Hebbian neuron to reach the steady state, might be frequency-dependent and as a result the time taken to reach to the steady-state at high-firing-frequency of presynaptic neuron may be longer than at lower-presynaptic-firing frequencies; therefore even there is steady-state increase of the synaptic efficacy at high-firing frequency of presynaptic neuron, it is not well observed due to the effect of short-term synaptic plasticity factors on the synaptic efficacy. Lisman and Spruston [5] have further added that this increase or decrease of synaptic efficacy at steady state is not merely based on spike arriving time to the synapses but also on the level of postsynaptic depolarization, rate of synaptic inputs and the phase of synaptic input relative to the ongoing frequency oscillations.

2 METHOD

Our modeled neuron had thousands of artificial units, named 'transmitters' and 'receptors'. The 'transmitters' in a presynaptic neuron contacted the corresponding 'receptors' in postsynaptic neuron dynamically according to the presynaptic activity by forming an artificial synaptic connection between the two neurons. Therefore, one can presumes that synaptic connection between the presynaptic neuron and postsynaptic neuron in our network as a dynamic connection which mediates the intercommunication between the presynaptic 'transmitters' and the corresponding postsynaptic 'receptors'. Furthermore these artificial units were two-state stochastic computational units which stochastically updated their signal release probability at time t, i.e. $P(t)$, according to the history of their activity by adapting to the mathematical model of Maass and Zador [6] which describes the signal release probability as a function of spike arrival time and the effect of short-term plasticity. The active state of a given artificial unit at a specified time *t* was determined by the release probability at that time and a threshold value *theta* (θ). The threshold θ was updated according to the feedback of a stability promoting mechanism which sensed the neuronal local excitation and the corresponding postsynaptic excitation as defined in eq. (1) and eq. (2). Thus, an artificial unit was in *active state* at time *t* if $P(t) > \theta$ and was allowed to transmit/receive signals between neurons; otherwise it was in *inactive state*.

3 EXPERIMENT

An experiment was conducted on fully connected neural network which had four neurons namely *A*, *B*, *C* and *D*. The neuron *A* and neuron *B* were set to process similar to the long-term plasticity by setting time decay constants to 30 min while neuron *C* and *D* simulated the short-term effects on the network with time decay constants 100 sec and 15 min respectively. We have shown that with this setting of the network, the neurons *A* and *B* formed a Hebbian pairing and was capable of demonstrating the characteristics explained in fundamental learning theories; Hebb's postulate and Stent's anti-Hebbian postulate, see Fernando, Yamada and Marasinghe [7]. The experiment had three stages where each stage consisted of two phases; correlated and uncorrelated, and each phase consisted of two sessions, namely training and testing sessions. In between sessions, a random delay was introduced. Throughout the experiment, the firing frequency of neurons *B*, *C*, and *D* remained in a constant firing rate at 1 Hz while neuron *A* updated its firing frequency accordingly as it was moved from one stage to the other. At stage-1, the firing frequency of neuron *A* was at 1 Hz, at stage-2 it was 2 Hz and stage-3 it was 0.5 Hz. Therefore, comparatively neuron *A* was in high-firing frequency at stage-2 and was in low-firing frequency at stage-3. At stage-1 the network was allowed to stabilize its activity as a one unit because all the neurons were firing at 1 Hz. Signals in terms of sine waves were externally fed to the network through neuron *A* and neuron *B* based on the phase and the session they were in. The phases were named according to the frequency of the sine waves applied to neuron *B*. Throughout the experiment the frequency of the sine waves applied to neuron *A* was at $f'_A = 1\,\text{Hz}$ and the frequency of the sine waves applied to neuron B (f'_B) was randomly selected from interval (0.95, 1.05) Hz at the correlated phase. At the uncorrelated phase f'_B was randomly selected either from interval (0.5, 0.8) Hz or from interval (1.2, 1.5) Hz. At the training sessions, the external signals were fed to the both neurons but at the testing sessions signals were not externally fed to the neuron *B*. At testing sessions, threshold values of all the four neurons were not updated; the threshold values trained at the training sessions were taken as constants at the corresponding testing sessions. Each neuron had 60,000 artificial units which were uniformly distributed between 'receptors' and 'transmitters'; and subsequently 'receptors' were distributed uniformly between 'receptor-groups'. Initially 1% of the receptors in each receptor group and 1% of the 'transmitters' in each neuron were set to an active state. Fig.1 shows the architecture of the network in abstract.

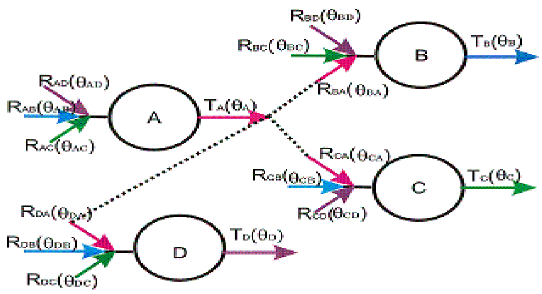

Fig.1. Architecture of the network with dynamic synaptic connections. The developed network had four neurons, each neurons had three 'receptor-groups', and set of 'transmitters'. $T_I(\theta_I)$ denotes the 'transmitters' in neuron *I* and its threshold value. Similarly, $R_{JI}(\theta_{JI})$ denotes the 'receptor-group' in neuron *J* that is contacted by the 'transmitters' in neuron *I*. For simplicity the figure illustrates the communication between the 'transmitters' in neuron *A* with relevant 'receptor-groups' of the postsynaptic neurons only. The dotted connecting lines in the network indicate the dynamicity of the synaptic connection between neurons since it depends on the number of 'active-transmitters' in neuron *A* and their signal release probability, and the number of 'active-receptors' in the relevant receptor-group of the corresponding postsynaptic neuron.

$$\theta_{JI}(t) = f\left(X_{JI}(t)/O_I(t)\right) \qquad (1)$$

$$\theta_I(t) = f\left(O_I(t).(X_{IJ_1}(t) + X_{IJ_2}(t) + X_{IJ_3}(t))\right) \qquad (2)$$

$f(x) = 1/\left(1 - e^{-x}\right)$, $X_{JI}(t) = \left|R_{JI}^{Act}(t)\right| / \left|R_{JI}\right|$, $O_I(t) = \left|T_I^{Act}(t)\right| / \left|T_I\right|$,
$|G|$ – number of components in G, and
$\left|G^{Act}(t)\right|$ - number of acitve components in G at time t

4 RESULTS

The distribution of the number of 'active-transmitters' in neuron *A* and their probability of signal release at each stage, and the distribution of the number of 'active-receptors' in the receptor group R_{BA} that is contacted by the 'transmitters' in neuron *A* through the artificial synaptic connection between neuron *A* and neuron *B* are shown from fig.2 to fig.5.

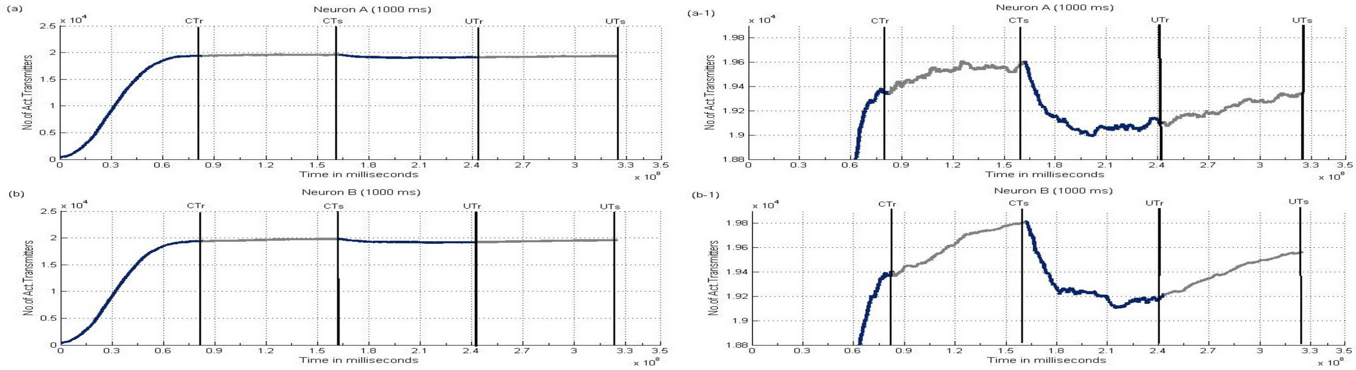

Fig.2. Distributions of 'active-transmitters' in neurons *A* and *B* at stage-1 over the time (a): 'active-transmitters' in neuron *A*, **(b):** 'active-transmitters' in neuron *B*, **(a-1):** Enlarged version of subfigure (a), and **(b-1):** Enlarged version of subfigure (b).

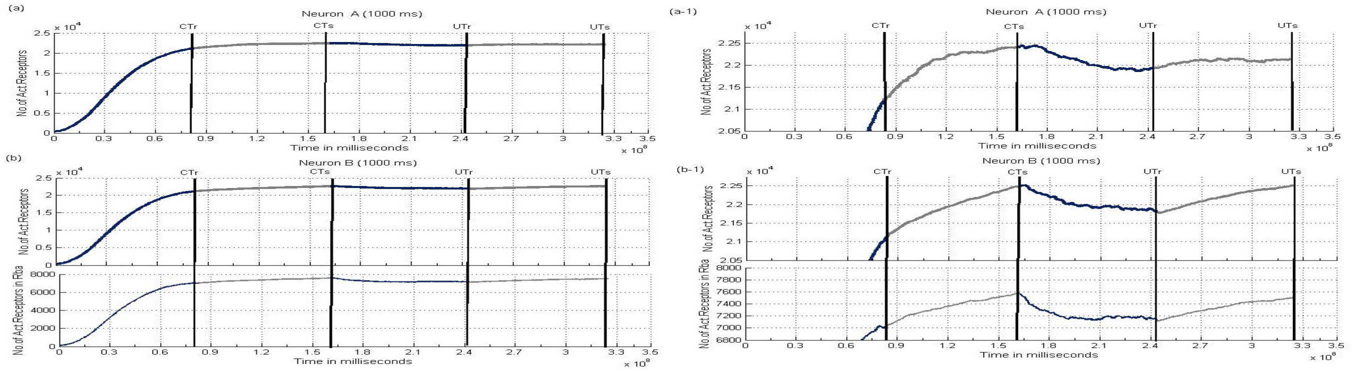

Fig.3. Distributions of 'active-receptors' in neurons *A* and *B* at stage-1 over the time (a): 'active-receptors' in neuron *A*, **(b):** 'active-receptors' in neuron *B* and in R_{BA} respectively, **(a-1):** Enlarged version of subfigure (a), and **(b-1):** Enlarged version of subfigure (b)

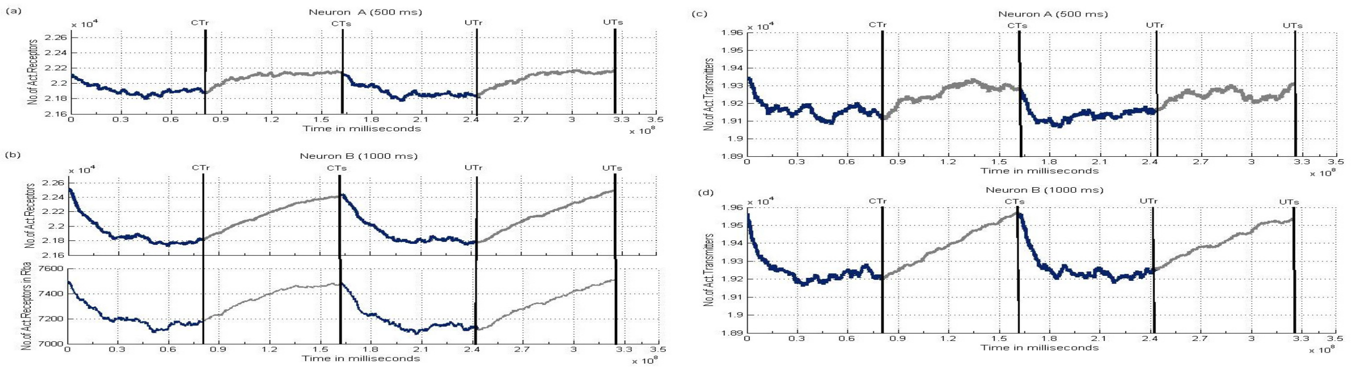

Fig.4. Distributions of active components in neurons *A* and *B* at stage-2 over the time (a): 'active-receptors' in neuron *A*, **(b):** 'active-receptors' in neuron *B* and in R_{BA} respectively, **(c):** 'active-transmitters in neuron *A*, **(d):** 'active-transmitters' in neuron *B*

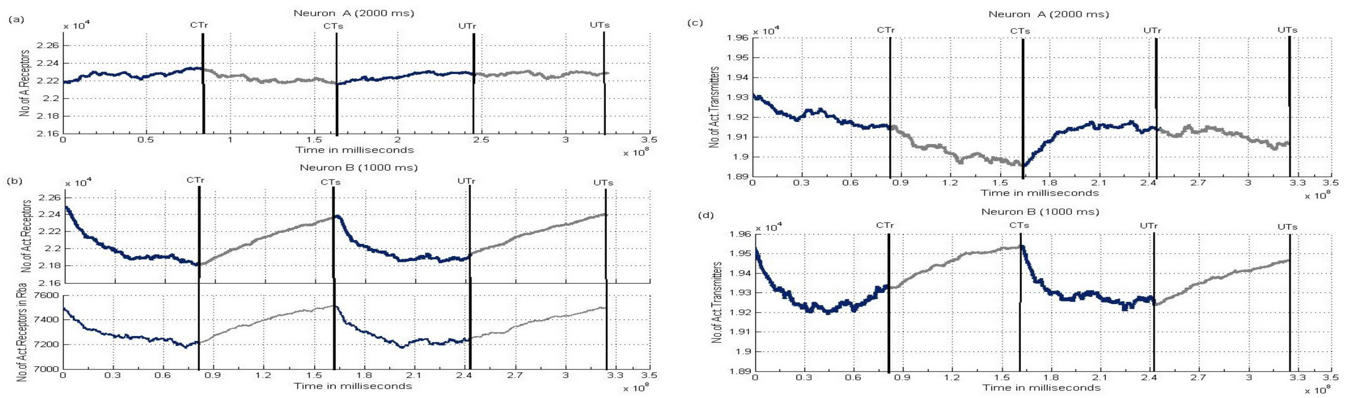

Fig.5. Distributions of active components in neurons *A* and *B* at stage-3 over the time (a): 'active-receptors' in neuron *A*, **(b):** 'active-receptors' in neuron *B* and in R_{BA} respectively, **(c):** 'active-transmitters in neuron *A*, **(d):** 'active-transmitters' in neuron *B*

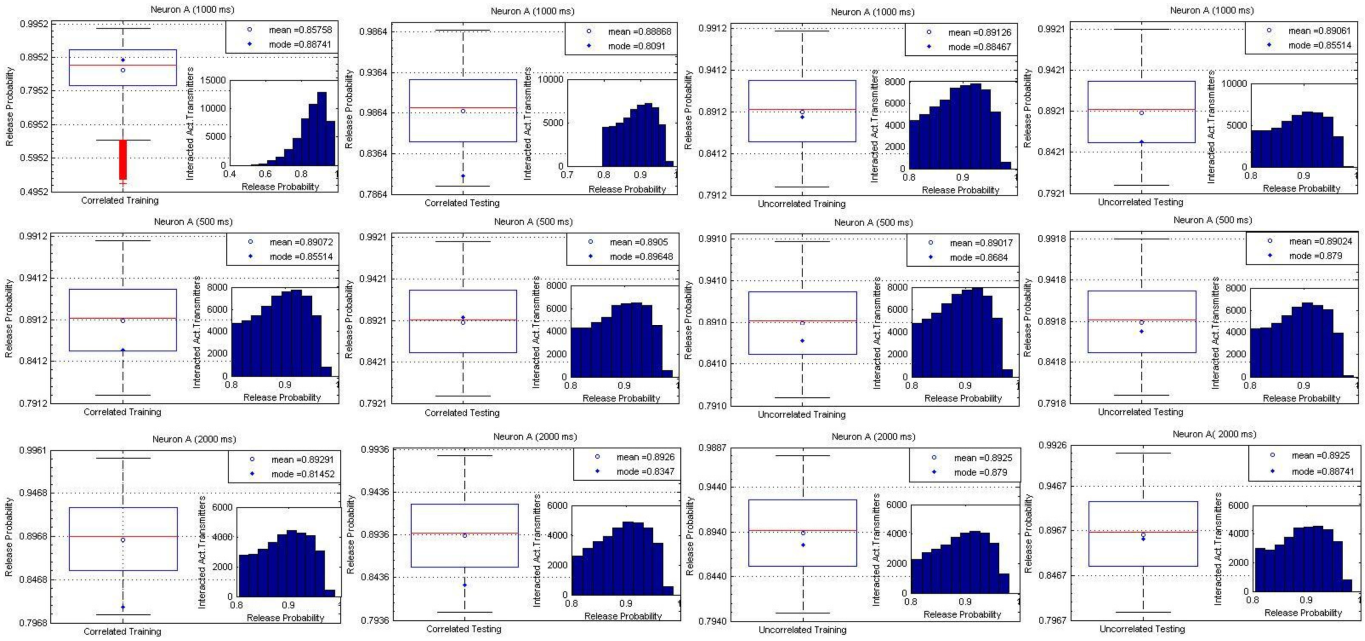

Fig.6. Box plot in each subfigure illustrates the variation of the release probability of the interacted 'active-transmitters' of neuron *A* (i.e., 'active-transmitters' that communicated with 'receptors' in R_{BA} receptor-group during the session). The inner histograms depict the variation of the number of interacted 'active-transmitters' in neuron *A* over the time against the signal release probability at the corresponding session of the stage.

5 DISCUSSION

According to the results of, from fig.2 to fig.5, the increase or decrease of the response of neuron *A* is a continuous insertion and deletion of the presynaptic 'active transmitters; and the redistribution of the number of 'active receptors' of the receptor group R_{BA} in the postsynaptic neuron *B*. Further this dynamic update to the number of presynaptic 'active transmitters' and the number of postsynaptic 'active receptors' in R_{BA} was remained in very short time period, and subsequently presynaptic neuron *A* attained to the steady state. However in long-run we could see that although neuron *A* at high-firing frequency (i.e. at 2Hz in stage-2) increased the number of 'active transmitters', it has not increased the average (mean) signal release probability at the steady state of the synaptic connection compared to when presynaptic neuron *A* fired at low-firing frequency(i.e. 0.5Hz in stage-3, see fig.6). In contrast, at the low-firing frequency of neuron *A,* even though the number of 'active-transmitters' in neuron *A* has decreased (compared to when *A* was at high-firing frequency), the average signal release probability of 'active transmitters' at the steady state has increased, see fig.6. Therefore, synaptic redistribution has improved the transmission for the first few signals in the signal train by dramatically increasing or decreasing the number of postsynaptic 'active receptors'. In long-term at low-firing frequency synaptic redistribution has increased the steady state synaptic efficacy of the synaptic connection (i.e. increase of the signal release probability of 'active-transmitters' in neuron *A*). Further, in our experiment the firing frequency of neuron *A* was always < 10 Hz. Therefore, according to Markram and Tsodyks [3] we were supposed to observe an increase in the efficacy at the synaptic connection between *A* and *B* at all the stages. But, we could observe an increase of the synaptic efficacy only at stage-3, i.e. when neuron *A* was in 0.5 Hz. Therefore the increase or decrease of synaptic efficacy at a steady state may not only base on rate of synaptic inputs but also on the phase of the synaptic input relative to the ongoing frequency oscillations of the network.

Abstract: In this paper, we investigate the effect of synaptogenesis on memories in the brain, using the abstract associative memory model, Hopfield model with the zero-order synaptic decay. Using the numerical simulation, we demonstrate the possibility that synaptogenesis plays a role in maintaining recent memories embedded in the network while avoiding overloading. For the network consisting of 1000 units, it turned out that the minimum decay rate to avoid overloading is 0.02, and the optimal decay rate to maximize the storage capacity is 0.08. We also show that the average numbers of replacement synapses at each learning step corresponding to these two values are 1187 and 21024, respectively.

Keywords: synaptogenesis, zero-order synaptic decay, associative memory, Hopfield model, forgetting process, overloading

1 INTRODUCTION

Memory was considered to consist of three processes: (i) learning and (ii) keeping information in the network, and then, (iii) recalling it when needed. Hopfield model [1], the best-known associative memory model, could reproduce the form of memory in the brain. By changing the synaptic strengths, the model stored memory patterns in the network. Thereafter, this network could retrieve the stored pattern even if given its noisy version. The properties of the associative memory model have been investigated over several decades [1]-[4].

The ordinary Hopfield model has a critical number of memory patterns that can be stably stored, $0.138N$, where N is the system size. The additional learning of new patterns beyond the value overloads the network system, and makes no patterns retrievable [4].

As a matter of fact, the past associative memory model missed the fourth factor of memory, i.e., forgetting old information. If the dynamics of the synaptic strength in the network have decay or saturation, overloading does not occur. The forgetting model, an alternative associative memory model to avoid overloading, was proposed by Mézard et al. [5]. In the forgetting model, every time the network learns a new pattern, the synaptic strength decays in proportion to itself. In this scheme, the old memory traces are erased exponentially with time. However, as yet there is no conclusive experimental evidence for the existence of such a system in the brain.

Recently, it has been reported that synaptogenesis, birth of synapses, continues to take place in certain regions of the postnatal brain including the hippocampal regions [6],[7]. Synaptogenesis, i.e., replacement of old synapses with new ones, seems to be crucial for the formation of neural networks. Thus, it affects neural network functions, especially memory formation. Furthermore, according to the previous neurophysiological experiment, synapses with smaller strength tend to be replaced with higher probability [7]. This raises questions about how this synaptogenesis affects memories in the brain. Should synaptogenesis, which breaks the memory circuit, be a negative factor for memories embedded in the network?

In this paper, we investigate the effect of this synaptogenesis on memories, modeling it mathematically: Hopfield model with the zero-order synaptic decay. In our model, every time the network learns a new pattern, all the synaptic strengths decay a constant value , i.e., decay rate α. This decay process represents the characteristics of the synaptogenesis more exactly than the forgetting model: The smaller synaptic strength is, the more easily synaptogenesis occurs.

From a computational perspective, we demonstrate the possibility that synaptogenesis plays a role in maintaining recent memories embedded in the network while avoiding overloading. Moreover, we show that the storage capacity (maximal number of retrievable patterns in the network) of our model depends on the decay rate. For the network consisting of 1000 units, it turned out that the minimum decay rate to avoid overloading, $\alpha_{\rm min}$, is 0.02, and that the optimal decay rate to maximize the storage capacity, $\alpha_{\rm opt}$, is 0.08. Finally, we show how many synapses are replaced with new ones at each learning step when the decay rate takes these two critical values. For the network consisting of 1000 units, it turned out that the average number of replacement synapses corresponding to $\alpha_{\rm min}$ is 1187, and that corresponding to $\alpha_{\rm opt}$ is 21024.

This paper is organized as follows: Section 2 gives a formulation of the zero-order synaptic decay process in the Hopfield model. Section 3 shows the numerical simulation results using our model. Section 4 gives our conclusions.

2 MODELING THE SYNAPTOGENESIS

2.1 Network dynamics

We begin by formulating a recurrent neural network with N units and $N(N-1)$ synapses. We assume that all the units work synchronously at discrete time $t = 1, 2, \cdots$. The network dynamics are determined by

$$s_i(t+1) = \mathrm{sgn}\Big(\sum_{j=1(\neq i)}^{N} J_{ij} s_j(t)\Big), \tag{1}$$

where $s_i(t)$ is the state of unit i at discrete time t. J_{ij} denotes the strength of the synapse connecting unit j to i, and it is symmetrical, i.e., $J_{ij} = J_{ji}$. We assume that the network is assumed to have no self-interaction, $J_{ii} = 0$. In Eq.(1), the sign function $\mathrm{sgn}(x)$ denotes the next state $s_i(t+1)$ of unit i as

$$\mathrm{sgn}(x) = \begin{cases} \;\;1 & x \geq 0, \\ -1 & \text{otherwise.} \end{cases} \tag{2}$$

According to Eqs.(1) and (2), when a weighted sum of its inputs $\sum_{j=1(\neq i)}^{N} J_{ij} s_j(t)$ exceeds 0 (threshold), the next state $s_i(t+1)$ becomes 1, representing the neuronal firing. On the other hand, $s(t+1) = -1$ represents that the unit is not firing at $t+1$. Equation (1) defines the time evolution of the system state. For any symmetric connection matrix $J_{ij}; J_{ij} = J_{ji}$, the network system has finite possible states. Starting from any arbitrary initial state, the system state of the Hopfield model always reaches an equilibrium or a periodic solution, and the period is known to be no more than 2.

2.2 Associative memory with the zero-order synaptic decay

Each element ξ_i^μ of the μ-th memory pattern $\boldsymbol{\xi}^\mu$, which is stored in the network, takes ± 1, and is generated independently with the probability,

$$\mathrm{Prob}[\xi_i^\mu = \pm 1] = \frac{1}{2}. \tag{3}$$

Here, we consider the following learning dynamics of the synaptic strength J_{ij}, reflecting the characteristics of the synaptogenesis. The synapse which has its small strength $\|J_{ij}\|$ tends to be replaced with new ones. We assume that if the synaptogenesis occurs, the new synapses rebuilds the connection to all the units except for self-coupling. We use the following synaptic decay process, which is equivalent to the above replacement procedure of synapses.

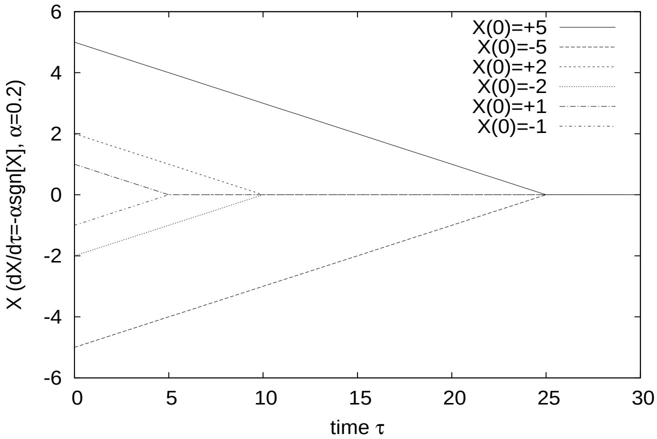

Fig.1: Dynamics of the zero-order synaptic decay process (the second term of the right-side Eq.(4), ordinate). The quantity τ (abscissa) denotes time. Convergence speed (i.e., decay rate $\alpha = 0.2$) is constant with the sign and the value of $X(\tau)$. Thus, the smaller the synaptic strength is, the faster it converges to zero.

$$\Delta J_{ij} = \xi_i^\mu \xi_j^\mu - \alpha \mathrm{sgn}[J_{ij}], \tag{4}$$

where α is the decay rate. The index μ of ξ_i^μ denotes the learning step. Note that $\mu = 1$ corresponds to the latest learning step. The larger serial number $\mu > 1$ signifies that pattern $\boldsymbol{\xi}^\mu$ was stored earlier than $\boldsymbol{\xi}^1$.

The first term of the right-side Eq.(4) denotes the Hebbian learning in the Hopfield model. Every time the network learns a new pattern $\boldsymbol{\xi}^\mu$, J_{ij} is increased by ξ_i^μ and ξ_j^μ, not depending on the global structure of the state.

On the other hand, the second term of Eq.(4) denotes the zero-order synaptic decay process, modeling the synaptogenesis. Every time the network learns a new pattern, J_{ij} decays at a constant rate α. Figure 1 illustrates the dynamics of the second term of Eq.(4). The smaller the synaptic strength is, the faster it converges to zero. On the other hand, the larger synaptic strength takes more time to converge to zero. If the sign of the synaptic strength inverts ($J_{ij} \geq 0$ and $J_{ij} + \Delta J_{ij} < 0$, or $J_{ij} \leq 0$ and $J_{ij} + \Delta J_{ij} > 0$), then the synaptic strength is reset ($J_{ij} = 0$). This procedure represents that the synapse with the small strength dies and the new one is born.

3 NUMERICAL SIMULATION

For simplicity, we assumed that neither number of units nor synapses does change over time in the following numerical simulation. The network consisting of 1000 neurons learned M memories, $\boldsymbol{\xi}^1, \cdots, \boldsymbol{\xi}^M$, one by one. The maximum value of M was set to 400 (i.e., $0.4N$), which was much larger than the critical value of the ordinary Hopfield model: $0.138N$. All of the initial synaptic strengths were set to zero, $\{J_{ij}\} = 0$. Every time the network learned a memory pattern, the synaptic strength $\|J_{ij}\|$ was weaken by the decay rate α. The smaller $\|J_{ij}\|$ is, the more frequently synaptogenesis occurs, i.e., $J_{ij} = 0$. Each stored pattern $\boldsymbol{\xi}^\mu$ ($\mu = 1, 2, \cdots, M$) was given as a initial state $\boldsymbol{s}(0)$ in the network dynamics. We assume that the system is forced to stop when the present state $s_i(t)$ equals the second to last one $s_i(t-2)$ in the network dynamics, considering the periodical solution of the network dynamics. Simulations were carried out on a computer by varying the decay rate α.

First, we investigate how many patterns are retrievable in the network with the zero-order synaptic decay. Because the synaptic decay process implies erasing the old memory traces gradually, a limit exists on the number of retrievable patterns. As the criterion of successful recall, we used the overlap m^μ between the μ-th memory pattern $\boldsymbol{\xi}^\mu$ and the stationary system state $\boldsymbol{s}$:

$$m^\mu = \frac{1}{N}\sum_{i=1}^{N} \xi_i^\mu s_i. \tag{5}$$

If $m^\mu \geq 0.8$, we regarded $\boldsymbol{\xi}^\mu$ as the retrievable pattern, and we counted it. The results are shown in Fig.2, which plots the number of retrievable patterns as a function of the number of stored ones, M. According to Fig.2, we see that the larger the decay rate α is, the earlier forgetting starts: for $\alpha = 0$, forgetting started at around $M = 140$; for $\alpha = 0.2$, it started at around $M = 30$; for $\alpha = 0.4$, it started at around $M = 10$. Our interest is in the properties of the network when the number of retrievable patterns is nearly saturated. The network for $\alpha = 0$, i.e., the ordinary Hopfield model could not recall any memory pattern when $M > 220$. On the other hand, for $\alpha \neq 0$, the Hopfield model with the zero-order synaptic decay could recall an almost constant number of memories when $M > 40$.

Second, we investigate how old stored patterns are retrievable in the network with the zero-order synaptic decay. Figure 3 plots the overlap m^μ as a function of the learning step μ for two values of the decay rate α. As shown in Fig.3, only the recent memories could be recalled correctly ($m^\mu \geq 0.8$). Moreover, Fig.3 predicts a phase transition phenomenon depending on the learning step μ: If the learning step is smaller than the storage capacity ($\mu < \psi$), the memory retrieval state ($m^\mu \approx 1$) is stable. On the other hand, if the learning step exceeds the storage capacity ($\mu > \psi$), the memory retrieval state becomes unstable, and the so-called spin-glass state ($m^\mu \approx 0$) appears.

Figures 2 and 3 show the number of retrievable patterns depends on the decay rate α. Thus, we investigate two critical decay rate: the minimum value to avoid overloading, $\alpha_{\min}$, and the optimal value to maximize the storage capacity, α_{opt}. Figure 4 illustrates the storage capacity ψ of the zero-order decay model as a function of the decay rate α. It turned out

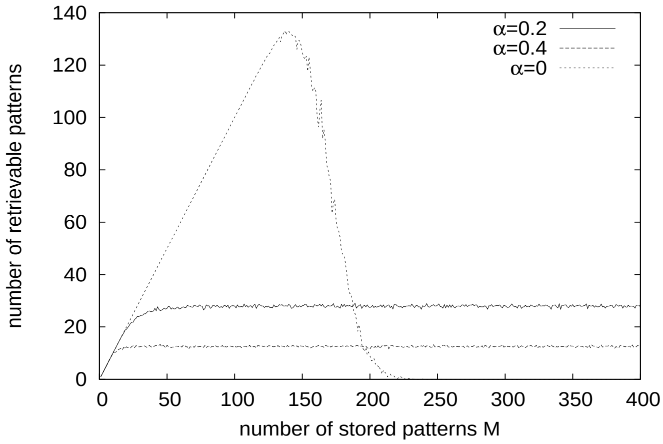

Fig.2: Relation between the number of stored patterns, M (abscissa) and that of retrievable patterns (ordinate). Each curve is the average of 10 samples ($N = 500$), illustrating how many memories so far learned were remembered. Solid curve is the result of the zero-order synaptic decay model with $\alpha = 0.2$, dashed one is that with $\alpha = 0.4$, and dotted one is that with $\alpha = 0$, i.e., the ordinary Hopfield model.

that for $N = 1000$, the minimum decay rate to avoid overloading ($\alpha_{\min}$, a point at the intersection of the abscissa with the solid curve in Fig.4) is 0.02. The optimal decay rate to maximize the storage capacity (α_{opt}, a point at the peak of the solid curve in Fig.4) is 0.08.

Finally, we approximate the number of replacement synapses at each learning step corresponding to these two critical decay rates. In other words, we investigate how many synapses should be replaced with new ones on average at each learning step to avoid overloading, or to maximize the storage capacity. Figure 5 plots the number of replacement synapses at each learning step for $\alpha_{\min}$ and α_{opt}, respectively. According to Fig.5, as time advances, the number of replacement synapses becomes nearly constant. Averaged by the number of stored patterns, M, the minimum number of replacement synapses at each learning step to avoid overloading is 1187, which corresponds to $\alpha_{\min}$. Moreover, the optimal one to maximize the storage capacity is 21024, which corresponds to α_{opt}.

4 CONCLUSION

In order to investigate the effect of synaptogenesis on memories embedded in the neural network, we proposed the Hopfield model with the zero-order synaptic decay. Using the numerical simulation, we demonstrated the possibility that synaptogenesis plays a role in maintaining recent memories while avoiding overloading. Moreover, it turned out that the storage capacity of this model depends on the decay rate α, which corresponds to the number of replacement

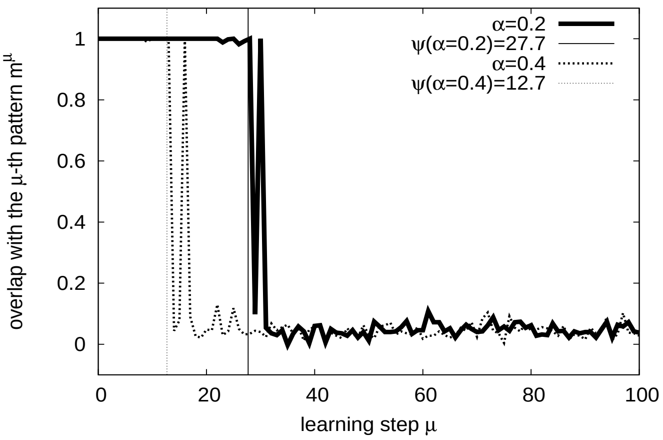

Fig.3: Overlap m^{μ} (ordinate) between the stationary system state $\boldsymbol{s}$ and the μ-th memory pattern $\boldsymbol{\xi}^{\mu}$ (abscissa). Note that $\mu = 1$ represents the most recently learned pattern, and that the larger μ is, the older $\boldsymbol{\xi}^{\mu}$ is. $N = 1000$, and $M = 400$. Heavy solid and dashed curves are the results when $\alpha = 0.2,\ 0.4$ (1 sample), respectively. Vertical solid and dashed curves are the storage capacity ψ when $\alpha = 0.2,\ 0.4$, respectively. Both values are taken from the results shown in Fig.4.

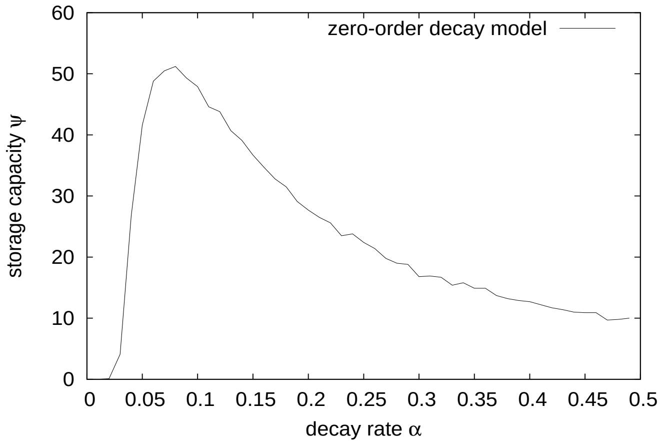

Fig.4: Storage capacity ψ of the zero-order decay model as a function of the decay rate α. Each curve shows the average of 10 samples ($N = 1000$, $M = 400$).

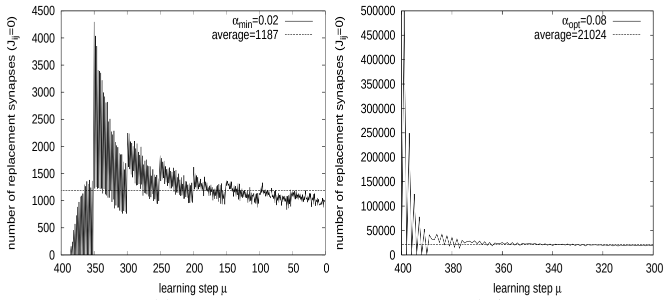

(I) (II)

Fig.5: Number of replacement synapses (ordinate) at each learning step μ (abscissa). Dashed line in each figure shows the averaged number of replacement synapses by the number of stored pattern M. $N = 1000$, and $M = 400$ (1 sample). (I) Minimum number of replacement synapses to avoid overloading corresponding to $\alpha_{\rm min}$. (II) Optimal number of replacement synapses to maximize the storage capacity corresponding to $\alpha_{\rm opt}$.

synapses. For $N = 1000$, the minimum decay rate to avoid overloading, $\alpha_{\rm min}$, is 0.02 and it is equivalent to an average of 1187 synapses replaced with new ones at each learning step. The optimal decay rate to maximize the storage capacity, $\alpha_{\rm opt}$, is 0.08 and it is equivalent to an average of 21024 synapses replaced with new ones.

The followings are our possible future works: (i) Since early times, it has also been reported that neurogenesis continues to take place in certain regions of the postnatal brain including the hippocampal regions[8],[9]. Moreover, it has been also demonstrated using numerical simulations that the Hopfield model with unit replacement, mathematically-modeled neurogenesis, avoids overloading and keeps the recent memories[10]. Thus, comparison of the properties between the synaptogenesis (zero-order synaptic decay model) and the neurogenesis (unit replacement model) should be done. (ii) Characteristics of the Hopfield model depend largely on how items are encoded in the pattern vectors to be stored. When most of the components of encoded patterns to be stored are inactivated and only a small share of the components are activated, the encoding scheme is said to be sparse[2],[3]. Investigation how synaptogenesis affects the sparsely encoded network will be done.

Abstract: This paper presents the pulse-type hardware neural networks circuit (P-HNNC) which could control pulse width modulation (PWM) servo motor of robots. Basic components of P-HNNC were pulse-type hardware neuron model (P-HNM). P-HNM generated oscillatory patterns of electrical activity such as living organisms. Basic components of the P-HNM corresponding to the cell body circuit, the axon circuit and the synaptic circuit. P-HNM had the same basic features of biological neurons such as threshold, refractory period, spatio-temporal summation characteristics and enabled the generation of continuous action potentials. P-HNM was constructed by MOSFETs without any inductors could be integrated by CMOS technology. As a result, we showed that P-HNNC could control the PWM servo motor from 0 to 180 degrees. Same as the living organisms, P-HNNC realized the control of PWM servo motor without using any software programs, or A/D converters.

Keywords: Pulse-type Hardware Neuron Model, Neural Networks, Servo Motor, Humanoid Robot.

1 INTRODUCTION

Programmed control by a microcomputer has been the dominant system among the robot control. However, some advanced studies of artificial neural networks have been paid attention for applying to the robot control. A lot of studies have reported both on software models and hardware models [1-3]. For example, oscillatory patterns of artificial neural networks have been used to operate movement of the robot. Oscillatory patterns of electrical activity are ubiquitous feature in nervous systems. Living organisms use several oscillatory patterns to operate movement, such as swallowing, heart rhythms, and so on [4]. To clarify oscillatory patterns, coupled neural oscillators are paid attention. Synchronization phenomena or bifurcation phenomena of coupled neural oscillators have been studied using the Hodgkin-Huxley model or the Bonhoeffer-van der Pol model. Therefore, the synchronization phenomenon of the coupled neural oscillators using mathematical neuron models has proposed for generating the oscillatory patterns of living organisms [5-7]. However, using the mathematical neuron models in large scale neural networks is difficult to process in continuous time because the computer simulation has been limited by the computer performance, such as the processing speed and memory capacity. In contrast, using the hardware neuron model is advantageous because even if a circuit scale becomes large, the nonlinear operation can perform at high speed and process in continuous time. Therefore, the construction of a hardware model that can generate oscillatory patterns is desired. The hardware ring coupled oscillators have already been studied as a system which can demonstrate the various oscillatory patterns and the synchronization phenomenon [8, 9]. The neural networks need various oscillatory patterns. For this reason, the ring coupled oscillators is expected to be a structural element of the cellular neural networks. However, most of the hardware models contain the inductor in circuit architecture [8-11]. If the system contains the inductor on the circuit system, it is difficult to implement the system to a CMOS IC chip.

We are studying about implementation of hardware neural networks controlling system to robot system. Previously, we proposed the pulse-type hardware neural networks which could generate the locomotion patterns to actuate the micro robot [12].

This paper presents the pulse-type hardware neural networks circuit (P-HNNC) which can control pulse width modulation (PWM) servo motor of robots. P-HNNC generates oscillatory patterns of electrical activity such as living organisms. P-HNNC is constructed by MOSFETs without inductor can be integrated by CMOS technology.

2 PWM SERVO MOTOR

Fig. 1. shows the example of pulse waveform to actuate the PWM servo motor. It is necessary to output the pulse waveform to control the servo motor.

Table 1. shows the pulse specifications of servo motor. The specifications were measured the control signal by oscilloscope.

It is shown that if the P-HNNC can output the waveform

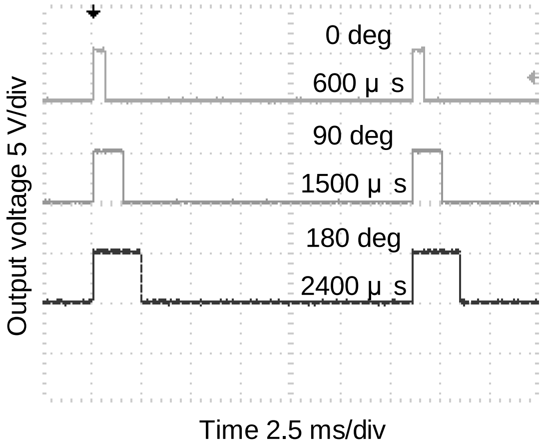

Fig. 1. Pulse waveform to actuate the servo motor

Table 1. Pulse specifications of servo motor (Hitec Multiplex Japan HSR-8498HB)

Pulse period	16040 μs
peak-to-peak voltage	5.04 V
motion range	0 to 180 degree
increase of pulse width per degree	10 μs
minimum pulse width (0 degree)	600 μs
maximum pulse width (180 degree)	2400 μs

such as shown in **Fig. 2.** satisfying the specifications of **Table 1.** the PWM servo motor can be control.

3 PULSE-TYPE HARDWARE NEURAL NETWORKS CIRCUIT

P-HNMs were used for the basic elements of the P-HNNC. P-HNMs consisted of a cell body model, synaptic model and axon model.

3.1 Neural networks

Fig. 2. shows the schematic diagram of P-HNNC. In the figure, C indicates cell body model, A indicates axon model and synapse indicates synaptic model. The cell body model were connected cascade, where n $(1 \le n \le 24)$ was number of cell body model. In addition, the axon model were connected cascade, where m $(1 \le m \le 136)$ was number of axon model. The cell body model and axon model were connected cascade such as ring neural networks. In the case of inputting the single external trigger pulse to C_1, the pulse propagated the ring neural networks with delay. If the delay of cell body model and axon model could set as 100 ms/number, 24 cell body model and 136 axon model could realize the pulse period (16040 μs) of PWM servo motor. In addition, n-th cell body model was connected to synaptic model. The synaptic model outputted the pulse waveform

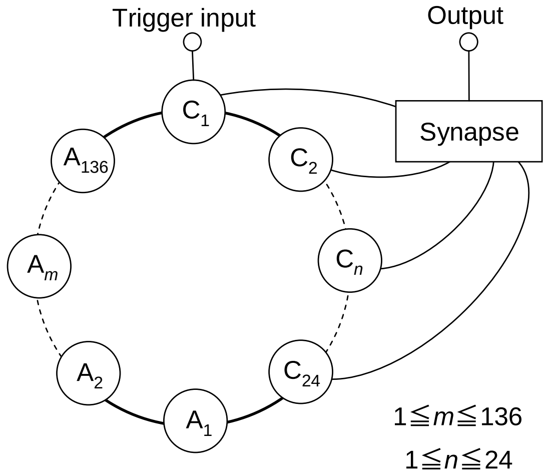

Fig. 2. Schematic diagram of pulse-type hardware neural networks circuit

which could control the PWM servo motor. The pulse width could vary from 600 μs to 2400 μs by switching the synaptic weights (1 or 0).

3.2. Pulse-type hardware neuron model

Fig. 3. shows the circuit diagram of n-th $(1 \le n \le 24)$ stage of cell body model. The cell body model consisted of a voltage control type negative resistance and an equivalent inductance, membrane capacitor C_{Mn}. The voltage control type negative resistance circuit with equivalent inductance consisted of n-channel enchantment-mode MOSFET M_{C1n}, p-channel enchantment-mode MOSFET M_{C2n}, and voltage source V_A, resistors R_{Mn}, R_{Gn}, and a capacitor C_{Gn}. The cell body model had the negative resistance property which changed with time like a biological neuron, and enabled the generation of a continuous action potential v_{Cn} by a self-excited oscillation and a separately-excited oscillation. Moreover, the cell body model could switch between both oscillations by changing V_A. The separately-excited oscillation occurred by direct-current voltage stimulus or pulse train stimulus. The circuit parameters of cell body model were as follows: C_{Mn}=1.8 nF, C_{Gn}=0.8 nF, R_{Mn}=10 kΩ, R_{Gn}=390 kΩ, R_{an}=20 kΩ, R_{bn}=15 kΩ, $M_{C3n}, M_{C4n}, M_{C5n}$: W/L=1. The voltage source were V_A=3.3 V, V_{DD}=5 V. The input current of n-th stage of cell body model was i_{cn-1} which was the output of (n-1)-th stage of cell body model. The output voltage n-th stage of cell body model was v_{cn}

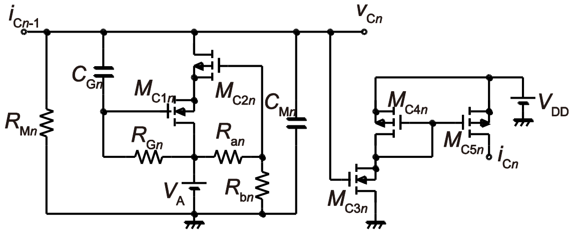

Fig. 3. Circuit diagram of cell body model

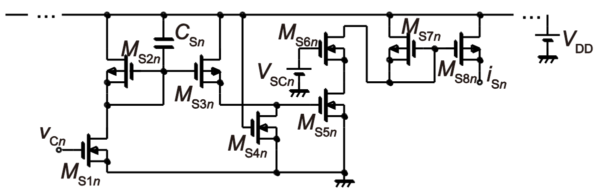

Fig. 4. Circuit diagram of synaptic model

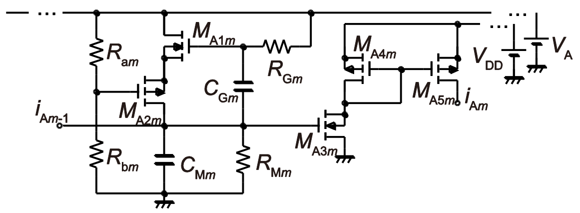

Fig. 5. Circuit diagram of axon model

which was the input voltage of synaptic model.

Fig. 4. shows the circuit diagram of n-th $(1 \le n \le 24)$ stage of synaptic model. The synaptic model spatio-temporal summated the outputs of cell body models according with synaptic weights. Synaptic weights were controlled by the voltage source V_{SCn}. In this paper, the synaptic weights were set as 1 or 0. The circuit parameters of synaptic model were as follows: C_{Sn}=1 pF, M_{S1n}:W/L=3, M_{S2n}, M_{S3n}, M_{S7n}, M_{S8n}:W/L=1, M_{S4n}:W/L=0.25, M_{S5n}:W/L=5, M_{S6n}:W/L=0.2. The voltage source was V_{DD}=5 V.

Fig. 5. shows the circuit diagram of m-th $(1 \le m \le 136)$ stage of axon model. The axon models were connected cascade. The axon model was active distributed constant line which had the threshold function and waveform shaping function. The input current of m-th stage of axon model was $i_{Am\text{-}1}$ which was the output of (m-1)-th stage of axon model. The circuit parameters of axon model were as follows: C_{Mm}=1.8 nF, C_{Gm}=0.8 nF, R_{Mm}=10 kΩ, R_{Gm}=390 kΩ, R_{am}=20 kΩ, R_{bm}=15 kΩ, M_{A3m}, M_{A4m}, M_{A5m}: W/L=1. The voltage sources were V_A=3.3 V, V_{DD}=5 V.

Fig. 6. shows the example of output waveform of P-HNNC. The simulation results of output waveform were given by PSpice. In the figure, angles of the PWN servo motor were 0, 90, 180 degree where pulse period was 630, 1490, 2390 μs, respectively. The output waveform was generated by waveform generator inputting the output waveform given by PSpice. It is shown that P-HNNC can output the waveform to actuate the PWM servo motor such as **Fig. 1.**

Fig. 7. shows number of neurons vs. pulse width and angle of servo motor. In the figure, solid circles indicate the pulse width, open circles indicate angle of servo motor and solid line indicates the theoretical line. This figure shows

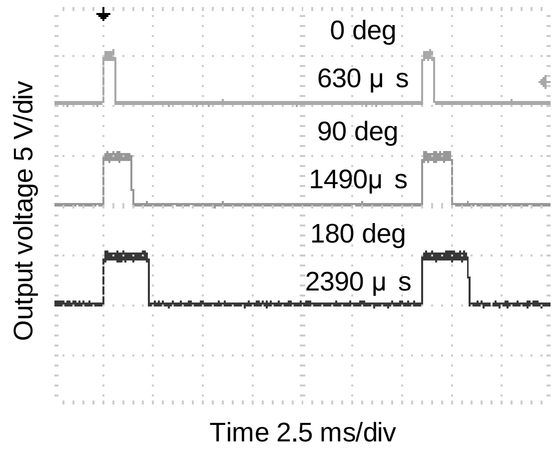

Fig. 6. Example of output waveform of P-HNNC

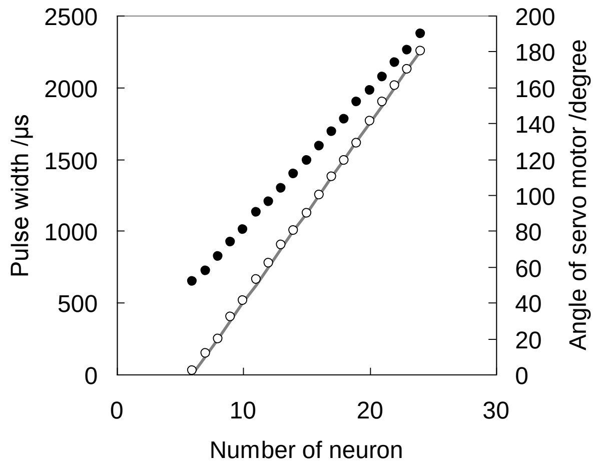

Fig. 7. Number of neuron vs. pulse width and angle of servo motor

that our P-HNNC can change the pulse width of output waveform by changing the number of neurons and controlled the PWM servo motor.

4 CONCLUSION

In this paper, we proposed pulse-type hardware neural networks circuit which could control pulse width modulation servo motor of robots. As a result, we showed that pulse-type hardware neural networks circuit could control the PWM servo motor. P-HNNC realized the PWM servo motor control without using any software programs, or A/D converters.

In the future, we will integrate pulse-type hardware neural networks circuit to the humanoid robot.

Abstract: This paper describes a parameter learning system for light energy saving control. It is very important to control the light system efficiently because the large electric energy consumer is the light system. In the home light control, so far, the brightness sensor system which controls each light has been developed. However it controls each light independently, the multiple light control system doesn't work well. There are a lot of lights in even a single room of the office or the school. Furthermore, user requirements for lighting intensity are different according to user locations in the room. Therefore, in order to control each light properly, we must calculate optimal brightness pattern quickly. In this study, we propose the lighting system to determine the brightness of the lighting system using genetic algorithms in public spaces. This system solves the trade-off between the user satisfaction and the energy saving.

Keywords: lighting, energy conservation, usability, sensor network, genetic algorithm

1 INTRODUCTION

Recently, promotion of energy efficiency regulations for greenhouse gas emissions has become active to address global warming issues. Therefore, the saving energy is closely watched in the home and office. The targets of energy saving are the lighting, the air conditioning, and the consumer electronics etc. Among them, it is very important to control the light system efficiently because the large electric energy consumer is the light system [1]. So, the lighting energy saving is desirable. In the home light control, so far, the brightness sensor system which controls each light has been developed. However it controls each light independently, the multiple light control system doesn't work well in the home. In the public space, such as the office and the school, the light control is achieved by more simple way which is switched on-off by detecting a human or comparing the brightness sensor with the fixed threshold value. Several works on the lighting control system providing a comfortable space for the end user and reducing power consumption in public space has been studied[2], [3]. There are a lot of lights in even a single room of the office or the school. Furthermore, user requirements for lighting intensity are different according to user locations in the room or the purpose. Therefore, in order to control each light properly, we must calculate optimal brightness pattern quickly. This problem is combinational optimization problem.

In this study, we propose the lighting system to determine the brightness of the lighting system using genetic algorithms (GA) in public spaces. This system solves the trade-off problem between the user satisfaction and the energy saving. Considering the sunlight, the total of power and the user requirement simultaneously, the lighting intensity must be controlled adequately. The genetic algorithm can solve this combinational optimization problem that decides the brightness of all lightings. To apply GA to control the light system, the genetic code is defined as the power level and brightness for each light. We considered the total electric power in a room and the amount of the differences between current and desired brightness of each light, to select good genes. In our method, fitness function is defined as the sum of these values, and gene is selected so that the function is minimized.

2 LIGHT POWER CONTROL SYSTEM

2.1 System configuration

Fig. 1 shows the lighting system configuration in this study. This system consists of the illuminance sensor, dimmable lighting and management PC. The end users have mobile device and can send the user preference information on brightness to management PC. Then, the desired brightness of each illumination is determined by gathering the user preference information. This system adjusts the brightness of each illumination near the desired brightness and uses the genetic algorithm to determine the optimal lighting pattern. If the environment changes, the desired brightness of each illumination is changed and the optimum lighting pattern of each illumination is determined again.

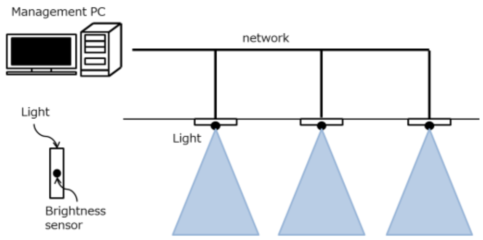

Fig. 1. Lighting system

2.2 Method to determine the optimal lighting pattern

This system uses the genetic algorithm to determine the optimal lighting pattern. The genetic algorithm is learning algorithm designed to model the biological mechanisms of genetic. This algorithm is superior to efficiently obtain the optimal solution. Therefore, the genetic algorithm has been shown to be effective systems for energy management plan [4], [5]. This section describes the flow of our system making use of genetic algorithm. Our system consists of the following 4 steps and repeats these steps to decide an adequate brightness. In the first step, we provide a plurality of individual. Fig. 2 shows the one example of an individual. The individual has a lot of gene. The gene has the value of power level and is prepared number of lighting in the room. The power level is divided by 8 intensities from level 1 to level 8 ,which is linked to the electric power and the brightness(in Table 1). In the second step, children's individuals are made with combination of the individuals. This process is called crossover. Then, in the third step, the outstanding individuals are selected from a collection of children's individuals. This process is called selection. The selection is used for the fitness function to evaluate whether the superior individual. This study used the following objective function,

$$F_n = W_{average} * Ld_{average} \qquad (1)$$

$$W_{average} = \frac{\sum_{i=0}^{L_{number}} w_i + 1}{L_{number}} \qquad (2)$$

$$Ld_{average} = \frac{\sum_{i=0}^{L_{number}} Ld_i}{L_{number}} \qquad (3)$$

$$Ld_i = \begin{cases} 0 & (Lc_i - Lt_i \geq 0 \quad and \quad Llv = 1) \\ |Lc_i - Lt_i| & (otherwise) \end{cases} \qquad (4)$$

where L_{number} is the number of lights. Fitness function F_n is defined as the multiplication of the total electric power in a room and the amount of the differences between current and desired brightness of each light, and the individual is selected so that the function is minimized. $W_{average}$ is the average of electric power to control all lighting(in eq.2). Ld_i represents the absolute value of the difference between current and desired brightness of each illumination. But, if the current brightness exceeds the desired brightness and the power level is level 1, this value is 0. In the final step, the selected individuals may mutate. This is mutation process.

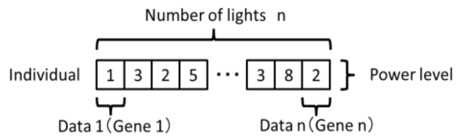

Fig. 2. One example of an individual

Table 1. Electric power and brightness

	Electric power	Brightness
Level 1	0 W	0 lx
Level 2	1 W	60 lx
Level 3	3 W	210 lx
Level 4	5 W	270 lx
Level 5	7 W	333 lx
Level 6	9 W	390 lx
Level 7	11 W	466 lx
Level 8	13 W	542 lx

3 PERFORMANCE EVALUATION

In order to verify the effectiveness of the proposed method in this study, we evaluated our system by computer simulation. This section shows our simulation environment and the results which is the brightness of each illumination and the number of generations created till the performance converges to the optimal solution.

3.1 Simulation Environment

Fig. 3 shows the simulation environment. The room of simulation environment has 12 lights which. Fig. 4 shows the coefficient representing the influence of the brightness from their neighbors. This coefficient is used to calculate the brightness considering indirect light. In this study, this coefficient calls the brightness coefficient. The brightness considering indirect light is calculated by summing up the multiplication of the brightness and the brightness coefficient. The specification of the PC performs simulation has a Core2Duo CPU, 3.0GHz memory and Windows7 OS. We evaluated our method in three environments where user requirement for lighting intensity are different. In the first environment, user requirements are uniformly distributed, in other words all requirements are equal. The second one is heterogeneous model, where the requirements are partially different. In the final environment, user requirement changes according to elapsed time.

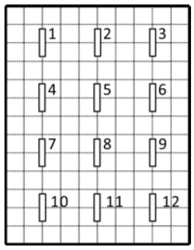

Fig. 3. Room of Simulation environment

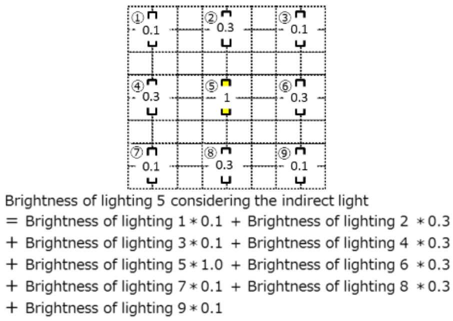

Fig. 4. Illuminance coefficient

Table 2. Parameters of Genetic Algorithm

	Number	Method
Initial individual	20	Random
Selection	10	Elitism
Crossover	20	Uniform crossover
Mutation probability	0.03	Random

3.2 SIMULATION RESULTS

3.2.1 Case 1: All requirements are equal

In the first environment, user requirement are uniformly distributed, in other words all requirements are equal. Table 3 shows the power level and brightness of each illumination. Table 4 shows the value of the optimal solution and the electric power. Fig. 5 shows the number of generations which is necessary to converge to the optimal solution. The simulation result shows that our method can satisfy the brightness of user requirements and reduce energy consumption. From table 3, the maximum difference among current brightness and desired brightness is about 37(lx). There is no problem because human eye cannot recognize such a difference. [6]. From Fig.5, the number of generations converges to the optimal solution in the first environment is the 158 generation and the convergence time is less than one second.

Table 3. Power level and brightness

Lighting Number	Power Level	Current Brightness	Desired Brightness
1	Level 4	402 lx	400 lx
2	Level 3	432 lx	400 lx
3	Level 4	402 lx	400 lx
4	Level 3	399 lx	400 lx
5	Level 2	363 lx	400 lx
6	Level 3	399 lx	400 lx
7	Level 3	399 lx	400 lx
8	Level 2	363 lx	400 lx
9	Level 3	399 lx	400 lx
10	Level 4	402 lx	400 lx
11	Level 3	432 lx	400 lx
12	Level 4	402 lx	400 lx

Table 4. Optimal solution and electric power

Optimal solution	Electric power
54.2	40 W

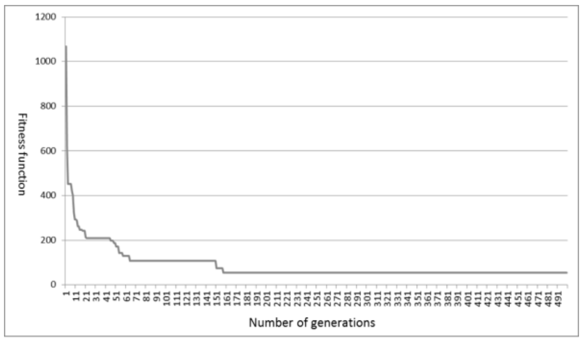

Fig. 5. Fitness function of generations

3.2.2 The requirements are partially different

The second environment is heterogeneous model, where the requirements are partially different. Table 5 shows the power level and brightness of each illumination. Table 6 shows the value of the optimal solution and the electric power. Fig. 6 shows the number of generations which is necessary to converge to the optimal solution. The simulation result also shows that our method can satisfy the brightness of user requirements and reduce energy consumption. But, there are great difference between current and desired brightness of lighting 9 and lighting 11. This is because the low desired brightness lighting is located next to the high desired brightness lighting. The number of generations converges to the optimal solution in the second environment is 3208 generation and the convergence time is less than one second, which is same as the case in the first environment.

Table 5. Power level and brightness

Lighting Number	Power Level	Current Brightness	Desired Brightness
1	Level 3	412 lx	400 lx
2	Level 3	427 lx	400 lx
3	Level 4	414 lx	400 lx
4	Level 7	595 lx	600 lx
5	Level 1	418 lx	400 lx
6	Level 4	399 lx	400 lx
7	Level 2	385 lx	400 lx
8	Level 4	445 lx	400 lx
9	Level 1	267 lx	200 lx
10	Level 5	396 lx	400 lx
11	Level 2	345 lx	400 lx
12	Level 5	378 lx	400 lx

Table 6. Optimal solution and electric power

Optimal solution	Electric power
111.2	44 W

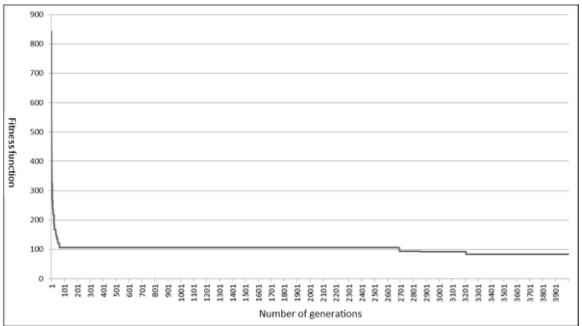

Fig. 6. Fitness function of generations

3.2.3 The end-user move in the room

In the third environment, user requirement changes according to elapsed time. One end-user moves as in Fig. 7 and requires 400[lx]. Fig. 8 shows the electric power of the user position. The simulation result shows that lighting intensities are adjusted adaptively according to varied demands.

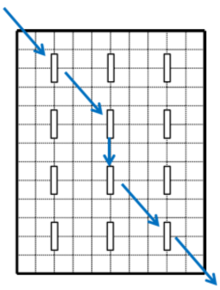

Fig. 7. Transfer pathway of the user in the room

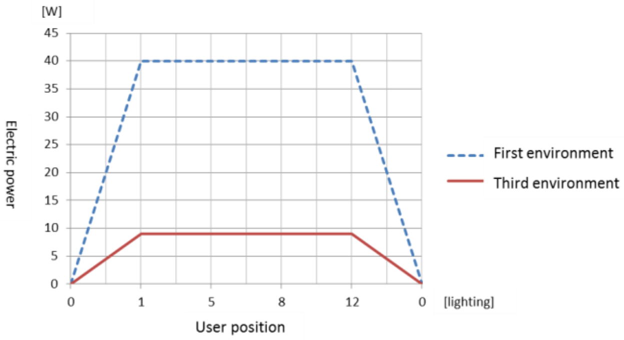

Fig. 8. Electric power of the user position

4 DISCUSSION

In summary, we propose the power saving control method for the lighting system to determine the brightness of the lighting system using genetic algorithms in public spaces. The simulation results in three environments show that the brightness provided by our method can satisfy the user requirements and reduce energy consumption. In the future, we would like to implement our method in a light power control system.

Abstract: In this paper, we address the control of flock behavior using the time to contact called the tau-margin. Recently, swarm intelligence has attracted considerable attention, and it has been applied to control various agents. The Boid theory proposed by Craig Reynolds (1987) is one such application. In ecological psychology, it is considered that animals perceive the time to contact with an object, instead of the distance to the object. In this study, we developed a simulator that simulates the dynamics of mobile agents and their visual system. We embedded modified Boid rules in which the tau-margin is considered instead of the distance. Our simulation results show the realization of flock behavior. In addition, we observe separation to avoid obstacles and reformation to pass through a narrow space.

Keywords: tau-margin, boid, flock behavior

1 INTRODUCTION

Recently, swarm intelligence has attracted considerable attention, and it has been applied to control various agents [1-7].

The Boid theory proposed by Craig Reynolds [1] is one such application. In this theory, we can simulate flock behavior by using three simple rules: separation, alignment, and cohesion. Therefore, the Boid theory was used in various conventional areas.

However, Boids are significantly different from real creatures. Thus, we cannot explain the mechanism of flock behavior of real creatures by using this theory. The difference lies in the information utilized for realizing flock behavior. In the Boid theory, information about the distances among agents is employed. However, most animals have no distance sensor and hence cannot perceive precise distance. Thus, most animals cannot utilize the rules of Boid.

On the other hand, in ecological psychology, it is considered that animals perceive the time to contact with an object, instead of the distance to the object [8]. This time to contact is called the tau-margin and is obtained from the apparent size of the object and its temporal change.

In our previous work, we assumed that the flock behavior of animals was realized by using the tau-margin. Moreover, we tried to realize flock behavior using the tau-margin instead of the distance [9]. However, there were no obstacles and the size of all the agents was the same. Therefore, the discussion on the validity of control using the tau-margin was restricted.

In this paper, we propose modified Boid rules in which the tau-margin is employed instead of the distance. We discuss the validity and effectiveness of this method by using obstacles and many agents whose sizes are different from each other.

2 TAU-MARGIN

In ecological psychology, it is considered that animals perceive the time to contact with an object, instead of the distance to the object. This time to contact is called the tau-margin. Fig. 1 shows the tau-margin when an object is approaching.

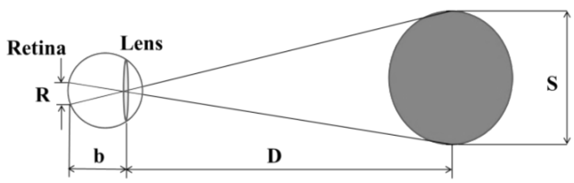

Fig. 1. Tau-margin

S is the diameter of the object, and D is the distance from the object to the crystalline lens. The distance from the crystalline lens to the retina is b.

In this case, the diameter of the retinal image of the object, R, is given by equation (1).

$$R = \frac{bS}{D} \tag{1}$$

By differentiating equation (1), we obtain equation (2).

$$\frac{d}{dt}R = \dot{R} = -\frac{bS}{D^2}\dot{D} \tag{2}$$

From equations (1) and (2), tau-margin τ is given by equation (3)

$$\frac{R}{\dot{R}} = \frac{\frac{bS}{D}}{-\frac{bS}{D^2}\dot{D}} = -\frac{D}{\dot{D}} = \tau \tag{3}$$

Equation (3) indicates that the time to contact $D/\dot{D}$ can be determined from the apparent size and its temporal change. In other words, the tau-margin is obtained from visual information instead of distance information.

3 FLOCK BEHAVIOR

In this section, we realize flock behavior by applying modified Boid rules using the tau-margin.

3.1 Model

We employ agents moving on the horizontal $x-y$ plane. To simulate the movement of the agents, we employ equation (4).

$$m\frac{d^2\mathbf{x}(t)}{dt^2} + C\frac{d\mathbf{x}(t)}{dt} = \mathbf{F} \tag{4}$$

m is the mass of an agent, and $\mathbf{x}$ is a position vector in the $x-y$ plane. C is the air resistance coefficient. $\mathbf{F}$ is the impellent force of the agent.

3.2 Modified Boid rules

We modify the conventional Boid rules by using the tau-margin instead of the distance. Boid theory consists of the three rules of separation, alignment, and cohesion. The modified rules are as follows:

<Separation>

Implement force to separate is given by equations (5) and (6), such that

$$F_x = -\cos\theta \cdot Kp \cdot \frac{1}{\tau} \tag{5}$$

$$F_y = -\sin\theta \cdot Kp \cdot \frac{1}{\tau} \tag{6}$$

where Kp is the proportional gain. F_x and F_y are impellent forces in the x and y directions, respectively. τ is the minimum tau-margin among neighboring objects. θ is the angle to the object that has the minimum tau-margin from the *x* axis, as shown in Fig. 2 (anticlockwise is positive).

When an object approaches the agent, τ converges to 0. Therefore, the implement force to avoid collision is generated by equations (5) and (6).

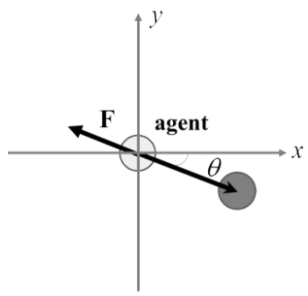

Fig. 2. Separation

<Alignment>

Implement force for alignment is given by equations (7) and (8).

$$F_x = -\cos\theta \cdot Kp \cdot \tau \tag{7}$$

$$F_y = -\sin\theta \cdot Kp \cdot \tau \tag{8}$$

When a neighbor object moves away from the agent, τ of the object has a negative value. Therefore, the behavior to follow the object is realized, as shown in Fig. 3.

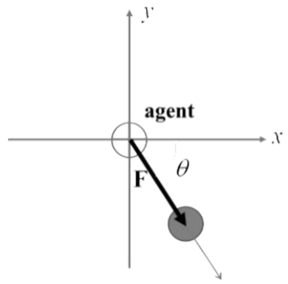

Fig. 3. Alignment

< Cohesion>

Implement force for cohesion is given by equation (9) and (10).

$$F_x = \cos\varphi \cdot Fc \tag{9}$$

$$F_y = \sin\varphi \cdot Fc \tag{10}$$

Fc is a positive constant. φ is an angle to the center of gravity of the apparent size of visible objects, as shown in Fig. 4. From equations (9) and (10), it can be found that the agent moves to the center of the flock by a constant force.

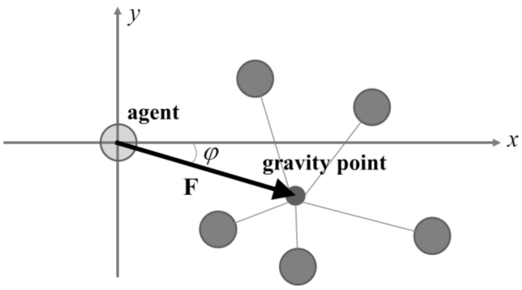

Fig. 4. Cohesion

<Selection of rule>

In the conventional Boid theory, a suitable rule is selected from separation, alignment, and cohesion, on the basis of distance. In contrast, in this study, we select a suitable rule on the basis of the tau-margin, details of which are provided in section 4.

4 SIMULATION

We employ one circular leader agent and nine circular follower agents. The leader agent has a radius of 0.5 m, and the followers' body size is set at random, with a radius within the range from 0.3 m to 2.5 m. Each agent has one eye, and its view angle ranges from -135° to +135°. The distance from the crystalline lens to the retina is 0.02 m. The mass of each body is 5 kg. The air resistance coefficient is $C = 1.8 \times 10^{-5}$. The proportional gain is 50, and Fc is 30.

In case of $0 < \tau \leq 5$, the rule for separation, in case of $-30 < \tau \leq 0$, the rule for alignment, and, in other cases, the rule for cohesion are selected.

4.1 Task 1: Avoiding an obstacle

4.1.1 Outline of simulation

We set agents on the left side of the field, a leader robot on the right side of the agents, and an obstacle (2.5m in radius) on the right of the leader robot. The task of the leader robot is to move to the right, avoiding the obstacle. The implement force of leader robot is applied to move to the right. The rule of separation is the only one employed; the rules of alignment and cohesion are not used. The other agents follow the leader by using modified Boid rules.

In this simulation, an agent is not aware of the positions and the actual sizes of the other agents; moreover, it cannot distinguish between the agents and the obstacles. Only the apparent size and its temporal change are employed for determining the tau-margin.

4.1.2 Simulation result

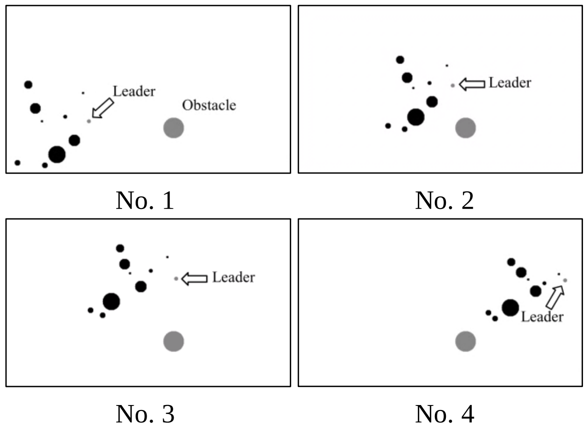

Fig. 5. Task 1

Fig. 5 shows the simulation result of Task 1. When the obstacle approaches the leader agent, the leader avoids the obstacle. Then, the follower agents follow the leader, avoiding collisions.

4.2 Task 2: Passing through narrow space

4.2.1 Outline of simulation

We set follower agents on the left side of the field, a leader agent on the right side of the other agents, and two obstacles on the right of the leader robot. The task of the leader robot is to move to the right. In this case, the leader robot does not have to avoid the obstacles. It can pass through the space between the obstacles. However, the space is so narrow that the flock should change its formation to pass through the space.

4.2.2 Simulation result

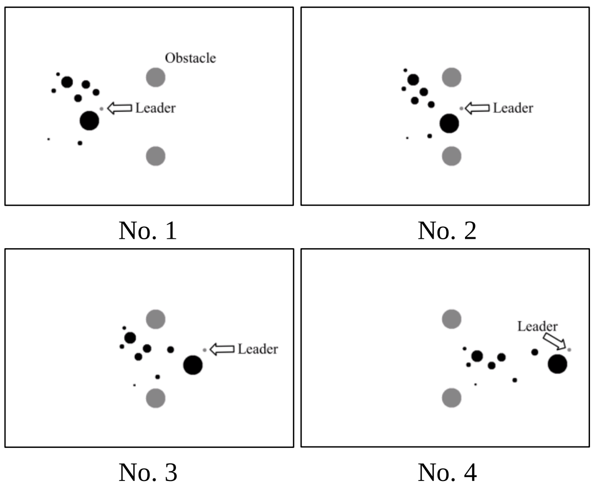

Fig. 6. Task 2

Fig. 6 shows the simulation result of Task 2. From the result, we observe that agents can pass through the space by changing their formation. In addition, we also find that they can avoid collisions with each other in spite of the fact that they are not aware of the distances between themselves.

4.3 Task 3: Avoiding obstacles and passing through narrow space

4.3.1 Outline of simulation

Task 3 is a combination of Task 1 and Task 2. We employ three obstacles, and the leader robot moves to the right, avoiding the obstacles. In this case, the movement of the leader agent is not straight and the other agents have to follow the leader, avoiding the obstacles.

4.3.2 Simulation result

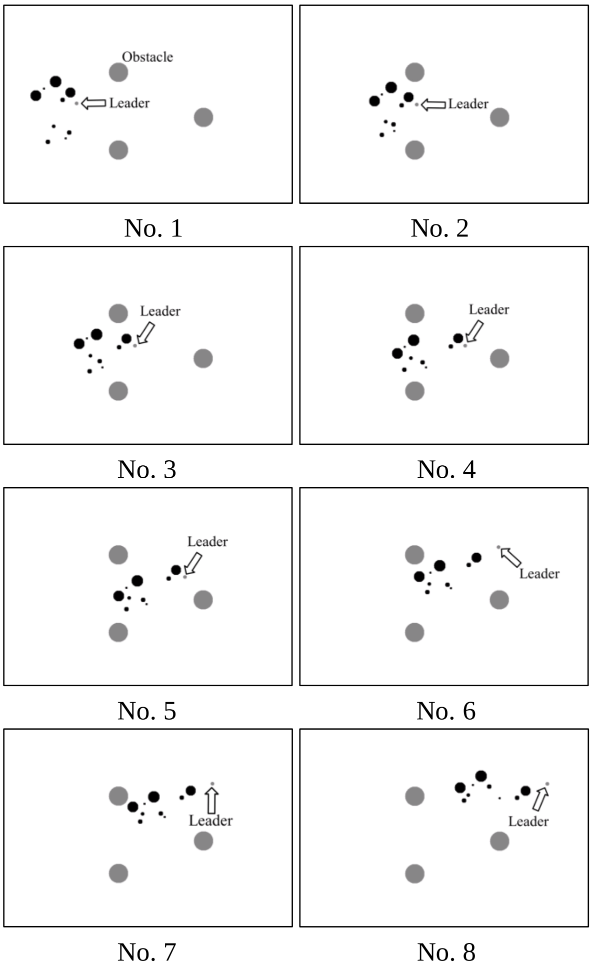

Fig. 7. Task 3

Fig. 7 shows the simulation result of Task 3. We observe that the rules of separation, alignment, and cohesion are suitably selected, and flock behavior to follow the leader agent, avoiding collisions, is realized.

5 CONCLUSION

In this paper, we addressed control of a flock behavior using the time to contact called the tau-margin. We proposed modified Boid rules in which the tau-margin is employed instead of the distance. To discuss the effectiveness of the modified Boid rules, we conducted simulations. From the simulation results, we confirmed that in all cases, agents avoid collisions and follow the leader agent without distance information.

We can conclude that flock behavior can be realized by using only the tau-margin that is obtained from visual information.

Abstract: This paper presents a new adaptive segmentation of continuous state space based on vector quantization algorithm such as LBG (Linde-Buzo-Gray) for high-dimensional continuous state spaces. The objective of adaptive state space partitioning is to develop the efficiency of learning reward values with an accumulation of state transition vector (STV) in a single-agent environment. We constructed our single-agent model in continuous state and discrete actions spaces using Q-learning function. Moreover, the study of the resulting state space partition reveals in a Voronoi tessellation. In addition, the experimental results show that this proposed method can partition the continuous state space appropriately into Voronoi regions according to not only the number of actions, and achieve a good performance of reward based learning tasks compared with other approaches such as square partition lattice.

Keywords: Q-learning, LBG, new Vector quantization method, State space partitioning

1 Introduction

Reinforcement learning [1] is a type of active learning in which the autonomous agent interacts with its initially un-known environment, observes the results of its actions, and adapts its behavior appropriately. This type of learning has been widely studied as a learning method for determining the optimal actions. In particular, Q-learning [2] is a common reinforcement learning algorithm that is being investigated in a variety of applications.

In this paper, we develop an efficient algorithm for partitioning the state space in terms of computation. There are multiple ways of partitioning the state space such that Voronoi tessellation. Since we consider a single-agent RL problem in high-dimensional continuous state space and discrete actions, we built two experimental models A and B in different environments, and conduct two experiments to test the efficiency of reward learning. Our proposed method is based on the use of LBG for experimental model B, therefore, we use adaptive vector quantization method and the quality of a partitioning algorithm could also be estimated according to the number of non-overlapping regions of the partitioned state space. However, in order to increase the performance of learning efficiency, it is essential to achieve a good reward on the action space.

The following is a detailed description of our approach. First, a review of reinforcement learning and basic algorithm of Q-learning is presented in Section 2. And then, the adaptive partitioning of the state space and performance of the algorithm is described in detail in Section 3. The characteristics of proposed algorithm using vector quantization method and the efficiency of reward learning are investigated in Section 4. Finally, a conclusion is given in Section 5.

2 Reinforcement learning framework

In a typical reinforcement learning model, a learning agent is connected to achieve a reward or to reach a goal through interactions with its environment. In each time step, an autonomous agent observes the environmental state and makes a decision for a specific action, and selects an action in a current state according to a control policy. The control policy specifies each admissible action as a function of the observed state. At the next time step, a reward is generated according to the agent's environment after executing the action, and learns by that reward. It works much like human learning, and search for the optimal policy that maximizes the total expected reward. This is achieved by estimating the action value function, which is the total expected reward of taking action at a state.

2.1 Q-learning algorithm

Q-learning algorithm due to Watkins [2] is a policy for estimating the optimal state-action value function, denoted by $Q(s_t, a_t)$, as the value of Q. In general Q-learning, it discretizes the state and gives the Q-value that corresponds to each state and action pair. Q-value shows the value of action, and these Q-values are initialized to small random values and gradually change to the optimal values through learning process. In the state where the agent observed, the action with the highest Q-value is considered as the optimal action, and learns by adding the random action to it. Q-value is updated by this following equation.

$$Q(s_t,a_t) = Q(s_t,a_t) + \alpha(r_t + \gamma \max_a Q(s_{t+1},a) - Q(s_t,a_t))$$

In this equation, $0 \leq \gamma < 1$ is the discount factor, α is the learning factor, and r_t is the reward given in current state s_t, $Q(s_t,a_t)$ is the Q-value of action a in state s at time t, $\max_a Q(s_{t+1},a)$ is a maximum Q-value of state at time $t+1$.

3 Experiments A

We experiment the implementation of the partitioning algorithm on 2-dimensional one state input and N-actions variables alternatively known as continuous state space and discrete actions. In this model A, the position of the agent is expressed as a state input, and the reward area is placed at the center of the action space as shown in Figure 1, and action space and state space completely coincide with each other. The aim of the learning agent is to develop an optimal control policy, in other words, to achieve a good reward within a short period of time.

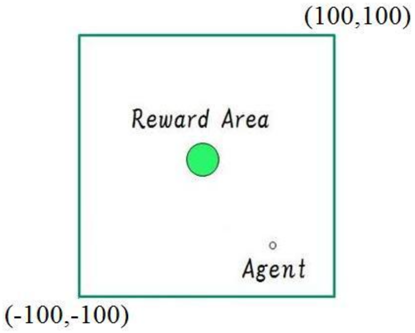

Fig.1. Experimental model A

We conducted a simple simulation experiment with a learning rate of 0.1, discount rate of 0.9 for Q-learning algorithm, and a random action rate was initialized to 0.3. A continuous action learning time is 20 thousand time for 1 episode and acts for 50 episodes, and perform 10 trials on each episode by changing the different initial seeds of random number. Furthermore, we examine the number of accumulated rewards by taking the average of each 10 trials for each episode.

3.1 Adaptive state space partitioning method (not use LBG method)

The idea of proposed partitioning algorithm is to group together states with similar action. In this way, the agent learns a suitable partitioning for a particular task and easily partition the state space using a clustering state transition vector (STV) or nearest-neighbor method. Our algorithm

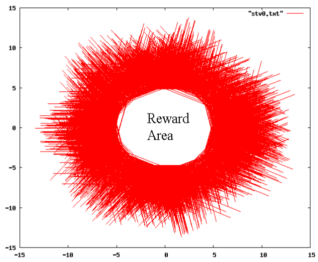

Fig.2.1. Collecting STV

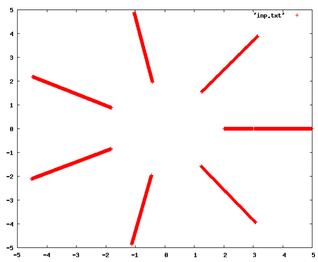

Fig.2.2. Seeking RV

for partitioning is performed on two steps. In the first step, we arrange the temporary points into lattice structure and collect the STV in regard to reward area that is a distance pointing from position of the agent to reward area that are described in Figure 2.1 when the agent enters the reward area. If the amount of rewards, in other words, the number of STV is accumulated 1000 or more, we group together STV by continuously taking the same actions, and seek those STV groups into representative vectors (RV) according to the number of actions are illustrated in Figure 2.2.

The accumulated STV with respect to a particular action is the sum of the total rewards received by taking the same actions. Then, the new Voronoi points are generated at the place of those representative vectors in relation to the reward area based on the number of actions, after all, we remove the temporary points in which the new Voronoi points are added. In essence, the continuous state space is partitioned into the number of N-actions subspaces as Voronoi regions shown on bottom of Figure 3.1.

In the second stage of partition formation, we collect the STV that come from temporary points to new Voronoi points of the quantized first-stage output, and group STV again which exceeds a threshold value by taking the same action. We do not take the STV that come from new Voronoi points to new Voronoi points. A threshold value is calculated dividing the number of accumulated STV 1000

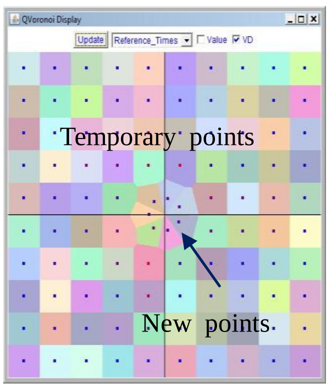

Fig.3.1. First stage of partition formation

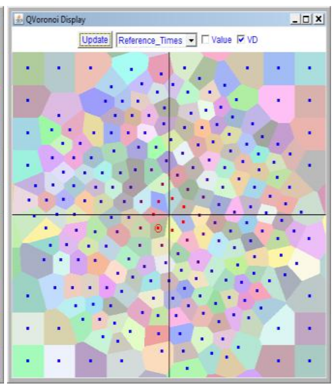

Fig.3.2. State space partition of 7-actions

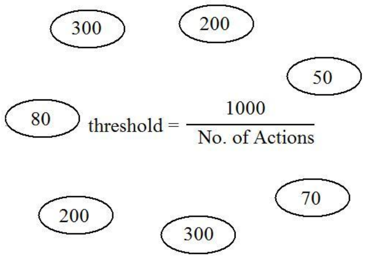

Fig.3.3. Calculation of threshold values for second stage formation

by the number of actions such that 7-actions, 6-actions. Figure 3.3 shows the formula quantization in order to make the group defined by threshold settings. Hence, the new Voronoi points are produced but it does not exactly the number of actions as new Voronoi points created in first stage formation (Fig.3.2). Moreover, we calculate the minimum distance between two new added Voronoi points to merge the points into one that are very close when we add the new Voronoi points of quantized second-stage process. If the distance between two new Voronoi points is less than the ratio of a minimum distance, we add the first entry Voronoi point. Furthermore, the reward numbers of state space partition are compared with square lattice partition.

3.2 Results

A summary of our experimental result is illustrated in Figure 3.4. It shows the comparison of two learning methods with the same number of Voronoi points. These two learning methods are partitioning of the state space using 7-actions on an experimental model A, and the regular arrangement of Voronoi points in a lattice structure are compared and discussed. As a result, adaptive partitioning the state space with N-actions has shown that

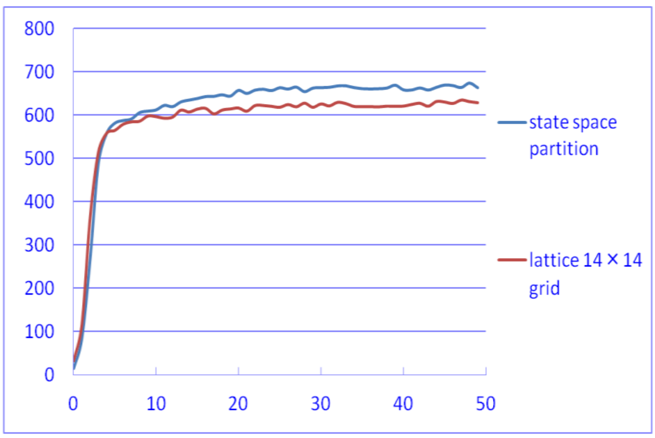

Fig.3.4. Comparison of learning performance using experimental model A for 7-actions
(X-axis: Episode number, Y-axis: Rewards number)

improved performance of reward learning, and it can accurately segment the state space as Voronoi tessellation with N-actions. However, the new points are not added if the ratio of the minimum distance is over 0.5 on the number of 3-actions and 4-actions.

4 LBG vector quantization algorithm

LBG (Linde-Buzo-Gray) is a typical technique of vector quantization algorithm. Modification of adaptive vector quantization method was introduced Enhanced LBG (Patane & Russo, 2001) [3], Adaptive incremental LBG (Shen & Hasegawa, 2006) [4]. Vector quantization method assumes that a set of input points is organized into a number of groups having approximately the same number of points closest to them. Each group is represented by its centroid point, as quantum vector (QV) idyllically known as representative vector. However, since the quantum vectors are not represented very well, we implemented the improved vector quantization algorithm as follow:

1. Collect the input vectors and tentatively place the QVs in random position.
2. Move the QVs in random directions by putting noise at the position of QVs.
3. Then, tentatively group the input vectors that are very close from the QVs, and move the QVs to the center position of input vectors.

We then repeated the above process until the number of QVs is -1, and reduce the amount of motion. Figure 4 describes an example of modified group vector quantization. Since the number of QV in clustering problem is not known a priori, we determines the number of QV by the index of their closest centroid which have smallest measurement error rates in group by changing the number of QV, and represents using that QV at a given time.

However, one group was represented with two QVs or two groups were represented with one QV. Therefore, we move the QVs of smallest measurement error to the

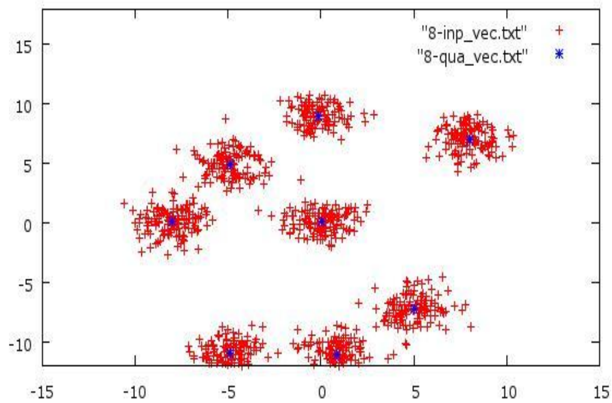

Fig.4. Input random vector quantization

position of the largest measurement error if the standard deviation is large. A standard deviation indicates that data are widely scatter condition of one group, and a small standard deviation is being able to represent as a representative vector, also known as quantum vector surely.

4.1 Experiments B

We test our approach by applying it in a continuous state space as shown in Figure 5. The agent learns to achieve optimal action, it means to arrive at a feeding area or reward area, and test its performance. If an agent reaches the goal, it receives a reward of +1, otherwise, if an agent collides into a border or wall, it was penalized by -1. For every reward, the agent is bounced to its new random position. The agent has 3 actions of straight forward, right rotation and left rotation, and observes the distance to a reward area and the angle between the direction of the agent forward movement and reward area, and learns by considering them as state inputs.

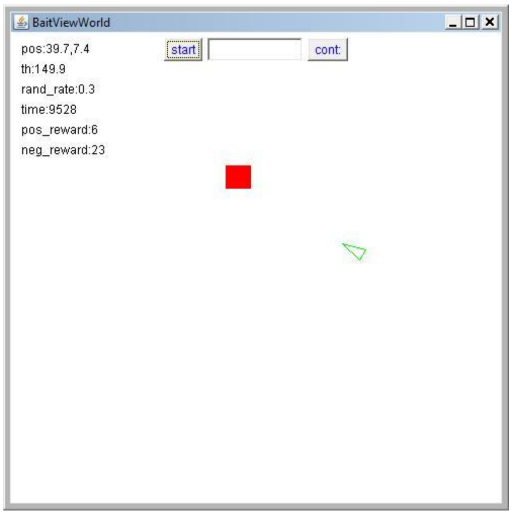

Fig.5. Experimental model B

Since the number of reward area is 1, these two state input values construct the 2-dimensional state space. The dimension of the state space goes up by two dimensions when one reward area is increased. We conducted experiments with one hundred thousand action learning times as 1 episode to 100 episodes and tested on 10 trials, and execute experiment as above.

4.2 Adaptive state space partitioning with LBG vector quantization algorithm

In this section, we do the same process of partitioning the state space that described in section 3.1 above. However, since the state input values and environments are different, the continuous state space is not partitioned into a number of N-actions subspaces. Further, we group together STV by using the LBG type of vector quantization algorithm and extract the representative vectors. We all take the STV (i.e, do not calculate a threshold value) for the second stage of partition formation.

4.3 Experimental results

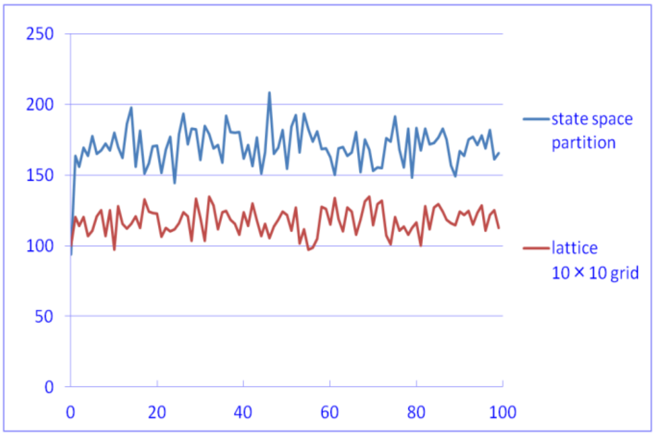

Fig.6. Comparison of learning performance using model B for 3-actions
(X-axis: Episode number, Y-axis: Rewards number)

The experimental results of Figure 6 show that our proposed approach raises the efficiency of the reward learning than the regular arrangement of lattice points.

5 Conclusions

This paper presented a new LBG vector quantization algorithm for partitioning the state space to Voronoi regions and adaptive continuous state space partition method. In our experiments, a simple experiment model by an agent was used in different environments with different state input values, and the effectiveness and efficiency of reward learning for two algorithms has been checked. When looking in terms of the reward, we see that our technique performs almost as good as square partition lattice and much better than its performance.

Abstract: Creativity plays an important role in almost all human activities and has been investigated by many researchers in a wide variety of fields. However, it is difficult to design a methodology for generating highly creative artifacts mainly because previous researches tended to depend a little too much on human subjective evaluation. One idea to tackle with creativity is to leave out the value aspect from the definition of creativity for the moment at least. This paper proposes Universal Creativity Engine (UCE), a conceptual organization for reproducing the creative process in human brain on the basis of the idea. It is characterized by a real-time property, representation universality and creativity based on two types of deviation. This paper also describes the design of UCE-ANT, the initial prototype implementation of UCE, for creation of melody and Lyrics based on the Ant system.

Keywords: Creativity, Ant colony optimization, Artificial life

1 INTRODUCTION

Creativity plays an important role in almost all human activities, and therefore, has been investigated by many researchers in a wide variety of disciplines such as psychology, cognitive science, philosophy, artificial intelligence, and engineering. We usually assume that creativity has an inseparable connection with the concept of value. For example, Boden defined creativity as the ability to come up with ideas or artifacts that are 1) new, 2) surprising and 3) valuable [1]. Therefore, it is extremely difficult to provide an objective definition of creativity and a reliable method for its evaluation. In a sense, it is thus reasonable that previous researches tended to depend a little too much on human subjective evaluation. However, for automatic generation of highly creative artifacts, it is important to develop a methodology that does not depend on human evaluation.

One idea here for tackling with creativity might be to leave out the value aspect when considering creativity for the moment at least. Dorin et al. [2] presented a value-free account: Creativity is the introduction and use of a framework that has a relatively high probability of producing representations of patterns that can arise only with a smaller probability in previously existing frameworks. If we accept such a formal and systematic account, when a solution to a problem can be cast in terms of a computational representation to be found in some definable representation space, then the problem can be tackled by applying some search algorithm to that space.

We hypothesize that new frameworks in this context can continue to be created by the coupling of two types of deviations, and propose *Universal Creativity Engine* (*UCE*), a conceptual organization for continuously generating the creative property based on the hypothesis. It accepts data streams from real world, updates the internal model representation of the world, and at the same time, generates data streams on a real-time basis just like human brain. It has representation universality in the sense that it stores and updates the internal representations in abstract and unified forms, and can treat any discrete data sequences in principle.

This paper describes the concept of UCE, and then reports on the initial prototype implementation, *UCE-ANT*. It composes a song, in other words, creates melody and lyrics at the same time using the same process based on one of the simplest ant colony metaheuristics, Ant system [3].

2 CONCEPTUAL ORGANIZATION OF UNIVERSAL CREATIVITY ENGINE (UCE)

Creativity is defined by Dorin et al. as *the introduction and use of a framework that has a relatively high probability of producing representations of patterns that can arise only with a smaller probability in previously existing frameworks*. Here, *frameworks* are defined as stochastic generative procedures. Their idea is shown in Figure 1. In this figure, Distribution 1 and 2 represent the old and new frameworks, respectively. Both are probability distributions over a common design space (horizontal axis). It shows that the new framework produces representation patterns that can hardly be produced by the old framework. They consider that the use of Distribution 2 relative to the prior use of Distribution 1 to generate one of these points is therefore creative.

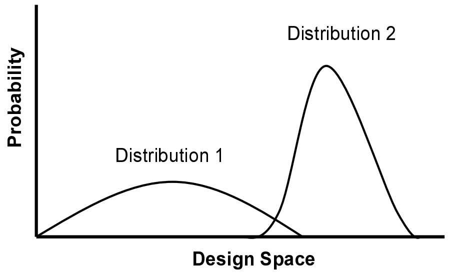

Fig. 1. The use of Distribution 2 relative to the prior use of Distribution 1 is creative.

We propose Universal Creativity Engine (UCE), a conceptual organization for reproducing the creative process in human brain (Fig. 1). UCE accepts data streams from real world, updates the internal model representation of the world, and at the same time, generates data-streams stochastically as the results of a creative process. The internal model is represented in a distributed manner, and the positive feedback loop is used to extract standard patterns inherent in the current data streams.

We considered the following requirements when designing UCE.

1. Real-time property
   UCE works on a real-time basis just like our brains. The world is changing every minute, and the existing frameworks captured in UCE should also change correspondingly to make the output streams creative. For example, timeline of Twitter can be used as an input data stream as described later.

2. Creativity based on two types of deviations
   We adopted the creativity concept proposed by Dorin, and embodied them in the following two types of deviation. Deviation from the frameworks that are updated by the input data streams from the world (I-deviation) and deviation from the frameworks of the output data streams themselves (O-deviation).

3. Representation Universality
   UCE stores and updates the internal model representations in abstract and unified forms, and can treat any discrete data sequences in principle. For example, melody and lyric are created using the same process based on two types of deviations in the prototype system.

3 PROTOTYPE IMPLEMENTATION (UCE-ANT)

We report on UCE-ANT, the initial prototype implementation of the UCE concept. It continues to compose a song: creates melody and lyrics at the same time representing the atmosphere of real world at the present moment, using the same process based on one of the simplest ant colony metaheuristics, Ant system [3][4].

UCE-ANT is composed of two layers: one for lyrics and the other for melody. Data streams (timeline) from Twitter and melody data from currently popular music scores are used as input for the melody and lyrics layers, respectively. Each layer has a directed network as an internal model of real world, in which each node represents a note or a word. Each link represents a connection from a node to the other with a pheromone value reflecting the strength of the connection. Two types of virtual ants: *Reflector* and *Performer* are moving from one node to another. The amount of the pheromone on link$_{ij}$ deposited by Reflector ants and Performer-ant$_n$ are described by T_{ij} and t^n_{ij}, respectively.

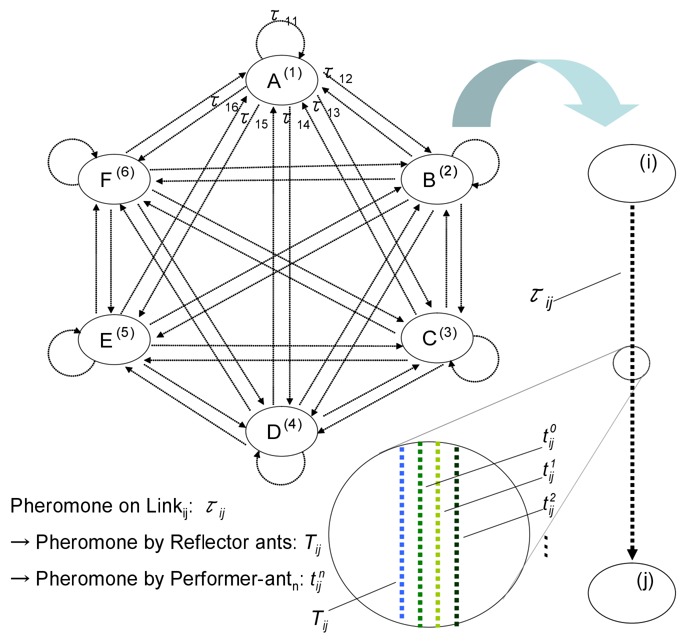

Fig. 3. Internal representation based on an ant colony metaheuristic.

While moving, they deposit pheromone on the links. The pheromone on the links evaporates slowly with time.

$$T_{ij} \leftarrow (1 - \rho_a) * T_{ij} \tag{1}$$

$$t^n_{ij} \leftarrow (1 - \rho_b) * t^n_{ij}, \tag{2}$$

where ρ is a parameter called evaporation ($0 \leq \rho \leq 1$).

UCE-ANT works as follows.

1) World representation by Reflector ants

Each reflector ant moves according to its input data stream (note or word sequence), and deposits their identical

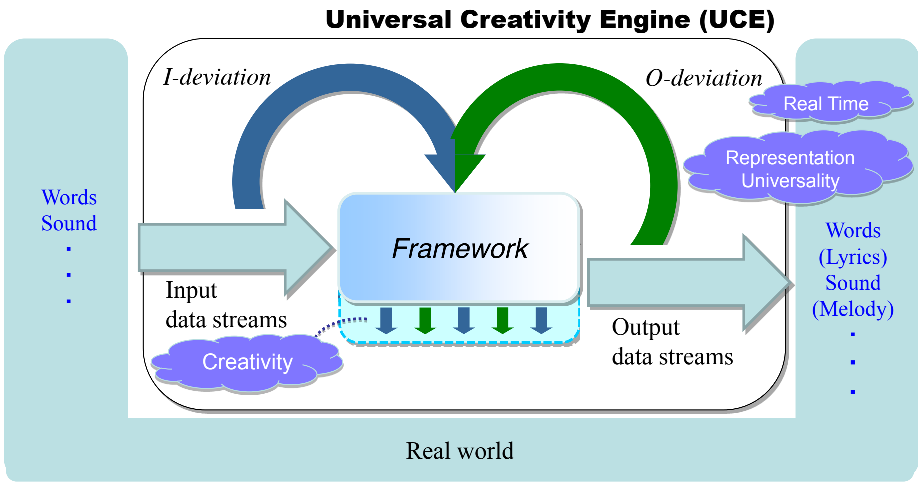

Fig. 2. Universal Creativity Engine (UCE).

pheromone on the link when moving. Each time a reflector ant moves from a node *i* to a node *j*, it deposits a pheromone quantity $T_{reflect}$ as follows:

$$T_{ij} \leftarrow T_{ij} + T_{reflect}. \tag{3}$$

The real world model is constructed and maintained actively as a pheromone distribution on the network on each layer through this process by Reflector ants and pheromone evaporation.

2) Exploration by Performer ants

Each Performer ant explores the network according to its pheromone distribution (deposited by itself and Reflector ants), creating melody or lyrics using an ant colony metaheuristic as follows.

When located at a node *i*, the probability for Performer-ant$_n$ to choose a node *j* is given by:

$$P_{ij}^n = \frac{T_{ij} + t_{ij}^n}{\sum_k (T_{ik} + t_{ik}^n)}(1 - \epsilon_n) + \epsilon_n, \tag{4}$$

where ε_n is a random selection rate for performer-ant$_n$ ($0 \leq \varepsilon_n \leq 1$). Each Performer ant has its own random selection rate, which affects the creative property of its output data stream as described later.

When moving from a node *i* to a node *j*, it deposits a pheromone quantity $t_{perform}$:

$$t_{ij}^n \leftarrow t_{ij}^n + t_{perform}. \tag{5}$$

Every when they reach a new node, the corresponding note or word is selected. The node sequences, melody and lyrics, selected by performer ants on both layers are combined to play a tune continuously.

3) Creativity control

We hypothesize that new framework can continue to be created dependent on the coupling of I-deviation and O-deviation in UCE. Furthermore, we assume that creativity would be optimized by letting both deviations to be certain values (I-deviation$_{opt}$ and O-deviation$_{opt}$), although it might be difficult to know the values a priori. In UCE-ANT, I-deviation$_n$ of Performer-ant$_n$ corresponds to the difference between pheromone distributions of Reflector ants and the pheromone distribution detected by Performer-ant$_n$ (pheromone deposit by itself and Reflector ants). O-deviation$_n$ corresponds to the difference between the current distribution and the past distribution (*N* steps ago) of pheromone detected by Performer-ant$_n$.

We defined these measures simply as follows.

I-deviation for a Performer-ant$_n$, I-d$_n$, is given by

$$I\text{-}d_n = \sqrt{\sum_i \sum_j (P_{ij}^n - \frac{T_{ij}}{\sum_k T_{ik}})^2}. \tag{6}$$

O-deviation for a Performer-ant$_n$, O-d$_n$, is given by

$$O\text{-}d_n = \sqrt{\sum_i \sum_j (P_{ij}^n - \frac{\sum_k P_{ijk}^n}{N})^2}, \tag{7}$$

where P_{ijk}^n is the past distribution (*k* steps ago) of pheromone detected by Performer-ant$_n$.

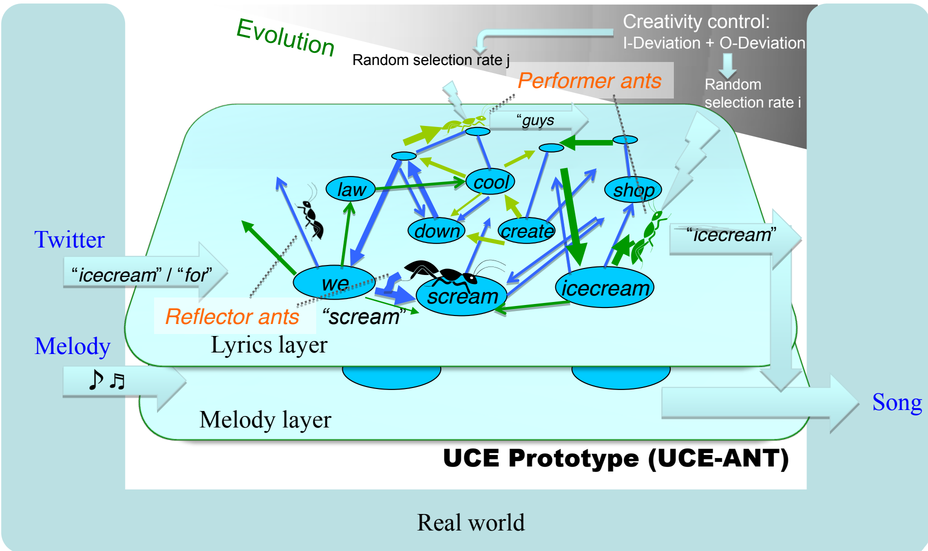

Fig. 4. Prototype Implementation of UCE (UCE-ANT).

Using these measures, Performer-ant$_n$ is evaluated as

$$E_n = \frac{1}{1 + |I\text{-}d_{opt} - I\text{-}d_n| + |O\text{-}d_{opt} - I\text{-}d_n|}, \quad (8)$$

where I-d$_{opt}$ and O-d$_{opt}$ are the values that are supposed to maximize the creativity.

Each Performer ant has its own random selection rate, which controls both deviations, I-deviation and O-deviation. Evolutionary processes are used to evolve Performer ants with the optimal random selection rate that maximizes E$_n$.

We are currently conducting some preliminary experiments to examine the basic behavior of UCE-ANT. We found that in terms of the balance between intensification (exploitation of the previous solutions) and diversification (exploration of the search solutions), the former due to the positive feedback loop provided by the pheromone-based metaheuristic [5] works stronger than expected. Therefore, sufficiently large values of I- deviation$_{opt}$ and O-deviation$_{opt}$ are necessary to work against it. However, it is also the case that excessively large random rates make the melody or lyrics generated by the Performer ant unattractive.

4 CONCLUSION

This paper hypothesizes that the creative process is dependent on the coupling of two types of deviations, and proposes Universal Creativity Engine, a conceptual organization based on the hypothesis. This paper also described UCE-ANT, the first prototype implementation of UCE based on an ant colony metaheuristic. We examined basic behavior of it and found some characteristic of its dynamics arising from the balance between intensification and diversification, although UCE-ANT is still under development.

We gave simple definitions of two types of deviations for UCE-ANT. The future work includes investigating the effects when changing the definition of the deviations. It might be also interesting to generate motion of dancing and singing robots by adding a Motion layer in which each node represents an action of a joint.

Abstract: In this study, we proposed and fabricated the simple system for detecting sound localization based on the biological auditory system. The proposed system is constructed with the simple circuit for detecting sound localization, two microphones, the photodiode, the motor and the rotation table. The test system was fabricated by the simple circuit for detecting sound localization by using the simple circuit constructed with discrete metal oxide semiconductor (MOS) transistors on the breadboard. The experimental results of the test system showed that the proposed system can detect the position of the sound of the target. We can realize novel target tracking system by applying the proposed system based on the biological auditory system.

Keywords: sound localization, auditory system, tracking system, analog circuit, digital circuit

1 INTRODUCTION

It is necessary for robotics vision, monitoring system and collision avoidance system to capture quickly the target in the visual field. However, it is difficult for the systems based on only the vision system to capture quickly the target in the visual field since the system cannot detect the position of the target when the target is not existed on the visual field. On the other hand, the animal can capture quickly the target in the visual field by using other functions such as the auditory system. The biological auditory system can process the sound information of the target and detects the position of the sound, even if the target is not existed on the visual field.

Recently, many researchers proposed and fabricated the simple system for target tracking based on the biological vision system [1]-[5]. These systems can track the target by using the motion signals. These systems are characterized by simple structure, low power consumption and high speed processing. However, these systems could not track the target when the target was not projected on the input parts since the systems were proposed by mimicking only the vision system. If the system based on the vision system is connected with the system based on the auditory system, it is able to track the target in various situations.

L. A. Jeffress proposed the model for detecting sound localization based on the biological auditory system [6]. Because the model is constructed with the delay line and the comparator, the model is simple structure. We proposed the simple analog-digital circuit for detecting sound localization based on the model by Jeffress [7]. The proposed circuits were constructed with the current mode delay line and the NOR circuits. The proposed unit circuit of delay line was constructed with 9 metal oxide semiconductor (MOS) transistors and 1 capacitor. The NOR circuit used as the comparator was constructed with 4 MOS transistors. Therefore, the proposed circuit is simple structure. We showed that the circuit can detect the position of the sound of the target. It is necessary to fabricate the system for detecting the position of the target (sound) by using the proposed simple circuit.

In this study, we tried to propose and fabricate the system for detecting sound localization. The proposed system is constructed with the circuit for detecting sound localization, two microphones, the photodiode, the motor and the rotation table. The test system was fabricated by using test circuit for detecting sound localization constructed with discrete MOS transistors on the breadboard. The experimental results of the test system showed that the proposed system can detect the position of the sound, and capture the target in the visual field.

2 MODEL AND CIRCUIT

2.1 A model

Figure 1 shows the model for detecting sound localization proposed by Jeffress [6]. The model is constructed with the delay line constructed with the delay neuron D and the comparator C. The Unit is constructed two delay neurons and one comparator, as shown in Fig.1.

I_{left} is input signal for delay line (left) generated by the left ear. I_{left} transmits the delay line (left) from D_1 to D_n. I_{right} is input signal for delay line (right) generated by the right ear. I_{right} transmits the delay line (right) from D_n to D_1. Therefore, delay neurons output the signal sequentially.

When the sound of the target is large, I_{right} and I_{left} become large. Inversely, I_{right} and I_{left} become small when the sound of the target is small. When I_{right} (I_{left}) is large, I_{right} (I_{left}) transmits the delay line quickly. When I_{right} (I_{left}) is small, the I_{right} (I_{left}) transmits the delay line slowly.

The output signals of delay neurons are input to the comparator. When both delay neurons in the Unit output the signal, the comparator outputs the signal.

When the sound of the target located on the right side, the Unit located on the left side outputs the signal. When the sound of the target located on the left side, the Unit located on the right side outputs the signal. When the positions of the sound of the target differ, the different comparator outputs the signal. Therefore, the Jeffress model can detect the position of the sound.

2.2 Circuits

Figure 2 shows the unit circuit of the delay line [5]. The unit circuit is constructed with 9 MOS transistors and 1 capacitor. The input current I_{in} flows into the capacitor C_n. Then, the voltage V_C is increased. The circuit transmits I_{in} to the neighboring unit circuit and outputs the output voltage V_o to the comparator.

When I_{in} is large, V_C is increased quickly. Then, the unit circuit outputs V_o quickly. When I_{in} is small, V_C is increased slowly. Then, the unit circuit outputs V_o slowly. The voltage V_{th} is the constant voltage. The voltage V_r is utilized to reset V_C.

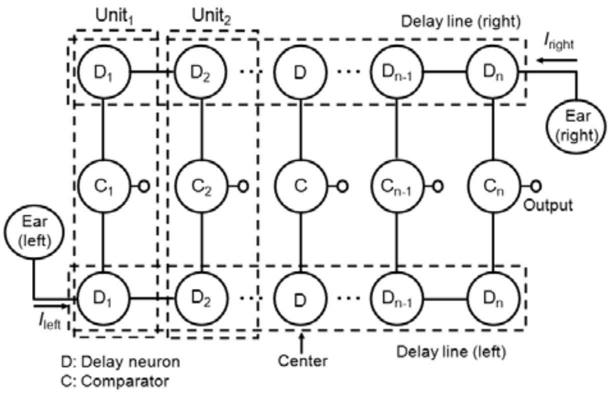

Fig. 1. The model for detecting sound localization

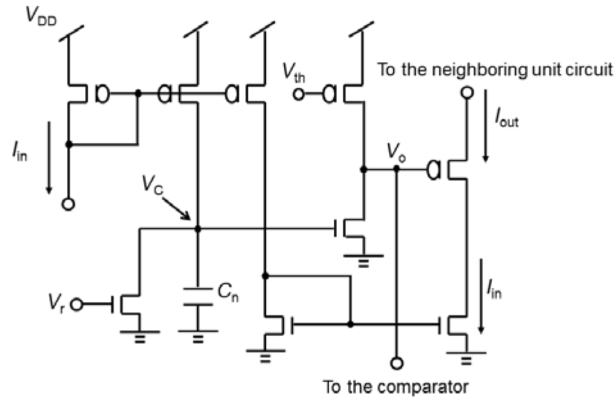

Fig. 2. The unit circuit of delay line

Figure 3 shows the NOR circuit used as the comparator. The NOR circuit is constructed with 4 MOS transistors. Therefore, the circuit is simple structure.

3 SYSTEM CONSTRUCTION

Figure 4 shows the proposed simple system for detecting sound localization. The proposed system is constructed with the simple circuit for detecting sound localization, two microphones, the photodiode, the motor and the rotation table. The output terminals of neighboring Units are connected each other. For example, the output terminals of Unit1 and Unit2 are connected, as shown in Fig.4. All of the terminals are connected with the capacitor and Reset line. The Reset line is connected with the terminals of V_r in Fig.2. When the voltage of the Reset line becomes supply voltage V_{DD}, the circuits are reset.

The voltage V_{right} is generated by connecting the output terminals of Units located on the left side. The voltage V_{left} is generated by connecting the output terminals of Units located on the right side. The output terminals of the Units located on the center are connected with the Reset line.

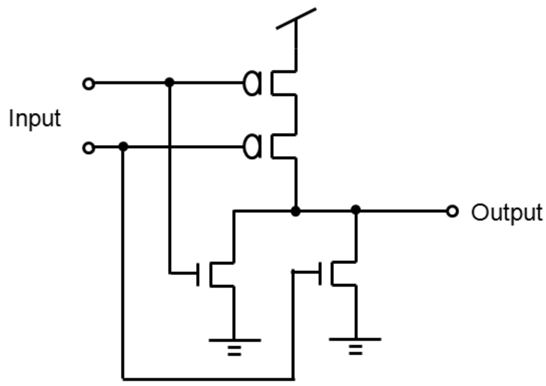

Fig. 3. The construction of NOR circuit

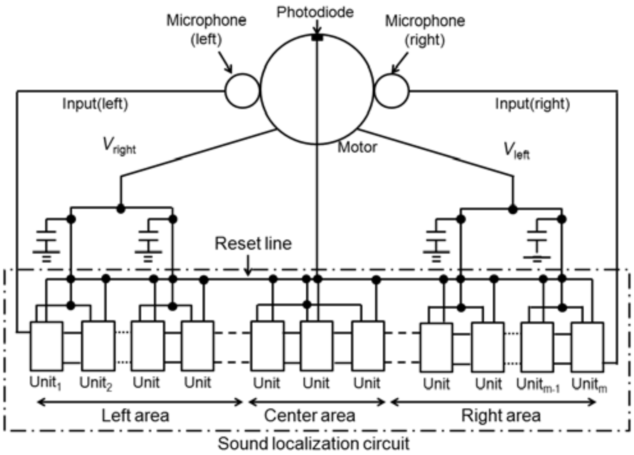

Fig. 4. Simple system for detecting sound localization

The microphones generate the input signal of the system. When the sound of the target is large, the signal of the microphone is large. When the sound of the target is small, the signal of the target is small.

The photodiode is connected with the Reset line. The photodiode is utilized as the visual sensor. When the target is projected on the photodiode, the signal of the photodiode becomes V_{DD}.

The terminal of V_{left} and V_{right} are connected to the motor driver. When V_{left} becomes V_{DD}, the motor rotates the rotation table from center to left. Inversely, the motor rotates the rotation table from center to right when V_{right} becomes V_{DD}. When both of the terminals of V_{left} and V_{right} are 0 V or V_{DD}, the motor does not rotate. The time of rotation was changed by the capacitance.

When the sound of the target is located on the right, the input signal of the right is larger than input signal of the left. Then, the output terminals of Units located on the left area becomes V_{DD}. V_{right} and the voltage of the Reset line become V_{DD}. Then, the motor rotates the rotation table from center to right. After that, the circuits were reset.

When the sound of the target is located on the left, the output terminals of the Units located on the right area becomes V_{DD}. Then, V_{left} and the voltage of the Reset line become V_{DD}. The motor rotates the rotation table from center to left.

When the sound of the target is located on the center, the terminal located on the center area becomes V_{DD}. Then, the system is reset by the voltage of the Reset line becomes V_{DD}.

When the target is projected on the photodiode, the system is reset by using the signal of the photodiode. Therefore, the proposed system can detect the position of the sound and can capture the target in the visual field.

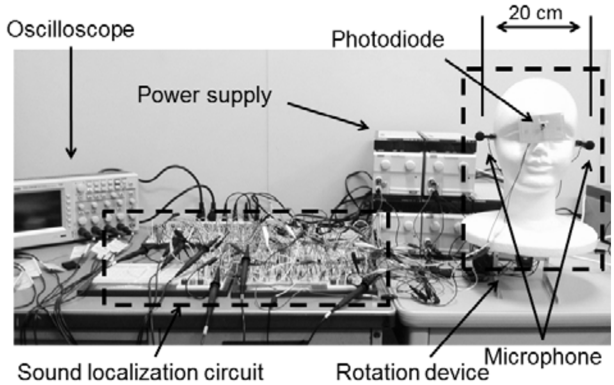

Fig. 5. The photograph of test system for detecting sound localization

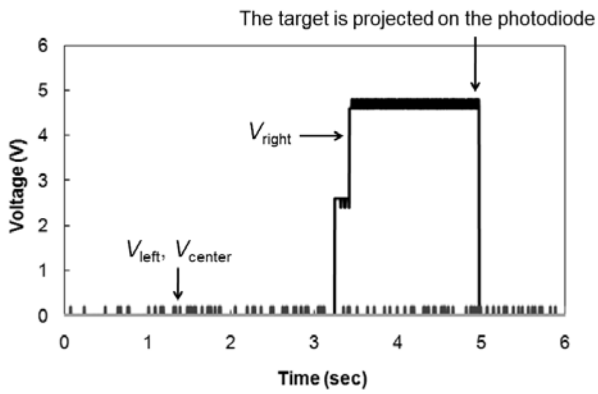
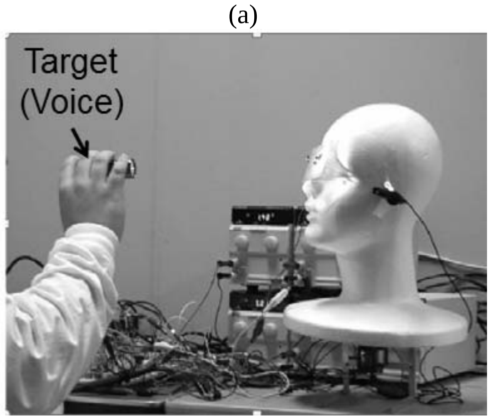
4 EXPERIMENTAL RESULTS

We tried to fabricate the test system for detecting sound localization. Figure 5 shows the photograph of the fabricated test system for detecting sound localization. The test circuit was fabricated by discrete MOS transistors (nMOS: 2SK1398, pMOS: 2SJ184, NEC) on the breadboard. The test circuit for sound localization was constructed with 7 Units. Unit1 and Unit2 were connected



(a)



(b)

Fig. 6. The experimental result of the test system when the target located on the right side. (a) Output voltage of the test circuit. (b) The measured results of the test system when the system captures the target.

with the terminal of V_{right}. Unit3, Unit4 and Unit5 were connected with the terminal of V_{center}. Unit6 and Unit7 were connected with the terminal of V_{left}. The voice was utilized as the target. The microphones (ECM-C115, SONY) and the photodiode were attached to a mannequin.

Figure 6 shows the experimental results when the sound located on the right side. When the sound located on the right side, V_{right} become about 5 V, as shown in Fig.6 (a). Then, the motor was rotated from center to right. The motor stopped when the target was projected on the photodiode, as shown in Fig.6 (b).

Figure 7 shows the experimental results when the sound located on the left side. V_{left} become about 5 V, as shown in Fig.7 (a). The motor was rotated from center to left, as shown in Fig.7 (b). The motor stopped when the target was projected on the photodiode.

Therefore, the proposed system can detect the position of the sound of the target.

5 CONCLUSION

In this study, we proposed and fabricated the simple system for detecting sound localization based on the model by Jeffress. The system is constructed with the simple circuit for detecting sound localization, two microphones, the photodiode, the motor and the rotation table. The experimental results of the test system showed that the proposed system can detect the position of the sound of the target and can capture the target in the visual field. We can realize novel target tracking system by applying the proposed system based on the biological auditory system.

1 INTRODUCTION

Living organism creates various shapes of an organ and the body by lamination of cells. An understanding of the generalized mechanism of biological morphosis is considered fundamental to applications in various fields, such as the mass-production of molecular machines in nanotechnology and artificial synthetics in biology (synthetic biology). Furthermore, it is difficult to construct large, complex machine systems that exceed a certain size, using a top-down approach. Therefore, such complex machine systems must be constructed using a bottom-up approach based on the phenomenon of biological morphosis.

Historically, researchers have attempted to develop a mathematical model to simulate the morphosis of living matter. Studies on the reproductive models of a body surface design, namely, the Turing model (Turing, 1952), and those on the leaf vein pattern of a plant (Feugier, 2005) and mollusk shell patterns (Meinhardt, 2003) are examples of previous research. In addition, many researchers have used a cellular automaton model to study tissue or tumor growth. Although these models can simulate a number of features of biological morphosis on a computer, they cannot reproduce the entire body on the basis of unified equations and rules, such as cytodifferentiation by gene expression → morphosis of cells → organogenesis → emergence of function.

2 OBJECTIVE

This study developed the model to simulate the morphogenetic mechanism of cells under the condition of two-dimensional cellular automata. Each cell of the automaton model expresses cell organelle and holds an various states in each cell. We modeled the mechanism of gene expression by the information exchange between the adjacent cells of the automaton model. Furthermore, shapes emergence of various creature organs was simulated by the rules of cellular differentiation and rules of hierarchical formation of cells. Simultaneously we also simulated the possibility of the self-repair.

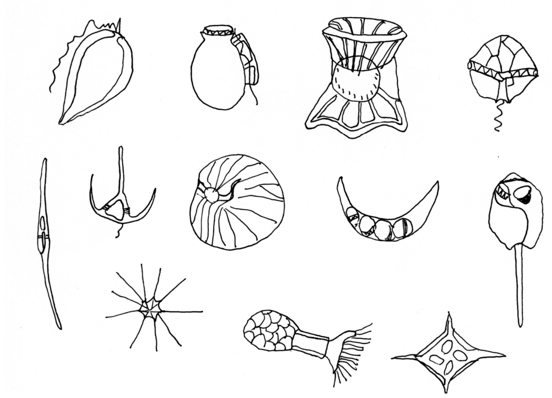

Fig. 1. Various shapes of the unicellular organism

With the real living organism, all forms are not described in DNA, and it is thought that the physical phenomena such as the diffusion of the chemical substance were used in living cells. For this reason, we considered not only the state transition rules but also the concentration diffusion of the field. Thus our model was able to simulate morphogenetic formation in few state transition rules and few parameters of concentration diffusion equations.

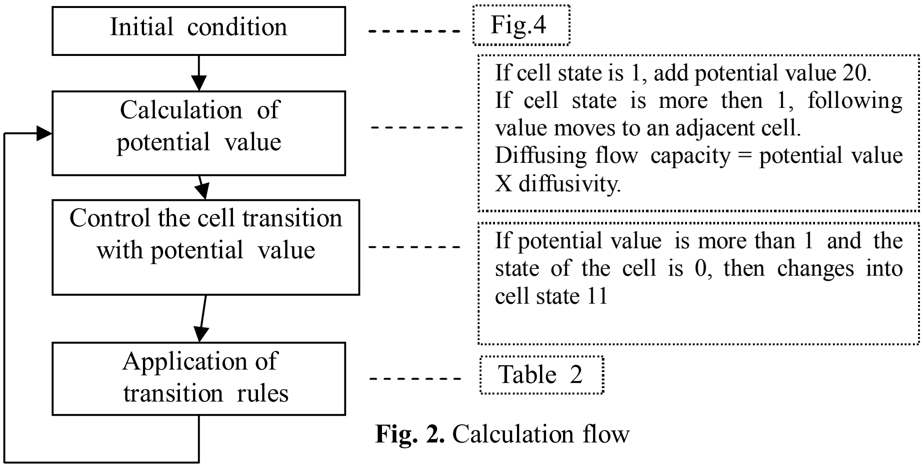

Fig. 2. Calculation flow

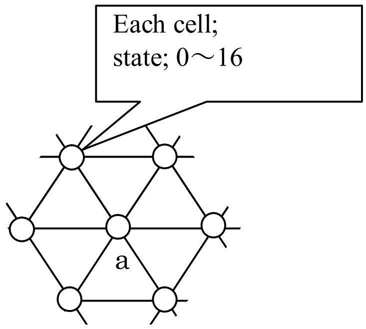

Fig. 3. Triangle grid model

The microbes such as protists create a variety of shapes by a single cell or a few cells (Fig.1). As trial simulation cases, we simulated the shape similar to various form of the microbe.

3 RESEARCH METHOD

3.1 Cellular automaton model

A two-dimensional hexagonal grid model was used in this study (Fig.3). The cell automaton was constructed according to the transition rules so that the state of the next step was determined by the state of the cell itself and the states of the six neighboring cells. Each cell had a state (0–16 states), Table 1 shows the content of 16 states.

Figure 2 shows the calculation flow. In a hexagonal grid, the calculations start from a certain initial condition. We calculates the potential value of gird fields, and control the cell transition with potential value. Then, we applied the transition rules, and settled the total states in all cells.

3.2 Transition rules

The transition rules are presented in Tables 2. We have not yet discovered a method with which to derive transition rules automatically according to a uniform law. Therefore, we constructed transition rules step-by-step according to the movements of the automaton.

3.3 Initial conditions

Figure 6 shows the notation of initial condition. Initial condition is consisted of 7 cells. Central cell is state 1 which has initial potential value. Around the central cell, we set 6 initial cells, which have state from 2 to 6, expressing by six columns of numerical value.

Table 1. States of cell

4 RESULTS

Figure 5 shows the calculation result in the initial case of 626262. A triangular cell is formed and some flagellars are formed. Figure 6 shows the process of cell membrane formation. Figure 7 is change of the result by the difference in initial condition. It is understand that various shapes were formed by the difference in initial condition. Figure 8 shows the change of the result by the difference in cell membrane condition from 13 to 18 in Table 2.

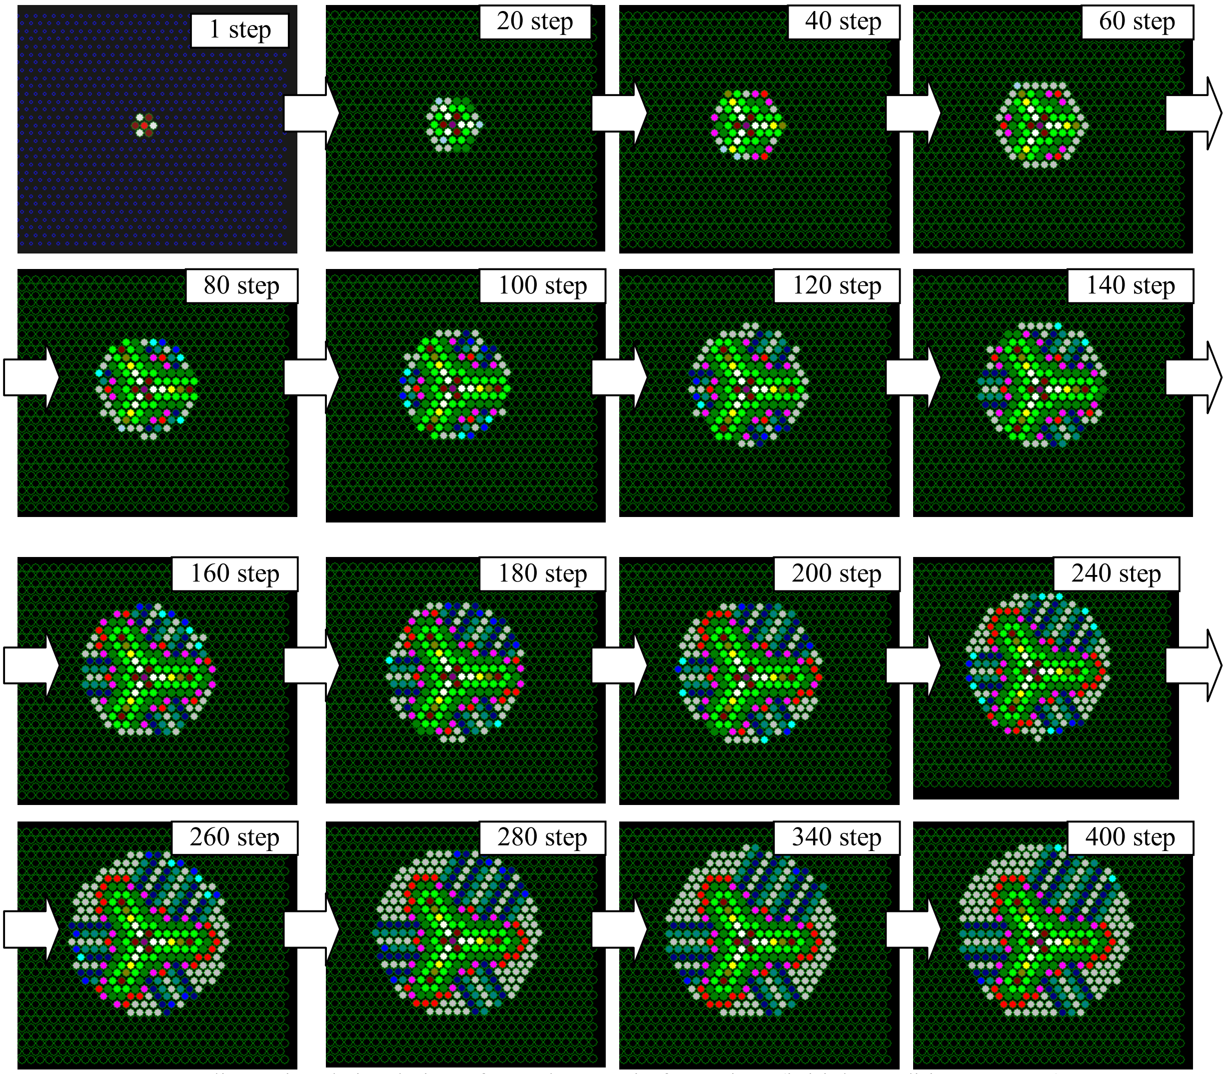

Fig. 6. Two-dimensional simulation of morphogenetic formation (initial condition 626626)

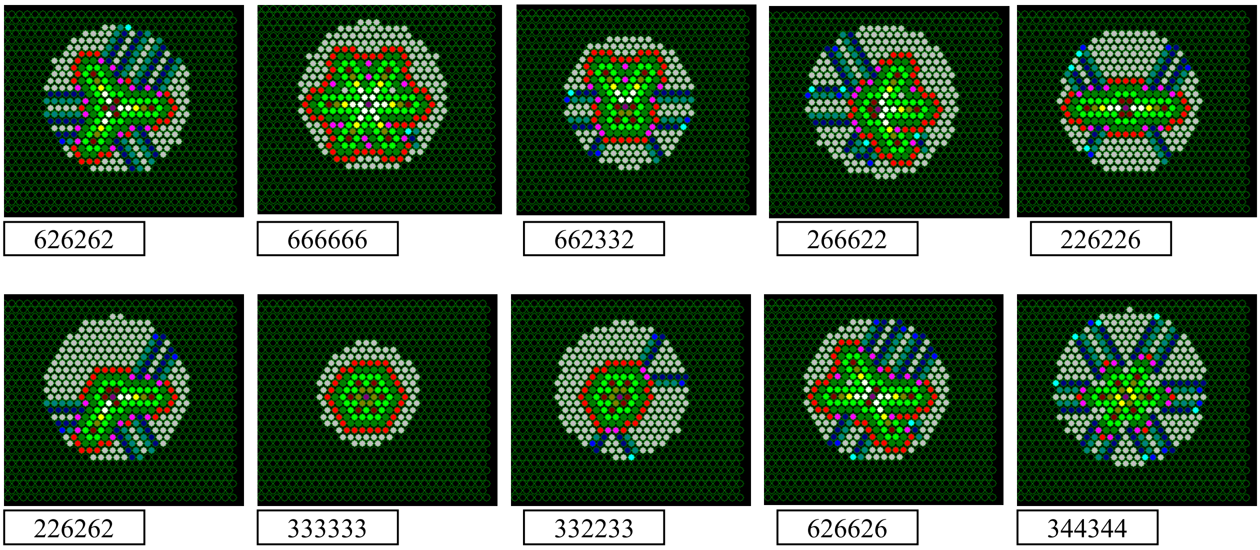

Fig. 7. Two-dimensional simulation of morphogenetic formation (Change of the result by the difference in initial condition)

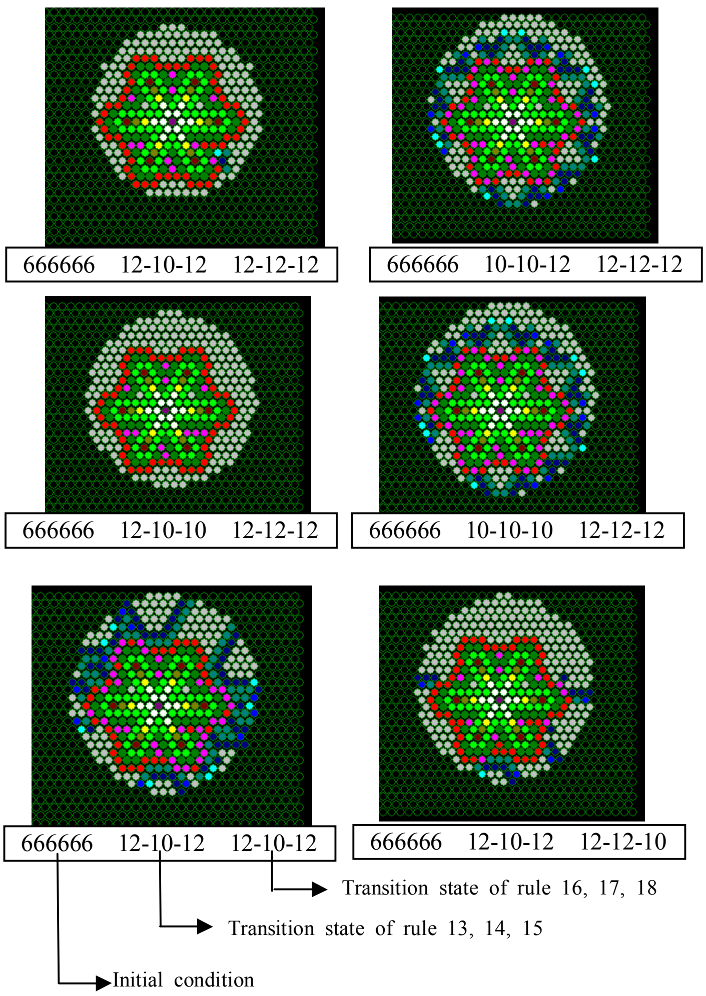

Fig. 8. Two-dimensional simulation of morphogenetic formation (Change of the result by the difference in cell membrane condition)

5 CONCLUSION

Using our model, we confirmed that the variety of shapes was emerged with the slight changes of some parameters value. Future directions are as follows:

- Find other transition rule sets.
- Find a way to automatically derive transition rules based on the uniformity law.
- Apply transition rules to chemical reaction system theoretically.

We believe that transition rules of this model can be applied to simulate self-organizing phenomena in real dynamic chemical reaction environment by applying transition rules determined in this study.

Abstract: This study presents a control method for a water flow to avoid seaweed twining in a cultivation pool. The water flow in the pool is modeled by the lattice Boltzmann method (LBM). Morphology of the seaweed is determined by L-system. Physics Modeling (PM) represents its physical model. Three physical properties, gradual collision, adhesiveness, and tear phenomenon for the seaweed are artificially introduced into simulation. Motion of the seaweed is examined in the virtual underwater pool by PM simulation. A water flow pattern is realized by controlling particles distributed in lattices. We ascertained that some water flow pattern can avoid the seaweed twining phenomenon by changing the water flow pattern in the simulation.

Keywords: Physics modeling, Seaweed, L-system, Computational Fluid Dynamics, Lattice Boltzmann Method

1 INTRODUCTION

The technology of renewable energy is required for solving the global warming problem. In recent years, seaweed has been attracted for this purpose [1]. It absorbs CO_2 and emits O_2 in growing. The growth rate of the marine plant is 10 times faster than the terrestrial plant. Because the marine plant grows in a rich nutrition sea and the terrestrial one grows in soil. The grown seaweed is available as a material of bio-ethanol. Growing seaweed in seawater dissolving high concentration CO_2 can accelerate the growth rate of seaweed.

There arise some difficulties to introduce seaweed cultivation in large-scale bio factory. One of problems is to control a water flow for avoiding seaweed twining. Factors of the environment for effectively growing the seaweed are CO_2 assimilation of seawater and water temperature. Physical motion of seaweed with the growth process is also an important factor. Twining of seaweed causes depression of assimilation efficiency of CO_2 and death. It makes an adverse effect to effective growing. Therefore, the control of water flow is required for solving these problems.

Understanding physical motion of seaweed in fluid is important. Seaweed motion in fluid is flexible. This is one of biological properties and cause seaweed twining. Finding out conditions to generate twining has significant meaning.

This study aims at making a simulation model that examines water flow conditions causing seaweed twining. We make a physical model of seaweed and develop a virtual underwater pool where some water flow occurs. The motion of the seaweed is physically realized in the virtual underwater pool and verifies that our model can simulate suitable seaweed motion and fluid flow.

2 ARTIFICIAL SEAWEED

The physical model of seaweed is represented by connecting some small rigid spheres. It has three degrees of freedom and approximates soft motion of plants.

2.1 Physical model

The algorithm called L-system can represent the growth process in plants [2]. It was proposed by Hungarian theoretical biologist and botanist, Aristid Lindenmayer. We adopt L-system for modeling seaweed morphology and the grow process. L-system is shown in (1)-(4). Notations to make a growth model in fig.(1) are introduced as follow; V is the replaceable set of rigid bodies shown in fig.1, S is the invariable set of rigid bodies, ω is the initial state and P is the replacement rule.

$$V = \{A, B, C\} \quad (1)$$
$$S = \{E, D\} \quad (2)$$
$$\omega = A \quad (3)$$
$$P : (A \rightarrow EBA), (B \rightarrow C), (C \rightarrow D) \quad (4)$$

The seaweed grows by iteratively dividing branches. By applying L-system, the growth process of the artificial seaweed is represented in a natural form of plants.

A physical model is designed as shown in fig.3. It consists of 340 rigid bodies. Each rigid body has the same volume as the sphere one with 0.25 meters in radius.

2.2 Physical property

In order to mimic real seaweed as much as possible, we give physical properties to the artificial seaweed model. Such properties are gradual collision, adhesiveness and tear.

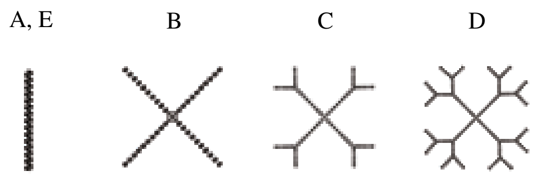

Fig. 1. The component of the physical model

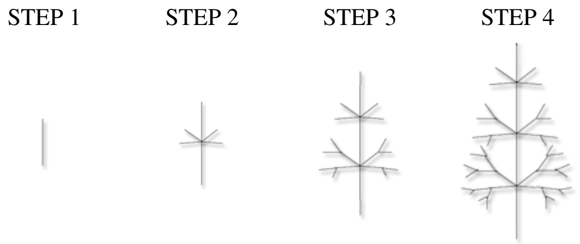

Fig. 2. The growth process of the physical model

2.2.1 Gradual collision

Gradual collision is observed among actual plants. An automatic calculation of collision by physical engine depends on a value of reflection coefficient. We set 0.05 to the value of reflection coefficient e. The gradual collision is realized by relatively reducing force in collision.

2.2.2 Adhesiveness

When some seaweeds colide each other, attractive forces among them appear. We model this phenomenon as adhesiveness. We add a small force similar to Coulomb one between two rigid bodies as the adhesiveness when a distance between two rigid bodies is less than the threshold r_t. This force is given by eq.(5),

$$F_A = k_a \frac{1}{r^2} \quad \text{for} \quad r < r_t \tag{5}$$

where k_a is an adhesive coefficient, r is a distance between two rigid bodies.

2.2.3 Tear

Seaweed is teared when a strong force works to it. In our model connection of rigid bodies is teared into two parts when receiving the external force larger than 10,000[N]. Teared parts cannot be reconnected any more.

3 VIRTUAL UNDERWATER ENVIRONMENT

A physical model for a virtual underwater pool is constructed by using PhysX that is the physical engine provided by NVIDIA cooperation. PhysX can do fast physical calculation and physical simulation on rigid bodies easily. However, functions for the buoyancy and drag forces in a fluid are not supported in the PhysX. We implement three forces as referred in [3].

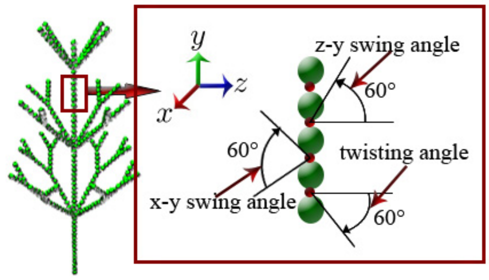

Fig. 3. The artificial seaweed model

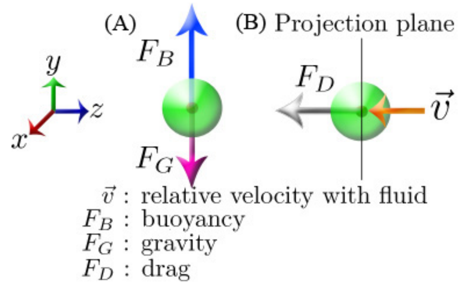

Fig. 4. Buoyancy and drag calculation

3.1 Buoyancy

In a fluid environment, the upward force called the buoyancy F_B works to the center of objects as shown in fig.4(A). A calculation of this force is given in eq.(6),

$$F_B = \rho V g \tag{6}$$

where ρ is a density of the water, V is a rigid volume, g is acceleration of gravity.

3.2 Drag force

Drag force F_D shown in fig.4(B) works to the rigid body in a fluid. This force that directs to opposite movement is proportional to a square of a relative velocity with a fluid. A calculation of this force based on fluid dynamics is given in eq.(7),

$$F_D = \frac{1}{2} \rho A C_D v^2 \tag{7}$$

where ρ is a density of the water, A is an area to which the drag works, C_D is a drag coefficient of inherent nature of rigid body, v is relative velocity of rigid with fluid.

4 WATER FLOW

In order to examine a pattern of water flow that makes avoiding seaweed twining, we require a realistic water flow model. Water is a fluid and its density is not changed by pressure. Therefore, the water flow can be treated as an incompressible fluid. In this study, it is modeled by the lattice Boltzmann method (LBM) [4].

4.1 Lattice Boltzmann Method

LBM is one of analytical techniques in computational fluid dynamics [5]. The method uniformly discretizes a simulating space into lattices and make it possible to simulate fluid movement as a continuum by use of particles distributed in the lattices. A particle distribution function is obtained by calculating ensemble average of a number of particles in each lattice. A fluid density and velocity is easily computed in this way. The number of particles is provided by real number. It can represent a high-precision flow without noise.

Particles have some velocities in LBM. In a discretizing time, they leave lattice or move to other lattice once at each time step $\quad t$. Some particles change the direction of velocity by collision. All particles are located in lattices at each time step. Particle collision appears in all lattices at the same moment.

4.2 Fluid model

We employ D3Q15 model as a particle distribution model in LBM [6]. The particles have velocities as shown in fig.5. The model only considers the mass conservation and momentum one.

4.2.1 Time evolution of particle distribution

To calculate a time evolution of particle distribution, we use the lattice Boltzmann equation defined by eq.(8).

$$f_i\left(x + e_i \quad t, t + \quad t\right) = \left(\frac{\lambda \quad 1}{\lambda}\right) f_i\left(x, t\right) + \frac{1}{\lambda} f_i^{eq}\left(x, t\right) \quad (8)$$

This equation is an evolution equation for the virtual particles. λ is a relaxation frequency. Particles move by iterating collision and they transit from a movement state to a equilibrium state at a constant rate. f_i^{eq} is a local equilibrium distribution. This particle equilibrium distribution function is given by eq.(9),

$$f_i^{eq}\left(x, t\right) = \omega_i \rho \left(1 \quad \frac{3}{2}\vec{u}^2 + 3\left(\vec{e_i} \quad \vec{u}\right) + \frac{9}{2}\left(\vec{e_i} \quad \vec{u}\right)^2\right) \quad (9)$$

$$\text{where, } \omega_i = \begin{cases} \frac{2}{9} & : \quad i = 0, \\ \frac{1}{9} & : \quad i = 1..6, \\ \frac{1}{72} & : \quad i = 7..14. \end{cases}$$

and ρ is a density of fluid, $\vec{u}$ is a velocity of fluid, $\vec{e_i}$ is a velocity of particle. By adding f_i^{eq} to the particle distribution function, eq.(8) guarantee a situation that fluid transit to the equilibrium state [6].

4.2.2 Boundary condition

In a lattice making a border as obstacles, the particle distribution function cannot give particles' direction to the fluid as obstacles. Therefore, we apply *bounce-back* to such lattices as a boundary condition. This condition rebounds particles into 180 degrees of direction from an obstacle shown in fig.6.

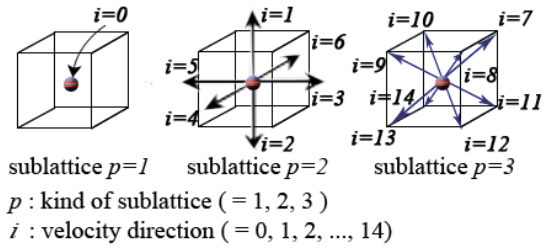

Fig. 5. D3Q15 Model

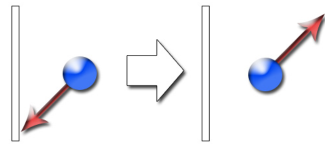

Fig. 6. This figure gives an overview of the translate and collide processes for a fluid lattice next to an obstacle.

5 NUMERICAL SIMULATION

In order to study the growth environment for avoiding seaweed twining, we examine two water flow patterns. We simulate physical motion of the artificial seaweeds in the virtual underwater pool considering in the water flow.

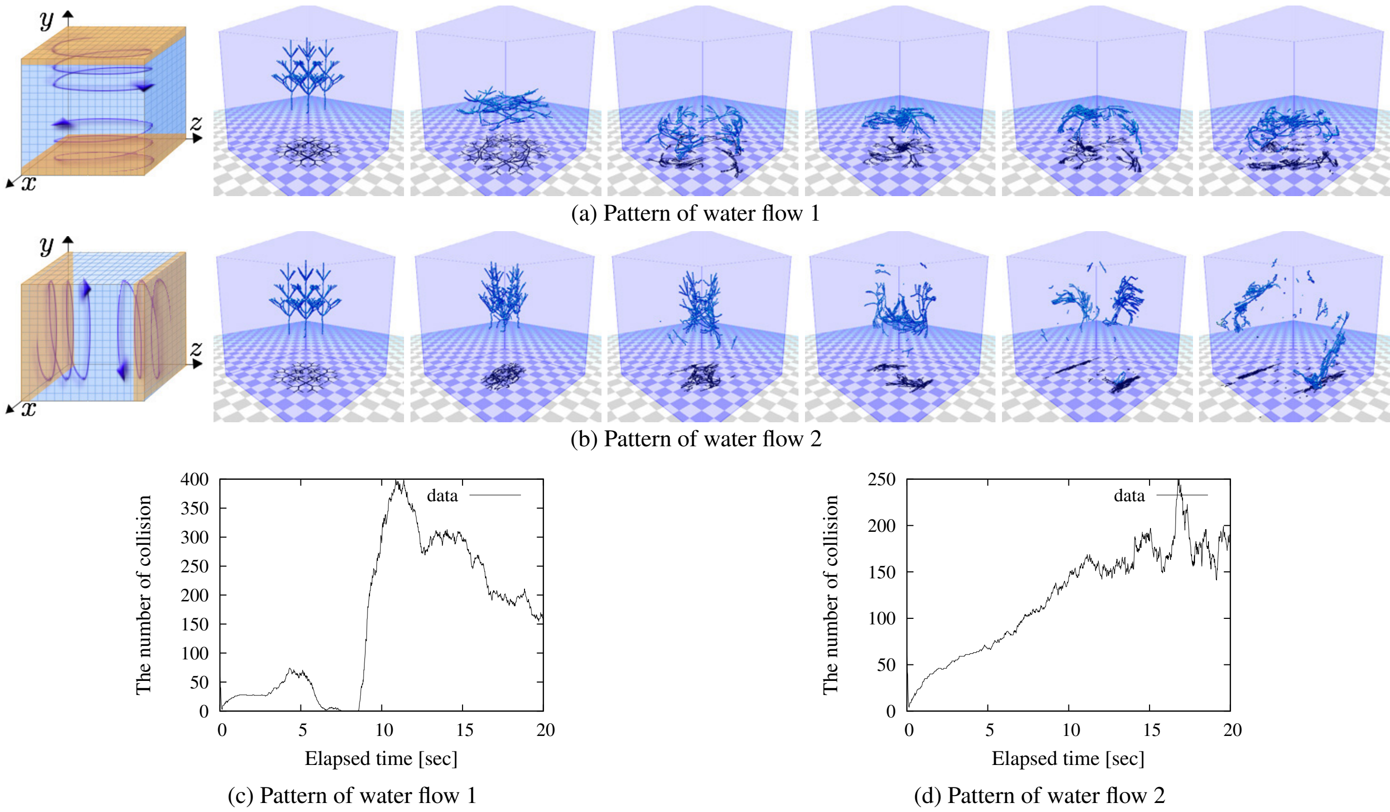
5.1 Conditions

Two patterns of water flow are experimented. The virtual underwater pool consists of 100 meters square cube and it is split up into 10^6 lattices. A central coordinate in the square cube is (0[m], 50[m], 0[m]).

We prepare two patterns of water flow as the forced convection. One of water flows is set by two spiral flows which are generated along y axis from 0[m] to 100[m] toward each other. The other is set by two spiral flows along z axis from -50[m] to 50[m] toward each other. The number of artificial seaweeds is four and initial positions of them are located at (10[m], 50[m], 10[m]), (-10[m], 50[m], 10[m]), (10[m], 50[m], -10[m]) and (-10[m], 50[m], -10[m]). A density of the model ρ_r equals to 1000.0[kg/m^3], a density of the water ρ 998.2[kg/m^3], drag coefficient C_D 1.0 and the project area A 0.25^2 . The initial state in the underwater is perfectly motionless. The simulation time is 20[sec]

5.2 Results of experiment

The results obtained from the computer simulation are shown in fig7. As for the pattern of water flow 1, the artificial seaweeds move outside in a spiral water flow from the upper surface. They move toward the position y=0 and are



(a) Pattern of water flow 1

(b) Pattern of water flow 2

(c) Pattern of water flow 1

(d) Pattern of water flow 2

Fig. 7. Results of physical motion of artificial seaweed in underwater. (a) and (b) shows two patterns of water flow 1 and 2 respectively. Two graphs show the number of collision between rigid bodies at each time.

involved in a vortex generated by convection. Then the artificial seaweeds repeat to move upward and are involved in a vortex. Fig.7(c) shows the number of collision among rigids calculated by physical modelling rapidly increases up to 12 [sec] and them it decreases gradually. This shows that twining is generated and a part of the artificial seaweed teared is lost.

As for the pattern of water flow 2, the seaweed moves to right and left surfaces in the generated water flow when two artificial seaweeds keep in contact each other. Fig.7(d), the number of collision increases with the elapsed time and the moving range of artificial seaweeds is gradually partitioned into two ranges. Note that the number of collision does not decrease. In two separated regions twined artificial seaweeds cannot be observed but tear phenomenon.

6 CONCLUSION

We present a seaweed model having physical properties and realized seaweed twining phenomenon by physical simulations. High density of seaweed in the virtual underwater pool is one of conditions to generate twining. A tear occurs by adding forces in multiple directions into rigids. Water flows and circulating realize seaweed twining including tear. However, a water flow along a specific orbit cannot be introduced. We would like to find some patterns for avoiding the tear and seaweed twining.

Abstract: This paper introduces the problem of floating-point rounding errors in physical simulation. A simple virtual creature is simulated in a physical environment for a specified number of time steps. The effect of rounding errors is illustrated by varying the initial position of the creature which causes a change in the fitness value computed by a simple distance-based fitness function. With a large evaluation time, these rounding errors can produce significantly large differences in fitness. A discussion is provided on the importance of this finding for evolutionary simulations, including suggestions to alleviate the problem.

Keywords: physical simulation, floating point, rounding errors, evolutionary computation, artificial life

1 INTRODUCTION

Physical simulation is gaining popularity in the artificial life community. It enables experimentation with physical models which reflect the physical nature of biological organisms. Such experiments are vital in real-world applied robotics research. Furthermore, physical simulation allows for a complex simulation environment, important for the study of theoretical problems.

Physics engines are made for the video gaming market and are not meant to be used for accurate scientific simulation. However, they are valuable as they offer an approximation to more accurate physical simulation but at real-time speeds. We present and discuss problems that occur when using video game grade physics engines for scientific simulation, focusing on the problem of floating-point rounding errors. We simulate a simple virtual creature in a simple physical environment and demonstrate the rounding error problem on fitness evaluation by varying the creature's initial position.

We show that the fitness performance is highly sensitive to small variations in the creature's initial position producing significant variation in fitness values. These rounding errors occur after only a few simulation steps and increase drastically over simulation time. While not generally destructive, these errors can impact the performance of evolutionary algorithms that use fitness-proportional selection. Having identified the problem and presented evidence of its occurrence, we offer solutions that can alleviate it.

2 TEST MODEL AND ENVIRONMENT

Floating-point is the most common method to represent real numbers in computers. However, it is often poorly understood by software developers and researchers alike [1]. The most common floating-point representation currently used is defined by the IEEE 754 standard. There are mainly two sources of error when using floating-point representation: not all real numbers can be exactly represented and rounding error is inherent in floating-point computation.

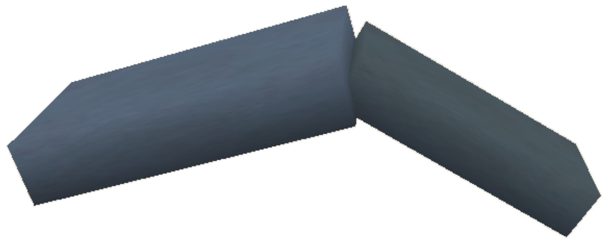

Fig. 1: Hand-crafted virtual creature used in the presented experiments composed of two bodies connected with a hinge joint. Neural network controller not shown.

The virtual creature model provides a simple yet powerful model for the study of evolution of morphologies and controllers for tasks such as locomotion [2] and light following [3]. We use a simple hand-crafted virtual creature, using the virtual creature model described in [2], composed of two blocks of different sizes joined with a hinge joint (shown in Fig. 1). The neural network consists of a sine wave generator neuron feeding into an effector allowing the smaller body part to rotate around the hinge joint.

The testing environment is composed of a simple plane simulation surface with friction. Virtual creatures are initially positioned above the surface and are allowed to drop due to the gravitational force. Once a creature rests on the ground surface and is stable from movement, the neural network of the creature is turned on which makes the creature move along the surface. We use a simple fitness function, measuring fitness as a simple displacement from the original resting position to the final resting position, to demonstrate the rounding error problem.

Physical simulation is performed using the Morphid

Academy software [2]. Morphid Academy is a virtual laboratory for the evolution of functional forms called Morphids. The software features physical simulation using the Open Dynamics Engine[1] (ODE) and NVIDIA PhysX[2] engines, graphical visualization through the OGRE graphics engine, and an ability to perform structured evolutionary experiments with a built-in genetic algorithm.

3 EXPERIMENTS AND RESULTS

We executed a suite of creature evaluation experiments to showcase the problem with physical simulation due to floating-point rounding errors. These experiments only performed creature simulation and fitness evaluation and did not have an evolutionary component. The position and evaluation time experiments were run using the NVIDIA PhysX engine while the precision experiments used ODE. The evaluated creature was recreated for each evaluation to prevent accumulation of internal state errors. For each evaluation, the creature was located at a certain (x,y) coordinate, along the simulation plane. The z-coordinate was kept constant.

3.1 Position

The initial creature position experimental results demonstrate the main problem of rounding errors in the floating-point representation producing unexpected behavior in physical simulations. Physics engines generally produce deterministic behavior (at least on the same hardware). When a fixed initial position is used (as in most virtual creature evolution systems), the behavior of a virtual creature is the same over a number of evaluations. However, modifying the initial position by a small amount can produce chaotic behavior with drastically different fitness values.

Fig. 2c illustrates this phenomenon showing the fitness values of the evaluated creature for 10000 initial positions centered around the origin and offset by multiples of a fixed position delta $\delta_x = 0.001$ along the x-axis. It is expected that the fitness will be independent of the initial x position value, producing a plot with a straight line. However, the fitness values vary greatly with a somewhat random distribution.

Additional experiments were performed varying the value of δ_x (not shown). Experiments with smaller values of δ_x have similar fitness behavior. With larger δ_x, somewhat periodic patterns of fitness values can be seen, which is likely due to the larger position values (in 100s). Similar results are observed varying δ_y along the y-axis.

3.2 Evaluation Time

Evaluation time is important for physical simulation since adequate evaluation time is required for the occurrence of certain behaviors. Evaluation time is expressed in terms of evaluation steps where each step is equal to one step of the physics engine. Fig. 2 shows the dependence of the evaluation time of 10, 1000, and 10000 on the error propagation in fitness values using $\delta_x = 0.001$.

These results indicate that the problem of rounding errors occurs quite early with only a few number of steps (10 evaluation steps in Fig. 2a). The rounding errors propagate over

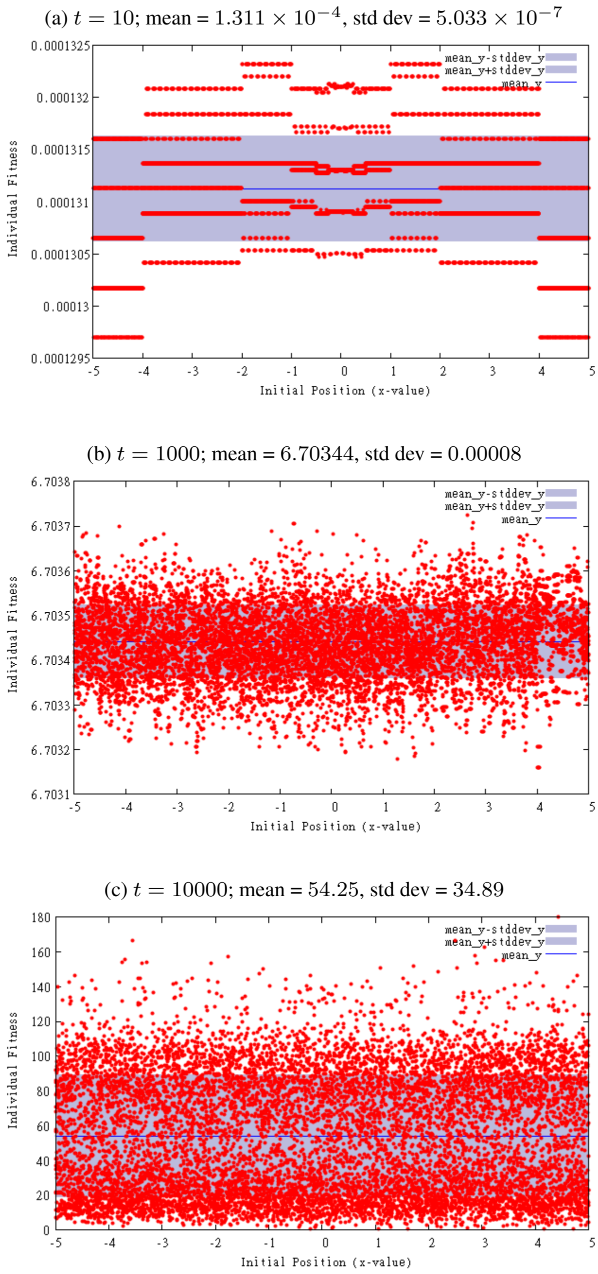

Fig. 2: Results of the evaluation time experiments with evaluation time t of 10 (a), 1000 (b), and 10000 (c). The x-coordinate of the initial creature position is plotted against the computed fitness value. Mean and standard deviation are displayed for each plot.

[1]ODE is available at `http://www.ode.org` under an open source license.

[2]The PhysX SDK is available for free from NVIDIA Corporation at `http://developer.nvidia.com/physx`.

evaluation time to a point where they produce a large range of results (as seen in Figs. 2b and 2c).

3.3 Precision

We run similar fitness evaluation experiments using the single and double precision versions of ODE with various evaluation time settings. ODE was used for these experiments since the NVIDIA PhysX SDK is only available in single precision. Selected results are shown in Fig. 3.

The results for smaller values of evaluation time (100 and 1000) show a larger dispersion of values using single precision. On the other hand, double precision produces more irregular fitness behavior within range $[-2, 2]$ (see Fig. 3a vs. Fig. 3b). With evaluation time of 10000, the single and double precision results are very similar with significantly large standard deviation values as demonstrated in Fig. 3c.

From these results, it is difficult to conclude whether the double precision fitness results are, in general, better than the ones with single precision, especially for a higher number of evaluation steps. It is interesting to note that while the mean fitness values for single and double precision are very similar with 100 and 1000 time steps, they are quite different with 10000 time steps (e.g., means of 96.434 vs. 69.447).

4 DISCUSSION

The floating-point rounding errors, presented by the examples in the previous section, are not necessarily a disadvantage of physics engines. The real world is inherently chaotic and capturing this behavior in simulations allows for results that appear more realistic and can be more suited to the real world. Artificial life simulations, especially involving a large number of interacting entities, are often criticized to be too orderly and thus not able to evolve novelty. Chaotic systems, such as physics engines, can be of benefit in this domain since they introduce inherent perturbations. Physically simulated ecosystems of evolving entities are a promising future for artificial life research.

The effect of this chaotic behavior has to be considered for each simulation since it can have a strong effect on the performance of the system and on the acquired results. In an evolutionary system where the fitness value decides on the reproductive strength of an individual, it needs to be calculated accurately for the algorithm to be effective. If the fitness of an individual significantly varies between different evaluations, the evolutionary algorithm might not select the individual for reproduction even though the individual is generally fit.

Fig. 4 illustrates the effect of the position-based rounding error problem on the performance of a genetic algorithm using the simple displacement fitness function. The variation in fitness values can be seen on the best of population line (in green). Furthermore, the evolutionary algorithm performance is decreased since good individuals can be eliminated from the population by worse performing individuals due to a significant variation in fitness values over different evaluations.

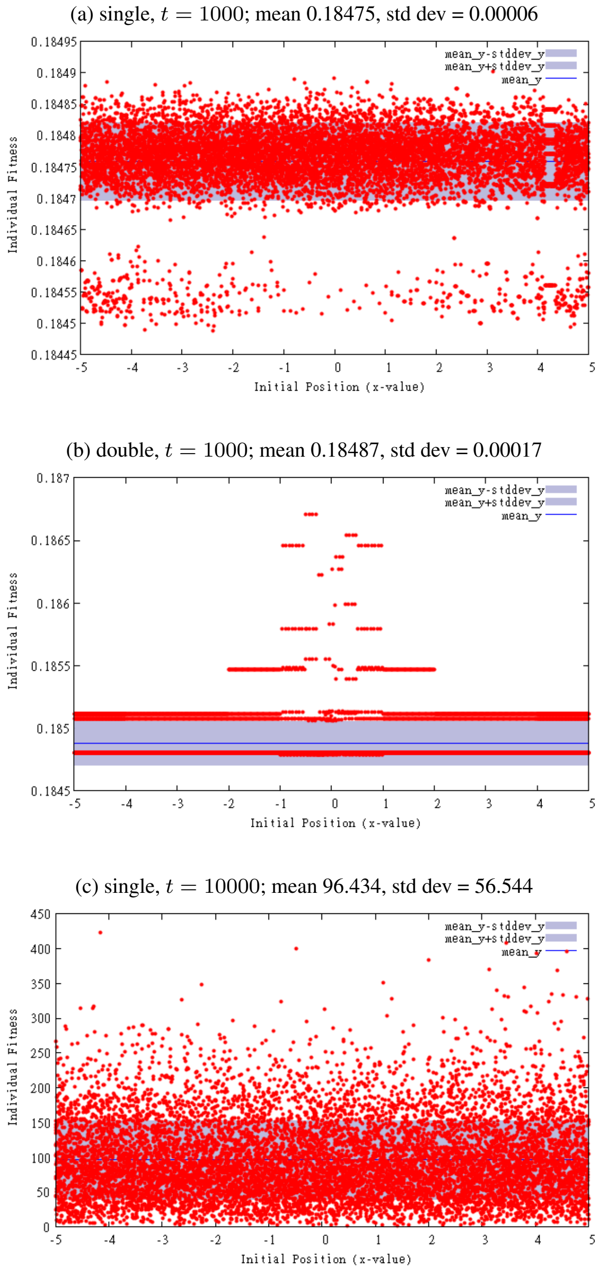

Fig. 3: Results of the precision experiments with single (a,c) and double (b) precision and evaluation time t of 1000 (a,b) and 10000 (c). The x-coordinate of the initial creature position is plotted against the computed fitness value. Mean and standard deviation are displayed for each plot.

The fitness values and their spread are greatly dependent on the fitness function used. Thus, care must be taken to craft a fitness function where the position-dependent fitness variation of a fit individual is still able to distinguish it from an unfit individual. The simple distance-based locomotion fitness

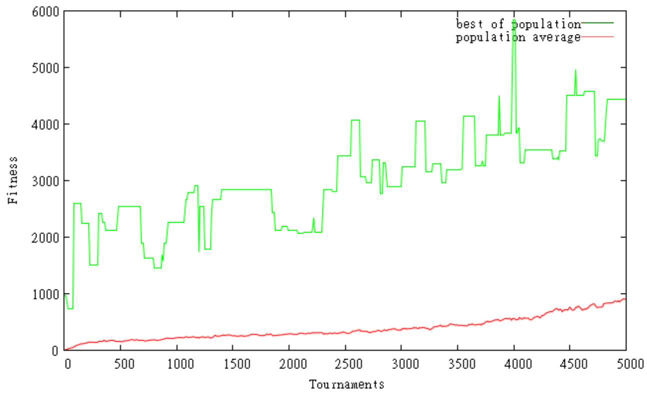

Fig. 4: Fitness plot of an evolutionary run with virtual creatures using the locomotion distance fitness function. The initial position of each evaluated creature is randomized. The best of population (in green) and population average (in red) are shown.

function used in the presented experiments was specifically chosen to demonstrate the rounding error and is not a good choice of a fitness function to alleviate the problem.

A simple solution to the initial position-based rounding error problem is to evaluate each individual at the same initial position. This idea works well with a simple evolutionary scenario where the evaluation of each virtual creature is separate. However, it is not well suited for co-evolutionary scenarios where multiple virtual creatures need to be evaluated in the same environment. Furthermore, a slight variation in initial position can prevent problems with the evolutionary system exploiting the position and can generally be beneficial if the effect of rounding errors can be minimized.

The floating-point precision setting can improve the results as we found the double precision performance in ODE more stable. However, with a large evaluation time, the problem is still significant. For closed source engines, such as NVIDIA PhysX, the precision is fixed and cannot be modified by the user. To alleviate the problem further, the floating-point representation can be replaced with a fixed-point representation if the range of required values does not need to be large. Fixed-point representation can provide more stable behavior but we are currently not aware of any free 3D physics engines that use a fixed-point representation.

A more important problem with floating-point arithmetic is that it is not guaranteed to produce the same results on different computer architectures and across different compilers or optimization settings as detailed in [4]. This can severely affect the reproducibility of results over different machines. The problem can be solved to an extent but solving it is considered to be very difficult [5].

5 CONCLUSIONS

We presented experimental results showing the effect of floating-point rounding errors on a sample fitness calculation of a virtual creature simulated using a physics engine. The variation of fitness values due to the difference in initial position of evaluation is evident and continues to increase with the evaluation time. The variation is significant on the time scale that is typically used for evolutionary experiments such as the virtual creature experiments presented.

This chaotic behavior can add beneficial randomness to the simulations but needs to be considered, especially for evolutionary experiments where the survival of an individual is directly related to its fitness value as compared with other individuals. In these evolutionary scenarios, a wrong choice of fitness function can have a negative effect on the evolutionary performance. We identified several possible methods of alleviating the floating-point rounding error problem.

The presented issue raises some important directions for future research. Can and should floating-point rounding errors be eliminated in physical simulations? Can evolutionary systems using well-crafted fitness functions harness the chaotic power of physics engines? How does this problem affect an evolutionary ecosystem simulated with a physics engine? The answers to these questions can situate physical simulation as a basis for future artificial life simulation systems studying open-ended evolution.

Abstract: The target of our study is the Monarch Butterfly, which is known for its multi-generational migration behavior: it migrates between southern Canada and Mexico over the course of one year within three to four generations. We approach this subject by using an evolutionary simulation that is an ecosystem consisting of artificial agents and five areas. We focus on the metamorphosis and the reproductive diapause, which are the ecological characteristics of the Monarch, and we design a model of agent which has the state as its inner parameter. We simulate under the environmental condition that the average annual temperature rises every year, which is modeled on the current global temperature rise. Our agents emerge the migration behavior similar to the multi-generational migration behavior of the actual Monarch. The migration process of the agents and their genetic factors are discussed, and our proposed model and the previous model are compared.

Keywords: Artificial Life, Adaptive Behavior, Monarch Butterfly, Evolutionary Simulation

1 INTRODUCTION

One academically valued of studying the behaviors of these organisms is evolutionary simulation based on models. Computer-simulated virtual ecosystems allow us to perform experiments rapidly and repeatedly, and the evolutionary processes of artificial organisms can be observed. Even if an agent has only a simple mechanism, if key aspects of behaviors are modeled, complex behaviors can be obtained through the evolutionary process [1].

The subject in our study is the Monarch Butterfly (*Danaus plexippus L., Nymphalidae, Lepidoptera*). This butterfly is known for its multi-generational migration behavior: it migrates between southern Canada and Mexico over the course of one year within three to four generations. Their life cycle has been detailed in reference [2] and our previous paper [3]. In spite of many reported studies [4], [5], [6], little is known about what influences their migration.

We have designed a model for the migration behavior of Monarchs by adaptiogenesis to environments with sensory agents in the previous research, but the previous model was incomplete because of many differences between the migration behavior emerged by agents and actual migration of Monarchs. In this paper, we focus on the metamorphosis and the reproductive diapause, which are the ecological characteristics of the Monarch, and we design a model of agent which has the state as its inner parameter. The agent changes its state depending on inner or outer information, and this changed state causes characteristic alterations. Additionally, we included the day length in the area models as an environmental factor because entomology shows that agent transformation depends on both temperature and day length. We show the advantage of our model by comparing the result with actual migration behavior of Monarchs and the previous model.

1.1 Area

The ecosystem has five areas that we label as $area_0$, $area_1$, ... , $area_4$ from south to north. Each area is modeled after the area of North and Central America (Table 1) where the migration of Monarchs actually occurs and consists of a two-dimensional 40×40 grid. $area_i$ has three environmental parameters, which are temperature, day length, and foods. These three environmental factors have significant effects on the migration of the Monarch. Each parameter is explained below.

Table 1. Five areas.

$area_i$	Model city
$area_4$	Minneapolis, U.S.A.
$area_3$	Kansas City, U.S.A.
$area_2$	Oklahoma City, U.S.A.
$area_1$	Austin, U.S.A.
$area_0$	Michoacan, Mexico

1.1.1 Temperature.

Temperature is decided by two kinds of environmental changes: long-term and short-term. A long-term change is an annual temperature rise and a short-term change is a daily change of temperature. To configure short-term change, we used real data from the past 20 years in each original area (collected by the National Climate Data Center [7]) and calculated the average annual data by trigonometric function. Thus, we define a temperature $tmpr_i(y,d)$ in $area_i$ at year y and day d as

$$tmpr_i(y,d) \quad = \quad short_i(d) + 0.01 \times y, \tag{1}$$

where $short_i(d)$ is short-term change in $area_i$. In this paper, the average annual temperatures of all areas rise $0.01°$ F every year.

1.1.2 Day Length.

In this paper, we newly focused on the day length as one of the environmental factors. The day length is defined as the time difference from sunrise to sunset. We can compute the time of sunrise and sunset using latitude, longitude, and altitude by the computation approach in reference [8]. We use real data to compute day length of each area.

1.1.3 Food

Each area has foods used as source of vital energy for the agents. The number of foods N_i in $area_i$ is determined by

$$N_i(t) = N_i(t-1) + \mathrm{M_F} \times incFood(\mathrm{S_F}, tmpr_i(t)), \tag{2}$$

where t is the number of steps ($t = \mathrm{DAY} \times y + d$, where DAY is a certain fixed number of days in one year), $\mathrm{M_F}$ is the maximum increment of foods in one day, and $\mathrm{S_F}$ is the most suitable temperature for increment of foods. $incFood()$ is the function which determines the increment of foods and outputs a real number while 0 to 1. The output of $incFood()$ is inversely proportional to the difference between $\mathrm{S_F}$ and $tmpr_i$. The life-span of the plant is $\mathrm{L_F}$. A food is removed from the simulation when it is eaten by the agent or reaches the end of its life-span.

1.2 Agent

An agent can sense internal information, and external information. By using sensory information, an agent decide its action and decide its state only once a day. In this paper, the behavioral strategy and the transformational strategy are expressed by n-output binary decision diagram (n-BDD) [9], which is an extension of BDD [10]. An agent $agent_j$ (j is identifier) has four genetic component and characterized as

$$agant_j(ea_j, cs_j, ast_j, sst_j), \tag{3}$$

where ea_j is a thermal sensitivity, cs_j is a cold resistance of the diapause agent, ast_j is the behavioral strategy, and sst_j is the transformational strategy. We describe ea_j and cs_j in Section 1.2.3, ast_j in Section 1.2.4, and sst_j in Section 1.2.5.

1.2.1 Action.

Five actions — W, E, R, Mn, and Ms — can be performed by the agent. An agent that selects W stays in the same grid of the same area for one day. An agent that selects E increase its energy by eating a food. If there is no food in its visual field, the agent moves at random looking for foods. An agent that selects R reproduces a new agent with another agent. If there is no agent in its visual field, the agent moves at random looking for agents. The Mn and Ms are the migration behavior. An agent that selects Mn migrates from $area_i$ to $area_{i+1}$ and that selects Ms migrates from $area_i$ to $area_{i-1}$ in 10 days. If there is no destination area, the agent changes their action to W.

1.2.2 State.

We newly focused on the "states" of the agents, which we neglected in the previous study. An agent has the state $state_j$ as its internal parameter. We defined three states — Cp, Dp, and Rp — which an agent can enter. The state determines which action an agent can select, if and when it can transition the state, and how long it can stay in the state.

The Cp state is the stage of an egg, a larva, or a pupa. An agent is in the Cp state, which is an initial state when it is first born. In the Cp state, only W and E are selectable actions and the agent can transition its state to either Dp or Rp. The Dp state is the reproductive diapause stage of an adult. An agent in the Dp state can select any action except R and can transition to Rp when the transition condition is met. The Rp state is an adult stage that can reproduce. All five actions are selectable in this state and can never transition back to the other two states. The age age_j, which is the maximum life-span of the agent in the state $state_j$, is initialized by L_{state_j} when the agent changes its states.

1.2.3 Sense.

All agents can sense the seven pieces of information. X_m has a truth-value, true or false. X_0 is information about whether the agent is in the diapause. X_1 is about whether the energy level is in the condition of "$in_j > \mathrm{I_B}$", where in_j is the amount of energy which agent stores and $\mathrm{I_B}$ is a specific energy level. An agent has a visual field (8-point neighborhood) and can sense the other agent and the food in its visual field. X_2 is information about whether other agents are in the visual field, and X_3 is information about whether foods are in the visual field. X_4 is information about the day length of the area; an agent can ask, "Are there more than 12 hours in this day?" X_5 and X_6 are information about the temperature of the area. To sense a temperature, each agent has up_lim_i and lo_lim_i, which are given by

$$lo\_lim_j = s_j - ea_j, \tag{4}$$

$$up\_lim_j = s_j + ea_j. \tag{5}$$

ea_j is an integer fulfilling $0 \leq ea_j \leq \mathrm{EA}$ (where EA is a constant) and represents the thermal sensitivity. An agent becomes sensitive to temperature changes when ea_j is small.

s_j is given by

$$s_j = \begin{cases} \mathrm{S_A}, & \text{if } state_j = \mathrm{Dp} \\ \mathrm{S_A} - cs_j, & \text{otherwise} \end{cases} \quad (6)$$

where $\mathrm{S_A}$ is the most suitable temperature of the agent and cs_j is an integer fulfilling $0 \leq cs_j \leq \mathrm{CS}$ (where CS is a constant). We observed that Monarchs in reproductive diapause pass the winter by reducing metabolic activity, so we set agents in the Dp state to be resistant to cold and agents in the Cp and Rp states to not be resistant. $X_5 = \mathrm{true}$ shows $tmpr_i < lo\_lim_j$, in which case the agent feels cold. $X_6 = \mathrm{true}$ shows $tmpr_i > up\_lim_j$, in which case the agent feels hot.

1.2.4 Action Decision Diagram.

The agent $agent_j$ decides which action $act_j(t)$ is performed every day by

$$act_j(t) = ast_j(X_0(t), \cdots, X_m(t)). \quad (7)$$

ast_j is expressed by 5-BDD with seven variables and five possible outputs: W, E, R, Mn and Ms.

1.2.5 State Decision Diagram.

The agent $agent_j$ decides to enter state $state_j$ by using counter $c_j(t)$, which is updated every day by

$$c_j(t) = c_j(t-1) + sst_j(X_0(t), \cdots, X_m(t)). \quad (8)$$

sst_j is expressed by 2-BDD with seven variables and two outputs: $+1$ or -1. The transition method of the two states is different. An agent, which reaches the end of its life in the Cp state ($age_j = 0 \wedge state_j = \mathrm{Cp}$), transitions a state. It can transition to Rp if $c_j(t) > 0$ or to Dp if $c_j(t) \leq 0$. In the Dp state, the agent can transition to Rp when $c_j(t) > 0$. In the Rp state, the agent cannot transition to another state.

1.2.6 Energy Level Update

After the action, the energy in_j is updated by

$$in_j(t) = in_j(t-1) + f(act_j(t), td), \quad (9)$$

$$td = |s_j - tmpr_i|, \quad (10)$$

where function f is the update function of the energy level. Increases or decreases to the energy level are directly determined by which action is selected and decreases are large if the value of td is also large. The E action is the only action by which an agent can increase its energy level and other actions decrease.

1.2.7 Reproduction.

An agent is generated from two agents by R action, which is the reproductive behavior. Four genetic parameters of a child agent are generated from that of both parents by crossover and mutation. We adopt two-point crossover for ea_j and cs_j, and uniform crossover for ast_j and sst_j. Let age_j, in_j, $state_j$, and c_j are each initialized by $\mathrm{L_{Cp}}$, $\mathrm{I_B}$, Cp, and 0, respectively.

1.2.8 Death.

If an agent suffers either one of the following conditions, it dies and is removed from the simulation.

$$in_j < 0 \quad \vee \quad age_j < 0, \quad (11)$$

Each condition means a starving and a natural death.

2 EXPERIMENTS AND DISCUSSION

In this section, we present the parameter settings and simulation results. We placed 200 agents with randomly generated genetic codes in $area_0$. Note that the experimental parameters in Table 2 are based on the actual biological features of the Monarch Butterfly and their habitat. We simulated 2000 years. All experimental results are the average of 30 trials.

Table 2. Parameters Setting.

DAY (1 year)	$\mathrm{S_F}$	$\mathrm{M_F}$	$\mathrm{L_F}$
365	65	30	30

$\mathrm{L_{Cp}}$	$\mathrm{L_{Dp}}$	$\mathrm{L_{Rp}}$
30	200	30

$\mathrm{S_A}$	EA	CS	$\mathrm{I_B}$
70	15	20	120

2.1 Experiment 1.

We simulated our proposed model. Fig. 1 shows the migration process from $area_0$ to the other areas that was obtained after 30 experimental runs. In the early simulations, many agents migrated to $area_1$ or $area_2$. Gradually, agents expanded their migration range with a temperature rise. In the later simulations, about 35 percent of the agents migrated to $area_4$. Our agents migrated from $area_0$ to $area_4$ within 3.76 generations on an average, which matches the fact that Monarchs migrate within 3 to 4 generations.

Fig. 2 shows the action decision diagram and the state decision diagram (variable nodes and outputs nodes appear in Section 1.2.1 and 1.2.2). X_0 is the next most significant information after X_1. The agent positively selects R and increases the number of agents because it can reproduce new agents only in the Rp state. The agent positively selects migration behavior, especially Ms, in the Dp state. It is clearly that the state is the agents, which we have newly focused on in this paper, is the essential factor for its behavioral decisions. On the other hand, X_5 and X_6 are the two most significant pieces of information for the agents in terms of deciding its states, while X_4 is third. This matches the behavior of actual Monarchs, which decide when to diapause and enter into a reproductive season on the basis of information about temperature and day length.

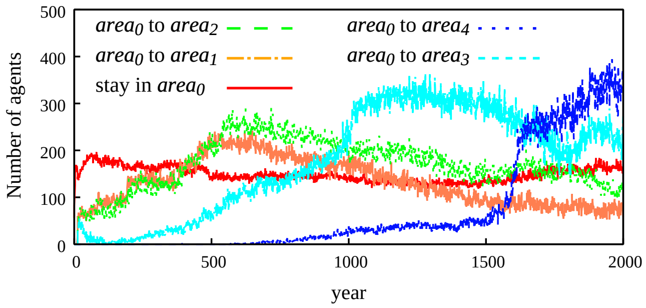

Fig. 1. The number of agents that stay in $area_0$ or migrate from $area_0$ to $area_n$ for 2000 years.

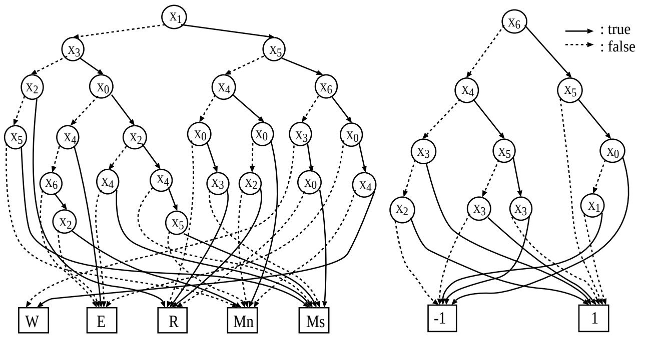

Fig. 2. Left: Action decision diagram (5-BDD), Right: State decision diagram (2-BDD).

2.2 Experiment 2.

We compared the annual migration of agents with that of actual Monarchs. Fig. 3 shows a time-line chart of migration. In the previous model, agents migrate from $area_0$ to $area_1$ between November and June of next year. Migrating toward colder areas in winter is completely different from the actual migration of Monarchs, which migrate south in fall and stay in wintering places to survive the cold winter. In contrast, agents proposed in this paper stay in $area_0$ from mid-December to February of next year. In spite of some differences in beginning and ending periods of migration, the migration cycle is similar to real one: the agents migrate north from spring to summer, migrate south from fall, and stay in $area_0$ from winter to next spring. We conclude that our proposed model extracts more significant key aspects of Monarchs' migration behavior than the previous model.

3 CONCLUSION

We presented an evolutionary model to simulate the multi-generational migration of the Monarch Butterfly. We build the model considering with the metamorphosis and the reproductive diapause. Agents emerged migration behavior similar to the multi-generational migration behavior of the actual Monarch. We show the advantage of our model by comparing with the result of the previous model.

Abstract: In the present paper, we study a prime sequence generation problem on one-dimensional cellular automata. We show that an infinite prime sequence can be generated in real-time by a one-dimensional cellular automaton with 8 states. The algorithm that we propose is based on the well-known sieve of Eratosthenes, and its implementation is realized on an 8-state cellular automaton using 301 transition rules.

Keywords: one-dimensional cellular automaton, real-time prime generation algorithm, sieve of Eratosthenes

1 INTRODUCTION

Cellular automaton is considered to be a good model of complex systems in which an infinite one-dimensional array of finite state machines (cells) updates itself in a synchronous manner according to a uniform local rule. In the present paper, we study a prime sequence generation problem on one-dimensional cellular automata. The sequence generation problem has been studied for many years and a variety of interesting sequences has been shown to be generated in real-time by one-dimensional cellular automata [1-9].

Arisawa [1971], Fischer [1965], Korec [1997, 1998] and Mazoyer and Terrier [1999] have considered the sequence generation problem on the cellular automata model. Umeo and Kamikawa [2002] showed that infinite non-regular sequences such as $\{2^n | n = 1, 2, 3, ..\}$, $\{n^2 | n = 1, 2, 3, ..\}$ and Fibonacci sequences can be generated in real-time and the prime sequence in twice real-time by $\mathrm{CA}_{1-\mathrm{bit}}$. Umeo and Kamikawa [2003] showed that the prime sequence can be generated in real-time by a $\mathrm{CA}_{1-\mathrm{bit}}$ having 34 internal states and 107 transition rules. The cellular automaton model $\mathrm{CA}_{1-\mathrm{bit}}$ is a special subclass of *conventional* (i.e., *constant-bit-communication*) cellular automata. Each cell having the 1-bit inter-cell communication link can communicate with its nearest neighbor cells by sending and receiving a 1-bit information at each step.

Korec [1997] has shown that the prime sequence generation problem can be solved in real-time by using sieve of Eratosthenes. He also presented a one-dimensional cellular automaton with 11 states which can generate the prime sequence. Later, Korec [1998] gave a one-dimensional cellular automaton with 9 states generating the prime sequence in real-time.

In this paper we improve the implementation by presenting a smaller implementation on the same computational model. We show that an infinite prime sequence can be generated in real-time by a one-dimensional cellular automaton with 8 states.

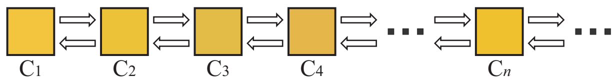

Fig. 1. One-dimensional cellular automaton.

First, in Section 2 we introduce a one-dimensional cellular automaton and define the sequence generation problem on the cellular automaton. In Section 3, we give a real-time prime sequence generation algorithm on a one-dimensional cellular automaton. The algorithm is based on the well-known sieve of Eratosthenes, and its implementation will be made on a one-dimensional cellular automaton with 8 states. The number of states implemented is the smallest one, known at present.

2 SEQUENCE GENERATION PROBLEM ON ONE-DIMENSIONAL CELLULAR AUTOMATON

A one-dimensional constant-bit-communication cellular automaton consists of an infinite array of identical finite state automata, each located at a positive integer point. See Fig. 1. Each automaton is referred to as a cell. A cell at point i is denoted by C_i, where $i \geq 1$. Each C_i, except for C_1, is connected to its left- and right-neighbor cells by a communication link.

A cellular automaton $\mathcal{A} = (\mathcal{Q}, \delta, \mathcal{F})$, where

1. $\mathcal{Q}$ is a finite set of internal states.

2. $\delta : \mathcal{Q}^3 \rightarrow \mathcal{Q}$ is a transition function. A quiescent state $q \in \mathcal{Q}$ has a property such that $\delta(q, q, q) = q$.

3. $\mathcal{F}$ is a special subset of internal states $\mathcal{Q}$.

The set $\mathcal{F}$ is used to specify a designated state of C_1 in the definition of the sequence generation.

We now define the sequence generation problem on the cellular automaton. Let M be a cellular automaton and $\{t_n | \, n = 1, 2, 3, ...\}$ be an infinite monotonically increasing positive integer sequence defined on natural numbers such that $t_n \geq n$ for any $n \geq 1$. We then have a semi-infinite array of cells, as shown in Fig. 1, and all cells, except for C_1, are in the quiescent state at time $t = 0$. The communication cell C_1 assumes a special state "0" (zero) in Q and starts its operation at time $t = 0$ for initiation of the sequence generator. We say that M generates a sequence $\{t_n | \, n = 1, 2, 3, ...\}$ in k *linear-time* if and only if the leftmost end cell of M falls into a special state "1" (one) in Q at time $t = kt_n$, where k is a positive integer. We call M a *real-time* generator when $k = 1$.

In designing algorithms for a cellular automaton, for ease of understanding and description of algorithms on cellular automata, we often use *signals* or *waves*, instead of transition tables. A signal (wave) is an information flow that is described as a straight line in the space-time diagram. Note that any signal cannot propagate at speed more than one cell per one step due to the definition of the transition function.

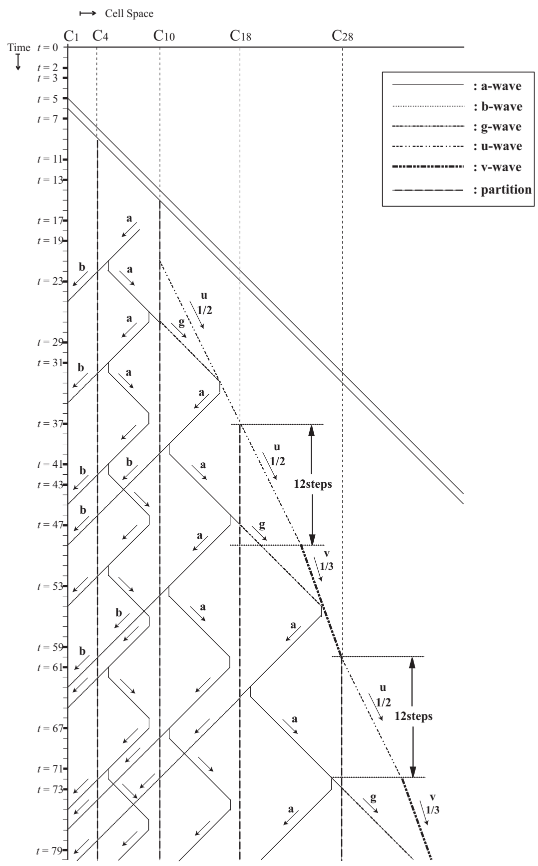

Fig. 2. Space-time diagram for real-time generation of prime sequence.

3 REAL-TIME GENERATION OF PRIME SEQUENCE ALGORITHM

In this section, we present a real-time generation algorithm for prime sequence on cellular automaton. The algorithm is implemented on an 8 state cellular automaton using 301 transition rules. Our prime generation algorithm is based on the classical sieve of Eratosthenes. Its cross out technique in the sieve of Eratosthenes is as follows. Imagine a list of all integers greater than 2. The first member, 2, becomes a prime and every second member of the list is crossed out. Then, the next member of the remainder of the list, 3, is a prime and every third member is crossed out. In Eratosthenes' sieve, the procedure continues with 5, 7, 11, and so on. In our procedure, given below, for any odd integer $k \geq 3$, every $2k$-th member of the list beginning with k^2 will be crossed out, since the k-th members less than k^2 (that is, $\{i \cdot k | \, 2 \leq i \leq k-1\}$) and $2k$-th members beginning with $k^2 + k$ (that is, it is an even number such that $\{(k+2i-1) \cdot k | i = 1, 2, 3, ...\}$) should have been crossed out in the previous stages. Thus, every k-th member beginning with k^2 is successfully crossed out in our procedure. Those integers never being crossed out are the primes. Figure 2 is a space-time diagram that shows a real-time detection of odd multiples of odds.

Our implementation that C_1 translate for state 0 when b-wave arriving C_1 and C_1 translate for state 1 when b-wave don't arriving C_1. The b-wave is generated by three ways. First, b-wave is generated when C_2 translate for state L. Second, b-wave is generated when C_3 translate for state L. Finally, b-wave is generated when a-wave collides with left partition.

3.1 Removing multiples of 2 and 3

In this section, we present a cross-out operation for multiples of 2 and 3. In the case of multiples of 2, the array repeats two states: R and L, alternatively on C_3. As for the case of multiples of 3, it repeats a state R, V and L on C_2 at each step. The cells C_2 and C_3 generate a b-wave, then they fall into the state L. A state transition into the state L on C_2 is done at time $t = 3k - 1 (k \geq 2)$ and the state transition into L on C_3 is done at time $t = 2k (k \geq 2)$. In this way the multiples of 2 and 3 can be removed.

We implemente Removing multiples of 2 and 3 algorithm.

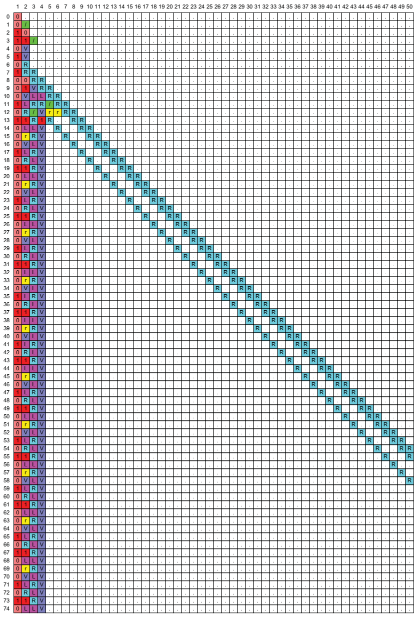

Fig. 3. Implementation of removing multiples of 2 and 3.

See the Figure 3 for implementation of removing multiples of 2 and 3. This figure is first partition generation on C_4, but this partition isn't need removing multiples of 2 and 3 algorithm. We generate first partition that it is easy to look.

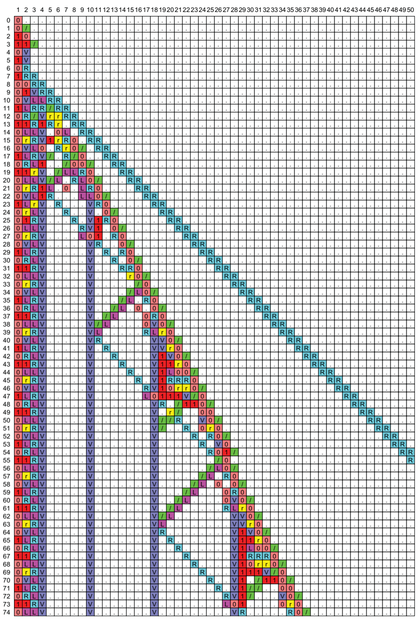

Fig. 4. Generation of partition.

3.2 Removing algorithm for odd multiple numbers greater than 5

In this section, we present a removing algorithm for odd multiples greater than 5. Those cross-out operations are done by a signal which moves around between partitions generated by the cellular automaton. The CA generates partitions, denoted by the state V on $C_{i^2+3i}(i \geq 1)$. We define the subspace $S_i, i \geq 1, i \in \mathcal{N}$, as the ith cellular space delimited by the consecutive partitions. The length of the space of S_i is $|S_i| = 2i+3$. The subspace $S_i, i \geq 1$ is used to generate a signal for removing odd multiples greater than 5, that is, $(2i+3)k, i \geq 1, k \geq 1$. The a-wave goes left and right between those partitions at a unit speed, one cell per one step. It changes into the b-wave, then it collides with the left partition. Those odd multiples greater than 5 are crossed out by the b-wave that goes through the partition in the left direction. The first partition is generated on C_4. See the Figure 4 for the real-time generation of those partitions.

We must generate the a-wave in each S_i. The a-wave generation in each partition is as follows: Thus the a-wave in S_2 is generated at $t = 34$ on C_{16} and the a-wave in S_3 is generated at $t = 56$ on C_{26}. The a-wave in S_1 is specially described in terms of finite states. At $t = 34$ the cell C_{16} generates a-wave which arrives on C_1 at $t = 49(= 7^2)$, and the a-wave generated on C_{26} at $t = 56$ arrives on C_1 at $t = 81(= 9^2)$. We use these a-waves to remove odd multiples greater than 5. The implementation of the generation of partitions can be done shown in Figure 4.

3.3 Real-time generation of prime sequence

In this section, we present a real-time generation of prime sequence algorithm. The algorithm is combination by "Removing multiples of 2 and 3" and "Removing algorithm for odd multiple numbers greater than 5". Those algorithms are implemented follows: section 3.1 and 3.2. Space-time diagram is shown in Figure 2. Figure 5 shows the transition table consisting of the 8 states and 301 transition rules where state '*' is a wall state of the left neighbor of C_1. Figure 6 shows some snapshots of the prime generation on 50 cells. Now we have:

Theorem There exists a cellular automaton having 8-states and 301-rules that can generate prime sequence in real-time.

4 CONCLUSIONS

We have studied a real-time prime sequence generation problem on a cellular automaton. The proposed real-time prime generator, based on the classical sieve of Eratosthenes, is implemented on a cellular automaton using 8 states and 301 transition rules. The implementation is the smallest one known at present.

Abstract: This paper describes control of the moving robots in an autonomous decentralized Flexible Manufacturing System (FMS) by moving robots according to its mind change. We propose Experience based Stimulation Adjustment by NN (ESAN) that is the method of efficiently changing the mind of the automated guided vehicles. The mind changes by various stimulation. In ESAN, the stimulation sent to the mind is adjusted to an appropriate value by using the neural network. The effectiveness of ESAN is evaluated with production simulations in an autonomous decentralized FMS virtual factory.

Keywords: Autonomous decentralized FMS, Mind, AGV

1. INTRODUCTION

The purpose of our research is to improve the productivity of the Autonomous Decentralized Flexible Manufacturing System (FMS) factory. In Autonomous decentralized FMS, many moving robots called Automated Guided Vehicles (AGVs) are operated. In this research, we focused on the action control of AGVs.

In a past research as a method of evading the interference with the route of AGV, the mind of AGV is modeled and the action control that gave AGVs was tried. [1][2] As a result, each AGVs could perform various actions according to the change of mind.

However, in Autonomous Decentralized FMS that has many AGVs, it took much time to evade the route interference, and because of this, we had many cases that the productive efficiency of Autonomous Decentralized FMS dropped. Then we thought the change of mind cannot always correspond to various situations.

To solve this problem, we propose Experience based Stimulation Adjustment by Neural network (ESAN). ESAN stimulates the mind to efficiently change the mind of AGVs.

2. ESAN AND MODEL OF MIND

2.1. Past method and ESAN

Fig.1 shows the comparison between the method of stimulating the mind in a past research and the method by ESAN. In a past research, when AGV failed in the action, the mind of the AGV had been stimulated directly. In ESAN newly proposes this time, stimulation is adjusted by NN according to the situation at that time, and the mind of AGV is stimulated afterwards when AGV fails in the action.

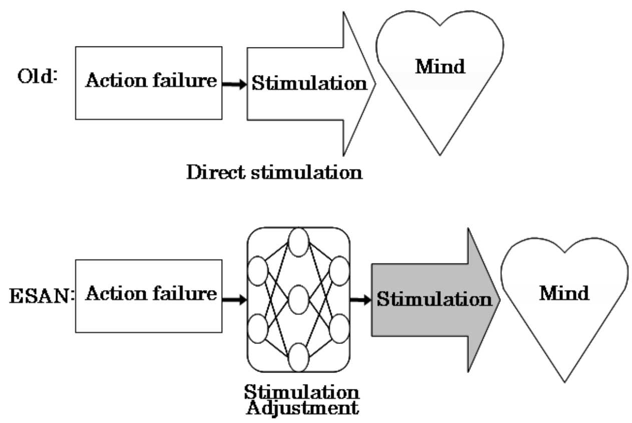

Fig.1 Comparisons between past method and ESAN

2.2. Element of mind

The mind is defined to have combined three elements which are the unit, the stimulation vector, and the load. (Shown in Fig.2-Fig.4.) The stimulation vector is an element that is tied to unit the load. The unit is composed of two numerical values of excited degree [E] and threshold [T]. [E] is able to increase and decrease by the value of the load. [T] is an upper bound of [E]. [E] is lowered to [T] when [E] exceeds [T], and it makes a signal to the stimulation vector. The unit for [E] of the unit to reach [T] is called excited and the unit that excited, and doesn't reach [T] is called calm. The state of mind is decided by combining units that have been excited

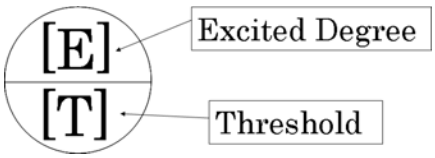

Fig.2 Unit

Fig.3 Stimulation vector

Fig.4 Load

2.3. Model of mind that uses ESAN

Fig.5 shows the model of the mind that uses ESAN. This model is a model to unite the load α, β, and γ with two units A and B by the stimulation vector. This model is divided into two parts. It is in the part where stimulation is received from the outside of the part, β, and γ that decides the state of the mind of A, B, and α.

There are two states of mind, which are an arrogant mind and a modest mind. AGV acts while doing these two minds in switches.

When A gets excited, AGV becomes modest, and takes a modest action that transfers the load to others. Moreover, when A is calm, AGV becomes arrogant, and takes an action that advances forcibly on the load and is arrogant. When the action rails because the mind of AGV is arrogant, the mind is received as stimulation through β. Then, this increases A[E]. Unit A gets excited when A[E] reaches A[T]. When the action fails because the mind of AGV is modesty, the mind is received as stimulation through γ. Then, this increases B[E]. Unit B gets excited when B[E] reaches B[T].

2.4. Generation of NN and its working in ESAN

The new function of ESAN includes the stimulation adjustment function that is caused by the NN after some AGVs experiences. The NN in ESAN uses Backpropagation method (BP method). The instruction signal used for this is made by performing the FMS production simulation beforehand, and using the result.

At first, the FMS production simulation is made visible, and animation on the FMS factory is made. Next, the action of AGVs in the animation is analyzed. The analysis is to understand whether the route interference is generated easily under what situation in the animation.

That is, look for the case with route interference to which the route interference is quickly evaded and time-consuming route interference. The states of mind of AGVs in these cases request either arrogance or modesty. The result of such an analysis is used as a instruction signal of NN.

The BP method is done based on this instruction signal and NN is generated. The generated NN stimulates two values of the mind of AGVs. Whenever AGV causes route interferences, the NN of ESAN receives five kinds of information. The five kinds of information are the destination of the AGV, previous destination, other nearby AGV number, other AGV number in goal direction, own current location as shown in Fig.5. In other words, these are the input information of NN. And, NN decides the two values in the model of the mind as an output. The mind of AGVs receive the value of β and γ from NN every time AGVs causes route interference. There are two states of mind. One is arrogant mind and the other is modest mind. The arrogant AGV forcibly moves, and the modest AGV makes way for other AGVs. AGV moves while in these two states of mind by switching one after another. One of the AGV acts while in these two minds in switches. When A has gotten excited, the state of mind is modest. At this time, AGV takes a modest action that transfers the load to others. Moreover, when A is calm, the state of the mind is arrogant. AGV takes an arrogant action that advances forcibly on the load. If AGV failed action in arrogant, the mind receives stimulation by β. Then, mind's A[E] is increased by the value of β. A gets excited when A[E] reaches A[T]. If AGV failed action in modesty, the mind receives stimulation by γ. Then, mind's B[E]is increased by the value of γ.

3. SIMULATION RESLUTS

Fig.6 shows CG of applied Autonomous Decentralized FMS. The model of the mind that used the above-mentioned ESAN for each AGV was transplanted. At this time, the value of β and γ was set to the numerical value of 1～4. And, the production simulation that operated this Autonomous Decentralized FMS for eight hours was done.

The production simulation was performed for eight hours with the Autonomous Decentralized FMS. The production simulations of the number of AGV 3, 5, 7, and 9 were carried out 20 times respectively.

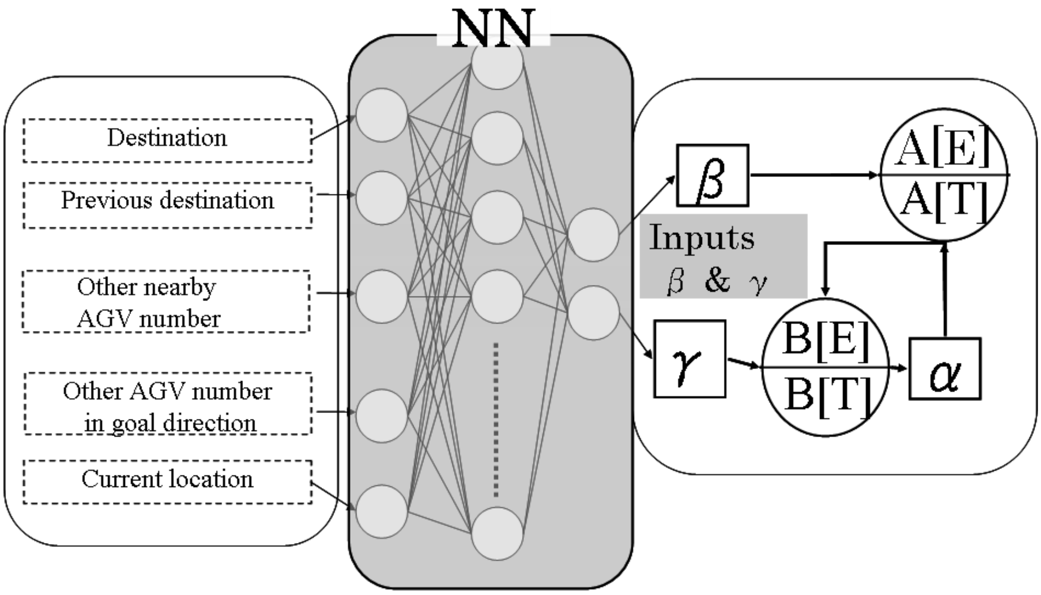

Fig.5 Model of AGVs' mind for ESAN

Table. 1 Average outputs and their increased rates

Methods \ Number of AGVs	3	5	7	9
past research methods outputs	111.7	162.15	199.65	228.6
ESAN outputs	115.3	171.2	215.25	249.4
Increased rate (%)	+3.22	+5.58	+7.81	+9.1

Table. 2 Route interference number and its increased

Methods \ Number of AGVs	3	5	7	9
past research methods	943.2	2715.0	5034.1	7643.8
ESAN	735.7	2412.2	4671.3	7178.2
Increased rate (%)	-22.0	-11.15	-7.2	-6.1

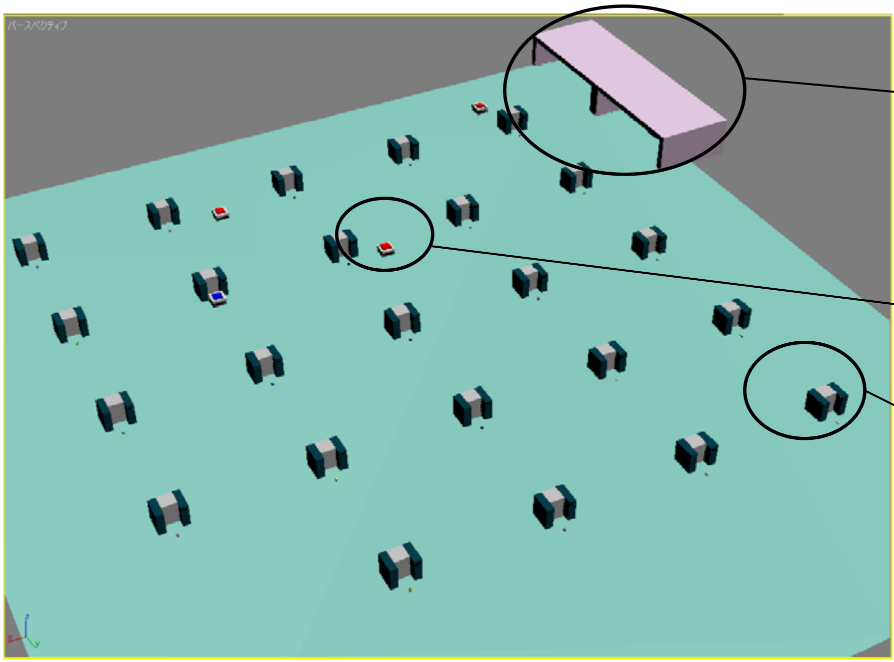

Fig.6 Autonomous decentralized FMS

The average outputs are shown in Table.1 and the number of route interference is shown in Table.2. The simulation result under this condition of old methods is shown for comparison. The increasing rate of the average production based on earlier methods and the increasing rate of the number of route interference are shown respectively.

For example, when the number of AGV is 3, the average outputs were 111.7 in the case where the past research method was used. On the other hand, the average outputs are 115.3 in the case where ESAN is used, and the average outputs increased by 3.22%. Route interference number decreased by 22% in ESAN compared with the past research method. Moreover when ESAN was used, the average production increased in any conditions. Especially, if the number of operating AGVs increases, average outputs are increasing more and more. In the same way, the number of route interference decreases by 22% in ESAN compared with earlier methods when the number of AGVs is three. (as shown in table.2) When ESAN is used, the number of route interference decreases in other conditions.

Based on the above-mentioned, it has been understood that the productive efficiency of the factory improves by using ESAN.

4. CONCLUSIONS

In this thesis, ESAN is proposed as the method of adjusting the stimulation sent to the mind to an appropriate value as a method of changing the mind of AGVs more efficiently. The method of using ESAN as the method of adjusting stimulation to mind by NN is compared with the simulation result of the old method.

Under all conditions, it was achievable that the mind was changed more efficiently. Thus, ESAN was proven to be more effective than earlier methods..

Abstract: Mental representation is a fundamental aspect of advanced cognition. An understanding of the evolution of mental representation is essential to an understanding of the evolution of mind. However, being a decidedly mental phenomenon, its evolution is difficult to study. This research addresses the question of how representation ability may emerge from non-representational cognition. We reformulate cognitive map ability, a paradigm case of mental representation, in terms of second order learning. We provide a neural network species with neural mechanisms for second order change and evolve them in an environment of randomly generated Tolman mazes, known to require mental representation. Some runs of this model evolve near-optimal performance, providing support for the hypothesis that mental representation is evolved second order learning.

Keywords: artificial life, cognitive map, evolution of mind, learning, mental representation, neural networks.

1 INTRODUCTION

Mental representation (MR for short) is, abstractly put, the ability to simulate or reconstruct in the mind aspects of the environment that lie outside the scope of one's current perception. The type of MR we focus on in this paper is the ability to navigate using "cognitive maps": mental representations of the layout of an environment (see Tolman [1]). Much of an environment may lie outside one's view, but mental representation of these parts makes it possible to take those parts into account nonetheless. Other types of MR are "mental time-travel" and "theory of mind" (see Takano & Arita [2], Minoya, Arita & Omori [3] for computational approaches to the latter). There too, inaccessible aspects of the environment (respectively: future and past, other minds) are mentally simulated or reconstructed.

The evolution of MR is not well-understood. MR is a highly structured and organized form of cognition, and already in the early decades of connectionism, it has become clear (contrary to common intuition) that adaptive processes such as evolution or learning do not, in general, produce such structured or organized AI (see e.g. Fodor & Pylyshyn [4]). This raises the question how MR can have evolved in biological cognitions. We propose that the representational nature of MR emerged from the interaction between adaptation processes, specifically: first and second order learning. We provide a proof of concept for this hypothesis in the form of a computational model in which a neural network species with the basic elements for second order change is evolved in an environment composed of maze tasks generally believed to demand cognitive map ability. If second order learning can be evolved into MR, this may improve our understanding of the evolutionary transition from non-representational to representational cognition.

2 TOLMAN MAZES

In experimental psychology, MR ability in biological species is often studied using Tolman mazes [1]. A Tolman maze has multiple paths from its start to its goal. Exploring the maze, subjects latently learn to take the shortest path. Subsequently, the shortest path is blocked, meaning they have to switch to a different path. However, the maze is set up so that after blockage of the shortest path, the new optimal choice of path depends on the location of the blockage (Fig. 1). Many species need to re-learn on the altered layout, while some species find the new optimal path without additional exploration (needing merely to observe the position of the blockage). The standard explanation is that the former category of species does not acquire a mental representation (cognitive map) of the maze during initial exploration, while the latter does. Animals that have acquired a representation of the maze can exploit that representation to infer the new optimal path without additional exploration.

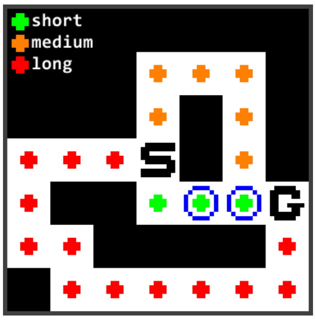

Fig. 1. Generated Tolman maze on 7x7 grid. S: Start G: Goal. Dot colours indicate path lengths. Blue circles indicate possible locations for the blockage. Blockage on the left blue ring obstructs only the short path, while blockage on the right blue ring blocks both the short and medium path.

3 HYPOTHESIS

Here we propose a different explanation, in terms of second order learning. MR can be viewed as acquired isomorphism between a mind's content and its environment. It has previously been established that innate isomorphism can emerge from interactions between evolution and learning (Arnold [5]). Acquired isomorphism might similarly emerge from interactions between first and second order learning.

Let us first give a working definition of first order learning: "advantageous change in behaviour, caused by exposure to pertinent information". Second order learning, then, must be advantageous change in (first-order) learning, caused by exposure to pertinent information. When after blockage of the shortest path in a Tolman maze a subject infers the new optimal path without additional exploration, we can view this inference as a split-second learning process: exposure to pertinent information (observation of the location of the blockage) produced an advantageous change in behaviour (the subject abandons the blocked path and switches to the new optimal path). Viewing it as such requires that we explain how this (first order) learning process can produce such a fast and effective behaviour-update (the information in the observation alone does not suffice to explain the update). Our explanation is that during exploration, not just the animal's behaviour has adapted to the maze (via a learning process), but that that learning process itself has been adapted to the maze as well. In other words, a second-order learning process optimized the (first-order) learning process to the current environment: the optimal change in behaviour (from selecting the blocked path to selecting the optimal path) has come to be causable by minimal information: mere observation of the location of the blockage has come to trigger this behaviour-update.

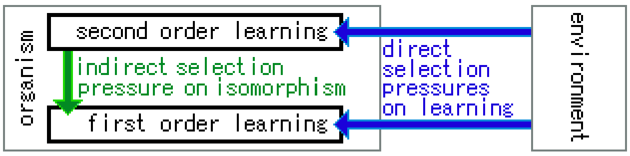

Fig. 2. Learning and isomorphism (MR).

A second order learning process associates possible future observations with suitable behaviour updates. This may sound infeasible, and for almost all first order learning schemes, it is. But if the first order learning scheme produces behaviour-implementations that are isomorphic with the environment, then second order learning suddenly becomes quite feasible: simply keeping the behaviour-implementation isomorphic with the environment (i.e. updating it continuously with present perception) keeps the behaviour optimal with respect to that environment. So when there is selection pressure on second order learning, then indirectly there is selection pressure on isomorphism-based first order learning schemes. Mental representation, then, could be this isomorphism.

The proposed reformulation might seem highly specific to the case of Tolman mazes, but equivalent reformulations can be given for many or all other situations that involve MR. We omit detailed examples here, but the general form is as follows. Consider an environmental object X to be represented. We (should) perceive our subject as representing X if and only if it can pre-emptively adjusts its behaviour so as to avoid or bring about specific unseen situations involving X after some period of observation of X. In all such cases, observation affects future changes in behaviour. To the extent such pre-emptive adaptation characterizes MR, explanation in terms of second-order learning should be applicable. In the focal case of cognitive maps, X is the maze, but the general scheme may equally well describe a scenario of spontaneous novel tool use (a scenario generally recognized as involving MR), with X being the tool.

4 MODEL

We test the hypothesis using a model in which neural nets with the basic elements for second order neural change are evolved in an environment composed of Tolman mazes.

Each individual's fitness is assessed on multiple Tolman mazes (randomly generated continuously over the course of the experiment). In each maze, the agent first gets 150 time steps to explore the maze (exploration phase), is then placed back at the start position and given exactly enough time steps to reach the target over the shortest path (exploitation phase). On a portion of the mazes, the shortest path is blocked at the start of the exploitation phase. When the agent arrives at the blockage, its remaining time steps are again set so as to make it only just possible to reach the target. Fitness is awarded for reaching the target. A population of size 100 is evolved, using a genetic algorithm with mutation but no crossover.

In addition to standard (activatory) connections, the network species has connection types that can be wired up to create second order changes in behaviour. These connection types are (1) activatory connections with lag, and (2) neuromodulatory connections. That two mechanisms are provided is merely to improve flexibility so as to facilitate evolution. Theoretically, one mechanism should suffice.

(1) Activatory connections with lag. These transmit activation signals much like standard connections, except with a short delay. This makes it possible for the nets to retain activation patterns over time. This sort of connection is common in recurrent neural networks. Retention of activation makes it possible for perception of a stimulus to af-

fect behaviour at some later point in time. For long-term change, one needs loops (in the simplest case, a single reflexive connection). Trivially, second order behaviour change can be construed too: if a retained local activation pattern A somewhere in a net affects behaviour, and another retained local activation pattern B affects A, then B has a second order effect on behaviour.

(2) Neuromodulatory connections. These connections convert activation into "modulation": the pre-synaptic neuron's activation arrives at the post-synaptic neuron as modulation. Typically, a neuron's modulation determines its connections' plasticity, in a simple (e.g. Hebbian) weight update rule (see Soltoggio et al. [6]). We let a gene pick from among a number of update rules (various combinations of pre- and post-synaptic activation and modulation values). Connection weight changes can change behaviour, and again quite trivially, they can change change in behaviour, too. Say change in connection X affects behaviour. Then weight change in connections that control change in X has a second order effect on behaviour.

Naturally these mechanisms can also be combined to create second order dynamics. Fig. 3 gives a schematic representation of the four possible circuits that produce second order dynamics (provided the connections are non-zero).

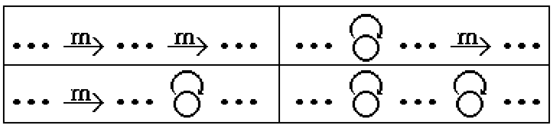

Fig. 3. Genotypic circuits for second order change. Any of these combinations occurring along a path from input to output neurons can cause second order changes. Arrows marked with M are modulatory connections. The lagged reflexive connections may produce local instead of reflexive connectivity in the phenotype, but either can support sustained change.

Informed by what's known about the neurology of spatial representation (See Moser et al. [7] for a review), we let the genotype encode not simple neurons, but neuron grids. We use square grids of three sizes: 1x1, 3x3, and WxW, where W is the size of the world (7 for our 7x7 world). Given the setup of the model, sizes larger than W offer no additional functionality (i.e. WxW is functionally equivalent to an infinite grid). The peculiar 3x3 size is included because it can concisely encode directional information. Connectivity is defined on two levels: inter-grid and intra-grid.

Intra-grid all connections are of the lagged activatory type. They can be reflexive or local. If a grid has a reflexive connection to itself, this means that all neurons in the grid get a reflexive connection to themselves. A local connection means that each neuron has connections to its four neighbours in the grid. So, connectivity within a grid is uniform (the genotype essentially defines connectivity for a single neuron, and the number of copies to make of that neuron). Propagation within a grid runs at a faster (24x) timescale than propagation among grids. Observe that reflexive connections allow retention of an activation pattern on a grid, while local connections lead to diffusion of activation patterns over time.

Grids can be connected by any connection type other than lagged activatory connections. If the genotype defines a connection between two grids, then the phenotype gets uniform connectivity between the neurons in the two grids. If the grids are equal in size, connectivity is one-to-one, otherwise all-to-all. This leads to a highly symmetrical connectivity, which by itself would cause the activation within a grid to remain uniform and redundant. This symmetry is broken by our neurotransmitter logic.

There are two global "neurotransmitter" values, nt-Bx and nt-By. These dynamically control (in two dimensions, as the neuron grids are 2D) which connection subsets of an all-to-all projection can transmit activation. When both are zero, then this set comprises connections linking corresponding neurons in the grids (e.g. the centre neuron in the pre-synaptic grid to the centre neuron in the post-synaptic grid). Non-zero nt-B values cause simple offsets, as illustrated in Fig. 4. Currently, nt-Bx and nt-By values are hardwired to reflect the agent's current x-coordinate and y-coordinate, so signal transfer can shift along with position in space. This makes it relatively easy for evolution to devise nets that store information in different locations in a grid depending on their own position in space: if a smaller grid projects to a larger grid, then the activation pattern on the smaller grid affects only a sub-region of the larger grid. We will call this sub-region the *focal area* of the smaller grid on the larger grid. Nt-B does not correspond directly to any biological neurotransmitter, but can be reduced to a biologically plausible neurotransmitter via a trivial network transformation (which increases network size dramatically).

Inclusion of coordinates in the input is unnatural, but preliminary experiments with a simple spatial memory task have shown it quite possible with our model to evolve agents that keep track of their own coordinates. Cognitively interpreted, the coordinates in the input and their linkage to the nt-B values make it trivially easy to evolve an innate sense of space as an extended medium in which movement predictably changes one's position. Construction of the ability to represent the volatile and non-uniform *contents* of space, however, is left to evolution.

The nets have one 3x3 grid and a number of 1x1 grids (i.e. single neurons) receiving input. The 3x3 grid encodes for each of the four cardinal directions whether there is a wall in that direction (on the 4 neurons adjacent to the middle neuron). The 1x1 grids encode whether the current position is the start position, whether the current position is the goal position, and the current phase (exploration or exploitation). Additionally, there are input neurons for bias (always 1.0) and noise (random real numbers from [0,1]). Output is read from two 3x3 grids. From the four neurons corresponding to the cardinal directions, the one with the highest activation is selected, and movement in that direction is performed (if possible). One set is read during exploration and the other during exploitation (so that the nets can easily evolve specialized behaviour per phase).

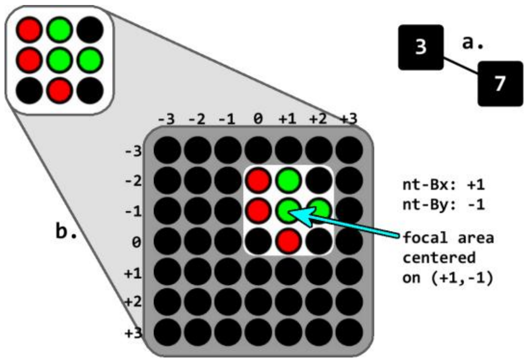

Fig. 4. Neural grids and nt-B. **a.** Genotype encoding a 3x3 grid, a 7x7 grid, and their connection. **b.** The corresponding phenotype. The 3x3 grid projects into the focal area of the 7x7 grid. The position of focal areas for projections between unequally sized grids is dynamically controlled by the global neurotransmitter values nt-Bx and nt-By. This mechanism lets the nets conveniently allocate neurons to spatial locations.

5 RESULTS

While success rates are very low, the model does occasionally produce networks with optimal performance on our Tolman mazes. We concisely describe an evolved solution here.

As the agent moves through the maze, the 3x3 input grid projects onto different regions of a 7x7 grid. Modulation working on the 7x7 grid records the paths travelled into the connectivity of this grid, replicating the maze layout. Activation diffusion in the grid then comes to follow this layout. The T-splits in the layout receive high activation due to their high connectivity, and consequently activation in other neurons on the grid comes to depend on proximity (along the replicated paths) to these T-splits. Effectively, local activation levels in the 7x7 grid come to indicate path length, and can thus be used to select the shortest path. Blockages are handled simply by updating (weakening) the connectivity in the grid at the position corresponding to the blockage. The activation pattern then settles into a new state with low activation on the blocked paths, as positions on these paths lose their proximity to one of the T-splits.

This solution is representational in nature: the connectivity pattern that forms on the grid during exploration is isomorphic with the maze, and the activation pattern on it identifies the paths and orders them by length. Also, the solution shows second order dynamics on the neural level. The neural circuit are of the bottom-left type in Fig. 3: a modulatory connection projects to a grid with activation retention (in the form of local connectivity). This second order circuit is crucial to the ability to solve the Tolman mazes (breaking either connection removes this ability).

6 CONCLUSION & FUTURE WORK

We proposed the hypothesis that mental representation is evolved second order learning, and tested this hypothesis using an artificial life model in which cognitive map ability, a paradigm case of mental representation, is evolved from the neural elements for second order neural change. Although success rates are very low, successful runs provide a proof of principle for our hypothesis. Future directions for our research are extension of this approach to other domains of representation, such as temporal or social forms.

How equity norms evolve?
- An evolutionary game theory approach to distributive justice

Abstract: A Nash demand game (NDG) has been applied to explain moral norms of distributive justice. In NDG, two players simultaneously make demands and receive them unless the sum of the demands exceeds the amount of the resource. Otherwise, they obtain nothing. This paper proposes the demand-intensity game (D-I game), which adds an "intensity" dimension to NDG in order to discuss various scenarios for the evolution of norms concerning distributive justice. We show basic analyses of the D-I game in game theory and then evolutionary simulations. Descriptive/evolutionary approaches show that three types of norms could evolve mainly dependent on the conflict cost in the game: egalitarianism, "wimpy" libertarianism and libertarianism in decreasing order of the cost. Although the wimpy libertarianism is classified as the libertarianism in the sense of claiming the full resource, it can achieve an egalitarian division without conflict cost as a result.

Keywords: Distributive justice, Evolutionary game theory, Nash demand game

1 INTRODUCTION

Game theoretic models have been successfully used in the studies on the evolution of moral norms which promote cooperation mainly in humans. Classical game theory is based on a normative theory of rational choice and prescribes what people ought rationally to choose ("normative approach"). Recently, researchers in various fields have tried a different approach based on evolutionary game theory that dispenses with strong assumption about rationality. Rather than asking what moral norms ought to be, they aim at describing how people will in fact choose or how can the existing norms have evolved ("descriptive/evolutionary approach") [1].

The Nash Demand Game (NDG) [2] has been widely employed to explain the emergence of moral norms, especially the evolutionary bases of *distributive justice* [3], [4], [5], etc. In NDG, each player simultaneously makes a demand and each obtains the claimed demand if the aggregated demand between both is no less than the full amount of resource. Otherwise, they obtain nothing. Every pair of the claimed demands that total 100% of the resource is a strict Nash equilibrium; however, people intuitively make the 50% demand [6]. Skyrms provided a game theoretic account of how norms of fair division might have evolved using replicator dynamics as a descriptive/explanatory approach [4]. With a finer step size of the demand than 0.1 and a higher probability of playing between similar strategies, the population always evolved into the fair division equilibrium. However, the assumption of correlated interactions of strategies have been criticized for the reason that it has no actual grounding in reality [7]. Instead, fair division has been achieved by spacial models [5] and two-population models [8].

Skyrmsian approach is evolutionary generalist as it entirely omits the psychological mechanisms, in contrast to evolutionary psychology, which emphasizes particular psychological factors of human behaviors [7]. This paper proposes the demand-intensity game (D-I game), which adds an "intensity" dimension related to some psychological factor (e.g. *bold* or *timid*) to NDG in order to discuss various scenarios for the evolution of norms concerning distributive justice, while keeping such simplicity that it can be analyzed by the concepts and tools of game theory. In NDG, if the sum of the demands exceeds the amount of resource, they obtain nothing. This rigidity in evaluation of the conflict cost is weakened depending on the intensity values of the players.

2 D-I GAME

Similar to NDG, the D-I game is a two-player one-shot game and deals with the problem of allocating a limited resource between two players as shown in Fig. 1, in which d_0, i_0, d_1 and i_1 represent self demand, self intensity, the other's demand and the other's intensity, respectively.

Each player has a strategy $S(d, i)$ noted as a set of parameters d and i $(0 \leq d, i \leq 1)$. The parameter d represents the demand, which is an demanding amount in supposing a total amount of the resource is 1. If the total demand between the two players is not over 1 (the full amount of resource), each player gains the demand as a reward, which equates to NDG.

Otherwise, the conflicted part of the resource $(d_0 + d_1 - 1)$ is divided according to the newly introduced parameter i, the intensity of the demand, as $1/2 + (i_0 - i_1)/2 : 1/2 + (i_1 - i_0)/2$. For example, $(i_0, i_1) = (0, 0)$, $(0.5, 0.5)$, $(1, 0.5)$ or $(1, 0)$ makes the conflicted part divided as $1:1$, $1:1$,

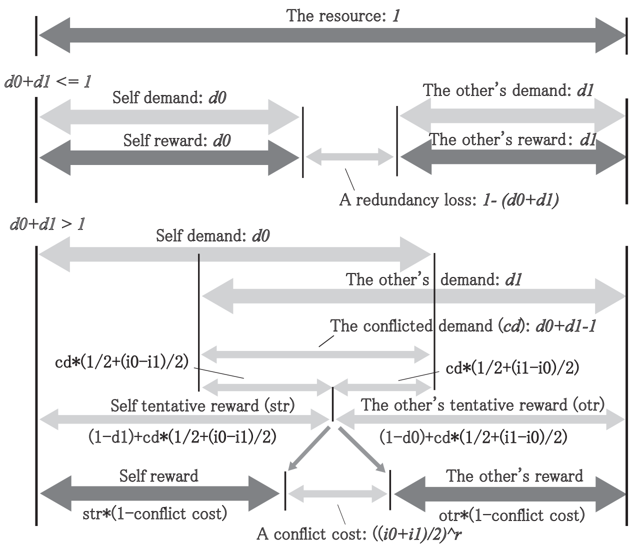

Fig. 1. Rewards in the D-I game.

$0.75 : 0.25$ or $1 : 0$, respectively. Finally, divided resources are reduced in reversely proportional to the sum of i_0 and i_1 as conflict cost. The larger the combined intensity between the players, the smaller rewards both gain. If the sum is maximum ($i_0 = i_1 = 1$), no reward is gained, as is the case with NDG. On the other hand, both share the resource without a loss of a conflict when the combined intensity is minimum ($i_0 = i_1 = 0$). Therefore, the game features two dilemmas: demand and intensity. Each player wants to receive more reward than the other and at the same time wants to avoid the conflict cost for the demand and the intensity.

The reward in the D-I game is shown as Eq. 1. (Fig. 1).

$$R(d_0, i_0, d_1, i_1) = \begin{cases} d_0 & (d_0 + d_1 \leq 1) \\ \{(1 - d_1) + (d_0 + d_1 - 1)(\frac{1}{2} + \frac{i_0 - i_1}{2})\}(1 - cost) & \\ & (else) \end{cases} \quad (1)$$

$$cost = \left(\frac{i_0 + i_1}{2}\right)^r \quad (2)$$

r specifies the game structure in terms of the conflict cost as shown in Eq. 2. At $r = 0$, the conflict cost is maximized and the game is equivalent to NDG.

We refer to a strategy of d below 0.5 as "generous" and above 0.5 as "greedy." Specifically, the cases that d is 0, 0.5 and 1 are defined as "unselfish," "even" and "selfish," respectively. The parameter i, the intensity of the demand, represents how strong people claim their own demand in a conflict. The strategy is referred to as "timid" if i is less than 0.5, and "bold" if i is more than 0.5. Specifically, the intensities i of 0, 0.5 and 1 are defined as "wimpy," "moderate" and "belligerent, " respectively.

Regarding d, there are two typical strategies: $d = 0.5$ and $d = 1$. Although debatable, we simply associate the former with egalitarianism and the latter with libertarianism. When $r = 0$, all strategies with $d = 0.5$ are ESS independently of i. Previous studies on a descriptive/evolutionary approach intended to describe how people could evolve this egalitarian norm. However, the strategies with $d = 0.5$ are not ESS except $r = 0$ and the norm becomes weaker as r increases. This is because a decrease of conflict cost (an increase of r) makes greed attractive.

When both players use the same greed strategy ($d_0 = d_1 > 0.5$), the reward is 0.5 at $i_0 = 0$ and decreases monotonically as i_0 increases when $r > 0$. Therefore, it is notable that ideal society in the sense of equality and efficiency can be achieved by not only a pure egalitarianism norm ($S(0.5, *)$) but also an eventual equality norm based on libertarianism ($S(1, 0)$) in the D-I game as shown later.

3 GAME THEORETIC ANALYSES

There are many efficient strategies in the D-I game according to a Nash equilibrium analysis as in NDG. An ESS (Evolutionary Stable Strategy) analysis leads to only three types of norms in these efficient strategies. The three norms (ESS) are egalitarianism (Norm A: $S(0.5, *)$, when $r = 0$), libertarianism (Norm B: $S(1, i^*)$ (i^* depends on r as shown in Fig. 3), when $r \geq 0.5$) and "wimpy" libertarianism (Norm C: $S(1, 0)$, when $0 < r < 0.773$). Fig. 2 shows the three norms in two dimensions of strategy: demand and intensity. The left, middle and right panels illustrate the cases of $r = 0$, $0 < r \leq 1$ and $r = 1$, respectively.

Norm A is represented as an ESS group of even strategies ($d = 0.5$) with any intensity value only when $r = 0$ (NDG setting) as shown in the left panel of Fig. 3. When $r > 0$, the egalitarian strategies are divided into two groups according to the the value of the intensity (X and Y in the middle and right panels of Fig. 3). The "bolder" egalitarian strategies (X) can be invaded only by all the egalitarian strategies (X+Y), while the "timider" strategies (Y) can be invaded not only by all the egalitarian strategies (X+Y) but also by other strategies. As r grows from 0 to 1, the range of bolder strategies (X) narrows from $0 \leq i \leq 1$ to $0.438 < i \leq 1$, and it finally vanishes when $r = 4.67$.

Although both Norm B and Norm C have a selfish property ($d = 1$, libertarianism), Norm B exists as an ESS under lower-cost conditions ($r \geq 0.5$) while Norm C exists as an ESS under higher-cost conditions ($0 < r < 0.773$) as shown in Fig. 3. Norm B bifurcates into two ESS at $r = 0.5$, $i = 0.25$. One of the bifurcated ESS becomes "timider" along with increased r, and the other "bolder." The "timider" ESS exists in $0.5 \leq r < 0.571$, whereas the "bolder" ESS exists till infinity. It should be noted that a society with Norm C is ideal from the aspect of equality and efficiency as in

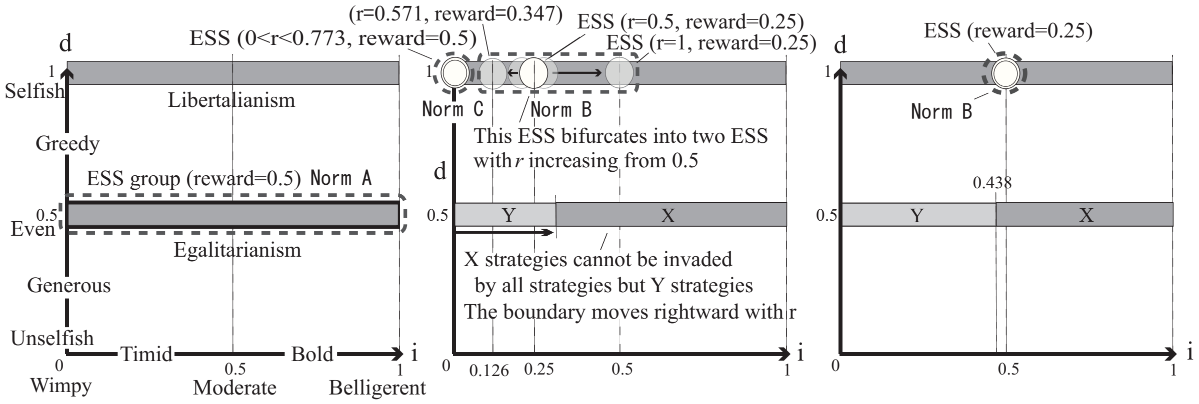

Fig. 2. Three types of norms in strategy space (Norm A: egalitarianism, Norm B: libertarianism, Norm C: "wimpy" libertarianism). The left, middle and right panels correspond to the cases of $r = 0$, $0 < r \leq 1$ and $r = 1$, respectively.

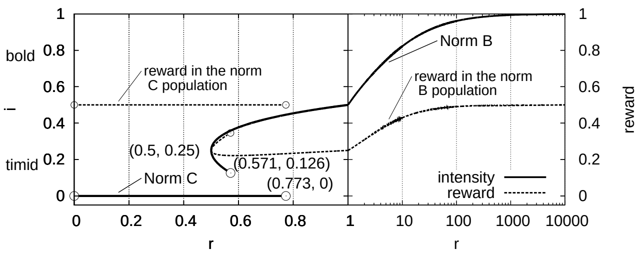

Fig. 3. Intensity i of two types of ESS (Norm B and Norm C). $d = 1$ (libertarianism). Rewards in the ESS population.

the case with Norm A, in the sense that each obtains the maximum reward (0.5) in the ESS population of selfish and wimpy strategies ($d = 1$ and $i = 0$). On the other hand, a society with Norm B is inefficient in the sense that each obtains less than 0.5 in the ESS population of "greed" and "bolder" strategies. The reward each obtains approaches 0.5 as r approaches infinity, in other words, the conflict cost approaches 0.

4 EVOLUTIONARY SIMULATIONS

We performed evolutionary simulations using a genetic algorithm. The population was composed of N individuals represented as the strategy parameters, d and i. The fitness of each individual was defined proportional to the total amount of rewards in playing the D-I game with all other members in the population. The strategy parameters d and i were and discretized into steps of size S_d and S_i in the range of $[0, 1]$, respectively. The initial populations consisted of N individuals with randomly selected d and i.

New individuals were generated by the three genetic operations: fitness-proportionate selection, crossover with a rate R_c, which simply exchanged the parent's intensity values, and mutation with a rate R_m, which selected another value for d or i, keeping them in the range of $[0, 1]$. We show

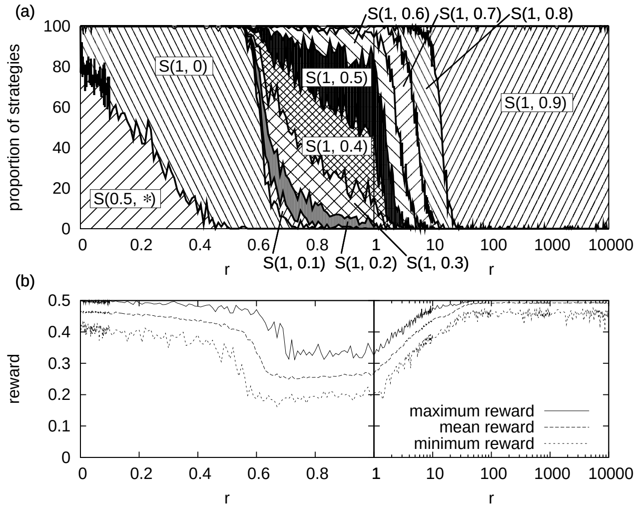

Fig. 4. (a) Proportion of the most common strategy in a population at the last generation over all 100 trials. (b) Average reward in the population. The graphs are the maximum, the mean and the minimum of the rewards over all 100 trials.

the result with $N = 100$, $S_d = S_i = 0.1$, $R_c = 0.5$, and $R_m = 0.05$.

Fig. 4 (a) illustrates a proportion of the most popular strategy at the last generation (1500th generation) over all 100 trials. For small r, the egalitarian strategies ($d = 0.5$) remained as the most common strategies until the last generation in many trials. While the proportion over all 100 trials decreased along with a growth of r, libertarian strategies ($d = 1$) became the most common strategies in more trials. The intensity of the libertarian strategies became larger as r increases.

The egalitarian ESS prevailed at $r = 0$ with 100% trials and the "wimpy" libertarian ESS prevailed for $0 < r < 0.773$ with the percentage of trials as shown in Fig. 4 (a). The egalitarian strategies remained until the last generation

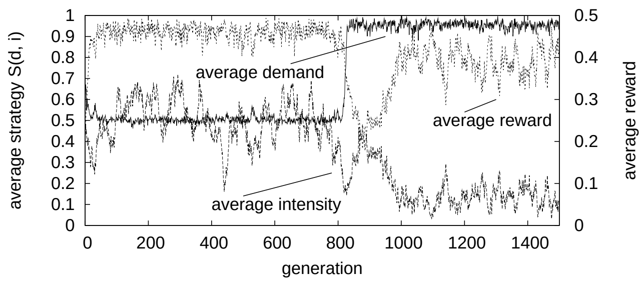

Fig. 5. Average demand, average intensity and average reward in a population through an evolutionary simulation for $r = 0.6$.

in some evolutionary simulations for $r > 0$. Fig. 5 shows the average demand, the average intensity and the average reward in a population for $r = 0.6$. Some trials kept egalitarian strategies until certain generation even when $r = 0.6$. The egalitarian strategies can be stabilized for $r > 0$ because a strategy distribution in a population is diverse through evolutionary simulations and thus the bolder egalitarian strategies (X in Fig. 2) can obtain a stability for some situations.

On the other hand, there was no coexistence between egalitarian strategies and libertarian strategies. Here we consider the reason of it. The generation in Fig. 5 sees a quick transition from an egalitarian to a libertarian population at about 800th generation. It is possible reason that a libertarian strategy obtains three times as much as an egalitarian strategy's reward when they play the game with each other under the same intensity. The difference is lager when i is smaller. Once libertarian strategies, especially the wimpy libertarian strategy, invade in a population, egalitarian strategies obtain the lower reward and can not remain in the population.

The most common strategy was various for around $0.6 < r < 10$ with a low reward in a population as shown in Fig. 4. The various strategies include not only the libertarian ESS but also other libertarian strategies. Furthermore, libertarian strategies coexisted with other libertarian strategies in trials for the range of r. It might be due to a little difference in the rewards between similar libertarian strategies.

For $0 \leq r < 0.6$, an ideal society was achieved with the successful reward in the population (0.5) by egalitarian strategies or the "wimpy" libertarian strategy. Fig. 4 (b) illustrates the average reward in a population at the last generation. The most successful trial for $0 \leq r < 0.6$ achieved the reward of around 0.5 ("maximum reward" in Fig. 4 (b)). When r approaches infinity (no conflict cost), an ideal society was also achieved, as a matter of course.

5 CONCLUSION

We proposed the D-I game, which adds an "intensity" dimension to NDG in order to discuss various scenarios for the evolution of norms concerning distributive justice. We did game theoretic analyses of the D-I game and performed evolutionary simulations. Descriptive/evolutionary approaches (an ESS analysis and evolutionary simulations) show evolution into three types of norms: egalitarianism, libertarianism and wimpy libertarianism. While the wimpy libertarianism is classified as the libertarianism for claiming the full resource, it can also achieve an egalitarian division in a population without conflict cost as a result.

A level of conflict cost has a large influence on what kind of norms emerge: the egalitarianism, the wimpy libertarianism and the libertarianism in decreasing order of the cost (which could be interpreted as a psychological cost). People may not feel conflict cost pressure so much when we share sweets among family members. We may act like a libertarian in this case and we may demand the whole sweets strongly. If the members are friends, we may feel more cost pressure. Then, we may act like a wimpy libertarian. If the share resource is money, we may feel more cost pressure than sharing the sweets and we may make an equal demand strictly as an egalitarian.

We believe that the D-I game provides us with a useful framework to study dynamics of distributive justice from an emergence perspective, beyond the question of whether strategies demanding equal share can dominate the population or not.

Abstract: Rules such as laws, institutions, and norms can be changed dynamically in our society, because they are shaped by interactions among social members who are affected by them. However, there are also some stable rules enhanced by interactions among rules. In this article, we discuss whether or not rules can be stabilized by interactions among the rules. To investigate this, we propose a multi-game model in which different games are played simultaneously by the dynamic cognitive agents. A minority game (MG) and an *n*-person iterated prisoners' dilemma game (NIPDG) are adopted. In our simulation, we found that the agents internalize the complex rules expressed as intricate geometrical shapes like strange attractors on the phase spaces, when the complex macro dynamics emerged. Furthermore, it showed that the macro dynamics shaped by the macro rules in the MG can be stabilized by interaction between the MG and the NIPDG rules internalized in the agents.

1 INTRODUCTION

There are many behavioral guidelines that have an influence on determination of our actions in our society. Rules such as laws, institutions, and norms can be regarded as the guidelines. We focus here on the institutions as the rules. North[1] claims that the institutions establish stabilities of themselves by making complex aggregates of them. Many institutions mutually support each other, and their functions are enhanced by other institutions. Aoki[2] defines this enhancing effect as institutional complementarity.

On the other hand, Nishibe[3] proposes an institutional ecology. This institutional ecology is defined as a dynamical system in which many institutions can be shaped and fluctuated through changes of human cognitions and behaviors by interactions among the institutions. He claims that the institutional ecology becomes a complex system, and diversity of the institutions is maintained, because the interactions among them are nonlinear.

The purpose of this article is to discuss whether or not rules can be stabilized through interactions between the rules actually. According to North's interpretation[1], the institutions are distinguished between formal and informal institutions. We refer to the formal institutions as global rules and the informal institutions as local rules. In this study, we assume that the local rules are the global rules internalized in the individuals and play an important role to stabilize the global rules and the macro dynamics based on the global rules, because their actions are affected by each internalized rules, and the global rules are shaped by the actions of all individuals.

In order to investigate what effects the interactions between the local rules of the individuals have on the stabilization of the global rules and the macro dynamics, we propose a multi-game model in which different games are played simultaneously by the dynamic cognitive agents who can internalize the rules through the learning process.

2 MULTI-GAME AND DYNAMIC COGNITIVE AGENT AS ITS PLAYER

2.1 Multi-game

We propose a multi-game model in which players play many types of games simultaneously. This is a game theoretical model to investigate what kind of the macro dynamics of the games the interactions between the rules internalized in the players form, and what rules for forming the dynamics the agents internalize through the learning process. The minority game (MG)[4] and the *n*-person iterated prisoners' dilemma game (NIPDG)[5] are adopted here.

The MG is a simple game, where n (odd) players must select one out of two actions (e.g., -1 or 1, like buy or sell) independently, and those who are on the minority side win. The NIPDG is a version of the IPDG with many players. In this study, we define the NIPDG as follows: each player has to choose one of two actions, defection (D) and cooperation (C) individually; the players who chose D always win if there is one or more player who chose C; namely, when all players select D, they lose. In the multi-game, the actions D and C in the NIPDG are expressed as -1 and 1, respectively.

2.2 Dynamic cognitive agent as its game player

We adopt a model of the dynamic cognitive agent with internal dynamics represented by a simple recurrent network with a self-influential connection (SRN-SIC), as proposed in our previous work[6] and illustrated in Fig.1. The internal states of humans change even in the situations in which the same external stimulus is constantly given or when no external stimulus is given. We refer to this autonomous change of the internal states as the internal dynamics.

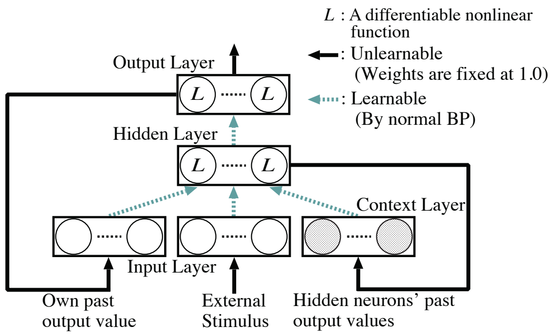

Fig. 1. The SRN-SIC proposed in our previous work as an architecture of a dynamic cognitive agent with internal dynamics.

The SRN-SIC is an Elman-type network[7] modified by adding recurrent connections between the output and input layers so that the agent can determine his/her own action based on his/her own past action, and the internal dynamics is produced by the recurrent connections.

2.3 The procedure of the multi-game

The procedure of the multi-game is as follows:

1. Except for initial time step, each agent independently decides their actions for the games based on their own past actions, internal states, and the results of the games at the last play.
2. A current game results, namely, winners' actions, are determined from all agents' actions.
3. The step is given an increment and goes to 1.

The procedure from 1 to 3 is called *one step*. By error back-propagatkon (BP) learning algorithm, all agents learn a time-series of the winners' actions in the games every 10,000 steps. A teacher's signal is the sequence of the actions at the last 100 steps immediately before the learning. We refer to the 10,000 steps as *one turn* between the learning processes.

3 SIMULATION RESULTS

Before describing the results, let's give the specification of the simulations[1]. The games are played until 10,000,000 steps; namely, 1,000 turns. The population size of the agents is 101.

[1]The settings and mathematical expressions of the SRN-SIC are omitted due to space constraints and for details to Sato and Hashimoto[6, 8].

3.1 Occurrence frequency of complex macro dynamics

First, we observe the macro dynamics expressed by a time-series of winners' actions in the games. Most of the macro dynamics have short period numbers, but sometimes complex macro dynamics represented as aperiodic motions are shaped, as illustrated in Fig.3 to be hereafter described. Fig.2 shows the average numbers of occurrences of the complex macro dynamics emerged in the games.

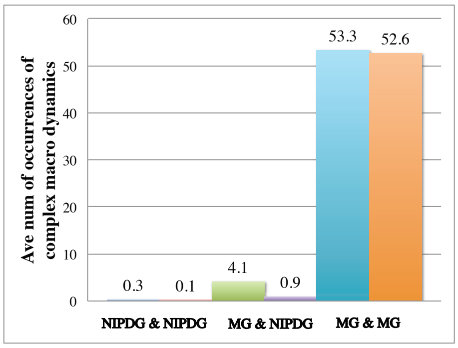

Fig. 2. Average numbers of occurrences of the complex macro dynamics in each game.

The two bar graphs on the left-hand side of Fig.2 indicate that the complex macro dynamics hardly emerge when the agents played the NIPDG and the NIPDG simultaneously. The middle two bar graphs of Fig.2 depict the results of the combination between the MG and the NIPDG. In this case, the complex macro dynamics in the MG is suppressed, although the MG is easy to shape such dynamics. The last two bars on the right-hand side of Fig.2 show the results in case that the agents played two MGs coinstantaneously. As can be seen, the number of occurrences of the complex macro dynamics is the highest of three types of game combinations. Also note that, in case of playing the MG by one group independently, the average number of occurrences of the complex macro dynamics is twenty and it was confirmed in our previous work[9]. Therefore, these results suggest that the rules shaped in the NIPDG hold enormous potential to stabilize the macro dynamics strongly, although the MG has a possibility to destabilize macro dynamics of the other game. However, the combination between the MG and the MG generates a synergistic effect to raise the frequency of occurrences of the complex macro dynamics.

3.2 Differences between the MG and the NIPDG

Second, we confirm the differences of the MG and the NIPDG from the viewpoint of the macro dynamics and the rules internalized in the agents.

Fig.3 show the examples of the complex macro dynamics[2] that emerged in the both of combined games simultaneously. Fig.3(a) illustrates the macro dynamics shaped in the MG

[2]The x-axis and the y-axis of each figure are the steps and the time-series of winners' actions converted to real numbers, respectively.

(a) Macro dynamics shaped in the MG and the NIPDG (b) Macro dynamics shaped in the MG and the MG

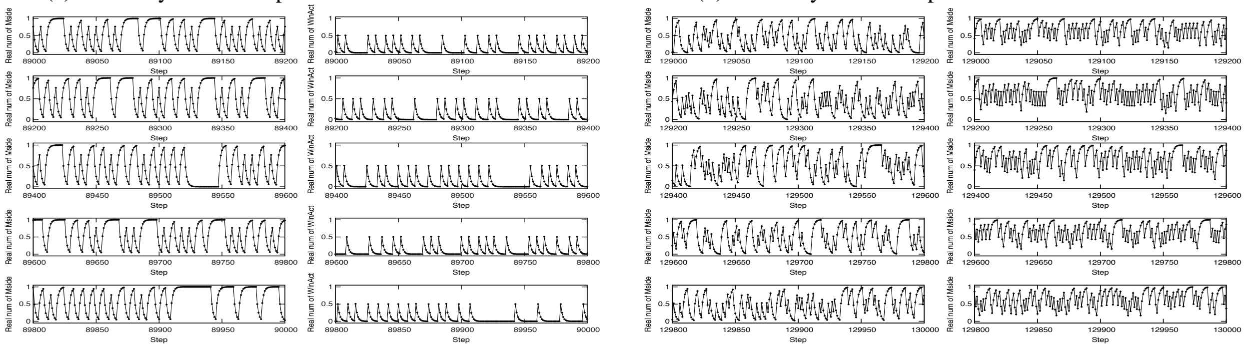

Fig. 3. Examples of complex macro dynamics.

(a) Internalized rules in the MG and the NIPDG (b) Internalized rules in the MG and the MG

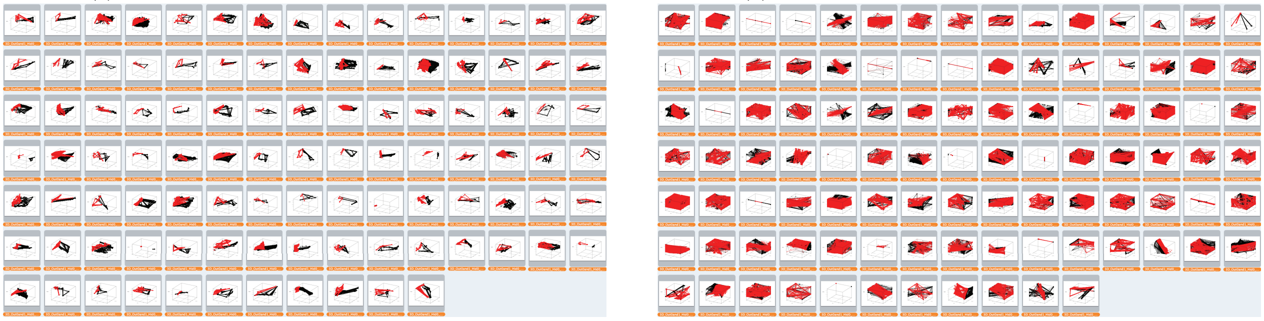

Fig. 4. Examples of rules internalized in the all agents through the learning process.

(left column) and the NIPDG (right column). Both of the dynamics are aperiodic, but change pattern of winners' actions in the NIPDG (right column) is relatively-monotonous than that of the MG (left column). In contrast, both the macro dynamics shaped by all agents who play two MGs simultaneously are very complex, as illustrated in Fig.3(b).

Fig.4 depicts the rules internalized in all agents who form the complex macro dynamics as illustrated in Fig.3. These rules are expressed as intricate geometrical shapes like strange attractors on the phase spaces which represent the relationship among two output and two hidden values[3]. The black and the red trajectories in Fig.4(a) are the internalized rules in the MG and the NIPDG, and that in Fig.4(b) are both the internalized rules in the MG, respectively.

As can be seen, each agent has two different rules to decide thier actions for the games. Furthermore, the points on the phase space of most of internalized rules illustrated in Fig.4(b) are so dense obviously. Most of these rules creates a one-to-many relationship from an input to the agent's actions, because the points on the phase space ranges over almost the entire area of the output (the x-axis on the phase space). That is to say: the rules internalized in the agents who play two MGs simultaneously, as illustrated in Fig.4(b), is more complex than that of the combination between the MG and the NIPDG, as illustrated in Fig.4(a).

[3]The x, y and z-axes of each figure are the values of the output neurons, the 1st and the 2nd hidden neurons, respectively.

3.3 Complex structures of internalized rules

In the previous section, we confirmed that the agents can internalize with different complex rules for each game through the learning process. Fig.5 gives the examples of the complex rules internalized in the agents in detail.

(a) (b)

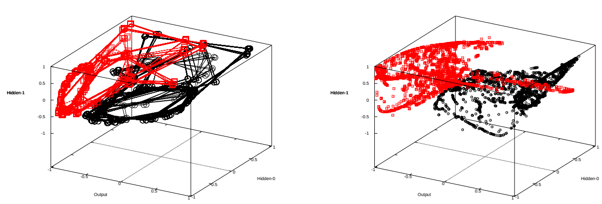

Fig. 5. Examples of complex internalized rules like combination between limit cycles and finite automaton with many states (a) and strange attractors (b).

Fig.5(a) shows the complex rules expressed by two combinations of limit cycle and finite automaton with many states. This means that the agent has the rules that can switch two action sequences with short and long periods according to the external stimuli.

Fig.5(b) can be easily imagined that the agent having this rule can output apperiodic actions. The aperiodic action may be chaotic dynamics. Chaotic dynamics has orbital instability, which expands small differences in the trajectories of agents' actions. Therefore, even a small displacement in an agents' group can induce a change in the macro level dynamics, if the number of agents with the rule that can generate the time-series of chaotic actions is much larger than that of agents without it. However, in case of playing two different games that can stabilize and destabilize the macro dynamics easily, it is considered that the agents are difficult to acquire the rules that can generate chaotic actions.

3.4 Degree of concordance of internalized rules

Finally, we analyze whether or not there is a difference between the internalized rules for the MG and the NIPDG and the ones for the two MGs. In comparison with the rules for the two MGs, it is often the case that both the rules for the MG and the NIPDG have similar or symmetric structures, as illustrated in Fig.4. This suggests that both actions decided by the rules for the MG and the NIPDG depend on the values of the same hidden neurons.

Fig.6 shows the degree of concordance of the internalized rules that are observed in the combination of the MG and the NIPDG and in the combination of the two MGs. The degree of concordance of the internalized rules is calculated as follows: correlation coefficients between each value of the output and the hidden neurons are calculated; the numbers of combinations between such neurons with strong coefficients (0.7 and more) are counted every the agents; the numbers are averaged for 1,000 turns; the averaged numbers are also averaged by the number of the agents.

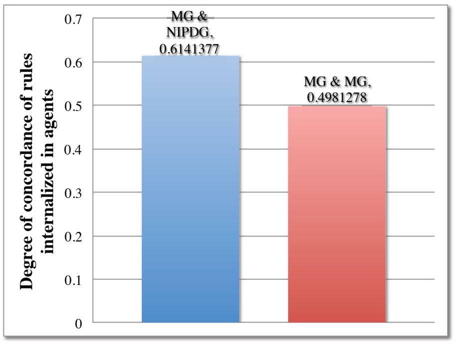

Fig. 6. Degree of concordance of rules internalized in agents

We found that there is subtle but important difference. The results in Fig.6 mean that the actions decided by both of the rules for the MG and the NIPDG are dependent on the values of the same hidden neurons than the ones determined by the rules of the two MGs. This can be interpreted that both the rules for the MG and the NIPDG have the same partial structures, and such structures can be internalized at an early stage of the games, because the agents shape only simple macro dynamics at the early stage even though they play the MG.

4 SUMMARY AND CONCLUSION

We proposed a multi-game model in order to investigate whether or not the interactions between the rules internalized in the individuals have an influence on the stabilization of the rules and the macro dynamics shaped by the rules. In this model, different games are played simultaneously by the dynamic cognitive agents who can internalize the rules through the learning process.

The simulation results showed that the agents can internalize different complex rules represented as strange attractors, but the agents are difficult to acquire the rules that can generate chaotic actions when playing simultaneously both two different games, where the macro dynamics can be stabilized easily in at least one of the games. Furthermore, we confirmed that both the rules for the MG and the NIPDG have the same partial structures, and it was suggested that such structures can be internalized at an early stage of the games, because the agents shape only simple macro dynamics at the early stage even though they play the MG.

From these results, we conclude that the followings are the important to stabilize the macro dynamics; the agents internalize different rules for each game in which at least one of the games has a feature to stabilize the macro dynamics easily, and the ones have the common partial structures between the different rules at an early stage of the games.

ACKNOWLEDGMENT

The author thanks Takashi Hashimoto and Zacharie Mbaitiga for their fruitful discussions. This work was supported by a Grant-in-Aid for Young Scientists (B) No. 22700242 from the Japan Society for Promotion of Science (JSPS).

Abstract: In this paper, a method of determining examination groups for new patients is presented, using self-organizing maps. Assuming that interview sheets are divided into four classes, the method copes with the examination determination as the classification of the sheets. The data are generated from handwriting sentences in the sheets. Some nouns in them are picked up as elements of the data. After map learning is complete, its neurons are labeled. The class of the sheet corresponding to the data to be checked is specified by the label of the winner neuron for the data. It is established that the multiple-map-based scheme achieves favorable classification accuracy.

Keywords: data classification, interview sheets, self-organizing maps, waiting time problems

1 INTRODUCTION

In Japan, long waiting time has been considered to be one of the major reasons that prevent chronic patients from going to hospitals. The condition of chronic patients keeps on worsening, and the fatal damage tends to suddenly befall to such patients. In Ji, Yanagawa, and Miyazaki [1], an event-driven network approach using queuing theory is presented to reduce the waiting time. The dispatching rules are suggested based on patients' expected visitation time and expected service time, and they are used to schedule the patients. The advisability of applying the rules is sometimes restricted by situations associated with the numbers of clinical testing equipments, medical doctors, nurses, medical technologists and so forth.

Managing the waiting time as part of the examination time is also a promising approach. Before consultation, a doctor first reads an interview sheet filled out by a new patient. The doctor then determines a set of examinations for the new patient, whereas the patient must wait for a while before the doctor make a determination. This medical protocol also prevents the doctor from allotting enough time to see the patient. The doctors are therefore anxious for the system that automatically checks the interview sheets and determines a set of the examinations.

In this paper, the determination of examination groups for new patients is presented, using self-organizing maps (SOM's). SOM's are applied as useful classification tools. In Kurosawa et al [2] and Ohtsuka et al [3], [4], SOM's have strong research interest as a means of expressing and/or processing clinical examination results. The proposed method assumes that each of the interview sheets filled out by new patients belongs to one of the four classes. It therefore copes with the examination determination as the classification of data corresponding to the sheets. An open source engine developed for Japanese language morphological analysis is applied to handwriting sentences in the sheets, and some nouns in them are picked up as elements of the data presented to the maps. After general SOM learning is complete, neurons in the maps are labeled. The class of the data to be checked is specified by the label of the winner neuron. The scheme using a single map for all of the patients and that dividing patients into five age groups and preparing a map for each of the groups are discussed. It is revealed that the latter scheme is useful in achieving favorable classification accuracy, compared with the former scheme.

2 PRELIMINARIES

A map consists of neurons, and a neuron has a reference vector with M element values if the M-dimensional data is presented to the map. General SOM learning is conducted using the following formulas.

$$NF(t) = r_0\left(1 - t/T\right), \quad (1)$$

$$\tau_i(t) = \tau_0\left(1 - t/T\right), \quad (2)$$

$$W_i(t) \leftarrow W_i(t) + \tau_i(t)\left(X^l(t) - W_i(t)\right). \quad (3)$$

$X^l(t)$ means the l-th training data. The neighborhood function around the winner neuron for the data presented at time t is defined by Eq. (1). $W_i(t)$ is the reference vector of the i-th neuron, C_i. If C_i is located inside the area specified by $NF(t)$, $W_i(t)$ is modified according to Eqs. (2)

and (3). $\tau_i(t)$ is the learning rate. T is the epoch number employed as the learning-termination condition.

This paper focuses on sentences handwritten in Japanese by new patients visiting the department of ophthalmology. They appear in interview sheets. It is probable that patients contracting different diseases undergo same examinations. According to common characteristics in terms of the examinations for the diseases, this paper divides examinations into the following four classes: Class 1 associated with fundus examinations, Class 2 associated with glaucoma tests, Class 3 associated with slit lamp tests, and Class 4 associated with oculomotor tests. Class 1 is strongly linked to cataract, diabetes, retinal disease, uveitis, and pediatric ophthalmology. Class 3 is strongly linked to corneal and/or conjunctival disease, lacrimal apparatus, and ametropia. A similar relationsip holds between Class 4 and each of strabismus, neuro-ophthalmologic disease, and trauma. Since a new patient undergoes the examinations belonging to one of the four classes, the interview sheets can also be divided into such four classes. The proposed method then copes with determination of examinations as classification of data corresponding to interview sheets with the four classes.

3 DATA GENERATION FROM INTERVIEW SHEETS

Handwriting sentences in interview sheets are first electronically registered from the keyboard. MeCab, which is the open source engine developed for Japanese language morphological analysis by Kudo, Yamamoto, and Matsumoto [5], is then applied to divide the words in them into some parts of speech. Several of the nouns are picked up per sentence by consulting the list of prohibited words. Table 1 shows examples of the prohibited words.

The proposed method next generates a matrix. Let us assume that N interview sheets whose classes are perfectly known are available. Let d denote the total number of nouns picked up in the above manner. The matrix then has N rows and d columns. In other words, the nouns are assigned to the columns, and each of the sentences (i.e., the interview sheets) corresponds to a row. Frequencies of appearance are initially given as follows: if the p-th noun appears in the l-th sentence m_{lp} times, the element specified by the l-th row and p-th column is set to m_{lp}, where $1 \le l \le N$ and $1 \le p \le d$. Fig. 1 depicts an example of the first matrix. In the following discussions, m_{lp} means the value given to the element specified by the l-th row and p-th column.

Table 1. Examples of prohibited words

Types of prohibited words	Examples
Numbers	1, 2, 0, 100, 36.5
Symbols associated with SI base units	m, mm, cm, kg
Geographical names	姫路/ Himeji, 佐用/ Sayoh
Words associated with time	週/ week, 金曜日/ Friday, 去年/ last year, 先月/ last month

Weighting element values adequately is useful in emphasizing the significance of the words corresponding to such values. The proposed method weights some values, based on the probability of words appearing. Let us assume that the p-th noun appear NA_p^q times in the set of registered sentences (i.e., the interview sheets) belonging to Class q, where $1 \le p \le d$ and $1 \le q \le 4$. In addition, let R_p^q denote the ratio of the number of the p-th nouns appearing in the sentences belonging to Class q, compared to the total number of the sentences belonging to Class q. Assuming that the latter number is denoted by NS^q, R_p^q is as follows.

$$R_p{}^q = NA_p{}^q / NS^q . \quad (4)$$

It is considered that nouns with comparatively high R_p^q's are of importance in specifying attributes of Class q. The threshold value associated with R_p^q is set to 0.055 when the noun is checked whether its element values are weighted.

The p-th noun is defined as a powerful word, if the value calculated by Eq. (4) is more than 0.055 for Class k solely, where $k \in \{1, 2, 3, 4\}$. We then have $R_p^k \ge 0.055$ and $R_p^q < 0.055$ for any q, where $q \in \{1, 2, 3, 4\}$ and $k \ne q$. If Eq. (4) calculates the value more than 0.055 for two classes, the noun is defined as a special word. In the case where the p-th noun is the special word, $R_p^q < 0.055$, $R_p^{k1} \ge 0.055$ and $R_p^{k2} \ge 0.055$ hold for $k1$, $k2$, and any q, where $k1$, $k2 \in \{1, 2, 3, 4\}$, $k1 \ne k2$, $k1 \ne q$, and $k2 \ne q$. The first matrix is modified as follows. Each of the element values on the columns corresponding to the powerful (or special) words is multiplied by 4 (or 2). For example, if Word 2 in Fig. 1 is the powerful word, element values on the second column are weighted and change from $(m_{12}, m_{22}, m_{32}, \ldots, m_{N2})=(0, 2, 0, \ldots, 1)$ to $(0, 8, 0, \ldots, 4)$. Besides, if Word 3 is the special word, we have $(m_{13}, m_{23}, m_{33}, \ldots, m_{N3})=(4, 0, 2, \ldots, 2)$ as weighted values.

It is difficult to specify the attribute of a unique class, using a noun that equally appears in the numerous sentences belonging to arbitrary classes. This is why targets of weighting are restricted to the nouns, each of which has the value calculated by Eq. (4) exceeding the threshold for at most two classes.

4 EXAMINATION DETERMINATION USING SELF-ORGANAIZING MAPS

For the use of SOM's, two schemes are available. The first scheme is based on using a single map, whereas the other prepares a map for each age group. The maps are constructed in the general manner using Eqs. (1)-(3). The general manner is also adopted in Ohtsuka et al [3], [4]. Note that a row in a matrix generated by the method in Sect. 3 is presented to a map as a member of the training data set.

Let us discuss the single-map-based determination. The information associated with age is added as the rightmost (i.e., the (d+1)-th) column to the matrix. One of the three-level values is given to each element in the (d+1)-th column. If the patient filling out the l-th sheet is younger than 11 years old, 0 is given as m_{ld+1}. If the age of the patient is more than 10 and less than 46, we have m_{ld+1}=6. If it is larger than or equal to 46, m_{ld+1}=12 holds.

Once general SOM learning is complete, neurons in the map are labeled as follows.

<Neuron labeling>

[Step 1] Let $F_q^{\,i}$ denote the frequency of the i-th neuron (C_i) firing for the training data belonging to Class q, where $1 \le q \le 4$. Set four $F_q^{\,i}$'s to 0, and set l to 1.

[Step 2] The l-th training data is presented, and $F_q^{\,i}$'s of the winner are updated. The value of l is incremented by 1.

[Step 3] If $l \le N$, go to Step 2; otherwise, go to Step 4. Note that N is the total number of training data.

[Step 4] Let LN^i denote the label of C_i. It is as follows.

$$LN^i = \arg\left\{ \max_q \left(F_q^{\,i} \right) \right\}. \tag{5}$$

Labels are assigned to the other neurons, using Eq. (5).

In this paper, each of the data unused for SOM learning is referred to as pilot data. The set of pilot data is also generated in the manner described in Sect.3. When one of the pilot data is examined, it is presented to the map with labeled neurons. The class of the data is considered to be that specified by the label of the winner for it.

Let us next explain the determination employing multiple maps. The following five age groups are defined: Group 1 with patients whose age is less than 31, Group 2 with patients whose age is more than 30 and less than 56, Group 3 with patients whose age is more than 55 and less than 66, Group 4 with patients whose age is more than 65 and less than 76, and Group 5 with patients whose age is more than 75. A training data set with four classes is generated for each group, and a map intended for exclusive use with a group is constructed by using it. The (d+1)-th column associated with age is ignored for learning, labeling, and data classification. The above labeling method is also adopted. Classifying the pilot data is also similar to that applied for the first scheme, except that the map used depends on age of the patient corresponding to the data.

5 EXPERIMENTAL RESULTS

The proposed method was applied to interview sheets provided from Tsukazaki hospital in Japan. A map with ten rows and ten columns is prepared. It is trained, subject to T=1000 in Eqs. (1) and (2). Besides, r_0=20 and τ_0=1.0 hold for initial values of in Eqs. (1) and (2).

Let $IS_q^{\,k}$ denote the number of pilot data, each of which is judged as Class q while its actual class is Class k, where k, $q \in \{1, 2, 3, 4\}$. The percentage of the number of pilot data whose classes are judged as Class q, compared to the total number of pilot data actually belonging to Class k, is calculated. The following value is referred to as the percentage of concordance associated with Class k, PC_k.

$$PC_k = 100 \times IS_k^{\,k} \,/\, \left(\sum_{q=1}^{4} IS_q^{\,k} \right). \tag{6}$$

The experimental results for the scheme using a single map are first shown. A set of data generated from interview sheets for 580 patients is used. The sheets were filled out from May through November 2010. The correspondence between a sheet and its class is perfectly known in advance. The sheets for hundred patients are randomly chosen, and a set of pilot data is generated from them. A set of training data is then generated from the remaining sheets, and a map is constructed by presenting members in the training data set. The classification capability of the resultant map is evaluated, using the pilot data set. A trial consisting of the above is repeated ten times, and mean values of PC_k's are obtained. The results are tabulated in Table 2. Note that unfavorable values associated with the percentages of discordance also appear in it. We have PC_1=82.0, PC_2=48.8, PC_3=62.8, and PC_4=48.8. PC_1 is the highest value of four PC_k's, and the proposed method achieves favorable PC_3. Both of PC_2 and PC_4, however, are less than fifty percent. This is due to the fact that the data actually belonging either to Class 2 or to Class 4 tend to be misjudged as the data of Class 1. Inhibiting misjudgment from Class 2 (or 4) to Class 1 is especially crucial in improving capability of the single-map-based classification.

Let us next show the experimental results for the five-map-based classification. The number of interview sheets is 2407. They were filled out from May through November 2010. The classes of data generated from them are perfectly known in advance. The data of fifty patients are randomly chosen as pilot data for each of the age groups (Groups 1 through 5). The remaining data are used as training data. Recall that a map is constructed for each group. The five-map-based method is evaluated by classifying the pilot data. A trial consisting of the above is repeated ten times, and the following value, PC_{ave}, is calculated for each group from averaged PC_k's.

$$PC_{ave} = \left(\sum_{q=1}^{4} PC_q\right)/4. \quad (8)$$

PC_{ave}'s are tabulated in Table 3. Patients in Group 3 suffer from a wide range of diseases compared with patients in any other group. This is why PC_{ave} is somewhat disappointing for Group 3. The method, however, achieves favorable PC_{ave}'s for other groups. It is thus established that the classification should be conducted for each age group.

6 CONCLUSIONS

This paper proposed the SOM-based method of determining examination groups for new patients from their interview sheets. MeCab is applied to handwriting sentences in the sheets, and several of the nouns are picked up per sentence. A matrix in which the sheets (or nouns) are related with the rows (or columns) is then generated. Frequencies of the nouns appearing in the sentences are basically given as element values in the matrix, and its row is presented to a map as a member of a training data set. The proposed method determines the examination group for some patient by classifying the data generated from the interview sheet filled out by the patient. The class of data is specified by the label assigned to the winner neuron for the data. From experimental results, it has been revealed that the scheme using maps for five age groups is superior in classification accuracy to the single-map-based scheme.

In future studies, the proposed method will be modified to improve the classification accuracy.

Table 2. Classification results achieved by single-map-based method

		Classification results (%)			
		Class 1	Class 2	Class 3	Class 4
Actualities	Class 1	82.0	4.0	12.0	2.0
	Class 2	42.4	48.8	8.4	0.4
	Class 3	21.6	0.0	62.8	15.6
	Class 4	36.8	1.6	12.8	48.8

Table 3. Classification results achieved by five-map-based method

Age groups	PC_{ave}'s (%)
Group 1	75.2
Group 2	65.2
Group 3	59.6
Group 4	72.2
Group 5	78.0

Abstract: The pharyngeal pumping motion to send food to the bowel is a rhythmic movement in *Caenorhabditis elegans*. We proposed a computer simulation of the pumping motion to investigate the mechanisms of rhythm phenomena in living organisms. To conduct the simulations we developed an electrophysiological model of the pharyngeal muscle that corresponds to the actual structure at a muscular level, and which generates the pumping rhythms. Each of 29 cells was modeled as a membrane potential model to simulate the internal response. The electrophysiological responses of the pharyngeal muscular cells were measured as an electropharyngeogram (EPG) that records the activities of the pharynx as a signal pattern, including the membrane potentials in multiple cells. We also developed an EPG model that calculated EPG based on the outputs of individual membrane-potential models. We confirmed that our model of the pharynx could generate rhythms similar to the EPG measured from *C. elegans*.

Keywords: *C. elegans*, electropharyngeogram, electrophysiological model, pharyngeal muscle, pumping motion

1 INTRODUCTION

Living organisms exhibit various rhythmic movements such as walking and myocardial pulsation, which are important for their survival. The mechanisms of generation and control of these rhythmic movements remain largely unknown. Further understanding of these mechanisms may help in the treatment of diseases caused by defects in rhythmic control. Further, if the mechanisms can be modeled, they can be applied to engineering systems including developing novel control methods of humanoid robots.

The nematode *Caenorhabditis elegans* is a well-studied model organism with a simple nervous system, and shows several rhythmic movements including the pumping motion for chewing and swallowing involving the pharyngeal muscle. The pharyngeal muscle is composed of only 20 muscular cells and 9 marginal cells. Various biological signals including membrane potentials have been measured in pharyngeal muscular cells using the electropharyngeogram (EPG), and there is evidence that the pumping rhythms are generated by the pharyngeal muscular cells and controlled by pharyngeal neuronal cells (neurons) [1]. In addition, we recently reported that the pumping rhythms temporarily change after ionizing irradiation [2]. Thus, the pumping motion in *C. elegans* is considered a useful system to investigate the mechanisms of rhythmic phenomena in living organisms. However, it is difficult to measure the membrane potentials of individual pharyngeal muscular cells by electrophysiological techniques, and as such the mechanisms of rhythm generation and control in pharyngeal muscular cells are not well understood.

In the present study, we propose a computer simulation with a mathematical model that is constructed based on the actual structure of the *C. elegans* pharynx, and which corresponds to the biological response at an individual cellular level. A previous study superficially simulated the pharyngeal motion sending food to bowel [3] and is impossible to represent the cell-level responses. Therefore, we propose a structure-based pharyngeal model that can be used for the cell-level analysis and simulation of rhythmic phenomena. The first step of these simulations involves developing a mathematical model of the pharyngeal muscle of *C. elegans* to reproduce the pumping rhythms.

In section 2, we give an outline of the pharyngeal pumping motion and introduce the EPG, which is caused by the electrophysiological responses of muscular cells. In section 3, we model individual cells in the pharynx at the membrane-potential level, and propose a method to tune multiple parameters included in the model comprised of individual muscular-cell models using a genetic algorithm. In section 4, we confirm that an appropriate set of parameters is obtained by our parameter-tuning method and that the model can generate rhythms similar to the EPG measured from *C. elegans*. In section 5, we provide a conclusion to our study and discuss future research.

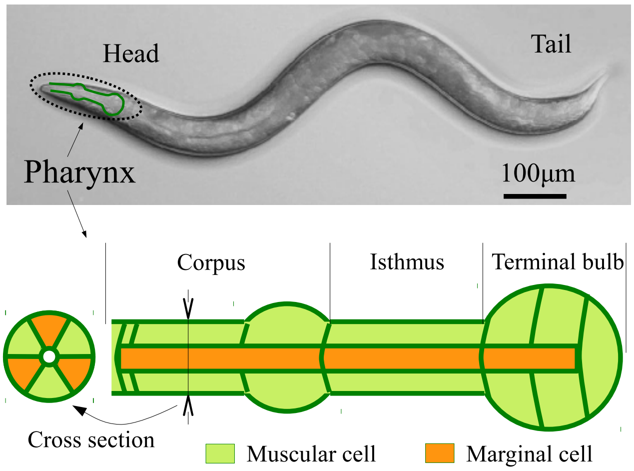

Fig. 1. Structure of the pharyngeal muscle in *C. elegans*.

2 PHARYNGEAL MUSCLE IN *C. ELEGANS*

2.1 Structure of the pharyngeal muscle

C. elegans has a simple cylindrical body approximately 1 [mm] in length (Fig.1, upper panel), and the body is composed of 959 cells. Neuronal networks consisting of 302 neurons include approximately 5,000 chemical synapse connections, approximately 600 gap junctions and approximately 2,000 connections between neurons and muscles [1]. The pumping motion (chewing and swallowing) is a rhythmic movement that is generated by the pharyngeal muscle and is required to send food (bacterial cells) to the bowel. The pharyngeal muscle alternatively contracts and relaxes 0.3 [sec]. It is structurally divided into the corpus, the isthmus and the terminal bulb (Fig.1, lower panel). The corpus is composed of four different types of 10 muscular cells (pm1, pm2VL, pm2VR, pm2D, pm3VL, pm3VR, pm3D, pm4VL, pm4VR and pm4D) and three marginal cells (mc1V, mc1DL and mc1DR). The isthmus is composed of one type of three muscular cells (pm5VL, pm5VR and pm5D) and three marginal cells (mc3V, mc3DL, and mc3DR). The terminal bulb is composed of three different types of seven muscular cells (pm6VL, pm6VR, pm6D, pm7VL, pm7VR, pm7D and pm8) and three marginal cells (mc3V, mc3DL and mc3DR). Muscular cells and marginal cells are alternately arranged in a radial manner (Fig 1, cross-section view). Each marginal cell connects with the adjacent pharyngeal muscular cells by gap junctions and does not contract and relax.

The functions of some pharyngeal neurons in the pumping motion have been elucidated, including the control of the interval between contraction and relaxation of the pharyngeal muscle and control of the pumping cycle. In addition, cell ablation studies have demonstrated that the rhythm of the pumping motion is generated by only pharyngeal muscular cells, as the pumping motion continues after all pharyngeal neurons are killed. Furthermore, the activity of muscular cells in the pharynx is synchronized by signal transduction via gap junctions between muscular cells, as mutants with a defect in the function of the gap junctions in the isthmus show disrupted synchronization between the muscular cell in the corpus and those in the terminal bulb.

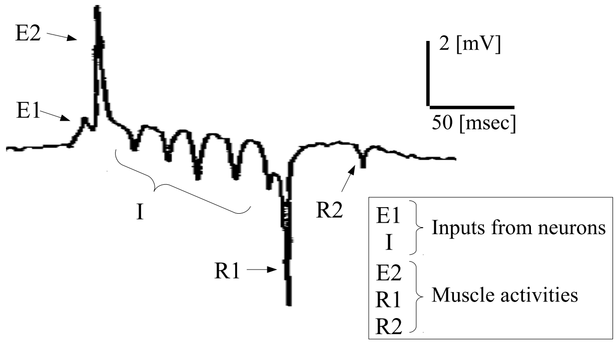

Fig. 2. The EPG recorded by Raizen et al. (revised Fig. 6A in the literature [5]).

2.2 Electropharyngeogram (EPG)

Several methods to measure activities of muscular cells in the pharynx have been developed, including membrane-potential recording [4], myoelectric-potential recording [5] and cell imaging [6]. In particularly, the myoelectric-potential recording is a popular method that can record the activities of pharyngeal cells as a signal pattern, including the membrane potentials, in the multiple pharyngeal muscular cells. The myoelectric potential in *C. elegans* is termed the electropharyngeogram (EPG). The EPG is measured by fitting a glass electrode into head of a fixed *C. elegans*, and is calculated as the difference of voltages between recordings with and without the pharynx. The EPG is composed of the time derivative of membrane potentials summed over all pharyngeal muscles and the input signals from neurons. Thus, each rapid positive change in membrane potential is observed as a positive spike in the EPG, and vice versa. However, the activity of the peristaltic motion present in the isthmus is not shown in the EPG. Each spike observed in the EPG is termed E1, E2, I, R1 and R2 (Fig. 2). E1 corresponds to the inputs by MC neurons, E2 corresponds to the contraction of the corpus and terminal bulb, I corresponds to the inputs by M3 neurons, R1 corresponds to the relaxation of the corpus and R2 corresponds to the relaxation of the terminal bulb. There is individual variability in the voltage level of the spikes depending on the electrical property of the membrane and/or the measurement environments. Therefore, we focused on the qualitative properties of the EPG including the spiking intervals that are largely independent of individual variance.

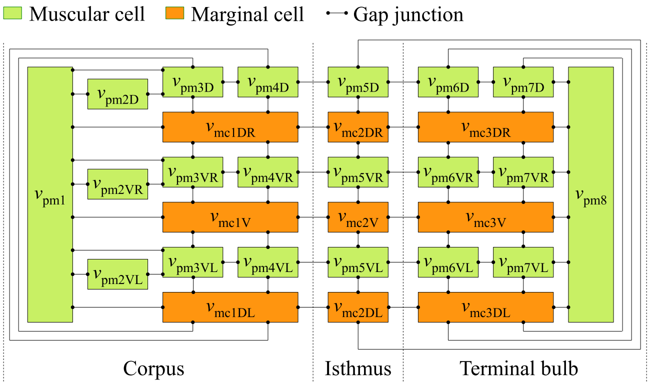

Fig. 3. Electrophysiological model of the pharyngeal muscle.

3 ELECTROPHYSIOLOGICAL MODEL OF THE PHARYNGEAL MUSCLE

In this next section, we propose an electrophysiological model of the pharyngeal muscle, which can reproduce the membrane potential of each cell and the EPG of the pharynx. This model is composed of two parts; a membrane potential model of individual cells in the pharynx (cell-level model) and an EPG model to reproduce the EPG based on the outputs of membrane potential models. The parameters of the membrane-potential models are then tuned to reproduce the actual EPG.

3.1 Membrane potential model (cell-level model)

The membrane potential of each pharyngeal muscular cell in the pharynx is important for the rhythm generation and synchronization in the pumping motion [7]. Therefore, we developed a mathematical model of each cell that shows the cell response at the membrane-potential level. Based on the actual structure of *C. elegans* [1], [8], we utilized all 29 cells in the pharynx (i.e., 20 muscular cells and 9 marginal cells), and modeled each of them individually. In the model of the cell $n(\in \mathrm{pm1}, \mathrm{pm2VL}, \cdots, \mathrm{mc3DR})$, the membrane potential is represented by v_n (Fig. 3). To describe the behavior of v_n, we introduced the FitzHugh-Nagumo model [9], [10], which is used for heart muscle modeling and analyses of various rhythmic phenomena. Cells, n and m, are connected by gap junctions based on the actual structure [8], and the connection weight is represented by $w_{n,m}$. Note that $w_{m,n} = w_{n,m}$. The electrical current from m to n is given by $w_{n,m}(v_m - v_n)$ using $w_{n,m}$ and the difference of potential between v_m and v_n. Therefore, the membrane potential, v_n, is represented by:

$$T_n \frac{dv_n}{dt} = c_n\{v_n - \frac{v_n^3}{3} - u_n + \sum_m w_{n,m}(v_m - v_n)\}, \quad (1)$$

$$T_n \frac{du_n}{dt} = \frac{1}{c_n}(a_n + v_n - b_n u_n), \quad (2)$$

where T_n is a time constant to account for the rapid change of the membrane potential in the pumping motion. a_n, b_n, and c_n are constants used in the FitzHugh-Nagumo model. u_n is a recovery variable. These parameters determine the cycle and the response rate of v_n, and should be tuned to generate rhythms in the pumping motion. This is the first model to reproduce the activities of individual cells in the pharynx at the membrane potential level.

Since the EPG can be used to directly observe the rhythms generated in the pharynx, we used the EPG to compare the rhythm of v_n with that of the pumping motion itself. For this purpose, we developed the EPG model to calculate the EPG based on the individual membrane potential models.

3.2 EPG model

We calculated the EPG based on the membrane potential, v_n, of each cell model in **3.1**. The EPG is measured as the time derivative of the membrane potentials summed over all pharyngeal muscular cells because there is a capacitance between the electrode and the head of the *C. elegans*. Therefore, the EPG, $V^{\mathrm{EPG}}_{\mathrm{model}}$, generated by $v_n(n \in \mathrm{pm1}, \mathrm{pm2D}, \cdots, \mathrm{mc3V})$ is represented by:

$$V^{\mathrm{EPG}}_{\mathrm{model}} = \sum_n R_n C \frac{dv_n^{\mathrm{act}}}{dt}, \quad (3)$$

$$v_n^{\mathrm{act}} = \max(v_n, 0), \quad (4)$$

where $v_n^{\mathrm{act}}(n \in \mathrm{pm1}, \mathrm{pm2D}, \cdots, \mathrm{mc3V})$ is an action potential, R_n is a resistance depending on the distance between the electrode and the cell body, and C is a capacitance. We can compare the rhythm of v_n with that of the pumping motion by using the EPG model.

3.3 Parameter tuning method for the pharyngeal muscle model

The parameters should be well tuned in order to reproduce the actual EPG using the model. To tune parameters included in the membrane potential model of each cell in **3.1**, we compared the actual EPG recorded from a *C. elegans* with the EPG calculated by the model in **3.2**. As the recorded EPG is affected by electrical properties of the membrane and/or measurement environments, there is individual variability in the voltage level of the spikes. Therefore, we used qualitative properties, in particular spiking intervals, which are largely independent of individual variability, for the parameter tuning. The spikes that correspond to muscular activities are E2, R1, and R2 (Fig. 2). Positive and negative membrane potentials in the corpus cells generate E2 and R1 spikes, respectively, while positive and negative membrane potentials in the terminal-bulb cells generate E2 and R2 spikes, respectively. Therefore, we tuned the membrane potential models

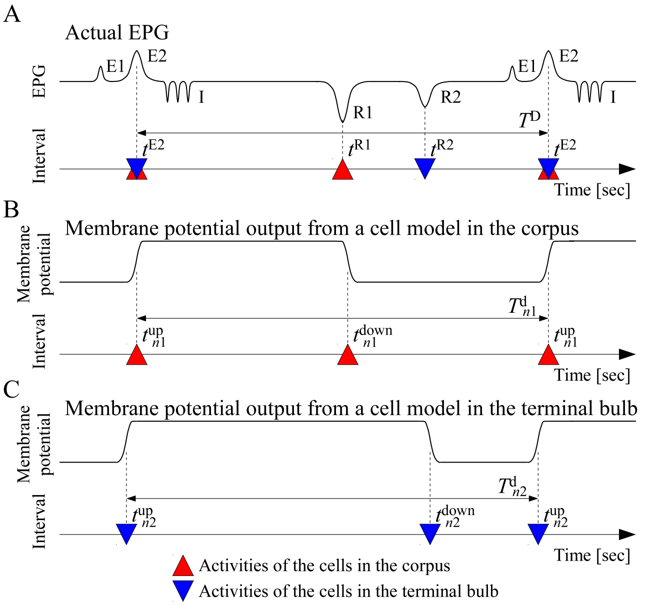

Fig. 4. Intervals of the activities of the corpus and the terminal bulb.

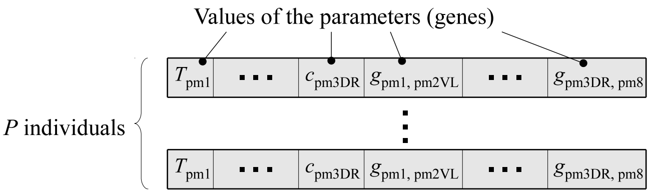

Fig. 5. The GA string.

to reflect the positive and negative membrane potential properties and the spiking intervals between each spike in the actual EPG.

t^{E2}, t^{R1}, and t^{R2} represent the intervals of E2, R1, and R2 (Fig. 4A), and are calculated as the peak value of each spike. In addition, the pumping cycle measured from the actual EPG is represented by T^{D}. The positive and negative intervals in the outputs of the membrane potential models in the corpus are represented by t^{up}_{n1} and t^{down}_{n1} (Fig. 4B), where $n1$ is the cell name (pm1, pm2VL, pm2VR, pm2D, pm3VL, pm3VR, pm3D, pm4VL, pm4VR, pm4D, mc1V, mc1DL, and mc1DR). The positive and negative intervals in the outputs of the membrane potential models in the terminal bulb are represented by t^{up}_{n2} and t^{down}_{n2} (Fig. 4C), where $n2$ is the cell name (pm6VL, pm6VR, pm6D, pm7VL, pm7VR, pm7D, pm8, mc3V, mc3DL, and mc3DR). These parameters are calculated as the maximum/minimum values of the time derivative of each membrane potential model. In addition, the output cycles of the membrane potential models of the corpus and the terminal bulb are represented by T^{d}_{n1} and T^{d}_{n2}, respectively.

To evaluate the fitness of the positive and negative intervals calculated by the individual membrane potential models of the pharyngeal cells, we defined the following error judgment standard that compares the intervals of membrane potentials output from individual cell models to the actual EPG in the pharynx:

$$E = \frac{E^{c} + E^{t}}{23}, \tag{5}$$

$$E^{c} = \sum_{n_1} \frac{|t^{E2} - t^{up}_{n_1}| + |t^{R1} - t^{down}_{n_1}| + |T^{D} - T^{d}_{n_1}|}{3}, \tag{6}$$

$$E^{t} = \sum_{n_2} \frac{|t^{E2} - t^{up}_{n_2}| + |t^{R2} - t^{down}_{n_2}| + |T^{D} - T^{d}_{n_2}|}{3}, \tag{7}$$

where E^{c} is an integrating error of the corpus cells, and E^{t} is an integrating error of the terminal bulb cells. As the activity of the isthmus cells is not shown in the actual EPG, we evaluated the fitness of 23 membrane potential models in the isthmus (6 membrane potential models were not used). The smaller the E, the more the EPG model reproduces the actual EPG. We employed a learning and evolutionary genetic algorithm (GA) to suitably tune the parameters included in the membrane potential models on the basis of E.

First, all the parameters included in the membrane potential models are represented as individual genes in a GA string (Fig. 5). A string arranging all the parameters (genes) is treated as an individual in the GA. P individuals are produced, where the initial value for each gene is given as a uniform random number. Next, all individuals of the current generation (the repeat number of calculation for the GA tuning) are evaluated by equation (5), which are used to produce the next generation. The elite R_{elite} [%] individuals with the superior error value, E, remain as a part of the next generation. $(100 - R_{elite})$ [%] of the population of the next generation is produced by the three operations of a GA; i.e., crossover for $R_{crossover}$ [%] of the population, mutation for $R_{mutation}$ [%] of the population, and copying for $R_{copying}$ [%] of the population. These procedures (evaluation, crossover, mutation, copying) are repeated every generation until the generation g reaches G. We essentially follow the procedures of GA operations we previously reported [11].

4 REPRODUCTION OF PUMPING RHYTHMS IN A WILD TYPE *C. ELEGANS*

We evaluated the effectiveness of our proposed pharyngeal muscle model. To generate the actual pumping rhythms in our model, we tuned the parameters included in the membrane potential models by the GA-based tuning method. As an example to reproduce the actual EPG, we used the EPG of a wild type *C. elegans* in which neurons except for the M4 neuron were ablated.

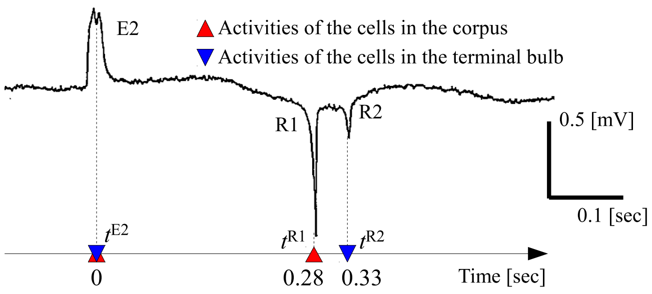

Fig. 6. EPG measured by Raizen et al. (revised Fig. 6A in the literature [5]).

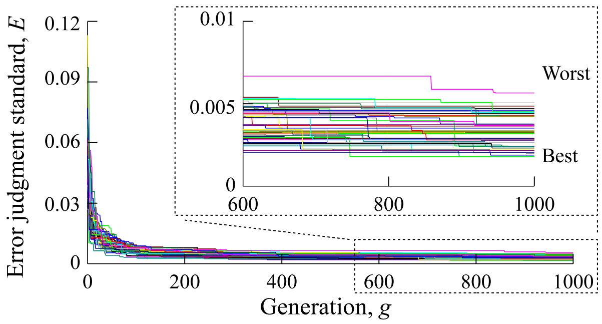

Fig. 7. Evolution of the error judgment standard, E.

4.1 Methods

The EPG includes E1 and I spikes corresponding to neuronal activity and E2, R1, while R2 spikes correspond to muscular activity. As the proposed electrophysiological model targets only muscular activity, we employed the EPG measured from a wild type *C. elegans* in which all neurons but the M4 neuron were ablated [5]. As shown in Fig.6, the EPG includes only E2, R1, and R2 spikes. Although the M4 neuron controls the peristaltic motion of the isthmus, the input from the M4 neuron to the pharyngeal muscle and the peristaltic motion are not shown in the EPG. Therefore, the spikes observed in Fig.6 can be treated as muscular activity only.

The data of the spiking intervals used for the parameter-tuning were derived from the EPG in Fig.6, where we defined the spiking interval of E2 as a standard time ($t^{\mathrm{E2}} = 0$ [sec]) and the spiking intervals of R1 and R2 were given by $t^{\mathrm{R1}} = 0.28$ [sec] and $t^{\mathrm{R2}} = 0.33$ [sec], respectively. The pumping cycle was given by $T^{\mathrm{D}} = 1.2$ [sec]. The spiking intervals calculated by the membrane potential models, t_n^{up} and t_n^{down}, were normalized by those generated by a cell near the glass electrode, pm4D ($t_{\mathrm{pm4D}}^{\mathrm{up}} = 0$ [sec]). The range of parameters used in this simulation were $T_n = [0, 0.1]$, $a_n = [0, 1]$, $b_n = [0, 1]$, $c_n = [0, 10]$, and $w_{n,m} = [0, 1]$. Parameters included in the models of the same types of cells are tuned as the same value. The condition settings of the GA were set to $P = 20$, $R_{\mathrm{elite}} = 5$, $R_{\mathrm{crossover}} = 76$ [%], $R_{\mathrm{mutation}} = 9.5$ [%], $R_{\mathrm{copying}} = 9.5$ [%], and the at-end generation was set to $G = 1,000$.

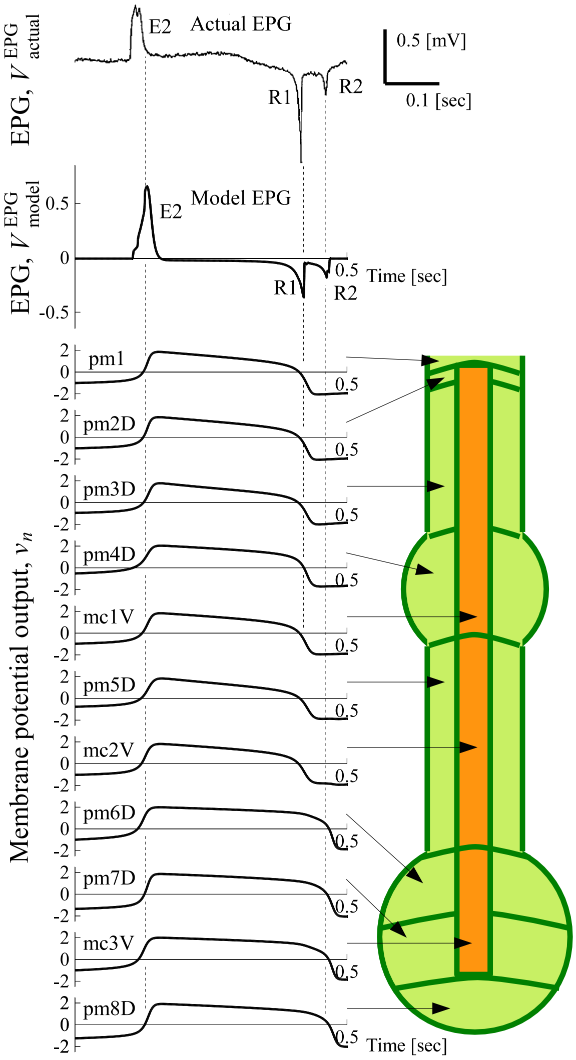

Fig. 8. Reproduction of pumping rhythms of a wild type *C. elegans* at the EPG level.

4.2 Results

We conducted 50 trials using different initial values for the GA-based tuning method. Evolution of the error judgment standard, E, in a top individual at each GA generation among 50 trials is shown in Fig. 7. Values of E among all trials decreased rapidly until $g = 100$, and were less than $E = 0.015$ at $g \leq 200$. After $g = 200$, values of E among all trials decreased slowly, and at $g = 1,000$ the maximal and minimal values reached $E = 0.0056$ and $E = 0.0018$, respectively (worst and best trials in Fig. 7).

The membrane potential output of individual cell models, v_n, employing a set of the parameters obtained at $g = 1,000$ and the EPG, $V_{\mathrm{model}}^{\mathrm{EPG}}$, calculated from v_n are shown in Fig. 8.

The output EPGs from the actual *C. elegans* and the proposed model, $V^{\mathrm{EPG}}_{\mathrm{actual}}$ and $V^{\mathrm{EPG}}_{\mathrm{model}}$, are shown on the top panel. $V^{\mathrm{EPG}}_{\mathrm{actual}}$ is a replot of Fig. 6. The EPG of the model was calculated based on v_n of the membrane potential models of 23 cells (equations (3) and (4)). Since the cells in the pharynx are divided into 11 types based on the function, a single example of output of each is shown on the bottom panel. The right panel shows the position of each cell in the pharynx. The capacitance included in equation (3) was set to $C = 276$ [pF] based on a previous report [4]. The resistances included in equation (3) were set to $R_{\mathrm{pm4VL}} = R_{\mathrm{pm4VR}} = R_{\mathrm{pm4D}} = 1$ [MΩ] and $R_{\mathrm{pm6VL}} = R_{\mathrm{pm6VR}} = R_{\mathrm{pm7D}} = R_{\mathrm{pm7VR}} = R_{\mathrm{pm7D}} = 0.3$ [MΩ]. The resistances corresponding to the isthmus were set to $R_n = 0$ [MΩ] as the activity of the cells in the isthmus is not shown in the actual EPG. Other resistances were set to $R_n = 0.01$ [MΩ]. From Fig. 8, we confirmed that the shapes of the membrane potential, v_n, were similar in all cells. In the membrane potential models of all cells, the rising time of v_n is the same as that of the spike E2 in the actual EPG. v_n in the corpus decreased corresponding to the decrease of the spike R1, and v_n in the terminal bulb decreased at the same time as R2 in the actual EPG. Furthermore, the EPG of the proposed model, $V^{\mathrm{EPG}}_{\mathrm{model}}$, calculated based on v_n, was similar to the actual EPG, $V^{\mathrm{EPG}}_{\mathrm{actual}}$. As such, the proposed electrophysiological model of the pharyngeal muscle composed of the membrane potential models accurately reproduced the pumping rhythms (i.e., spiking intervals of the actual EPG).

5 CONCLUSION

In this paper, we developed a membrane potential model of individual muscular cells in the pharynx based on the actual structure of the *C. elegans* to investigate the mechanisms of rhythm generation and control in living organisms. In addition, we proposed an EPG-level model that calculates the electropharyngeogram (EPG) based on outputs of individual membrane potential models. In the parameter tuning for the membrane potential models, we focused on the spiking intervals in the actual EPG and tuned the parameters so as to reproduce the intervals rather than the EPG itself. In our numerical experiment of rhythm generation, the proposed model successfully generated similar pumping rhythms to those observed in a wild type *C. elegans*.

As our model was based on the actual structure of cell connections and each cell corresponds to the actual cell in the *C. elegans*, by ablating each connection included in this model virtually, we can investigate the role of the gap junctions on the rhythmic phenomena. In pilot experiments, we virtually ablated gap junctions in the isthmus, as seen in the *eat-5* mutant that exhibits functional gap junctions deficits in the isthmus and shows disrupted synchronization between the muscular cells in the corpus and those in the terminal bulb. Similarly, we found that the membrane potential models generated rhythms that were not synchronized between the corpus and the terminal bulb (data not shown). Thus, this model will be useful for further studies examining mechanisms of rhythmic phenomena in *C. elegans*.

Abstract: Chukchee-Kamchatkan (ChKm) basic body-part name words (BBPs) in Swadesh 200 basic word vocabulary. were compared with ca. 1,300 basic words of 80 different Austronesian (AN) languages, which has resulted in finding 13 cognates of ChKm BBPs. Out of the 13 ChKm BBP word-items, 5.3 items were found to have cognate in Formosan, and 3.5 items in Paiwan. Chi-squared statistical test concluded that ChKm have evolved from the Paiwan language or its close kin language. The results were compared with the results from similar analyses of Formosan-related non-AN languages and Gilyak (Nivkh). Results were also discussed from aspects of mitochondrial and Y-chromosomal DNA-haplotype distributions.

Keywords: 3-6 key words or phrases in alphabetical order, separated by commas.

1 INTRODUCTION

The Origin of Chukchee-Kamchatkan (ChKm) language family is unknown. ChKm is divided into Chukchee-Koryak branch (Chukchee, Koryak, Alutor) and Itelmen (Itel) branch, the latter consisting of Northern and Southern dialects (N.Itel, S.Itel) of Western Itelmen (W.Itel = Western Kamchadal) and distinct Eastern Itel and Southern Itel (Kurebito [1]). The aim of this paper is to elucidate phylogenetic position of ChKm language family by basic word (BW)-comparison method, and to provide basic knowledge for analyzing recently accumulating data of mitochondrial, Y-chromosomal and HLA haplotype distribution in Eurasia, Oceania, and Americas.

2 METHODS, RESULT and DISCUSSIONS

BBP comparison: Basic body-part name words (BBPs) (ca.32 word items for human and animals, See [2]), defined as body-part name words included in Swadesh 200 basic words (Sw200W), were taken from ChKm vocabulary in the references, Kure* (Kurebito [1]), Worth*, and Bogo*, listed in Table 1, and compared with ca. 1,300 Austronesian (AN) basic words listed in Tryon's "Comparative Austronesian Dictionary" (CAD* in Table 1), and with representative Eurasian languages. AN cognates of ChKm BBPs thus found are listed in Table 2, where BBP items are classified to 5 AN subgroups (FORM, W.MP, C.MP, SHWNG, and OC in Table 1) to which AN cognates most similar to the corresponding ChKm BBPs belong. Cognates found in Niger-Kordofanian are also given in Table 2. Abbreviations used in Tables 2-6 are listed in Table 1.

Closest similarity analysis (CSA): CSA (Ohnishi [3]) was revised and employed to this study. Cognates most similar (= closest) to these ChKm BBPs were found in the frequencies as below. Cognates were found in 13 ChKm BBP items, out of which 11.2 BBP items are found in AN, and 1.8 items are in non-AN languages. The 11.2 items consists of (**Formosan 5.3** (**Paiwan 3.5**, Tsou 1, Atayal 0.8), Western Malayo-Polynesian(=W.MP) 3 (Philippines 1 / Borneo 0 / Sundic 2/ Sulawesi 0), CentralMP= 0.5, Oceanic = 2), as shown in Table 3. These values, which we call here "closest similarity (CS)-scores", are calculated by the method shown detailedly in Table 3, using the cognate data in Table 2. The CS-scores, thus calculated for each of the 5 AN subgroups, tell us the subgroup to which ChKm would be most closely related. In the case of Table 3, Formosan seems to be most closely kin to ChKm.

Chi-squared test: In order to statistically evaluate the result of CSA in Table 3 and Table 4, χ^2-test for the degree 2 of freedom was employed as below (Snedecor [4]).

χ^2 is given by

$$\chi_X{}^2 = \Sigma_i\, (Observed_i - Expected_i\,)^2 /(Expected_i)$$
$$= (O_X - E_X\,)^2 /E_X + (O_{non\text{-}X} - E_{non\text{-}X}\,)^2 /E_{non\text{-}X} \qquad \text{[Eq.1]}$$

By letting

Number of AN languages listed in CAD*: $N_{AN} = 80$.

Number of languages in a subgroup X of AN family: n_X

Number of languages in the remaining subgroup (non-X) of AN family: $n_{non\text{-}X} = N_{AN} - n_X$

Number of word items whose closest cognate is observed in subgroup X: O_X

Number of word items whose closest cognate is observed in subgroup $non\text{-}X$: $O_{non\text{-}X}$

Number of total number of word items whose closest cognates are found in AN: $O_{AN} = O_X + O_{non\text{-}X}$,

we have

$E_x = O_{AN}\ (n_x / N_{AN}),\ E_{non\text{-}X} = O_{AN}\ (n_{non\text{-}X}/N_{AN})$. [Eqs 2]

From Eqs 2 and Eq.1, we obtain the value of $\chi_X{}^2$ for subgroup X.

For $O_{FORM} = 5.3\ (O_{AN} = 10.8)$, and $O_{Paiwan} = 3.5\ (O_{AN} = 10.8)$, in Table 4, we can conclude $P < 0.05$ for both cases, as is shown in Table 4..

Thus we can conclude thast ChKm is most kin to Formosan, especially to Paiwan language. It is very plausible that ChKm have evolved from an ancient Paiwan language or its kin language. Results of similar CSA and χ^2-test for other possibly Formosan-related languages, Mayan, Eskimo, and Mongolic, taken from Ohnishi [3], are also given in Table 4, for the sake of compasison with ChKm. Further relationship among these possibly Formosan-related languages needs to be analyzed in future.

AN cognates of ChKm non-BBP vocabulary are also searched in CAD*, and listed in Table 5.

In order to know whether or not the Nivkh (= Gilyak) language is related or not related to ChKm, CSA and χ^2-test were similarly done for analyzing AN cognates of Nivkh BBPs, and the result is given in Table 6 and Table 3. Nivkh is now concluded to be closely kin to Oceanic (P < 0.005), and is therefore unrelated to Nivkh.

Relationship to DNA haplotype distribution: Chukchee and Eskimo share some haplotypes such as Q and N3 haplotypes of Y chromosome, A2 and D2 haplotypes of mitochondrial DNA (Sakitani, 2008[5], p.13, p.p.31; Adachi *et al.*[6]). It seems to be interesting to answer the question whether or not these and/or some other haplotypse might be shared by some different language groups of possible Formosan origins.

3 CONCLUSION

ChKm is a language derived from ancient Formosan, most plausibly from a Paiwan-like language. Eskimo seems to be considerably kin to ChKm, but seem to have been derived from different branches of Formosan or Formosan-related AN languages. Closest similarity analysis and chi-squared test concerning the distribution of basic body-part word cognates in AN subgroups was found to be an efficient method for finding phylogenical relationship to various subgroups of Austronesian.

Abstract: In this paper, we studied the contribution of the cutaneous sensation in the perception of the line segment's length and direction through psychophysical experiments where a mechatronic stage was utilized to express virtual line segments. The perceived lengths and directions were compared to the true values, and the mean errors, the standard deviations, and RMSE (Root Mean Square Error) were examined. As the results of the examinations, it was found as for the mean error of the perceived length that the more the length is increased from 10 to 90 mm, the more the subjects perceived decreased length from about 0 to 30%. As for the mean error of the perceived direction, another finding was that the subjects can recognize the direction with less than errors of about 10 degrees in the counter-clock wise direction.

Keywords: haptic display, length perception, direction perception, cutaneous sensation.

1 INTRODUCTION

Support systems have been developed to improve communication and quality of life for the people in need. Human can accept objects' geometrical information such as the lengths and directions of the line segments as the results of physical contacts [1]. Therefore, as an alternative for visually impaired persons, to create mental images of the objects, researchers have been studying human haptic sensational characteristics in the object perception. As for the objects, the representative ones are line segments, and they were provided as the raised dots and edges, rods, and ditches [2, 3, 4, 5], and, nowadays, by virtue of the development of robotic technologies [6, 7], the objects can be virtually represented by a feedback force as in this paper.

Here, the perceptual processes with the contacts can be categorized from the two viewpoints. The first is the sense organs; (1) the cutaneous sense on a fingertip abdomen (where the index finger is often used) (2) the proprioceptive sense such as the joint rotation and the kinematic/force sense relating to muscle expansions and contractions, and (3) the combination of both the cutaneous and the proprioceptive.

The second sense, i.e., the proprioceptive sense is with the movements of his/her hand, and it works only when his/her hand moves. Here, the person can take initiative against the outside world in the perceptual process, and the person moves his/her hand voluntarily: the mode of movement is called "active" in this paper [19, 20]. On the other hand, the outside world, vice versa, can take initiative against the person in the perceptual process, and his/her hand is forcibly moved by external actuators: the mode of movement is called passive movement [19, 20]. That is, as for the proprioceptive sense, we should consider the two modes: (1) the passive movement when the person has his/her hand motion activated by actuators, and (2) the active movement when the person voluntarily activates his/her hand to gain some haptic information about the outside world. Therefore, relating to the proprioceptive sense, both active and passive movements should be considered, which results in the following four modes: (1) PrPa mode (proprioceptive passive), (2) CoPa mode (combined passive), (3) PrAc mode (proprioceptive active), and (4) CoAc mode (combined active) [8, 9, 10, 11, 12, 13, 14, 15, 16, 17, 18, 21]. As a result, five modes would be considered in the haptic perception, and these five modes is considered to be important in practical situations.

As for the sense, i.e., the cutaneous sense itself, even though his/her hand is stationary or not, the cutaneous sense works if the touched object moves relatively to his/her fingertip, and causes slip to the fingertip abdomens. Thus, we can consider a mode, i.e., (5) CuPa mode (cutaneous passive): the person keeps his/her hand stationary while the outside object moves, and he/she passively gets information through the physical interactions between the fingertips and the outside object.

The cutaneous sense is considered to enhance the performance of the proprioceptive sense in the combination, and, therefore, the CuPa mode must be a key issue in considering the performances of the above mentioned five modes since the CoPa mode is an integration of CuPa and PrPa, and the CoAc mode is an integration of CuPa and PrAc.

In this paper, we studied the contribution of the cutaneous sensation in the perception of the line segment's length and direction through psychophysical experiments where a mechatronic stage was utilized to express virtual line segments.

2 EXPERIMENTAL METHOD

2.1 Apparatus

Fig.1. shows the experimental apparatus. The length, width and height of table base are 510 × 500 × 610 mm, respectively. It consisted of a power supply, a controller, an acrylic plate with a hole, a flat plate, a linear actuator and a rotation board. The acrylic plate was mounted on top of the flat plate. The hole was at the center of the acrylic plate. The gap between the two plates was set at 6 mm. The flat plate was attached on the top of the linear actuator (IAI-ICSA series) and it could be moved in the left and right direction in 300 mm range. The linear actuator was mounted to the top of the rotation board so that it could be rotated 360 degrees.

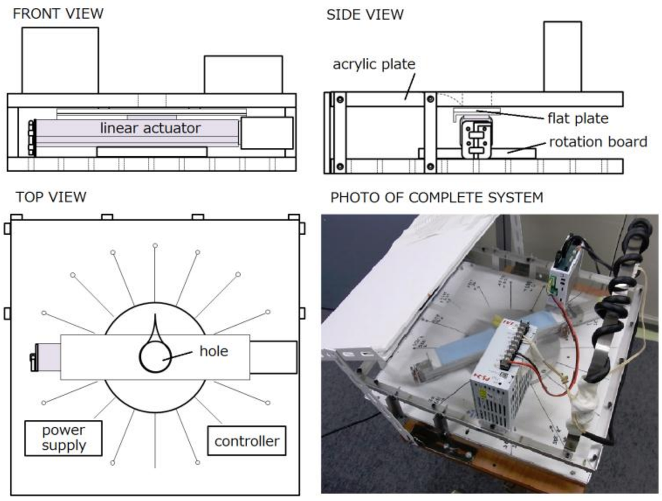

Fig.1. Experimental apparatus

2.2 Subjects

Eight right-handed subjects (male students, aged 22 to 35 years) volunteered for their participation. None of the subjects had a neurological disorder affecting the hands and fingers. None of subjects had any previous experience with the stimuli or tasks used in this study.

2.3 Task

The line lengths presented were 10, 30, 50, 70, 90 mm and the directions were 0 to 360 degrees with the interval of 22.5 degrees: the number of pieces of the presented lengths is five and that of the directions is 16. Subjects were asked to choose which line segment corresponded to the tested one among the multiple solutions presented on the answer board. This answer board consisted of a reference pattern as shown in **Fig.2.,** that was composed of concentric circles of which radiuses were 5 to 125 mm with the interval of 5 mm. All the patterns of 80 line segments with 5 lengths by 16 directions were presented in pseudo random order. All the experiments were carried out with a speed of 50, 100,141 and 200 mm/s.

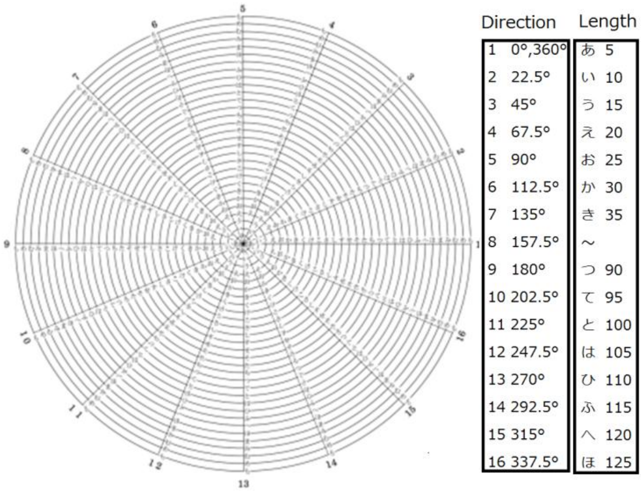

Fig.2. Answer board

2.4 Procedure

Fig.3. shows the experimental views. The subjects were comfortably seated in a chair (**Fig.3.(b)**) with their right hand on the acrylic plate (**Fig.3.(a)**). During experiment, subjects were instructed to relax, close their eyes, and focus on the perception of the length and direction of the presented line segment through the cutaneous sensation of his/her index finger. The subjects put their index fingertip abdomen on the surface of the flat plate (**Fig.3.(a)**), at that same time the subjects arm angle was positioned at 90 degrees or horizontal to table base (**Fig.3.(c)**). The subject shoulder was on the mid-sagittal axis, aligned with the hole in the acrylic plate (**Fig.3.(d)**). Headphones with white noise were provided to the subject to prevent hearing the sound generated by linear actuator. The white noise was played at a volume just below the irritation threshold to mask any remaining sound cues and avoid any side effects on the spatial perception. Stimulation starts when fingertip is at an end of the line stimulus and stops when it reaches the other end. The velocity is generated by the linear actuator controlled with a computer and the software X-SEL. It should be noted that the speed of movement is driven with a rectangular velocity pattern. The direction of the linear actuator was set by manual operation each time. The velocity and angle were pseudo-randomly assigned for each subject. After the experiment, subjects open their eyes

and, by looking at the answer board, they give their perceived direction and length by stating a number between 1 and 16 and a letter between A and HO (**Fig.3.(b)**). The whole experiment took 25-35 minutes per subject.

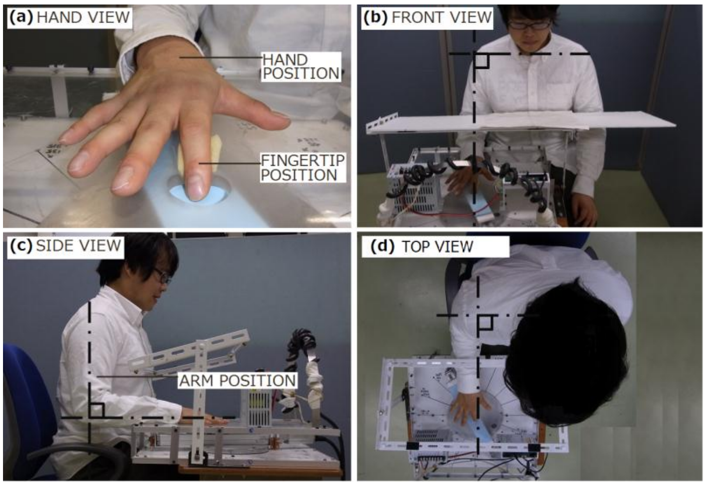

Fig.3. Experimental view

3 RESULTS AND DISCUSSION

3.1 Analysis of length

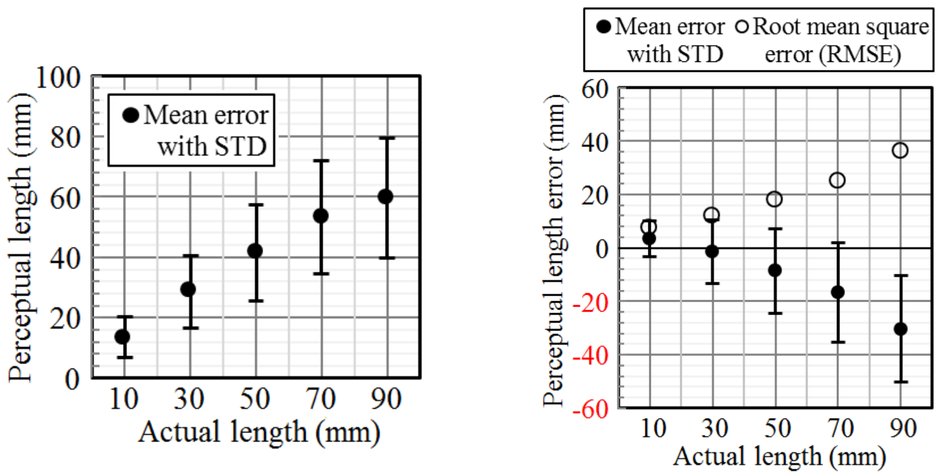
Fig.4. shows the experimental results with the length perceptual error characteristics.

(1) **Fig.4.(a)** shows the actual-perceptual length relationship. Form this data, the errors were obtained and plotted in **Fig.4.(b)**.

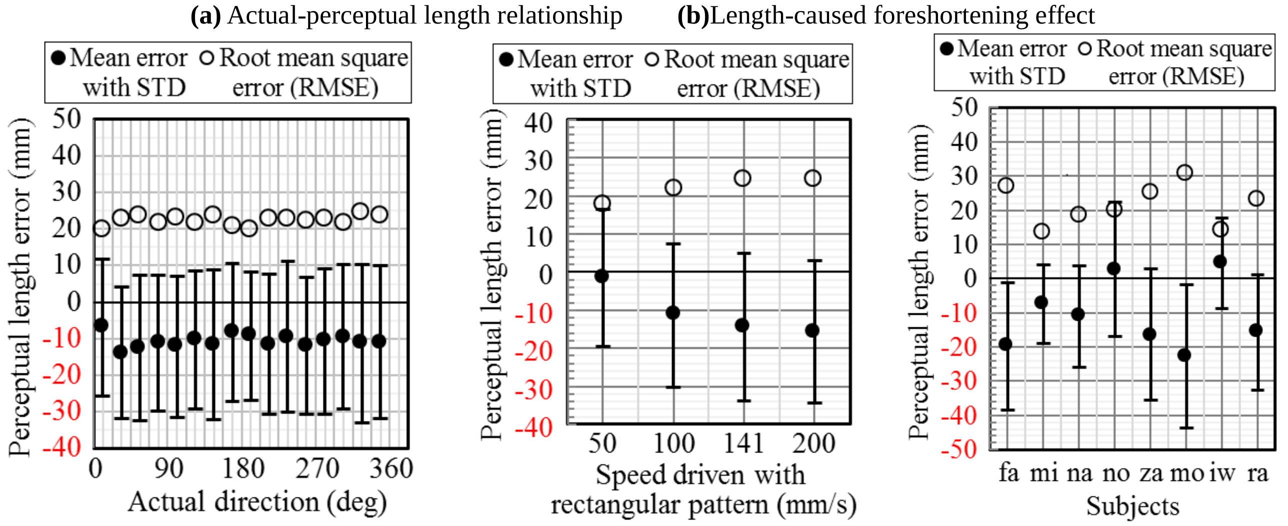
(2) **Fig.4.(b)** shows the length-caused foreshortening effect with the length perceptual error.

The systematic errors: in the case of the actual length of 10 mm, the perceptual length mean error was positive with less than 5 %. On the other hand, the longer the actual length was than 30 mm, the more the magnitude of the perceptual length mean error increased in the negative value up to 30 % at 90 mm of actual length.

The random errors: for all the variations of the actual lengths, the longer the actual length was, the more the



(a) Actual-perceptual length relationship **(b)**Length-caused foreshortening effect



(c) Directionally isotropic characteristic **(d)** Speed-caused foreshortening effect **(e)** Individual variation with subjects

Fig.4. Experimental results with the length perceptual error characteristics

STD of the perceptual length deviations increased, Therefore, RMSE (Root Mean Square Error) was raised up.

(3) **Fig.4.(c)** shows the directionally isotropic characteristic with the length perceptual error. The direction of subjects shows RMSE stayed constant at approximately 20 degree.

(4) **Fig.4.(d)** shows the speed-caused foreshortening effect with the length perceptual error. Perceptual the length was perceived shorter as velocity increased more than 100 mm/s and this became significant as the length became longer.

(5) **Fig.4.(e)** shows the subjects with the length perceptual error. Individual variation with the eight subjects was observed, and its STD was given by 10 mm.
For six out of the eight subjects, a more or less beneficial effect was found of having perceptual length.

3.2. Analysis of direction

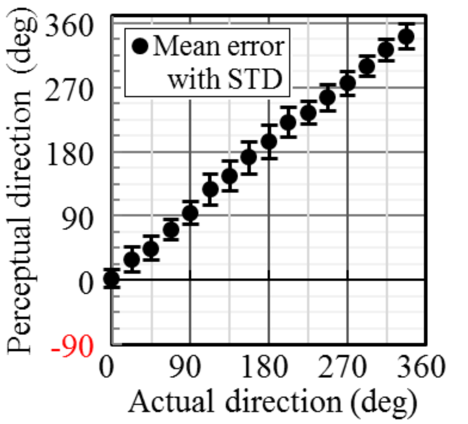
Fig.5. shows the experimental results with direction perceptual error characteristics.

(1) **Fig.5.(a)** shows the actual-perceptual direction relationship. Form this data, the errors were obtained and plotted in **Fig.5.(b)**.

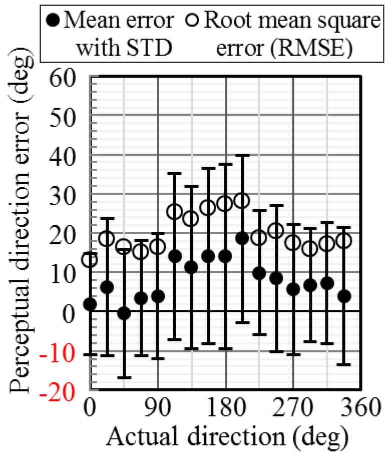
(2) **Fig.5.(b)** shows direction-related rotating effect: the subjects perceived the direction with the additional value of about 0 to 15 degrees in the counter-clock wise direction. The rotating effect of the mean error shows greater by about 15 degrees in the upper-left direction (in the region of actual direction between 112.5 and 202.5 degrees where the rightward direction is defined as zero degree), meanwhile, it shows less by about 0 to 5 degrees in the remaining direction. As for the STD, they are almost identical over the whole direction.

(3) **Fig.5.(c)** shows the length invariant characteristics with the directional perceptual error. The mean errors and RMSE shows no significant change against the actual length variation.

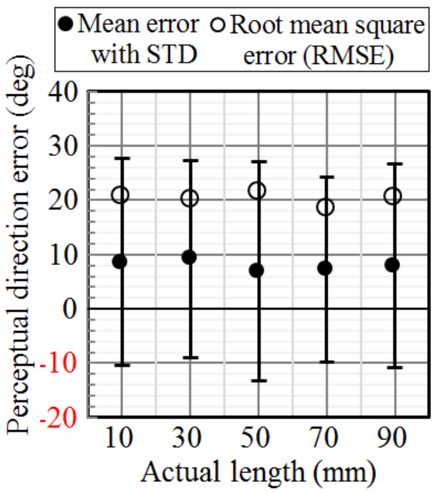
(4) **Fig.5.(d)** shows the speed invariant characteristics with the directional perceptual error. The mean errors and



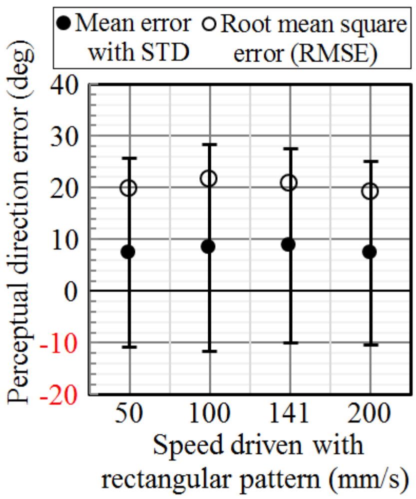
(a) Actual-perceptual direction relationship



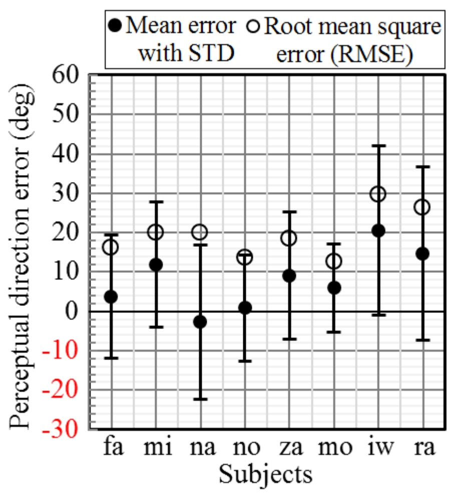
(b) Direction-related rotating effect



(c) Length invariant characteristic



(d) Speed invariant characteristics



(e) Individual variation with subjects

Fig.5. Experimental results with the directional perceptual error characteristics

RMSE shows that no significant change was found when changing the speed.

(5) **Fig.5.(e)** shows the between-subjects individual variation with the directional perceptual error. The mean error with the directional perception shows that all the subjects have different sensitivity between 0 and 20 degrees in the counter-clock wise direction.

4 CONCLUSIONS

The perceived lengths and directions were compared to the true values, and the mean errors, the standard deviations, and RMSE were examined. The results are

(1) As for length perception, the more the length is increased from 10 to 90 mm, the more the subjects perceived decreased length from about 0 to 30% .

(2) As for the direction perception, another finding was that the subjects can recognize the direction with the mean errors of about 10 degrees in the counter-clock wise direction.

Abstract: The development of visual cortical circuits is strongly influenced by the sensory experience during a restricted critical period, as demonstrated by the loss of neural responses to the eye that has been briefly deprived of vision. It has been suggested that to reflect the sensory experience into the pattern of synaptic weights, the competition between groups of correlated inputs to an identical postsynaptic cell is essential and that spike-timing-dependent plasticity (STDP) may provide the basis of this type of correlation-based competition. To predict the consequences of competition by STDP in natural physiological conditions, I here investigate the effects of nonlinear interspike interaction in STDP that is experimentally observed in the visual cortical cells. The simulations show that the interspike interaction can prevent the induction of competition and counteract the effect of activity-dependent feedback (ADFB) that facilitates competitive functions. However, once the competition occurs, the level of competition is not affected by the interspike interaction. These results may suggest that the interspike interaction in STDP acts to delay the induction of experience-dependent plasticity through suppressing synaptic competition, thereby leading to a delay in the onset of critical period plasticity in the visual cortex.

Keywords: Critical period, Visual cortex, STDP, Activity-dependent feedback.

1 INTRODUCTION

Neural circuits are developed through reflecting sensory experience during a critical period in postnatal development [1]. A representative example is an ocular dominance plasticity observed in visual cortical cells [1-3]: if either one eye is briefly deprived of vision within a critical period, the response of many visual cortical neurons is dominated by the non-deprived eye following deprivation; in contrast, the monocular deprivation before or after the critical period does not significantly affect the cell responses.

Both experimental and theoretical studies have suggested that the ocular dominance plasticity may involve the competition between different groups of inputs that originate from each eye and are correlated within each group [1, 4-6]. In the presence of correlation-based competition, the strengthening of the inputs from one eye leads to the weakening of those from the other eye. Therefore, the neural response can be dominated by one eye, as observed experimentally, and which group becomes dominant depends on the sensory experience, thereby inducing experience-dependent plasticity [4]. Furthermore, recent modeling studies have shown that spike-timing-dependent plasticity (STDP), wherein the magnitude and direction of plasticity depends on the precise timing of pre- and postsynaptic spikes, may provide a physiological mechanism that underlies correlation-based competition [4, 7].

To investigate the consequences of correlation-based competition by STDP in natural physiological conditions, I examine in this study the effects of interspike interaction in STDP [8], which is experimentally observed in the visual cortex, on the dynamics of synaptic population. The interspike interaction in STDP has been suggested to exert a suppressive effect on synaptic modifications such that the occurrence of a spike weakens the level of plasticity caused by a successive spike in the same neuron. The level of the suppressive effect of the preceding spike on the present spike follows an exponential function of the time interval between the two spikes, suggesting that the interspike interaction nonlinearly affects STDP [8]. In this study, I construct a conductance-based pyramidal neuron that receives many random inputs from synapses following STDP, as in *in vivo* conditions, and demonstrate that the interspike interaction in STDP tends to prevent the occurrence of competition between two groups of correlated inputs. This may suggest that the interspike interaction functions to suppress the ability of neurons to embed the correlation structure to synapses during early development and can contribute to delaying the onset of the critical period of ocular dominance plasticity in the visual cortex.

2 METHODS

2.1 Conductance-based neuron model

I constructed a two-compartment conductance-based pyramidal neuron, which comprises a soma and a dendrite, and is described by the following equation [4]:

$$C_m \frac{dV_s}{dt} = -I_{leak} - I_{Na} - I_K + \frac{g_c}{p}(V_d - V_s) + I_{inj}, \qquad (1)$$

$$C_m \frac{dV_d}{dt} = -I_{leak} - I_{Na} - I_K - I_{Ca,V} - I_{AHP} + \frac{g_c}{1-p}(V_s - V_d) - I_{syn}. \qquad (2)$$

Here, V_s and V_d are the membrane potentials of the somatic and dendritic compartments, respectively. Both the compartments contain leak (I_{leak}) and voltage-dependent Na^+/K^+ currents (I_{Na}/I_K). The voltage-dependent calcium currents ($I_{Ca,V}$) and calcium-dependent K^+ currents (I_{AHP}) are included in the dendrite to reproduce spike frequency adaptation observed in pyramidal cells [9]. g_c is a coupling conductance between the two compartments, and I_{inj} and I_{syn} are the injected and synaptic currents, respectively.

2.2 Synaptic inputs

The dendritic compartment receives random inputs, which are activated by Poisson processes, from 4000 excitatory (mediated by AMPA and NMDA receptors) and 800 inhibitory (GABAergic) inputs [10]. To explore the influences of input correlation, I divided excitatory inputs into two equally sized groups and introduced the same magnitude of correlation into each input group [11]. Any two inputs that belong to different groups are uncorrelated. All the inhibitory inputs are uncorrelated and activated by random homogeneous Poisson processes. Mean input frequencies are 3 Hz for all the synapses. Taking into account the low success rate (around 10 %) of synaptic transmission observed in central synapses [12], the input frequency of 3 Hz corresponds to the presynaptic firing rate of 30 Hz. This firing rate can be considered physiologically relevant as the sensory-evoked response of neocortical cells [9]. To quantify the level of the competition between the two groups of excitatory inputs, I introduced synaptic competition index (SCI) defined as $|\bar{w}_1 - \bar{w}_2| / (\bar{w}_1 + \bar{w}_2)$ with the average weight $\bar{w}_i$ for group i [4]. SCI of 0 means that the two groups have the same average weight, whereas SCI of 1 means that synaptic weighs of either one group converges to 0 and only one group contributes to the postsynaptic activity.

2.3 Biophysical STDP model

A previously proposed biophysical STDP model [13] was applied to all the excitatory synapses. In this model, plasticity induced by each pre- and postsynaptic spike pair is determined based on an STDP map $\Delta w(\Delta t,\ \tau_{NMDA},\ g_{NMDA})$, which was constructed by using an *in vitro* pairing protocol simulation based on intracellular Ca^{2+}-dependent plasticity, and decides the magnitude of plasticity Δw as a function of an interspike interval between pre- and postsynaptic spikes Δt, NMDA receptor (NMDAR) peak conductance g_{NMDA}, and NMDAR decay time constant τ_{NMDA} [13]. Theoretical studies suggest that an approximate balance between LTP and LTD is required to activate competitive function of STDP [4, 7]. To attain the balanced state, I introduced activity-dependent feedback (ADFB) mechanism, in which the NMDAR peak conductance and decay time are dynamically regulated as a function of postsynaptic firing rate f_{post}:

$$\tau_{decay} = (1-\rho)\tau_1 + \rho\tau_2 - k_1 \rho f_{post}, \qquad (3)$$

$$g_{NMDA} = g^0_{NMDA} - k_2 \rho f_{post}. \qquad (4)$$

The parameter ρ represents the expression level of NR2A subunits in NMDARs, which considerably increases during early development [14-16]. In this model, the increase in ρ values functions to strength the ADFB modulation. ρ = 0 corresponds to a state where the ADFB function is absent because of very low level of NR2A subunits, whereas ρ = 1 corresponds to a state where the ADFB modulation is sufficiently strong due to a large number of NR2A-containing NMDARs. The first two terms in the right-hand side of Eq. 3 describes the alteration in the decay kinetics of single NMDAR currents by the increase in the NR2A-containing receptors [17, 18]. The ADFB model of STDP describes the activity- and subunit-dependent desensitization of NMDARs based on experimental observations and can contribute to facilitating the correlation-based competition [4, 19, 20].

2.4 Interspike interaction in STDP

I introduced the nonlinear interspike interaction observed in visual cortical STDP [8]. To incorporate the interspike interaction, each spike is assigned an efficacy, which is determined as a function of the time interval from a preceding spike in an identical neuron:

$$\varepsilon^f_K = 1 - \exp[-(t^f_K - t^{f-1}_K)/\tau_K], \ (K = \text{pre or post}) \qquad (5)$$

where the subscript K denotes the pre- or postsynaptic activity, ε^f_K is the efficacy assigned to the *f*th spike, t^f_K and t^{f-1}_K are the *f*th and (*f*−1)th spike timing of the K neuron, τ_{pre} = 28 ms and τ_{post} = 88 ms are the time constants by which the influence of a prior spike decays exponentially for the pre- and postsynaptic cells, respectively [8]. The change in the synaptic weights induced by the pair of the *f*th presynaptic spike and *f'*th postsynaptic spike is described as $\varepsilon^f_K \varepsilon^{f'}_K \Delta w(\Delta t, \tau_{NMDA}, g_{NMDA})$. The weight updating rule is assumed to be additive [21] and the effect of all the spike pair on STDP is taken into account.

3 RESULTS

To explore the influence of interspike interaction in STDP on its competitive property, I have examined dynamics of synaptic population when a neuron receives correlated inputs from two groups of STDP synapses. As shown in the previous study [4], in the absence of interspike interaction, STDP elicited strong competition where one group dominates over the other in the equilibrium state (Fig. 1a). However, in the presence of the interspike interaction, competition disappeared and the two input groups were shown to converge to the same average weights (Fig. 1b). The interspike interaction did not significantly alter the average weight of all the synapses (Fig. 1a, gray).

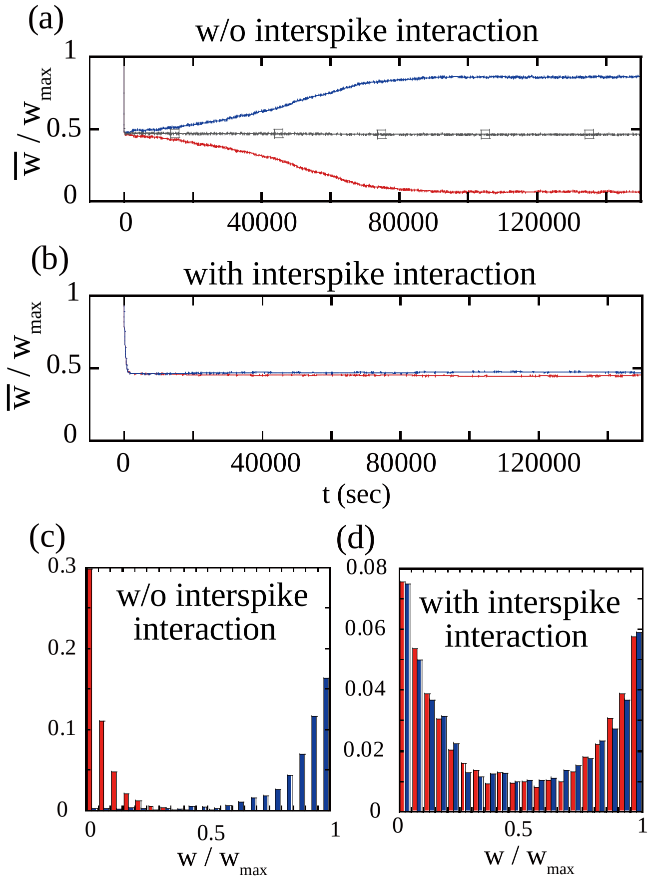

Fig. 1. The predicted effects of nonlinear interspike interaction in STDP on the correlation-based competition. (a and b) The time courses of weight averages for the two groups are shown by red and blue lines. The gray line in (a) denotes the average weight of all the inputs. (a) and (b) show the cases without and with the interspike interaction, respectively. (c and d) The final weight distributions of the two input groups are depicted by red and blue bars for the cases without (c) and with (d) interspike interaction.

These results have been clarified by examining the weight distribution at the equilibrium state (Fig. 1c and 1d). The figures show that without the interspike interaction, the weight distribution differs between the correlated groups such that the synaptic weights of one group accumulates near 0 whereas those of the other group tends to be pushed toward the maximum weight (Fig. 1c). However, without the nonlinear interaction, the weight distribution is nearly the same for the two groups, implying the lack of correlation-based competition.

To examine physiological significance of interspike interaction, I calculated the weight averages of the two groups with changing ρ, a parameter representing the level of NR2A subunit expression in NMDAR channels (Fig. 2a). The result shows that the interspike interaction significantly increases a threshold value of ρ required to induce the between-group competition. Accordingly, a threshold ρ value, above which SCI becomes positive, is significantly larger in the presence of interspike interaction (Fig. 2b). Interestingly, once the competition occurs for sufficiently larger ρ values, the level of competition is nearly the same independent of whether the interspike interaction is incorporated. These results suggest that the interspike interaction in STDP in the visual cortex can contribute to regulating the induction of competition and the resulting occurrence of critical period such that the nonlinear suppression delays the timing of the critical period, but does not affect the level of plasticity once it occurs.

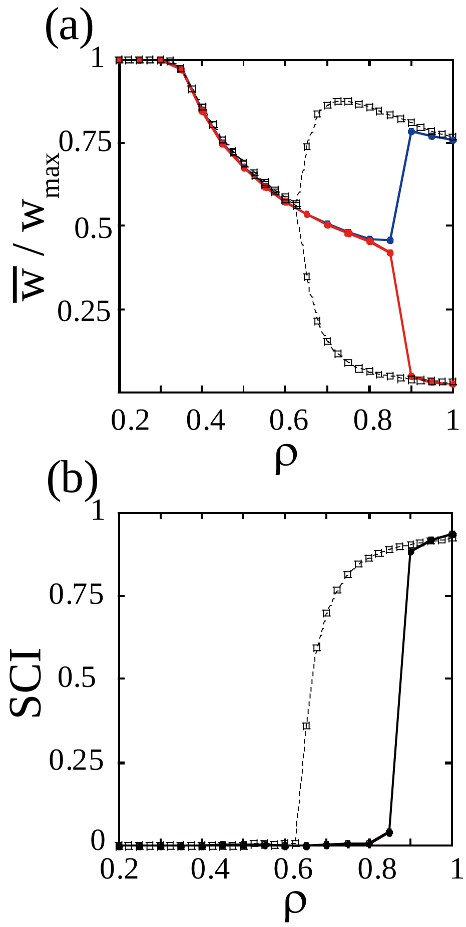

Fig. 2. The weight averages of the two groups (a) and synaptic competition index (SCI) (b) are plotted as a function of the strength of ADFB modulation ρ. Solid lines show the case of introducing nonlinear interspike interaction in STDP, whereas dashed lines show the case of not incorporating interspike interaction.

4 DISCUSSION

In this report, I have studied the effects of nonlinear interspike interaction in STDP on the competition between inputs based on their correlation structure, and have found that this interaction may function to prevent the occurrence of competition. This effect could be attributable to the net decrease in the correlation between the pre- and postsynaptic activity, because the nonlinear interaction would tend to weaken the actual influence of presynaptic inputs on the postsynaptic spike, particularly when the postsynaptic spikes occurs repetitively within a short time interval. The variance of the level of ocular dominance plasticity within the visual cortical cells might be partly explained by the variance in the level of the interspike interaction, although additional experiments would be clearly required to sort out how the effects of nonlinear interaction are physiologically regulated in individual neurons.

Abstract: Allocation of attentional capacity is an important consequence of visual attention, but its psychophysical mechanism has not been understood very well. We, in this study, investigate a procedure to estimate a high-resolution density map of the attentional capacity allocation on a visual field by analyzing a set of cognition performances on randomly located tasks. We propose a logistic regression model with multi-scale basis functions in order to achieve high-resolution density map, and an experimental scheme with different sizes of square shaped regions of attractors. Our preliminary results on two subjects showed that the corresponding shapes of attentional capacity allocation were different from those of the attractors which may reflect a hidden allocation mechanism of computational resource in brain.

Keywords: visual attention, attentional capacity, logistic regression

1 INTRODUCTION

Attention is a function of human or mammals brain, to select objective information from sensory organ. We must quickly and efficiently detect and distinguish important information in the environment such as food and predators, otherwise probability to survive can decrease. However, limited computational resource of brain does not allow us to process all of sensory input information simultaneously with high accuracy. Therefore, we concentrate computational resources to a selected set of important objects. This selection process is called *allocation of attentional capacity*. A large resource to a specific area enhances quickness and accuracy of the corresponding information processing.

Visual attention, especially, concentrates information processing resources to specific visual items; namely positions, objects, and features[11]. A large resource to a specific visual item enhances corresponding cognition performances, such as sensitivity to subtle differences in colors, directions, and shapes[8]. Several experiments had proven that the enhancement in human-subject's cognition performances in visual tasks, shortened reaction times and improvement in cognition accuracies[9].

Although we have not fully understood the mechanism of attentional capacity allocation yet, we can indirectly observe the amount of attentional resource allocation via a fluctuation of cognition performance. Thus, attentional capacity allocation is regarded as one of important topics in recent studies on visual attention. Deep relationship has been found between attentional capacity and various problems, processing of bottom-up information (ex. saliency) and top-down information (ex. intention, goal, and preferences)[1], serial and parallel search of objects with visual attention[3, 10], and problems in a relationship between visual attention and eye movement (ex. premotor theory of attention)[2, 4].

In this study, we investigate spatial resolution of attentional capacity allocation. When a human subject put an attention to a region of interest with a certain size and shape, how does the corresponding resource allocation reflect the size and shape? How can we estimate the detail shape of allocation from an observed change in cognition performance? We apply logistic regression model to represent a density map of cognition performance as a set of multi-resolution spatial bases. According to our model, spatial distribution of visual attention itself is estimated by removing background factors coming from direction of gaze effect which directly affects cognitive performances. We have conducted experiments in which subjects have to direct attention to a specific region and assign cognition tasks whose accuracy depends on attentional capacity allocation at specific location in visual field. We construct density maps of attentional capacity allocation based on the logistic regression model and investigated differences between conditions.

There have been many recent works that constructed density maps on visual field. Famous examples are saliency map[6] and Bayesian surprise[5], which predicted direction of gaze. In general, however, directions of gaze and visual attention are not always consistent, and density map of spatial attention itself should be constructed by subtracting gaze effect. There have a few attempt (ex. [7]) to estimate the attention map, however, the estimated shape of a density map is limited to several candidate patterns and did not represent general spatial patterns. We, in this study, extended these studies to investigate general shape of density map of visual attention capacity allocation with subtracting gaze effect.

2 MODEL

We applied following logistic regression model that represents spatial allocation of attentional capacity. In this model, an accuracy of a visual task is represented as a function of target position $\boldsymbol{x}$ at which the visual task appeared. The odds ratio of the accuracy is regarded as a sum of attentional capacity term and background term. The background term reflects a difference in cognition accuracy between fovea and peripheral vision that is believed to be task independent, which should be subtracted in order for the attentional capacity term to reflect the effect of task dependent allocation of attentional capacity. The parameters of each terms are determined to fit the experimental data.

2.1 Logistic Regression Model

The odds ratio of accuracy in trial j, is written as a function of the corresponding target position $\boldsymbol{x}_j$ as follows:

$$\begin{aligned}\ln\left(\frac{p(\boldsymbol{x}_j)}{1-p(\boldsymbol{x}_j)}\right) &= \beta^{(0)} + \beta^{(g)} f^{(g)}(\boldsymbol{x}_j) + \sum_{k=1}^{K} \beta_k^{(a)} f_k^{(a)}(\boldsymbol{x}_j) \\ &= \boldsymbol{\beta}^T \boldsymbol{f}(\boldsymbol{x}_j) \qquad (1)\end{aligned}$$

$$f^{(g)}(\boldsymbol{x}_j) = \exp\left(-\frac{(\boldsymbol{x}_j - \boldsymbol{x}^{(\text{fix})})\Sigma^{-1}(\boldsymbol{x}_j - \boldsymbol{x}^{(\text{fix})})}{2}\right)$$

$$f_k^{(a)}(\boldsymbol{x}_j) = \begin{cases} 1 & (\text{if } \boldsymbol{x}_j \text{ in } k \text{ th grid}) \\ 0 & (\text{otherwise}) \end{cases}$$

where $\boldsymbol{x}_j$ and $\boldsymbol{x}^{(\text{fix})}$ denotes 2-d coordinates of the target position at the jth trial and the fixation point of eye-gaze in the experiment, respectively. $p(\boldsymbol{x})$ is a true probability of correct answer that is a function of the target position. $\beta^{(0)}$, $\beta^{(g)}$, and $\beta_k^{(a)}$ are parameters corresponding to bias term, fixation term, and attentional effect at the kth grid, respectively. The kth grid is defined by the basis function $f_k^{(a)}(\boldsymbol{x}_j)$ which takes value of either one or zero if a position $\boldsymbol{x}_j$ is included in the kth region of interest or not, respectively. $f^{(g)}$ denotes background effect determined as a Gauss function peaked at the fixation point $\boldsymbol{x}^{(\text{fix})}$.

In a set of experiment, we observe a corresponding set of results $t_n \in \{0, 1\}$, where $t_n = 1$ and 0 denote correct and incorrect answer at the nth task trial, respectively. The nth task links to the nth position $\boldsymbol{x}_n$. Thus, total log-likelihood of the unknown parameters based on the set of experimental results is given as,

$$L(\boldsymbol{\beta}) = \sum_{n=1}^{N} \{t_n \ln p_n + (1 \quad t_n) \ln(1 \quad p_n)\} \qquad (2)$$

$$p_n = \frac{1}{1 + \exp(\quad \boldsymbol{\beta}^T \boldsymbol{f}(\boldsymbol{x}_n))}. \qquad (3)$$

We estimate the parameters $\beta^{(0)}, \beta^{(g)}$, and $\beta_k^{(a)}$ that fit the observed data by maximum likelihood estimation with regularization term. Using the estimated parameters, we achieve corresponding density map of attentional capacity by $\text{MAP}(\boldsymbol{x}) = \sum_{k=1}^{K} \beta_k^{(a)} f_k^{(a)}(\boldsymbol{x})$ that reflects a level of correspondence of attentional capacity to the odds ratio of task performance with subtracting the other factors, bias and gaze effect.

2.2 Designing basis functions $f_k^{(a)}$

$f^{(a)}(\boldsymbol{x})$ in eq. (1) denotes a basis function that determines spatial extension in the visual field, where we considered multiple layers of base sets corresponding to multiple scales of unit bases. The first scale consists 20 32 grids of bases whose size are 1 1 as like in the left panel in the fig. 1. And, the second scale is made by picking all 2 2 grid in the first scale as in the right panel in the fig. 1. Similarly, we repeated the same procedure until the sixth scale which has all 6 6 size of grid in the first scale.

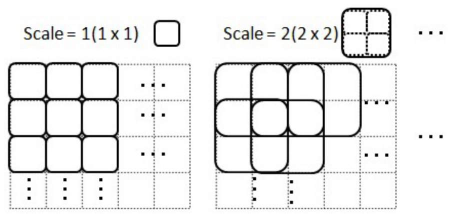

Fig. 1. Determination of multi-scale square grid. The k-th scale grid is made from all possible $k \quad k$ patches that are overlapped each other.

2.3 Ridge Regularlized Maximum Likelihood Estimation

This model is highly redundant because of overlap between the six scales, which makes it impossible to solve without regularization. We calculate parameters that maximizes likelihood function with a Ridge regularization term.

$$\hat{\boldsymbol{\beta}}_{ML \quad R(\lambda)} = \arg\max L(\boldsymbol{\beta}) \quad \lambda||\boldsymbol{\beta}||^2 \qquad (4)$$

where $L()$ is the log-likelihood function and λ is a regularization parameter. We calculated $\boldsymbol{\beta}$ in (4) by Newton-Raphson method. The regularization parameter is determined in a cross-validation procedure.

3 EXPERIMENT

In order to investigate spatial allocation of attentional capacity of human subjects, we conducted the following experiment.

The experiment consists of hundreds of unit tasks for each condition. A single unit task includes the following steps.

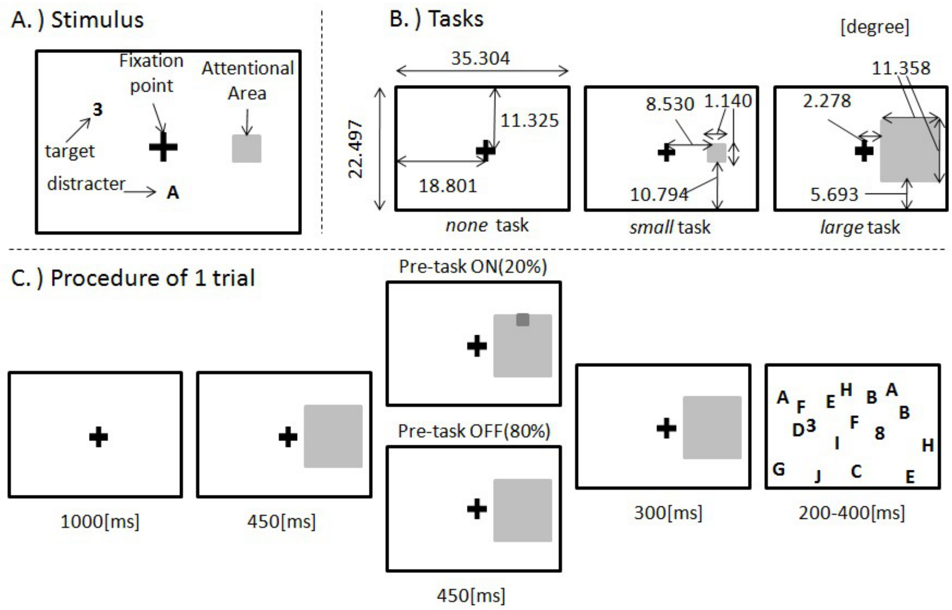

Fig. 2. A.) Stimulus in our experiment. Size of targets and distractors is 1.424 degree. B.) Position and size of pre-cue. C.) Procedure of 1 trial. *None* task do not have pre-task.

First, a pre-cue that specifies a certain region of a screen panel is shown for a subject to draw attention. Then, 10-15 alphabet and two digit letters are displayed simultaneously in a screen panel. The subject is asked to detect the two digit letters and answer them with fixing eye-gaze on the fixation point at the center of the screen. Since there are alphabet letters as distractors and all the letters disappears in a short while, the subject cannot answer correctly if the digit letters are displayed in the area where attentional capacity is not payed enough. (See Fig. 2(a), (c) for detail.)

We compared three types of pre-cue settings; they are (1) large square (2) small square, and (3) none. (See Fig 2(b) for detail.) The duration time to show the letters is set at a value from 200msec to 400msec depending on individual subject so that the task is not too easy nor difficult and the accuracy at a location takes a value from 10 to 90 percent.

In order to confirm that the subject really payed attention to the pre-cued area, a sub-task is asked; color of a small square in the pre-cued area is slightly changed with a certain probability and the subject is asked if the change occured after the main task. In order to confirm that the subjects fixed their eye gaze to the fixation point, the eye movement is observed by an eye-tracker device, EYE-LINK.

Two healthy adult male subjects conducted 360 trials of the unit task for each of three pre-cue settings with 5 minutes rest in less than every 120 trials. The resultant performance data, set of record of correct/wrong answers with the locations of digit letters, is integrated to form a density map of attentional capacity allocation in each condition.

In order to obtain the density maps of attentional capacity allocation in the *small* and *large* tasks, we treated the *none* task as an origin of common background factor. And, since there were statistical variance in the estimated background factor, we estimated a null standard deviation σ of odds ratio of the *none* task by calculating 4-fold cross-validation. We normalized the estimated odds ratio of the *small* and *large* tasks by using the estimated mean and standard deviation of the common background factor. Regularization factor was set at $\lambda = 400$ at which cross-validation likelihood was maximized.

$$\ln\left(\frac{p(\boldsymbol{x}_j)}{1 \quad p(\boldsymbol{x}_j)}\right) = {}^{(0)} + \sum_{k=1}^{K} {}^{(a)}_{k} f_k^{(a)}(\boldsymbol{x}_j) + \mathrm{MAP}^{none}(\boldsymbol{x}_j) \quad (5)$$

$\mathrm{MAP}^{none}(\boldsymbol{x}_j)$: $\mathrm{MAP}(\boldsymbol{x})$ learned by data of *none* task.

The result is shown in Fig. 3. Strong allocation of attentional capacity was observed around the center of pre-cued attractor region for both of small and large square tasks. But, detail size and shape of the allocated regions were different between the two conditions. Attentional capacity allocation in small task was concentrated at smaller area than those in large square task, which suggested that total resource of the subject was limited and had to distribute it when a large area was attracted. In detail, however, the size of the region of allocated attentional capacity did not seem proportional to those of the corresponding region of attractors. The shape were also different between the attention allocation and the region of attractors; in small task, significant enhancement of attentional capacity was observed even in the regions around the small attractors; in large task, the enhanced region did not fill all the corners of the large square shaped region of attractors. These differences suggested a kind of limitation in spatial resolution of attentional capacity allocation.

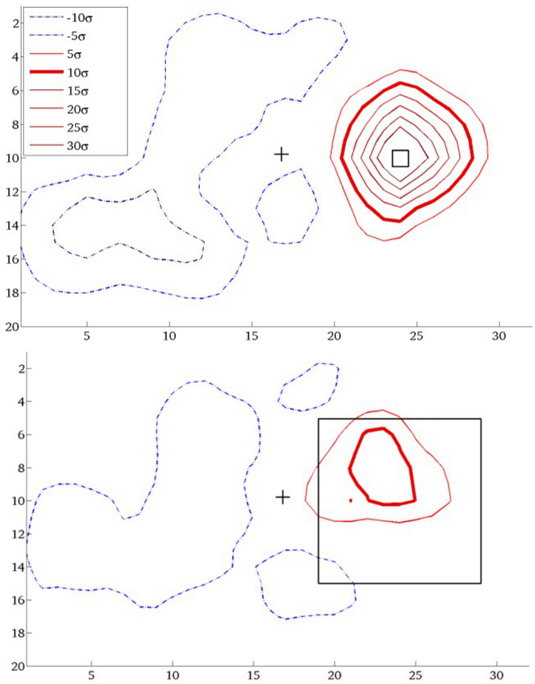

Fig. 3. Estimated density maps of *small* and *large* tasks are shown in top and bottom panels, respectively. Maps of a single subject in two subjects are shown. Contour lines denotes normalized odds ratios whose values are normalized by an estimated standard deviation σ of *none* task. Black square indicates pre-cued region of attention attractor. Black cross indicates fixation point.

4 DISCUSSION

We have constructed spatial density map of attentional capacity allocation by using a logistic regression model with multi-scale basis functions. Based on this model, we have investigated spatial resolution of the attentional capacity allocation. For different settings of pre-cued region of attractors, small and large squares, we found different results in size and strength of attentional capacity allocation, however, the shape of the attentional capacity did not obviously reflect the square shape of pre-cued region of attractor, which suggested a limited spatial resolution of attentional capacity allocation.

Our final goal is to understand mechanism of allocation of attentional capacity. We will increase the number of subjects and unit tasks of experiment, and establish the model of allocation of attentional capacity. In this paper, we have confirmed that allocation of attentional capacity is done as the shape of area where subjects attend and added some modification. In the future, we aim to discover the factors and mechanism related to the model of allocation of attentional capacity.

In addition, we will improve logistic regression model. For example, we change the designing basis functions $f_k^{(a)}$ to that has more biological validity. Furthermore, we add the factors which affect cognition performance(ex. saliency, Bayesian surprise) to our model in addition to attentional term and fixation term. By these improvement, we aim to represent density of attentional capacity more accurately.

Abstract: Brain Computer Interface (BCI) is a system to connect brain of human and computer in order to realize a though of human. In recent years, many such interfaces have been researched and applied for practical applications. Up to now, BCI systems, which have already applied practically, use expensive and large devices to measure the electroencephalographs(EEG). They are for almost all of users to be used for medical treatments. As a result, the BCI systems can't get the popularization to use easily. So, subjects of this study are construction of a BCI system using inexpensive commercial EEG sensor with one-channel, and investigation of the ability to apply it for utilization in various way. In this paper, using the methods of analyses for EEG that have already existed or have improved, we show that the BCI system using inexpensive commercial EEG sensor with one-channel is also useful.

I. INTRODUCTION

In recent years, Brain Machine Interfaces (BMIs) to operate devices using electrical signals generate during brain activity have been researched extensively. In particular, Brain Computer Interfaces (BCIs) to operate computer applications using the electroencephalograph (EEG) have many fruitful achievements.

These technologies are applied to support patients with paralysis, such a Amyotrophic Lateral Sclerosis (ALS) and spinal cord injury patients, etc. who are difficult to communicate others by means of gesture and speech [1]. By use of techniques of BCIs, improving of QOL (Quality of Life) is expected

However, these techniques are low awareness except some prevalent hospitals. Therefore, this study aims at creating a computer application using commercial EEG sensors at cheap and readily available. To realize that, we intend to improve conventional feature extraction methods, validation method. We use the single-channel EEG sensor called "MindSet" manufactured by NeuroSky Corp. [2].

In this research, BCI system using neural network classifiers with Fourier transform, averaging and feature extraction by nonlinear normalization [8] is used. First, to improve the above-mentioned conventional method, we propose to adopt 1) restricting the frequency bands within the scope seemed to be effective in identifying, 2) introducing the support vector machine classifiers. Second, performance verification of the proposed classifier is carried out using benchmark data. Finally, we also study the usefulness of the proposed BCI system with single channel EEG, that is, using the MindSet through the computer simulation of distinguishing color information on display.

II. Feature extraction and Identification technique

In this section, we explain the basic method [8] and the proposal technique based on [8].

2.1. The basic method

In this paper, we use the method using Self Organization Map (SOM) and Multi Layer Perceptron (MLP) [8]. This method uses the Fourier transform (Eq. (1)), the averaging and nonlinear normalization (Eq. (2)) in the feature extraction, and use SOM and MLP in the feature discrimination.

$$F(\omega) = \int_{t=0}^{T} f(t)\big(\cos(\omega t) - i\sin(\omega t)\big)dt \tag{1}$$

$$f(x) = \frac{\log(x-\min+1)}{\log(\max-\min+1)} \tag{2}$$

Examples of above mentioned each processing and the figu re of discriminator are shown in Figs. 1 and 2, respectively. In Fig.2, X means input vector, W means connecting weights between SOM and MLP

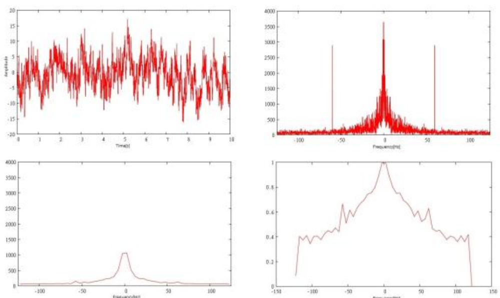

Fig. 1. Upper left: Electroencephalographic data. Upper right: Fourier Transform. Lower left: Equaliz ation. Lower right: Nonlinear normalization

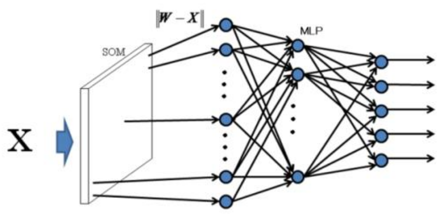

Fig. 2. Discrimination circuit by SOM and MLP

2.2 Improved method

Jie. Li, et al. [10] verified relation between frequency bands of EEG and the brain activity, that is, what frequency bands different stimulus and brain activities are related to. But, such things aren't considered in [8]. So, we intend to enhance the ability of feature extraction by changing the averaging used in [8] for restricting the frequency bands within the scope validated by [10].

Furthermore, in the feature discrimination, we intend to improve the ability of the feature discrimination by using Support Vector Machine (SVM) that is known to the model with the higher generalization performance for unlearned data rather MLP used in [8].

2.3 Multiple classification by SVM

SVM can't discriminate over 3 classes of data, because of the method of discrimination. Therefore, in this paper, in order to discriminate the multiclass of data using the SVM, we set multi SVMs.

For example, we have the data of 3 class labeled A, B and C . Then, a SVM can't correspond to discriminate of these dat a. So, we set any combination of the two among these three classes. Final judge is done by majority of each winner of t he two. In the case of Fig. 3, we decide that input data X belongs to the class A. If the number of majority is the sa me, we judge it "No Decision".

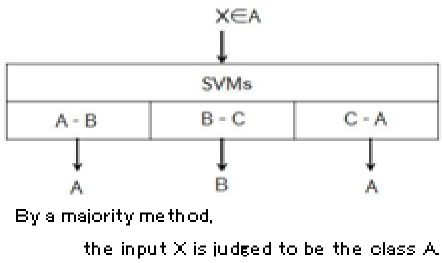

Fig. 3. Multi-class discrimination circuit by SVM

III. Simulation

In section 2, we showed the methods of EEG analysis. In section 3, we verify the performance of each methods through computer simulation using benchmark EEG data.

3.1 The Benchmark EEG data

The benchmark EEG data we used in the simulation is open ed in web sites of Colorado University [3]. The data are ta ken at 250Hz on sampling ratio for 10 seconds on measure ment time. And, these data have been measured using 6 EE G sensors and a EOG sensor to measure the electromyogra m of eye movements as shown in Fig. 4. The number of the subjects to measure these signals is seven healthy young me n. Furthermore, kinds of the mental tasks measured are sho wn to Table 1.

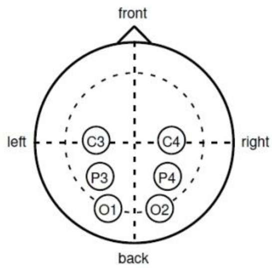

Fig. 4. Brain-waves measurement positions

Table. 1. Contents of mental tasks

Mental task	Contents
Baseline	It relaxes as much as possible.
Multiplication	It calculates multiplication mentally.
Letter-composing	It considers the contents of the letter.
Rotation	It imagines rotation of a three-dimensional object.
Counting	It imagines writing a number in order.

3.2 Term of simulation

The term of this simulation is shown in Table 2.

Table. 2. Simulation conditions

The simulation conditions of a feature extraction method	
The number of data samples after equalization	20
The restriction range of a frequency band	4～45[Hz]
The simulation conditions of SOM	
Initial connection weights	-0.1～0.1
Form of a map layer	Tetragonal-lattice type
The number of nodes of one side of a map layer	50
The number of times of study	30,000
Distance with the input vector of a map layer	Euclid distance
The simulation conditions of MLP	
Initial joint load	-0.1～0.1
The number of the units of a hidden layer	20
Activating function	Sigmoid function
Learning rate	10^{-2}
The number of times of learning	30,000
The simulation conditions of SVM	
The initial value of a Lagrange multiplier	0.0～1.0
Learning rate	10^{-3}

A kernel function and the parameters of each function	Polynomial kernel $K(x_1, x_2) = (a{x_1}^T x_2 - b)^p$ $a = 0.1, b = 0.5, p = 1$ Sigmoid kernel $K(x_1, x_2) = \tanh(a x_1^T x_2 - b)$ $a = 0.1, b = 0.5$ Gauss kernel $K(x_1, x_2) = \exp\left(\frac{-\lVert x_1 - x_2 \rVert^2}{2\sigma^2}\right)$ $\sigma = 2$
the number of SVM	10
The discernment determination method	Majority method

3.3 The process of simulation

In the simulation, we perform the following stems:

① Provide N sets of T kinds of Mental task data .
② Perform feature extraction on each of input sample N.
③ As training data, take n samples out of each mental tasks randomly, the rest of samples (N-T × n) are treated as test data.
④ Execute training for classifier by using the training data.
⑤ Determine the type of mental tasks of the test data using the learned classifier.
⑥ Repeat any times from ② to ⑤.

3.4 Simulation results

The case of seven channels EEG data for all subjects

The number of samples of EEG signals measured at each subject is 60 for each of 5 mental tasks, 12 samples is for test data in it, and the rest is for training data. Changing the test samples, repeat the above experiment five times.

Results of discrimination using each of the methods have been shown in Table 3.

In the results, the best result is the discrimination ratio of 75% of the improved method using Gaussian Kernel. This result is 4% better than the result of the conventional method with 71%. This improved result may be due to improvements of restricting the frequency bands in Feature Extraction and introduction of SVM. It can be seen that the Gaussian kernel is the most appropriate in the kernel trick used in this study.

Table 1 Discernment results by each method in the case of seven-channel electroencephalographic data for seven subjects

		B	M	L	R	C	Average
SOM + MLP	SOM 50	58	76	63	87	70	71
SVM	Alignment	50	62	58	70	60	60
	Polynomial	50	60	63	72	65	62
	Gauss	60	64	82	85	78	75
	Sigmoid	52	70	66	73	59	64

In the case of one channel using EEG data for one subject

Excluding EEG, Data are measured by 6-channel EOG electrodes and discernment of the data is carried out. The EEG data of the subject 1 is used. The data of subject 1 are measured 10 times per each of the five mental tasks, a total is 50 samples. Two samples for each 5 mental tasks, that is, 10 samples are taken as test data, and the remaining 40 samples are used as training data. Discernment testing is executed five times changing test samples.

In addition, the improved method uses the Gaussian kernel in SVM showing high recognition rate in Section 3.3 and 3.4.

Table 4 shows the discernment results of each method.

In this simulation, overall, the improved method with the Gaussian kernel shows better results. From this one channel used results, it is said that the improved method is effective even for a single-channel EEG data, like the case of multi-channel.

Table 2 Discernment result by each method in the case of one-channel electroencephalographic data for one subject

		B	M	L	R	C	Ave.	All the averages

IV. Experiment

Next, using a Gaussian kernel SVM showed good results in the simulation, discernment testing for EEG data obtained f rom single-channel EEG sensors, MindSet, is executed.

4.1 Inexpensive commercial EEG sensor with one-ch annel

The MindSet has two electrodes which are attached to left ear and forehead. It measures a potential difference between before-mentioned two electrodes. The sampling rate for measurement is 512Hz.

In addition, the MindSet has no recording equipment of EEG data, it only has the ability to measure EEG data. Therefore MindSetRearchTool, a research tool MindSet (MRT), is used to compensates for their function. The MRT has various functions: the EEG recording, saving features, which is also equipped with connectors for use with software such as MATLAB, numerical analysis software.

Fig. 5. MindSet made by NeuroSky Ltd.

4.2 Measuring method

The subjects is one healthy male in his 20s. Brain waves of the subject with the MindSet on the head sitting in a chair are measured. Mental task is looking the blinking image, changing black, red and blue, every two seconds and the EEG data are measured when viewing.

The measurement time is 10 seconds and the measurement is made for three colors each, then set in the one-minute break before the next measurement.

As described above, measurement is done 10 times for each mental task. The total number of data is 30. The subsequent experiments are done using these 30 data set.

4.3 Experimental conditions of Feature Extraction

Restricting range of frequency bands for feature extraction method in an improved process is 4-125 [Hz]. These EEG and EEG data are the different benchmarks such as intellectual thought during the simulation. Therefore the restricting range of frequency bands are set arbitrarily.

4.4 Experimental conditions of Support Vector Machines

Table 5 shows the condition of the SVM in this experiment.

Table 3. Experimental condition of SVM

The initial value of a Lagrange multiplier	0.0～1.0
Learning rate	10^{-3}
A kernel function and the parameter of each function	Gauss kernel $\sigma = 2$
The number of SVM	3
The discernment determination method	Majority method

4.5 Experimental procedure

Discernment test of experiments was carried out as same as in the simulation.

4.6 Experimental results

Under the experimental conditions described above, the results of discernment test are shown in Table 6. In this experiment, the lowest diecerment rate of 60%, the highest recognition rate of 80%, 70% were discerned on average. This is not said that very high recognition rate. However, it is said that the one channel EEG sensors "MindSet" EEG data can be discerned, this may show that 1 channel commercial EEG sensor are applicable to the engineering fields .

Table 4. Experimental result

	Black	Red	Blue	Average
Gauss kernel	60	70	80	70

5. Conclusions

By incorporating the existing proposal as the basis of the BCI system, BCI system with high generalization performance as shown in this simulation and experiment was able to be constructed. It is also found that mental tasks can be identified in single-channel EEG sensors.

However, results of this research are only shown to be useful for identifying a simple mental task. We don't have practical applications yet. Therefore, the goal of future studies are

① Seeking viable mental tasks can be identified by MindSet,

② Development of real-time BCI system that can be Identified.

The construction of viable applications using the MindSet is remained.

Abstract: Recent imaging techniques enable us to observe activities of hundreds of neurons simultaneously as spike sequences. The objective of this study is to estimate the network structure based on such spike sequences. Our method is an extension of existing sparse regression technique, in which we have implemented the following three ideas: (1) Each spike time-series obeys a non-stationary Poisson process whose Poisson intensity is given by an auto-regression model. (2) Spike response functions are represented by a linear summation of smooth basis functions. (3) A group-LASSO regularization is applied to obtain a sparse regression solution. When applied to simulation datasets, our method showed a better estimation performance than that by an existing state-of-the-art method.

Keywords: Computational neuroscience, network estimation, sparse estimation, generalized linear model

1 INTRODUCTION

To estimate underlying structures of networks is one big challenge not only in the field of data mining but also in various biological fields. A typical application in the field of neuroscience is to estimate the network structure from neurons' spike sequences. Recently, a variety of high-throughput measurement systems of neural networks have been proposed; for example, multi-electrode array (MEA) [1] measures neurons' action potential by inserting an electrode array into a specific brain region. Another way is a high-throughput Calcium imaging, which is now available with as much as 1000 Hz. Not only these new technologies but also the development of sophisticated statistical methods have enabled us to estimate the network structure based on a rather limited data amount. Granger causal modeling (GCM) [2] and dynamic causal modeling (DCM) [3] are such innovative statistical methods. GCM estimates causal connections between neurons based on the predictability. According to DCM, on the other hand, we assume a dynamic equation between neurons, and the total dynamical system is identified by means of, say, Bayesian statistical method. In this study, we aim to present a robust network estimation method based on modification of existing generalized linear modeling (DCM). Since this is a simple sparse regression technique, it may work especially when the available data amount is rather small (Fig.1). Here, estimation of spike response functions has an important role.

The estimation of spike response functions has been done by hierarchical Bayesian modeling [4, 5], but it has some concerns on the stability of computation and appropriate setting of priors. In many applications of structure estimation methods, the target network is partially observable, i.e., there are some hidden structures which cannot be directly observed. In such cases, the structure estimation may be affected by indirect relationship between observable elements through unobservable structures. Even in such hard situations, there may be a way to separate observable elements into clusters based on their spike response functions. This is one advantage of network estimation via the estimation of spike response functions. Therefore, we put our focus on network estimation methods based on the estimation of spike response functions in this study.

2 GENERALIZED LINEAR MODEL

Our method is based on the generalized linear model (GLM) presented formerly by Stevenson et al. [4]. After briefly introducing GLM, we describe our extensions.

2.1 Poisson process with an auto-regression model

Let $N_i(t)$ be a random variable denoting a spike event; when $N_i(t) = 1$, the i-th neuron emits a spike once in the t-th frame, and when $N_i(t) = 0$, it does not emit a spike in the frame.

Following the formulation by Stevenson et al., each spike event of neuron i obeys a non-stationary Poisson process with the time-variant Poisson intensity $\lambda_i(t)$. Here, the continuous time axis is segmented into frames with a fixed interval $\Delta t > 0$, which is small enough to make each segmented time frame (with a center at t and a width of Δt) to include at most one spike event. With these notations, the binary random variable $N_i(t)$ obeys a Bernoulli distribution: $P(N_i(t) = 1|\lambda_i(t)) = 1 - \exp(-\lambda_i(t)\Delta t)$.

Stevenson et al. assumed the Poisson intensity is given by

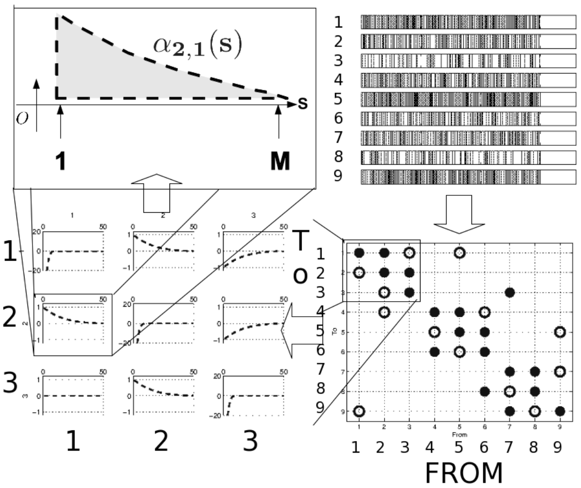

Fig. 1. Our objective is to estimate the network structure (right lower panel) from spike sequences over constituent neurons (right upper panel). In the right-lower matrix, a symbol ○ (●) denotes there is an excitatory (inhibitory) connection from neuron 'From' to neuron 'To'. No circle means no connection. The left lower panel shows the spike response functions of nine connections in the right lower panel (inset). The left upper panel shows a spike response function $\alpha_{2,1}(s)$, connectivity from neuron 1 to neuron 2.

the following auto-regression model:

$$\begin{aligned}\lambda_i(t) &= \lambda_i(t;\boldsymbol{\alpha}_i) \\ &= \exp\left(\alpha_{i,0} + \sum_{c=1}^{C}\sum_{s=1}^{M}\alpha_{i,c}(s)N_c(t-s)\right), \quad (1)\end{aligned}$$

where $\boldsymbol{\alpha}_i \equiv \{\alpha_{i,0}, \alpha_{i,c}(s) | i = 1, \cdots, C, c = 1, \cdots, C, s = 1, \cdots, M\}$ are coefficients of the auto-regression model. Since the vector $\boldsymbol{\alpha}_{i,c} \equiv (\alpha_{i,c}(s))$ represents the connection from a pre-neuron c to a post-neuron i, it is called a spike response function.

2.2 Introduction of basis functions

According to the model (1), the spike response function for a neuron pair (i, c), $\boldsymbol{\alpha}_{i,c}$, may take an independent value for each time-delay s, i.e., M-dimensional. Since the spike response function is determined based on data, this large degree of freedom may be disadvantageous especially when the delay time is long (M is large). Moreover, since the spike response function is represented biophysically in reality, it should be smooth; that is, the difference between $\alpha_{i,c}(s)$ and $\alpha_{i,c}(s+1)$ is not very large. In order to reduce the effective dimensionality whereas allowing long time delay of the spike response function, we assume it to be represented by a linear summation of temporally smooth basis functions:

$$\begin{aligned}\lambda_i(t) &= \lambda_i(t;\boldsymbol{\alpha}_i) \quad (2)\\ &= \exp\left(w_{i,0} + \sum_{c=1}^{C}\sum_{s=1}^{M}\sum_{k=1}^{K} w_{i,c,k}b_k(s)N_c(t-s)\right),\end{aligned}$$

where $b_k(s), k = 1, \cdots, K$ are K pre-fixed basis functions, and $\boldsymbol{z}_i \equiv \{w_{i,0}, w_{i,c,k}, i = 1, \cdots, C, c = 1, \cdots, C, k = 1, \cdots, K\}$ are their linear coefficients (parameters). When $K \ll M$, the effective dimensionality of the spike response function is much reduced from the original M-dimensional one, thus the estimation variance from a fixed amount of data and computational cost are both reduced. Determining the parameters $\boldsymbol{z}_i$, we have the spike response function $\boldsymbol{\alpha}_i$, because $\alpha_{i,0} = w_{i,0}$ and $\alpha_{i,c}(s) = \sum_{k=1}^{K} w_{i,c,k}b_k(s)$. When $K = M$ and $b_k(s) = I(k = s)$, the model (2) becomes identical to the original GLM (1). Here, $I(A)$ is an indicator function, which takes 1 if the condition A is true and 0 otherwise. From this observation, the model with basis functions (2) is one extension of GLM.

We in particular used logarithmic cosine functions for the basis functions $b_k(s)(k = 1, 2, \cdots, K)$:

$$b_k(s) \equiv \begin{cases} \cos^2(D_1\log(1+(s-1)D_2)\pi/2 - (k-2)\pi/4) \\ (\text{if } D_1\log(1+(s-1)D_2)\pi/2 \in \\ [-\pi/2+(k-2)\pi/4, \pi/2+(k-2)\pi/4]) \\ 0 \\ (\text{else}) \end{cases}.$$

Here, D_1, D_2 denotes the scale parameter and is set arbitrarily. These basis functions have fine and coarse temporal resolutions when the corresponding delay times are short and long, respectively. This setting allows the resultant spike response function to represent well the rapid change of postsynaptic membrane potential after the spike input but to reduce the effective dimensionality simultaneously.

2.3 Optimization problem

We estimate the linear coefficients of the basis functions, $\boldsymbol{z}_i$, such to minimize the following loss function with a regularization term:

$$\boldsymbol{z}_i^* = \mathrm{argmin}_{\boldsymbol{z}_i}\mathcal{L}_i(\boldsymbol{z}_i) + \Lambda\mathcal{G}(\boldsymbol{z}_i), \quad (3)$$

where $\mathcal{L}_i(\boldsymbol{z}_i)$ is the loss function for the i-th neuron, and $\mathcal{G}(\boldsymbol{z}_i)$ is the regularization term that is explained in the section 2.4. $\Lambda > 0$ is a balancing factor between the loss function and the regularization term, whose value is determined by a cross-validation method such to show a good generalization performance.

Since we assume that the random variable $N_i(t) \in \{0, 1\}$, $i = 1, \cdots, C$, $t = 1, \cdots, T$ obeys an independent

Bernoulli process, the log likelihood is given by

$$\sum_{t=1}^{T} \log P(N_i(t)|\lambda_i(t)). \tag{4}$$

Since the Poisson intensity $\lambda_i(t)$ is determined by the parameter vector $\boldsymbol{z}_i$ (equation (2)), the log likelihood is a function of the parameter vector. Then, the maximum likelihood estimation of the parameter vector is equivalent to the minimization of the following loss function with the auto-regression model (2) in terms of the parameter vector $\boldsymbol{z}_i$:

$$\mathcal{L}(\boldsymbol{z}_i) \quad = \quad -\sum_{t=1}^{T} \left(N_i(t) \log \lambda_i(t) - \lambda_i(t)\right), \tag{5}$$

where we have used the likelihood of the Bernoulli process.

2.4 Group-LASSO regularization

The regularization term in equation (3) is given by

$$\mathcal{G}_i(\boldsymbol{z}_i) = \sum_{c=1}^{C} \sqrt{\sum_{k=1}^{K} w_{i,c,k}^2} \quad , \tag{6}$$

which is a kind of group-LASSO regularizer. A linear regression method employing an L^1 regularizer $\mathcal{G}_i^{(\mathrm{L}^1)} = \sum_{c=1}^{C} \sum_{k=1}^{K} |w_{i,c,k}|$ is called LASSO and tends to produce a sparse solution whose linear coefficient is likely to be zero. A group-LASSO is an extension such that the sparseness works in each group of linear coefficients. According to the regularization term (6), $\{w_{i,c,k}|k = 1, \cdots, K\}$ constitutes a group, and the variables in a single group are often estimated as zero simultaneously. In our particular application, $w_{i,c,k}, k = 1, \cdots, K$, should be simultaneously zero if a neuron pair (i, c) has no connection. When applying to estimation of neuronal network structure, therefore, a group-LASSO-based regularization method would work well.

3 SIMULATION

The proposed method was applied to simulation spike datasets.

3.1 Simulation setting

Simulation 1 Kim et al. [2] prepared a network model consisting of nine neurons (Fig. 2), and produced a spike dataset by introducing specific spike response functions to the connected neuron pairs. Although the spike response functions are not presented, the simulated spike sequence is open for public[1]. The spike sequence with a frame rate of 1,000 Hz is for 100,000 frames (100 seconds).

[1]http://www.neurostat.mit.edu/gcpp

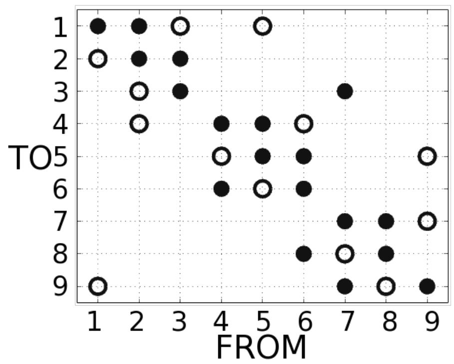

Fig. 2. The connection matrix showing the true network structure in simulation 1

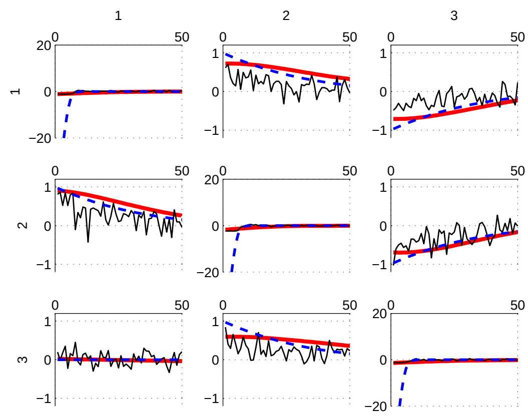

Fig. 3. The true spike response function and its estimation in simulation 2. The figure shows spike response functions between three neurons out of nine neurons. A dotted line is the true one. A thick solid line and a thin solid line show the estimated response functions with and without the logarithmic cosine basis functions, respectively.

Simulation 2 Since the true spike response functions are unknown in the Kim et al.'s dataset, we did a simulation by applying our own spike response functions (therefore, we know the truth) to the same network structure as that used by Kim et al.

3.2 Estimation of spike response functions

Fig. 3 shows the spike response functions obtained by applying the proposed method to the dataset in simulation 2. In particular, this figure shows the performance of the logarithmic cosine bases, which can be seen by comparing the group-LASSO regression with (thick solid line) and without (thin solid line) logarithmic cosine basis functions. In both cases, the regularization coefficient Λ was set at 10. We can see that the smoothness constraints due to the logarithmic cosine functions worked well to obtain smooth and hence biologically natural response functions.

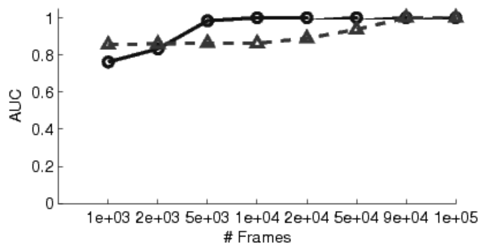

Fig. 4. Network estimation when applied to the dataset of simulation 1. A dotted line and a solid line show the AUC values by Kim et al. and our method, respectively.

3.3 Estimation of network structure

Based on the estimated spike response functions, we can estimate the network structure.

We say there is an excitatory (inhibitory) connection from a pre-neuron c to a post-neuron i if the auto-regression coefficient $\alpha_{i,c}(s)$ is consistently positive (negative) for all delay times $s = 1, \cdots, M$. We also say there is no connection from c to i if $\alpha_{i,c}(s)$ is consistently zero. However, it may be the case of estimation that $\alpha_{i,c}(s)$ is positive with some delay times but negative with other delay times. Such an estimation result may be obtained due to the estimation variation and/or to the mixture of direct effects and indirect (i.e., multi-synaptic) effects. In order to extract a reasonable structure from such ambiguous spike response functions, we needed a heuristic criterion; by defining the connectivity strength: $Q_{i,c} = \sqrt{\sum_{s=1}^{M} \alpha_{i,c}^2(s)}$ and the connectivity polarity: $R_{i,c} = \text{sign}(\sum_{s=1}^{\tilde{M}} \alpha_{i,c}(s)), \tilde{M} < M$ we determined as follows, either excitatory, inhibitory or no connection from pre-neuron c to post-neuron i.

- If $Q_{i,c} > h$ and $R_{i,c} = 1$, an excitatory connection.
- If $Q_{i,c} > h$ and $R_{i,c} = -1$, an inhibitory connection.
- If $Q_{i,c} < h$, there is no connection.

In the above criterion, h is a positive threshold to be pre-tuned. Although we tuned it heuristically in this experiment, it should be determined by controlling the false positive rate in more realistic applications [2].

In our method, we obtained spike response functions from the given spike dataset, and then the network structure was determined by applying the above criterion to the estimated spike response functions. We also applied the network estimation method by Kim et al. to the same dataset. Here, we examined the estimation performance by varying the number of frames (i.e., sequence length).

From Fig. 4, we can say that the proposed method shows a good performance for network estimation over a wide range of available number of frames. Here, AUC (area under the receiver-operator curve) shows the general accuracy by integrating both of the false positive rate and false negative rate; the larger it is, the better the classifier is.

4 CONCLUSION AND DISCUSSION

In this study, we presented a GLM-based network estimation method employing smooth basis functions such to reduce the effective dimensionality whereas maintaining the representation capability of the model. In addition, the group-LASSO-type regularization introduced an effective and biophysically natural sparseness into the estimation, and hence was effective for stabilizing the estimation.

There are some remaining issues in our network estimation method. First, performance of network estimation will be deteriorated when the target network receives structured inputs from external networks. One possible solution is to incorporate location information of each network element into our model. Second, we have not established a good criterion to extract the network structure from the estimated spike response functions. We have applied a cross-validation technique to determine the threshold value in the criterion, but also found its result behaves unstably especially when the data amount is not sufficient. There are some remaining issues like above, and we will cope with them in our future study.

Abstract: In this study, we tackled the reduction of computational complexity by pruning the *igo* game tree using the potential model based on the knowledge expression of *igo*. The potential model considers *go* stones as potentials. Specific potential distributions on the *go* board result from each arrangement of the stones on the *go* board. Pruning using the potential model categorizes the legal moves into effective and ineffective moves in accordance with the threshold of the potential. In this experiment, 5 kinds of pruning strategies were evaluated. The best pruning strategy resulted in an 18% reduction of the computational complexity, and the proper combination of two pruning methods resulted in a 23% reduction of the computational complexity. In this research we have successfully demonstrated pruning using the potential model for reducing computational complexity of the *go* game.

Keywords: Monte-Carlo *go*, Potential, Pruning, Range search

1 INTRODUCTION

Monte-Carlo *go* [1] is the computer *igo* which satisfy the strength without the knowledge expressions of *igo*. Monte-Carlo *go* is very computationally intensive. However, reduction of the computational complexity is possible by properly pruning the *igo* game tree. In this study, we tackled the reduction of computational complexity by the pruning the *igo* game tree using the potential model.

2 PROPOSED METHOD

The proposed method in this research is consists of Monte-Carlo *go* and potential model.

2.1 Monte-Carlo *go*

Monte-Carlo *go* evaluates legal moves at each phase to choose the next move by simulation based on the Monte-Carlo search. Monte-Carlo search consists of many moves of a simulation. This simulation is called "Play Out." Play Out involves both sides constantly choosing the next move alternately and randomly from the current phase to the end game. Play Out calculates an estimation ($\overline{X_\iota}$) for each legal move (i). (s_i) is the number of times of Play Out. (X_i) is the total considerations of Play Out. In Play Out, if the offensive wins, the consideration is 1, and if it loses, the consideration is 0. As a result, the move which has the best estimation is selected as next move.

$$\overline{X_\iota} = \frac{X_i}{s_i} \tag{1}$$

2.2 Potential model

Stones influence the possibility of the surrounding intersection becoming their territory. The potential model is to quantify these influences by assuming *go* stones as potentials following earlier studies [2-4].

2.2.1 Definition of potential

The definition of potential in this experiment is shown in Formula (2-4) and Table 1. The plus and minus of Formula (3) is switched by the setting of proposed method. A potential gradient are calculated by Geographical Information Systems [5].

$$r = \sqrt{(X - x_i)^2 + (Y - y_i)^2} \tag{2}$$

$$P_i = \pm \frac{1}{2^r} \tag{3}$$

$$P_{all} = \sum_{\mathrm{k}=1}^{\mathrm{n}} P_i(X, Y) \tag{4}$$

Table 1. Mathematical expression

r	Euclidean distance
x_i, y_i	Intersection of $Stone_i$
$P_k(X, Y)$	Potential to intersection (X, Y) from $Stone_k$
n	Total number of stone on the *go* board
$P_{all}(X, Y)$	Total potential to
$PG(X, Y)$	A potential gradient at an intersection.

2.2.2 Pruning using potential model

Potential Filters

Potential Filters are pruning instruments in this experiment. At each phase to choose the next move, these Filters pruned legal moves according to the following procedures:

i. Calculate potential distribution result from arrangement of go stones on the *go* board.
ii. Rank legal moves by each magnitude of potential (or potential gradient.)
iii. Categorize the ranked legal moves into effective and ineffective moves in accordance with thresholds for the ranking. (Each Potential Filter has unique threshold levels.)
iv. Eliminate the ineffective moves from candidates for the next move. (Run Monte-Carlo search only on effective moves.)

In accordance with the number of eliminated legal moves, the computation load of Monte-Carlo search is reduced. Said differently, the Potential Filters reduce the range of search spaces on the *go* board.

Configurations of Potential Filters

Table 2 shows the threshold conditions of the 5 kinds of Filters. Each Potential Filter ranked legal moves in descending order of potential or potential gradient values, and categorized in accordance with each threshold condition for the ranking. All Filters mutually reduced by half the number of legal moves. Thus all Filters reduced by half the computational load at each phase to choose the next move.

On and Off Switch of Potential Filter

Potential Filters had a switching point, which switched their states ON and OFF. This switching point was within a range of legal intersection numbers on the *go* board. A switching point was selectable from 2 to 81 when the board size was 9 x 9 (= 81), or from 2 to 169 when the board size was 13 x 13 (= 169).

During the course of a game, in the case a remaining legal move number on the *go* board was above a switching point, the Potential Filters were ON. If a remaining legal move number was under a switching point, the Potential Filters were OFF. In this experiment, boundaries where Potential Filters became ineffective from effective were measured by changing the switching point. The boundaries were the points where winning percentages crossed an average winning percentage between two normal Monte-Carlo *go*.

Monte-Carlo search has higher performance when a game tree is small. In contrast, Monte-Carlo search has low performance when a game tree is large. Thus, pruning is effective in the opening game. However, afterwards, pruning gradually becomes ineffective.

3 STRENGTH OF MONTE-CARLO *GO* WITH POTENTIAL FILTERS

The strength of Monte-Carlo *go* with Potential Filters was indicated by its winning percentage against normal Monte-Carlo *go*. Monte-Carlo *go* with Potential Filters used the initiative move while normal Monte-Carlo *go* used the passive move. In a match-up between two normal Monte-Carlo *go*, the winning percentage of the initiative move was 57% when board size was 9 x 9, or 51% when board size was 13 x 13. (The winning percentage of initiative exceeded 50% because the initiative move was advantageous.) Therefore, 57% or 51% is considered the average level of normal strength.

4 RESULTS AND OBSERVATION

The strength of Monte-Carlo *go* with Potential Filters is shown in Fig. 1, upper (board size: 9 x 9) and lower (board size: 13 x 13) graphs, left axis. Strength transitioned with Filters and switching points. A winning percentage of 57% or 51% and calculating the results of the Random Filter were important for comparing and evaluating the effects and tendency of Potential Filters. Total Play Out numbers needed in one game are shown in Fig. 1, upper and lower graphs, right scale. Total Play Out numbers transitioned with these Filters and switching points.

In theory, when the Random Filter was used, the next move became the best move by Monte-Carlo search 50% of the time and the second or several moves thereafter by Monte-Carlo search the other 50% of the time.

In the case that the number of legal moves was large, Monte-Carlo search had low precision. Thus, there was no big decrease of strength, because there was no defining difference between the best move and the second or several moves thereafter by Monte-Carlo search. The precision of Monte-Carlo search increased with a decrease in the number of legal moves. The strength of the Random Filter decreased gradually with a decrease in the number of legal moves.

Potential Filter 1 became the bias around which black stones gathered. In the opening game, these collective black stones effectively strengthened initiative territory. However, in the middle game, the initiative move could not expand its territory. As a result, the passive move acquired more territory than the initiative move on the *go* board. When strength exceeded average (57% or 51%), Potential Filter 1 properly pruned ineffective moves that Monte-Carlo search was unable to do. Thereafter, the strength of the Potential Filter 1 decreased gradually with a decrease in the number of legal moves and an increase in the precision of Monte-Carlo search. In fact, the pruning of Potential Filter 1had encumbered the precision of Monte-Carlo search.

Potential Filter 2 became the bias where black stones were attracted around white stones. In the opening game, black stones effectively suppressed white stones. However, in the middle game, black stones were removed easily by collective white stones. As a result, the passive move acquired more territory than the initiative move on the *go* board. When strength exceeded average (57% or 51%), Potential Filter 2 properly pruned ineffective moves.

Potential Filter 3 became the bias where black stones were scattered on the *go* board. These black stones were removed easily by collective white stones. As a result, the passive move acquired more territory than the initiative move on the *go* board. In the opening game, Potential Filter 3 barely pruned ineffective moves. However, Potential Filter 3 decreased the strength in comparison with other Filters more gently.

Potential Filter 4 became the bias where black stones were attracted around black and white stones, and areas between black and white stones were closed. This is important in *igo*. Potential Filter 4 could prune more properly than the other Filters, but decreased the strength in comparison with other Filters more drastically in the middle game.

Potential Filter 5 became the bias where stones were attracted around black and white stones. Potential Filter 5 could prune more properly than the other Filters, but decreased the strength in comparison with other Filters more drastically in the middle game as well as Potential Filter 5.

As for Combination, Potential Filter 5 and Potential Filter 3 combined pruned a game tree more properly than Potential Filter 5 alone. In the opening game, Potential Filter 5 was effective and this initiative had high strength. However, in the middle game, Potential Filter 5 decreased the strength in comparison with other Filters more drastically. On the other hand Potential Filter 3 decreased the strength in comparison with other Filters more gently. So the strength keeps the average for a longer time by switching Potential Filter 5 to Potential Filter 3 at the point where the strength of Potential Filter 5 began to decline (switching point 68 or 145).

4 CONCLUSION

In this study, we tackled the reduction of computational complexity by pruning the *igo* game tree using the potential model based on the knowledge expression of *igo*. In our experiments, 5 kinds of pruning strategies (Potential Filters) were evaluated for their removal effect. Maintaining normal strength of Monte-Carlo *go*, Potential Filter 4 or 5, based on potential gradient distribution or homopolarity potential distribution, could reduce up to 18% of total Play Out numbers needed in one game. Potential gradient and homopolarity potential could identify important areas around black and white stones as well as close areas between black and white stones. In addition, combining Potential Filter 5 and Potential Filter 3 could reduce up to 23% of total Play Out numbers by switching Potential Filter 5 to Potential Filter 3 at the point where the strength of Potential Filter 5 began to decline (switching point 68 or 145). This shows the tendency of *igo* transition as the game progresses.

In this research we successfully demonstrated pruning using the potential model for reducing computational complexity of the *go* game. However, our experiments were limited as the Play Out number was set at 100 and the board size was set at 9 x 9 or 13 x 13. For our future research, we intend to expand the proposed strategy to tackle more complex games with larger Play Out numbers and *go* board size.

Abstract: Meme refers to a unit of human cultural transmission, analogous to gene in biological evolution. Meme propagation has an autocatalytic property in the sense that it increases its reproductive rate by duplicating the source of propagation. The purpose of this study is to gain general knowledge about dynamics of meme propagation. This paper presents a minimal model based on physical movement of particles for investigating the relationship between the behavior of the hosts (velocity of particles) and the autocatalytic property of the meme. It is demonstrated that two extreme memes, the fastest and the slowest ones, have a strong tendency to survive by autocatalytic properties at individual and aggregate levels, respectively, although all memes seem neutral in terms of fitness in the model definition.

Keywords: Agent-based model, Artificial life, Autocatalytic reaction, Meme

1 INTRODUCTION

Meme [1] refers to a unit of human cultural transmission, analogous to gene in biological evolution. A meme parasitizes a human brain and propagates from one brain to another mainly by imitation. For a meme to be successful, it has to have "fecundity", "longevity" and "accuracy of replication", which are recognized as the main components of the fitness of memes.

In principle, meme propagation has an autocatalytic property in the sense that it increases its reproductive rate by duplicating the source of propagation. When comparing it with chemical autocatalytic reactions, we see a big difference arising from the difference between duplication of materials and information. This autocatalytic property of memes will be more strengthened if the meme has a greater fecundity, in other words, a greater tendency to make the host behave for propagating the meme. Bura [2] successfully demonstrated that this type of autocatalytic process could evolve memes which are detrimental to their hosts. In his model MINIMEME, the interaction between the memes and the host animals are modeled, and the following autocatalytic phenomenon was found: memes provoked the gathering of their hosts, which led to a situation in which they reinforced each other and their replication was made easier. Thus, memes that kill their hosts by overcrowding could survive and even become dominant.

The purpose of this study is to gain general knowledge about dynamics of meme propagation. Specifically, this paper presents a minimal model based on physical movement of particles for investigating the relationship between the behavior of the hosts (velocity of particles) and the autocatalytic property of the meme. It is demonstrated that two extreme memes, the fastest and the slowest ones, have a strong tendency to survive by autocatalytic properties at individual and aggregate levels, respectively, although all memes seem neutral in terms of fitness in the model definition.

2 MODEL

Particles move around on a two-dimensional square field with boundaries in the model. Memes inhabit the particles and decide the velocity of the hosts. There are seven kinds of memes, each corresponding to a different velocity: "meme0", "meme1", ..., "meme6" in ascending order of velocity. Fig. 1 shows the relationship between an agent and memes. A meme is represented as an arrow of which length corresponds to its velocity. Each particle has four memes (allowing duplication of kinds), and moves forward with the velocity specified by one of these memes at each step. In-use meme is represented as a solid arrow and the others are represented as a dashed arrow in this figure. The velocity of each particle is switched according to a randomly selected meme from these four memes with a fixed probability at each time step. Each particle keeps its moving direction unless it switches its in-use meme or collides with other particles or boundaries.

Fig. 2 shows an example of meme transmission. Each particle has an interaction area represented as a circle (all particles have the same radius in this paper). While two interaction areas overlap, both particles send their in-use meme to the other at the same time at each step. When receiving a meme, a randomly chosen meme is replaced by the received meme. The thick and solid arrows represent the transmitted

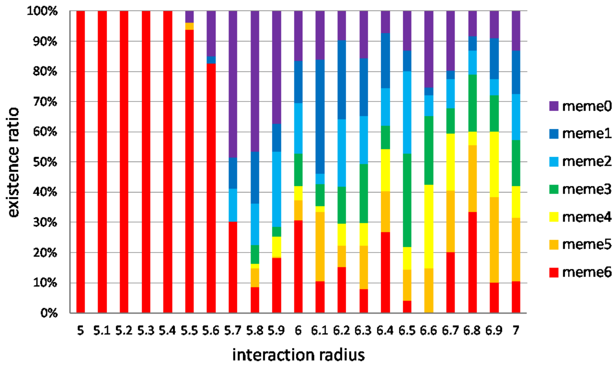

Fig. 3. Existence ratio after convergence.

memes in this figure. Therefore, through each meme transmission, the number of the in-use memes is increased by one unless they are replaced by the meme transmitted by the other particle or they replace the same meme of the other particle.

3 EXPERIMENTS

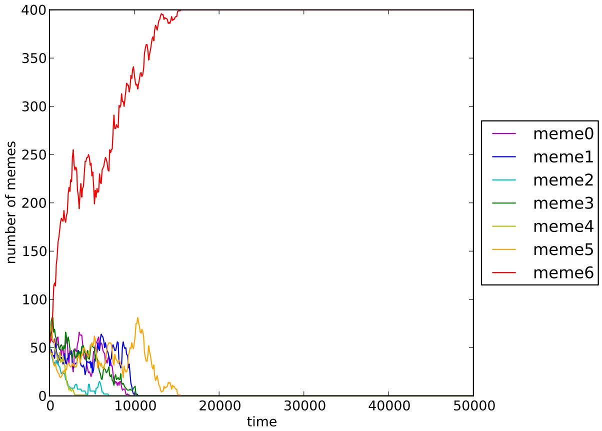
In the initial population of memes, we put particles at random in the field and allocated memes to each particle randomly. We ran the model until the time step reached 50,000. Table 1 shows the parameters to be used. We conducted experiments by changing the value of the interaction radius from 5.0 to 7.0.

Fig. 3 shows the existence ratio of each meme in the population during the last 100 time steps in the different cases of the interaction radius. Each value is the average over 10 trials.

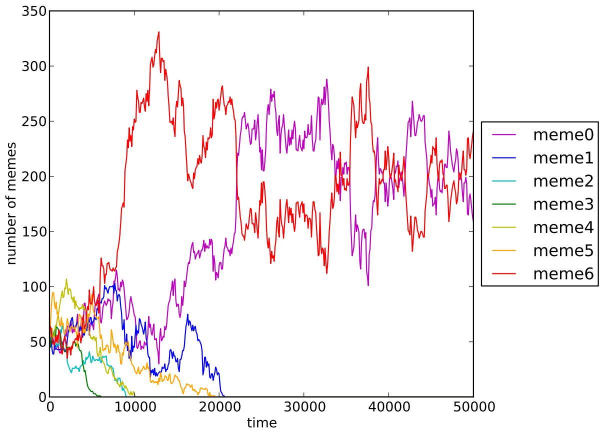
We see that the behavior of the population is strongly dependent on the interaction radius. When the interaction radius was small, 5.4 or less, the population converged to the fastest meme (meme6) in all trials. As the interaction radius increased until around 5.7, the existence ratio of the slowest meme (meme0) increased, and thus the fastest and the slowest memes tended to coexist. As the interaction radius got larger, we observe that memes with intermediate velocity survived and tended to coexist but their ratio fluctuated significantly.

Fig. 4 shows examples of the transition of the number of memes in the population with three typical settings of interaction radius (a: 5.4, b: 5.6 and c: 6.0). In order to analyze the actual behavior of particles in each case, we visualized example snapshots of the model in Fig. 5. Particles are represented as small circles and their color represent their in-use meme.

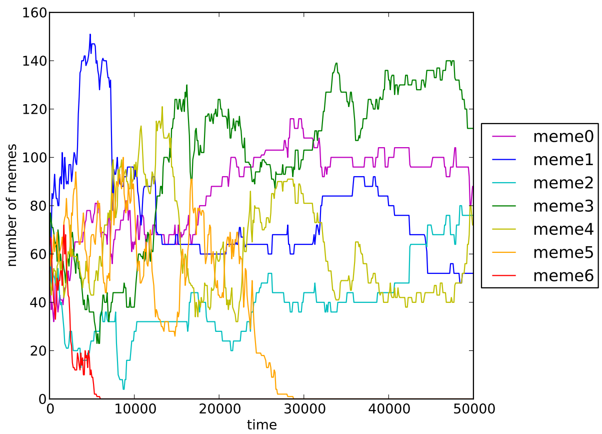
In the case (a), the population was quickly dominated by the meme6, which had the highest velocity. When two particles interact, the in-use meme of a particle is guaranteed to overwrite one of four memes of the other particle. On the other hand, the probability that the in-use meme of a particle is overwritten by the in-use meme of the other particle is 1/4. Therefore, in general, in-use memes can replicate itself in the population by an interaction because of this asymmetric property in probability of meme propagation. In other words, the more a particle interacts, the more frequent opportunities it has to increase the ratio of its in-use meme. Therefore, whether memes increase or not is dependent on the frequency of the propagation of memes. If the interaction radius is small, memes with higher velocity can invade into the population because they enable particles to interact



(a) Interaction radius: 5.4.

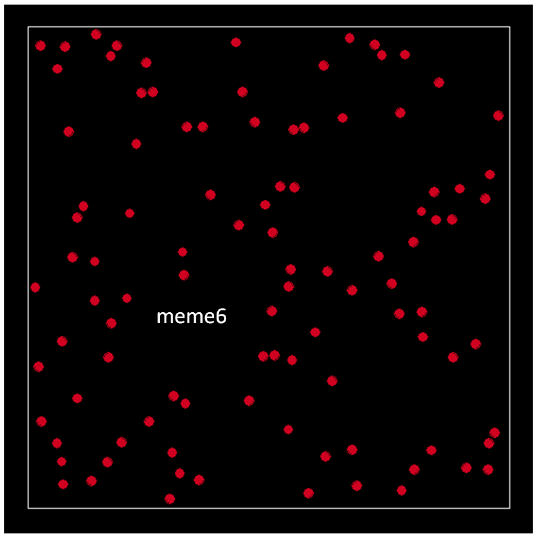


(b) Interaction radius: 5.6.

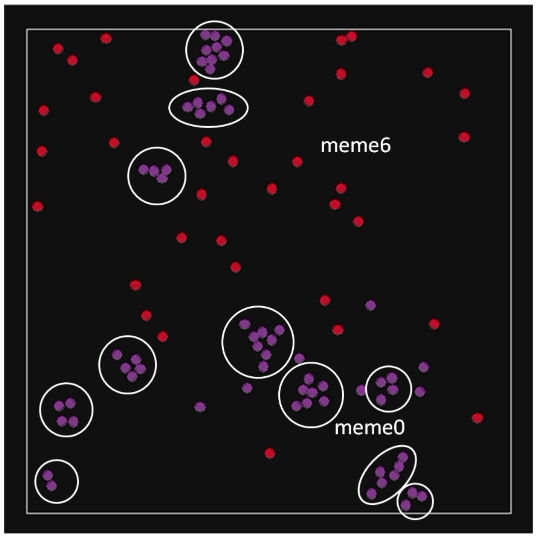


(c) Interaction radius: 6.0.

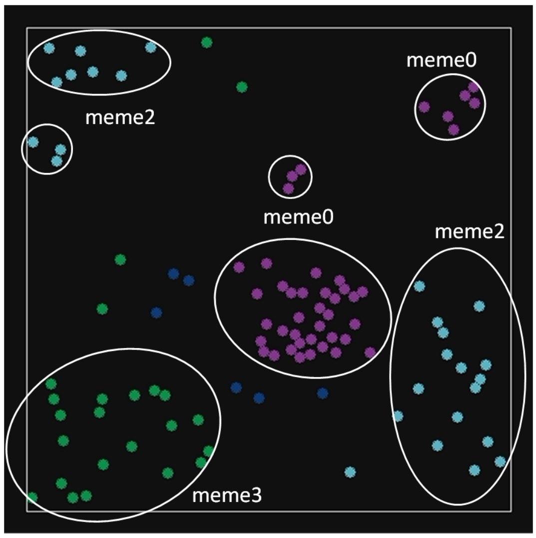
Fig. 4. Examples of the transition of the population.



(a) Every particle has four meme6 (interaction radius: 5.4).



(b) Particles with meme0 gather in the moving particles with meme6 (interaction radius: 5.6).



(c) Particles with each kind of meme gather (interaction radius: 6.0).

Fig. 5. Example snapshots of the population (almost every particle has one kind of meme).

with many other particles by moving around the field. Thus, we can say that meme6 is dominant due to this autocatalytic property at individual level.

In the case (b), the population converged to the state with meme0 and meme6. We can observe the clusters of the meme0 in Fig. 5(b). Note that the white and open circles in Fig. 5 represent the clusters of each meme. The detailed analyses of the behaviors of particles showed that the particles with the meme0 maintained their clusters by trapping incoming particles with the meme6, while they were scattering very slowly. Fig. 6 shows the transition of the proportion of interaction events when a particle received the same kind of meme as the one it sent to the other particle among events when a particle sent the focal kind of meme (the interaction radius = 5.6). Because the percentage of meme0 is large, we can say that the meme0 replicated and increased their frequency via interactions among particles in their clusters due to the larger interaction radius. This makes incoming particles into the clusters receive the meme0 very frequently, and thus they tend to become a part of the clusters. From these facts, despite meme0 has the lowest autocatalytic property at individual level, we can say that meme0 was dominant because of this autocatalytic property at aggregate level.

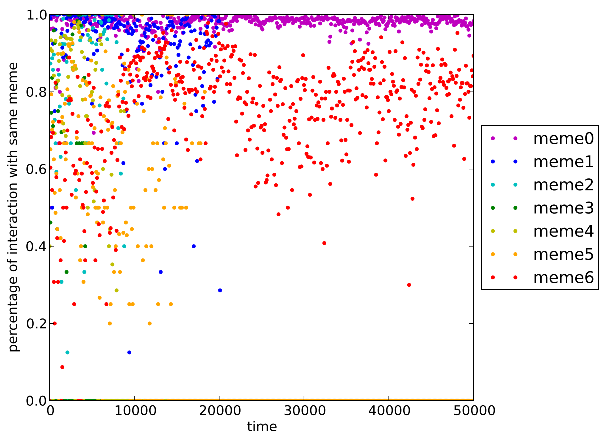


Fig. 6. Transition of the proportion of the interactions between the particles with the same kind of in-use memes.

However, as the interaction radius increased further, such as case (c), the population converged to the state with more kinds of memes as shown in this example. We did not observe dominant memes because of large variations in each trial within the limited number of the time step 50,000. It is expected to be due to the fact that the larger interaction radius makes effects of the difference in the velocity of memes on the behavior of particles less significant, by making interaction events frequent and global. Thus, we did not observe emergence of autocatalytic behaviors at both individual and aggregate level, which are based on the two extreme properties of memes.

4 CONCLUSION

We presented a minimal model based on physical movement of particles for investigating the relationship between the behavior of the hosts and the autocatalytic property of the meme. The simulation results showed that two types of autocatalytic processes could emerge at individual and aggregate levels, which evolve two extreme memes, the fastest and the slowest ones, respectively. It is a noticeable fact that the evolution was not based on the explicit fitness definition. If we consider the model describes religious propagation, the fastest meme and the slowest meme might correspond to a popular religion and a cult, respectively.

Our model assumes a direct relationship between a meme and the movement of its hosts. It would be interesting to associate the assumption with the recent experimental finding by Hommel et al. that religious practice can not only affect spatial and temporal characteristics of stimulus selection but also control processes devoted to action regulation [3].

Sayama is developing the Swarm Chemistry model [4], which is an artificial chemistry framework that can demonstrate self-organization of dynamic patterns of kinetically interacting heterogeneous particles. One of the promising directions would be to enhance our model towards Sayama's model to aim to make our model capable of open-ended evolution while keeping neutrality of memes in terms of fitness in the model definition.

Pre-historical multiple movements of modern humans from Old World to Americas: Evidence based on comparing basic body part-name words with Austronesian

Koji Ohnishi[1,2]

[1]Faculty of Science, Niigata University, Niigata 950-2181, Japan
(Tel: 81-25-262-5237, Fax: 81-25-262-5237)

Abstract: Basic body-part name vocabulary of representative Native American languages (NAmLs) and Eurasian languages was compared with ca. 1300 Austronesian (AN) basic words and with basic words of Eurasian languages. By applying closest similarity analysis of occurring frequencies of thus found AN cognates (of non-AN vocabulary) in subgroups of AN, NAmLs are concluded to have been derived from various branches of AN family, by human movements not only via Behring land-bridge but also via trans-Pacific sailing rout (as represented by Maipuran language in Amazonian area). Such independent human movements to Americas are concluded to be much more frequent than has been generally considered.

Keywords: basic Austronesian origins, body-part names, closest similarity analysis, trans-Pacific movement to America

1 INTRODUCTION

Origins of Native American languages (NAmLs) and peoples are generally considered to be yet unknown [1]. However, most of representative language families/groups in Eurasia have been strongly suggested by Ohnishi [2,3,4] to share many cognate basic words with Austronesian (AN) language (Lg) family, and therefore, seem to have been derived from AN Lgs. This paper aims to find multiple origins of NAmLs by basic word comparison, and present a new classification of modern human Lgs.

2 METHODS, RESULTS AND CONCLUTION

Basic body-part name words (BBP) (for 30 ~ 32 word items) in Swadesh' 200 basic words (SW200W) (See Ref. YH* in Table 1) or body part names (BP) of representative NAmLs were extensively compared with vocabulary of Eurasian and Pacific Lgs, especially with ca. 1,300 AN basic words listed in "Comparative Austronesian Dictionary (CAD*)" (See CAD* in Table 1). CAD* lists basic vocabulary for 80 AN Lgs consisted of 4 Formosan (FORM), 26 Western Malayo-Polynesian (W.MP), 6 Central MP (C.MP), 2 South Halmahera-West New Guinean (SHWNG), and 41 Oceanic (OC) Lgs, as is given in the uppermost lines in Table 3.

The 30~32 meanings of BBPs in Sw200W are as follows:

(i) [in Swadesh basic 100 words (Sw100W)] 25 ~ 26 word-meanings: belly (or bowels), blood, bone, breast(s), (egg), ear, eye, fat (or grease), feather, foot, hair, hand, head, heart, horn, knee, liver, meat (or flesh), mouth, neck, nose, saliva (or spit), skin, tail, tongue, tooth.

(ii) [in Sw200W other than Sw100W] 5~6 word-meanings: arm, back, (breath, to breathe), leg, lip, wing

When two or more different words have the same meaning of a Swadesh basic word, AN and Eurasian cognates of the two or more words were also searched and analyzed. Cognates having different meanings, whether ancestral meanings or derived/converted meanings, were also considered to be cognates of the (B)BPs. Searching such cognates having converted meanings is very important in increasing sensitivity of finding distantly relationship between different language families.

Closest similarity analysis (CSA): Based on thus found AN cognates of vocabulary in NAmLs and Eurasian Lgs listed in Table 2, every basic word item of non-AN Lg(s) (or Lg groups) were analyzed by CSA described in Ohnishi [6]. CSA determines the AN subgroup (in the above five) to which the morphologically most similar AN cognate word belongs. Cognates having different meanings, whether ancestral meanings or derived meanings, were also considered to be cognates of (B)BPs. Thus found cognates of BBPs or BPs, or of general (basic) words are listed in Table 2, as classified by most similar subgroup out of the five AN language groups. When two or more different basic words have the same meaning of a Swadesh basic words, cognates of the two or more words were also searched and analyzed. After such detailed analyses, occurring frequencies of most similar cognates of ca.30 BBPs in the 5 AN subgroups were counted and listed in Table 3, and statistically tested (by χ^2-test, as described in [5]) for finding an AN subgroup which is most closely kin to the "query" language (e.g. Quechuan, Yahgan, Mongolic, etc.) ?". Results of χ^2-test are indicated in Table 3 by #, +, ++, *, and **, for significant levels $P < 0.1$, < 0.05, < 0.025, < 0.01, and < 0.005, respectively.

Conclusion: From Table 3, we conclude that: (1) Native American and Eurasian Lgs and language families listed here are have been derived directly or indirectly from various branches of AN Lg family. (2) Maipuran has derived from Maori, via ancient trans-Pacific sailing to South America (See "Hah-Vah-Ee-Kay" (=Hawaikii) story in [6] (Jpn. trnsl. ed. p.163, p.515) and [2], p.115.). (3) Comecrudo, Aymara, Yamanan, and Mixe-Zoquean are also (directly or indirectly) of OC-origin, some of which might have moved via trans-Pacific rout. (4) Koasati-Alabaman is Philippines-derived. (5) Multiple movements to Americas are evident. (6) Further details will be published elsewhere.

Abstract: In this paper, we describe an analysis of the nonlinear dynamical phenomenon associated with a silicon neuron. Our silicon neuron integrates Hodgkin-Huxley (HH) model formalism, including the membrane voltage dependency of temporal dynamics. Analysis of the bifurcation conditions allow us to identify different regimes in the parameter space that are desirable for biasing our silicon neuron. This approach of studying bifurcations is useful because it is believed that computational properties of neurons are based on the bifurcations exhibited by these dynamical systems in response to some changing stimulus. We describe numerical simulations and measurements of the Hopf bifurcation which is characteristic of class 2 excitability in the HH model. We also show a phenomenon observed in biological neurons and termed excitation block. Hence, by showing that this silicon neuron has similar bifurcations to a certain class of biological neurons, we can claim that the silicon neuron can also perform similar computations.

Keywords: Silicon Neuron, Hopf bifurcation, Hodgkin-Huxley equations, neuromorphic engineering.

1 INTRODUCTION

Neuromorphic engineering is a research field where microelectronics meets biology. The link between both is done by computational neurosciences which model and emulate a part of brain activity. Neuromorphic systems emulate biological structures in the hope of retaining its remarkable computational efficiency. Analysis of the bifurcation is useful because it is believed that computational properties of neurons are based on the bifurcations exhibited by these dynamical systems in response to some changing stimulus [1] [2]. These artificial systems would be useful to neuroscientists for exploring neural computation. Contrarily to computer simulation, analog circuits are inherently suitable for simulating differential equations in real time and in parallel [3]. The hardware simulation further facilitates the building of a hybrid network connecting artificial and biological neurons to create a real-time loop or can be even used to replace nonfunctional neurons as a prosthesis.

Pioneering work in modeling the dynamics of a biological neuron was done by Hodgkin and Huxley (HH) [4]. In the most detailed family of neuron models, known as conductance-based models, ionic and synaptic currents charge and discharge a capacitor representing the neuron membrane. All of these models find their origins in the HH formalism. Each ionic channel (sodium, potassium, calcium, etc.) is represented by a time and voltage dependent conductance: this electrophysiological description makes these models particularly well-suited to an implementation involving analog electronics [5]. The main advantage of this formalism is that it relies on biophysically realistic parameters and describes individual ionic and synaptic conductances for each neuron in accordance with the dynamics of ionic channels.

Hodgkin classified biological neurons mainly into two classes according to their response properties to a sustained current stimulus [6]. The cells that show Class 1 neural excitability can fire with an arbitrarily low frequency by applying a sufficiently close-to-threshold current. The frequency increases monotonically as the current increase. The cells that show Class 2 neural excitability transitioned from silence to firing at an arbitrary nonzero frequency. Furthermore, the Class 1 characteristic is can be associated with a saddle-node bifurcation at the transition from silence to spiking. As shown by bifurcation analysis, the Class 2 excitability is observed when the resting state loses its stability via an Hopf-bifurcation.

The Hodgkin-Huxley model belongs to Class 2. Its dynamical properties with a constant stimulus have been studied extensively [7] [8], and these have shown that the Class 2 neural excitability of the HH model is generated by Hopf bifurcations.

Innovative work in modeling of a simplified silicon neuron that exhibits HH type dynamics was done in [9] and in [10]. On the other hand, some designs have faithfully replicated full Hodgkin-Huxley dynamics, resulting in large footprints for each neuron [5]. We implement in our chip the HH model with an approximation: we use a fixed time constant to reduce the silicon area required by the neuron implementation in the chip. In this paper we present an analysis of the nonlinear dynamical phenomenon associated with our silicon neuron. We show a Hopf bifurcation which is characteristic of class 2 excitability in the HH model in our approximated model. We also show a phenomenon observed in real neurons and termed excitation block.

2 HH MODEL IN VLSI

2.1 The Hodgkin-Huxley Formalism

We chose to implement neuron model following the Hodgkin-Huxley formalism. Electrical activity of a neuron is the consequence of the diffusion of different ionic species through its membrane. The HH formalism provides a set of equations and an equivalent electrical circuit which describes conductance phenomena.

The current flowing across the membrane is integrated on the membrane capacitance, according to expression (1):

$$C_M \frac{dV_M}{dt} = -\sum I_I + I_S \tag{1}$$

where V_M is the membrane potential, C_M is the membrane capacitance, and I_S is a stimulation or synaptic current. I_I is the current for a given channel type and its associated equation is:

$$I_I = g_I.m^p.h^q.(V_M - E_I) \tag{2}$$

where g_I is the maximum conductance; m and h represent the activation and inactivation terms, respectively. They are dynamic functions, which describe the permeability of membrane channels to its specific ion. E_I is the ion-specific reverse potential and p and q are integers.

According to the first order differential equation (3), m relaxes back towards its associated steady-state value m_∞, which is a sigmoid function of V_M (4). The time constant for convergence is τ_m which is also voltage dependent of the membrane voltage V_M.

$$\tau_m(V_M)\frac{dm}{dt} = m_\infty - m \tag{3}$$

$$m_\infty = \frac{1}{1+\exp\left(-\frac{V_M - V_{Offset,m}}{V_{Slope,m}}\right)} \tag{4}$$

In (4), $V_{Offset,m}$ and $V_{Slope,m}$ are the offset and the slope of the activation sigmoid respectively. The inactivation parameter h follows identical equations, except for the sign inside the brackets, which is positive.

The HH model describes sodium, potassium and leakage channels, with p = 3 and q = 1; p = 4 and q = 0; p = 0 and q = 0 respectively, in expression (2). These channels are responsible for action potential generation. For more complex activity patterns, such as bursting or the discharge of action potentials with adaptation phenomena, additional channels such as slow potassium (p=1 and q=0) and L-Type calcium for bursting (p=2 and q=1) have to be taken into account. Our chip has a large range of validity domains for the parameter to reproduce different kind of neurons like: Fast Spiking (FS), Regular Spiking (RS), Intrinsically Bursting (IB), and Low Threshold Spiking (LTS) [11]. Although these HH-type models sometimes exhibit much more complex dynamics than the original HH model, they share common nonlinear characteristics and dynamics with the HH in many aspects.

2.2 The model dedicated to our integrated circuit

Our system is composed of our most recent chip called Galway and the dedicated board named Ekerö. This chip includes analog operators for the computation of the HH formalism, and for the construction of neural networks, multi-synapses that consist of gathering all synaptic inputs in one electronic input. We implement in our chip the HH model with an approximation: we use a fixed time constant in (3). We made this choice to reduce the size of the chip. So the only difference between the model for the VLSI and the HH model presented in [12] is the approximation used for the gating variable.

2.3 Hopf bifurcation

The Hopf bifurcation theory [8] asserts that if a parameterized system possesses an equilibrium point and two of the eigenvalues of the Jacobian matrix of the system linearized around the equilibrium point are conjugate pure imaginary numbers and the others have negative real parts, one of the following bifurcations takes place as the parameter changes:

1) A bifurcation from a stable equilibrium point to an unstable equilibrium point with a stable limit cycle around it; or a bifurcation with the opposite direction. We refer to this bifurcation as supercritical.

2) A bifurcation from an unstable equilibrium point to a stable equilibrium point with an unstable limit cycle around it; or a bifurcation with the opposite direction. We refer to this bifurcation as subcritical.

2.3 Simulation

To validate our approximation we used continuation of solutions in AUTO, an open source mathematical package that can produce bifurcation curves for equilibria as well as for periodic orbits, to get the complete bifurcation diagram of the system. We compare the simulations between HH based model and our implemented HH model.

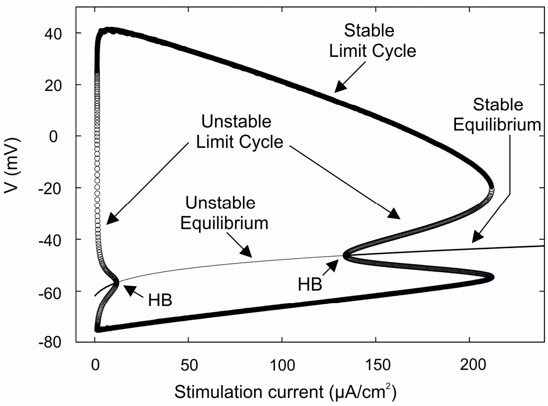

Fig. 1. Bifurcation diagram for our approximated model.

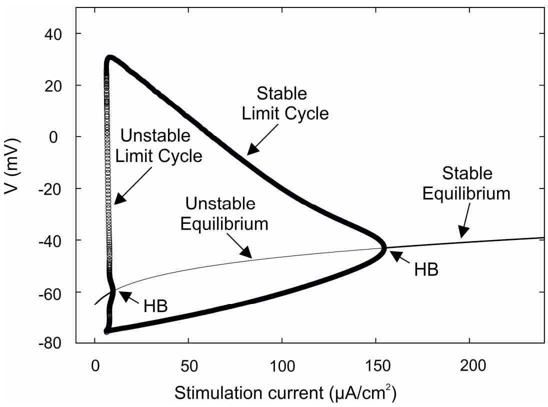

Fig. 2. Bifurcation diagram for HH model.

Fig. 1 shows the resulting bifurcation diagram of our HH approximated model where solid thick and solid thin curves represent stable and unstable equilibria respectively while solid and dashed circles denote stable and unstable limit cycles. It can be seen that the limit cycles are born initially through a fold bifurcation of cycles. Both the Hopf bifurcations are subcritical as they involve an unstable limit cycle. The amplitude of the stable limit cycle keeps on reducing until it coalesces with the unstable limit cycle in another fold bifurcation. The resting state loses stability via the subcritical Hopf bifurcation at the first point HB in Fig. 1. At the second point HB in Fig. 2, a stable limit cycle and an unstable one arise via the fold bifurcation. Bifurcation diagram in Fig. 1 illustrate how the repetitive firing emerges when we apply sustained stimulus current. Stable limit cycle corresponds to repetitive firing.

For a comparison with HH model, its bifurcation is also shown in Fig. 2. The Hopf bifurcation for smaller current is subcritical. The limit cycle appears by a fold bifurcation and disappears by a supercritical Hopf bifurcation. The reduction in amplitude before the subcritical Hopf bifurcation is similar to the Fig. 1. It can be seen in Fig. 2 that the limit cycle is born by a fold bifurcation but terminates in a supercritical Hopf bifurcation. The bifurcation diagrams shown in Fig. 1 and Fig. 2 share the topology in a biologically meaningful range of stimulus current. The qualitative nature of the plots (Fig. 1 and Fig. 2) is similar as the reduction in amplitude of the limit cycle before its disappearance is present in both pictures.

3 RESULTS IN VLSI

3.1 Firing rate

In Fig. 1, the system state jumps to the stable limit cycle when the stimulus current exceeds the Hopf bifurcation point. In this case the firing frequency cannot be zero at the bifurcation point for the Class 2. Steps of input current are important type of stimulus typically used to characterize the behavior of neuron models. The resulting spike frequencies for different values of stimulation current are plotted in Fig. 3. This figure shows a behavior typical of class 2 neurons where the spiking frequency does not tend zero upon reduction of the input current. In other word, the disappearance of the limit cycle is not associated with its frequency reducing to zero like in class 1 neurons.

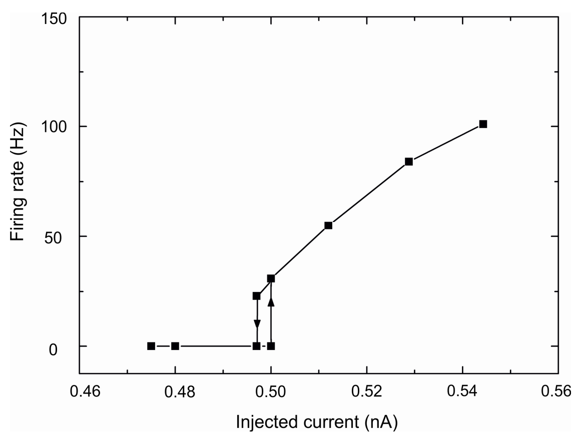

Fig. 3. Hardware measurements of the frequency versus stimulation current curves of our silicon neurons. Arrows describes the existence of bistability; onsets of firing are different when the stimulus increased or decreased.

3.2 Effect of current impulses

Fig. 4 shows the effect of current impulses of different values in our silicon neuron. Larger current pulses shifts the initial condition beyond the unstable limit cycle leading to spontaneous oscillations. We used four different current pulses of increasing amplitude to stimulate our silicon neuron. It can be seen in Fig. 4 that for the first two case the neuron come back to resting state and in the third and fourth case it start the oscillations. This demonstrates the existence of the threshold that in our silicon neuron is 0.5 nA.

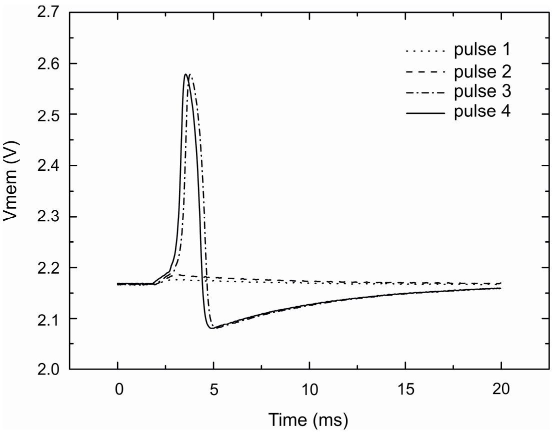

Fig. 4. Hardware neuron membrane voltage depending on current impulses.

3.3 Excitation block

To prove that the silicon neuron reproduces similar dynamical properties of biological neuron, we also explored the phenomenon known in biology and termed excitation block. In this case, there is the cessation of repetitive spiking as the amplitude of the stimulus current increases. The equilibrium regains stability through a Hopf bifurcation which may be subcritical or supercritical. To observe this phenomenon a slowly increasing ramp of current was injected. In Fig. 5 is showed that for much larger value of the stimulus the equilibrium becomes stables again.

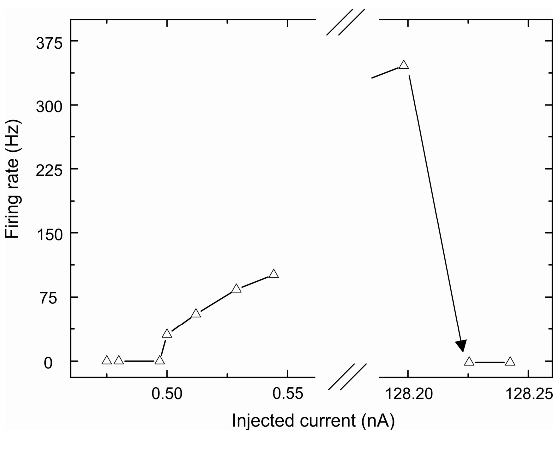

Fig. 5. Measured data of the excitation block where the input current is slowly increased.

4 CONCLUSION

In this paper, we described an analysis of the nonlinear dynamical phenomenon associated with a silicon neuron. We implemented an approximated HH model using fixed time constant. We showed numerical simulations of the Hopf bifurcation which is characteristic of Class 2 excitability in the HH model. We compared the results with the HH model showing that our model shares the dynamics with the full HH model. We also showed the firing rate and then the phenomenon observed in real neurons and termed excitation block. Hence, by showing that this silicon neuron has nonlinear dynamical phenomenon similar to a certain class of biological neurons, we can claim that the silicon neuron can also perform similar computations.

Abstract: The problem of balancing a two wheeled robotic platform has been intensively studied and well understood. However in such studies, the mathematical model of the robot is commonly derived under the assumption that the robot remains constant contact with the ground. This assumption limits the movement of the robot to continuous ground surface. In other words, any momentary airborne situation, such as traversing down a flight of stairs or falling off edges will render the control algorithm ineffective and cause the robot to fall upon landing. In this paper, the dynamics of a free falling two wheel robot are investigated and a novel attitude control scheme is proposed. We proposed using the wheel of the pendulum as a reaction wheel to provide control torque for correcting the robot's attitude in air and ensure a safe landing. The effectiveness of the proposed approach is demonstrated through both simulations and actual implementation.

Keywords: two-wheeled balancing robot, free fall, dynamic balancing, attitude control

1 INTRODUCTION

Mobile robots that are deployed into human environment will need to traverse through non-continuous terrains such as steps or stairs in order to navigate around certain area. Various kinds of robots have been designed to tackle this problem. Most notably biped type humanoid robot such as ASIMO [1] are able to traverse up and down stairs. However, due to its complexity and price of manufacturing, deployment of biped type humanoid robot is still uncommon and not economically practical. As for wheeled robots, maneuvering through non-continuous terrains remains a challenging open problem.

Various statically stable mobile wheeled robots have been developed for tackling such problem. For example the Sojourner [2] developed by NASA and the Shrimp robot [3] developed by EPFL uses a combination of adaptive legs with the efficiency of wheels to enable the robot to traverse through uneven terrain and steps. These approaches rely on the redundancy of static points of support on the base to provide stability to the robot during climbing up/down steps. Drawbacks on these robots are increased complexity in structure and control and increased size. In human environment where workspace is limited, their navigation ability may be restricted since they typically require a larger workspace.

In contrast, dynamically stable robots like JOE [4], Ballbot [5] which use active control to achieve balance possess greater flexibility in maneuvering and are more resistant to external disturbance. These robots also have a smaller footprints and possess a near-zero turn radius for moving in a limited space. Given the robustness against applied external forces, these robots prove to be more usable when deployed into human environment.

This paper explores the possibility of a two wheeled robot to traverse down a non-continuous ground step. The dynamics of the free falling motion are investigated and a novel attitude control scheme is proposed. The proposed approach extends the ability of the two wheeled robot to traverse through rough and edgy terrains. During free fall, a two wheel robot behaves similarly to a reaction wheel pendulum, with pivot point at the center of mass. Hence it is possible to use the momentum of the wheels to generate correction torque to alter the orientation of the robot and ensure a safe landing. Two separate feedback control schemes designed using the linear-quadratic controller (LQ) are employed for two phases of airborne falling and ground contact. A switching controller selects the adequate controller according to the situation. The effectiveness of the proposed approach is demonstrated through simulations and actual implementation.

2 RELATED WORK

IHop [6] developed by the Flow Control and Coordinated Robotics Labs, UCSD uses an interesting approach, similar to our proposed technique to balance a hopping robot. IHop demonstrated that it is possible to use the wheels as reaction wheels to alter the movement of the center of mass of the robot to achieve dynamic balancing. However in the case of IHop, dynamic balancing of the robot is demonstrated only on flat ground. Experiment on traversing through steps was not demonstrated. Kikuchi et al [7] proposed using vibration of a 2-DOF system as a hopping mechanism for the robot. The robot uses a moving mass and potential energy stored in springs to achieve soft landing through a vertical step. However, the robot presented is statically stable and exhibits drawbacks that were discussed earlier.

3 DYNAMIC MODEL

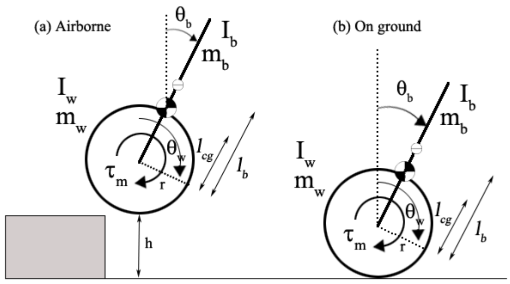

Fig. 1: The schematic of two wheeled robot

In this section, the dynamics of the robot is presented. To simplify the problem, a few assumptions are made. First, it is assumed that the orientation of the robot in roll direction remains constant during flight and hence attitude control in roll direction is negligible. Under this assumption, the problem can be simplified into a two dimensional pendulum problem. Second, the moment of inertia of the wheels is sufficiently large in order to be able to act as a reaction wheel to alter the momentum of the robot. This assumption ensures that the system is controllable without introducing additional actuating mechanism. Mathematical models of the robot during ground contact and airborne phases are derived according to the schematic shown in Fig.1 corresponded to the parameters in Table 1. On ground, the robot behaves just like an ordinary two wheeled pendulum robot whereas during airborne phase, the robot behaves like a reaction wheel pendulum with the pivot point on the center of mass of the robot. Due to large available literatures on derivation of the dynamic models of two wheeled pendulum and reaction wheel pendulum [8][9][10], detailed step-by-step derivation of the mathematical model is omitted.

Table 1: List of symbols

m_b	Mass of body
m_w	Mass of wheels
I_b	Inertia of body around center of mass
I_w	Inertia of wheels around center of mass
r	Wheel radius
l_b	Length of wheel axis to body's center of mass
l_{cg}	Length of wheel axis to robot's center of mass
g	Gravity
θ_b	Tilt angle of robot body
θ_w	Rotational angle of wheels
τ_m	Motor Torque

3.1 On ground

Using Lagrangian mechanics the equation of motion of the robot traveling on ground can be easily obtained [10]. The equations of motions are then linearized and put into the form of state-space representation for controller design as described in the next section,

$$\dot{x}_g = F(x, u) = A_g x_g + B_g u \tag{1}$$

where $x_g = \begin{bmatrix} x_{g1} & x_{g2} & x_{g3} & x_{g4} \end{bmatrix}^{\mathrm{T}}$ is the state vector and u is the scalar motor torque input. By choosing $x_{g1} = \theta_w$, $x_{g2} = \dot{\theta}_w$, $x_{g3} = \theta_b$, $x_{g4} = \dot{\theta}_b$, and $u = \tau_m$, we obtain

$$A_g = \begin{bmatrix} 0 & 1 & 0 & 0 \\ 0 & 0 & a_{g23} & 0 \\ 0 & 0 & 0 & a_{g34} \\ 0 & 0 & a_{g43} & 0 \end{bmatrix}, \quad B_g = \begin{bmatrix} 0 \\ b_{g2} \\ 0 \\ b_{g4} \end{bmatrix} \tag{2}$$

The values of a_{g23}, a_{g34}, a_{g43}, b_{g2} and b_{g4} are specific to actual robot configuration [10].

3.2 Airborne

Similarly, using Lagrangian mechanics, the equations of motions of the robot during airborne can be derived, linearized and put into state space form as shown below,

$$A_a = \begin{bmatrix} 0 & 1 & 0 \\ a_{a21} & 0 & 0 \\ 0 & 0 & 0 \end{bmatrix}, \quad B_a = \begin{bmatrix} 0 \\ b_{a2} \\ b_{a3} \end{bmatrix} \tag{3}$$

Here, only three of four available states are used to describe the motion of the robot, namely θ_b, $\dot{\theta}_b$ and $\dot{\theta}_w$. The rotational angle of the wheel are not controlled during airborne phase and hence not included into the motion model. Note that in the case of airborne, unlike conventional reaction wheel pendulum where the pivot lies on the base of the pendulum, the pivot point actually lies on the center of mass of the robot.

4 CONTROL

The control of the robot is divided into two phases. When the robot is moving on the ground, a linear quadratic(LQ) controller designed around equation (2) is employed. The feedback control torque τ_m is given by

$$\tau_{gm} = -K_g x_g + k_{g1}\theta_{wref} \tag{4}$$

where $K_g = [\ k_{g1} \quad k_{g2} \quad k_{g3} \quad k_{g4}\ ]$ is the feedback gain obtained from the LQ controller and θ_{wref} is the reference value for controlling the rotational angle of the wheel and hence the horizontal position of the robot.

When the robot falls off a step, a different LQ controller designed based on equation (3) is employed to control the attitude of the robot. The feedback control torque in this case can be written as

$$\tau_{am} = k_{a1}(\theta_{bref} - \theta_b) - k_{a2}\dot{\theta}_b - k_{a3}\dot{\theta}_w \tag{5}$$

where k_{a1}, k_{a2} and k_{a3} are feedback gains computed from LQ controller. θ_{bref} is the reference body tilt angle during airborne.

Additionally, a simple switching controller is used to select appropriate controller depending on the height of the robot above ground.

$$\tau_m = \begin{cases} \tau_{gm} & \text{for} \quad |h| \leqq h_{threshold} \\ \tau_{am} & \text{for} \quad |h| > h_{threshold} \end{cases} \tag{6}$$

where h is the height of the robot above ground and $h_{threshold}$ is the height threshold value determined experimentally.

5 SIMULATION RESULTS

Before building an actual experimental platform, computer simulation is carried out to test the viability of the proposed idea. Based on our assumptions made in section 3, our problem is simplified into a 2 dimensional problem and hence in simulating the problem, a 2 dimensional simulator, Box2D [11] physics engine is used. The simulation results show that

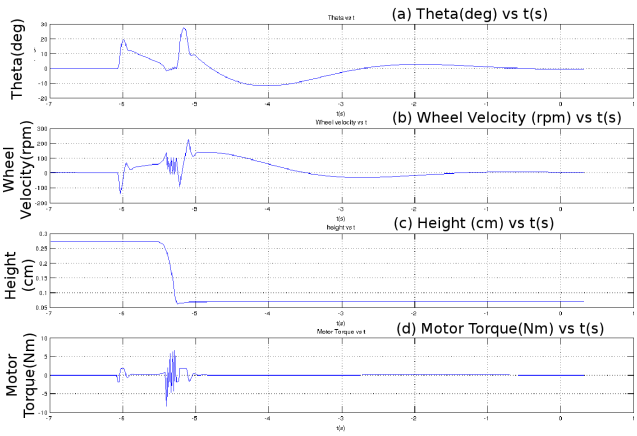

Fig. 2: Simulation results: freefall using attitude control

the robot is able to land and remain upright from a fall height of 0.25 meters. By actively controlling the rotation of the wheel, it is possible to generate sufficient torque to alter the angle of tilt of the robot body to ensure safe landing. However in this simulation, issues on motor torque limit versus motor size were not taken into consideration and hence simulation results might be biased.

6 EXPERIMENTAL PLATFORM

In addition to simulation results, an experimental two wheeled mobile robot platform (Fig.3) is constructed to evaluate the validity of the controllers. The robot is equipped with an inertia measurement unit (IMU) consists of a 3-axis accelerometer and a 2-axis gyroscope and a DC motor with encoder. Kalman filter is used to estimate the angle of tilt and angular velocity of the body. As for calculating the angular velocity of the wheel, instead of direct differentiating the measurements of encoder to obtain the angular velocity, an alpha-beta filter is used for estimation. This is due to the fact that direct

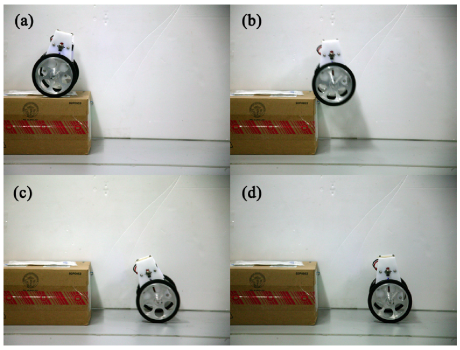

Fig. 3: Free fall of a 2 wheeled pendulum robot

differentiation of encoder measurements will introduce additional noises from non-linearities such as gear backlash. The alpha-beta filter is a simplified kalman filter with constant update gains. Values of α and β are experimentally chosen. An ultrasonic distance sensor is fitted onto the bottom of the robot to measure the height of the robot above ground. All the sensor information is measured and processed using a 32-bit ARM microcontroller running at a clock speed of 96MHz.

7 EXPERIMENT AND DISCUSSIONS

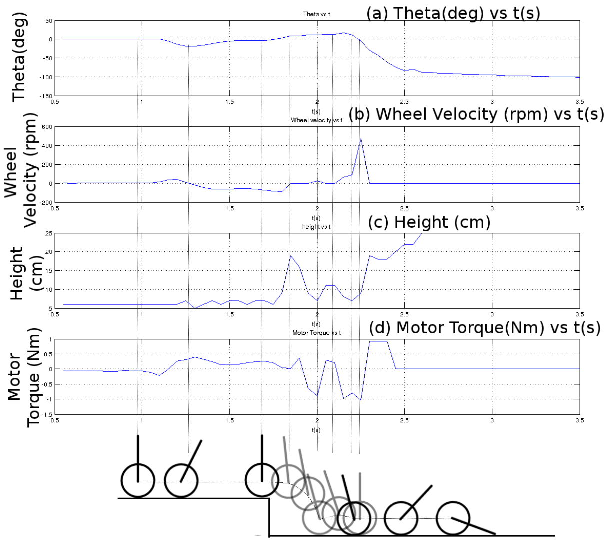

Fig. 4: Free fall using conventional feedback control

In our experiment, the robot is commanded to fall from a 20cm step (roughly same height as the robot). Figure 4 shows the experiment results of the free fall dynamics of the 2 wheel pendulum robot using conventional feedback controller. During free fall, the robot lost contact with the ground and is unable to generate balancing torque. This triggers the feedback controller to increase the feedback signal and spins the wheel faster. On landing with fast spinning wheels, large torque is applied on the robot and causes it to loose balance and fall. We have also experiment with turning off the motor

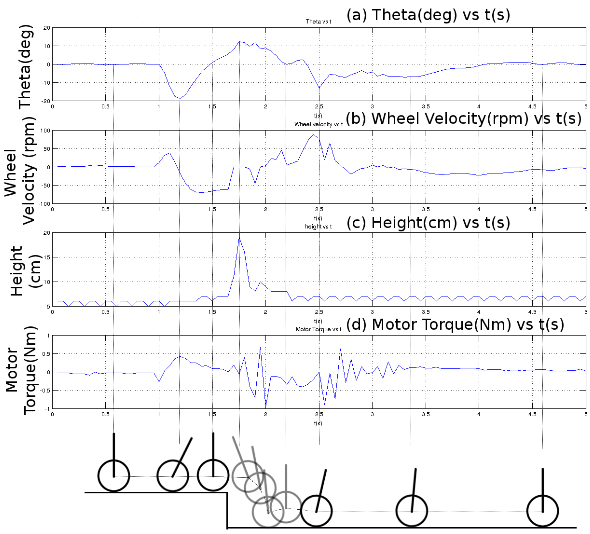

Fig. 5: Free fall with attitude control

during airborne. However, forward momentum from the fall is too large and the robot failed to recover. Figure 5 shows the experiment results of our proposed method. During the fall, the robot tilts backward in order to cope with the forward momentum during landing. Tilting control is achieved by spinning the wheels. Upon landing forward momentum neutralizes the tilt and brings the robot straight up. On-ground feedback controller take over and ensures the robot remains balance. The process of safe landing from a fall is illustrated in Fig.5.

8 CONCLUSION

In this paper we presented a unique solution enabling 2 wheeled pendulum robots to traverse down a non-continuous ground. During free fall, the 2 wheeled pendulum robot acts like a reaction wheel pendulum with pivot point at the center of mass. Hence, by actively controlling the spin of the wheels, it is possible to generate attitude controlling torque to ensure a safe landing. On ground and airborne dynamic models are presented along with two feedback controllers designed accordingly. The idea is simulated before an actual experimental platform is built. The experiment results show that the proposed method is viable and extends the maneuvering ability of 2 wheeled robots. Currently the airborne tilt angle are chosen experimentally. Future work will aim to automate airborne tilt angle control, as well as safe landing from increased height.

Abstract: There is growing expectation for a wireless sensor network. A wireless sensor network has great potential as a means of realizing a wide range of applications, such as natural environmental monitoring and environmental control in residential spaces or plants. To facilitate a ubiquitous environment by a wireless sensor network, however, its control mechanism should be adapted to the variety of types of communication, i.e., one-to-one, one-to-many, many-to-one, and many-to-many, depending on application requirements and the context. This paper proposes a new adaptive communication protocol for the long-term operation of such a ubiquitous sensor network. We evaluate the proposed protocol using computer simulation experiments and discuss its development potential.

Keywords: Sensor Networks, Ubiquitous Environments, Adaptive Communication Protocol.

1 INTRODUCTION

Various network services have been provided. They include inter-vehicle communication, which is a network service in intelligent transport systems, environmental monitoring and control, and ad-hoc communication between mobile nodes in such emergent situations as disasters. As a means of realizing the above network services, autonomous decentralized networks, such as a mobile ad-hoc network, a wireless sensor network, and a mesh network, have been intensively researched with great interests. Especially, a wireless sensor network, which is a key network to facilitate ubiquitous information environments, has great potential as a means of realizing a wide range of applications, such as natural environmental monitoring, health monitoring, environmental control in residential spaces or plants, object tracking, and precision agriculture[1-4].

In a general wireless sensor network, hundreds or thousands of static micro sensor nodes, which are compact and inexpensive, are placed in a large scale observation area, and sensing data from each node is gathered to a sink node by inter-node wireless multi-hop communication. Each sensor node consists of a sensing function to measure the status (temperature, humidity, motion, etc.) of an observation point or object around it, a limited function of information processing, and a simplified wireless communication function, and it generally operates on a resource with a limited power supply capacity such as a battery. Therefore, a data gathering scheme capable of meeting the following two requirements is mainly needed to prolong the network lifetime.

(1) Efficiency of data gathering
(2) Balance of communication load among sensor nodes

As data gathering schemes for the long-term operation of a wireless sensor network, clustering-based data gathering[5,6], synchronization-based data gathering[7,8], gradient-based data gathering[9], and bio-inspired data gathering[10,11] are under study, but not all the above requirements are sufficiently satisfied. In a wireless sensor network, the communication load is generally concentrated on sensor nodes around a sink node during the operation process. In cases where sensor nodes are not placed evenly in an observation area, the communication load is concentrated on sensor nodes placed in an area of low node density. The above data gathering schemes[5-11] do not positively ease the communication load concentration to sensor nodes around a sink node, which is the source of problems in the long-term operation of a wireless sensor network. Intensive data transmission to specific nodes, such as sensor nodes around a sink node and sensor nodes placed in an area of low node density, results in concentrated energy consumption by them, and causes them to break away from the network early. This makes long-term observation by a wireless sensor network difficult. To solve this communication load concentration problem, data gathering schemes for a wireless sensor network with multiple sink nodes have been proposed[12,13]. In comparison with the case of a one-sink wireless sensor network, the communication load of sensor nodes around a sink node can be reduced. Especially, the scheme in Utani et al.[13] can actualize autonomous load-balancing data transmission to multiple sink nodes and can sufficiently reduces the load of load-concentrated sensor nodes. This balances the load of nodes autonomously.

To facilitate a ubiquitous environment by a wireless sensor network, however, its control mechanism should be adapted to the variety of types of communication, i.e., one-to-one, one-to-many, many-to-one, and many-to-many, depending on application requirements and the context. This paper proposes a new adaptive communication protocol for the long-term operation of such a ubiquitous sensor network. We evaluate the proposed protocol using computer simulation experiments and discuss its development potential. In simulation experiments performed, the effectiveness of the proposed protocol is investigated in detail. The rest of this paper is organized as follows. In Section 2, the existing representative protocol for adaptive communication in a wireless sensor network is outlined. In Section 3, the proposed protocol is described. In Section 4, the experimental results are reported, and the effectiveness of the proposed protocol is demonstrated by comparing its performances with those of existing protocols. Finally, we give our conclusions and ideas for further study in Section 5.

2 DIRECTED DIFFUSION

Recently, a few adaptive wireless sensor network protocols to facilitate ubiquitous information environments, which are directed diffusion[14] and rendezvous-based communication protocols[15,16] have been proposed. This paper focuses on directed diffusion that is a most representative protocol for adaptive communication in a wireless sensor network and applicable to various requirements from many sensor nodes constructing a network. The purpose of directed diffusion is to establish efficient *n*-way communication between one or more sink nodes and source nodes. Directed diffusion, which is also a data centric communication protocol, consists of the following protocol family,

(1) Two-phase pull diffusion and one-phase pull diffusion

(2) Push diffusion

where the above protocol family in directed diffusion are introduced by considering the types of communication.

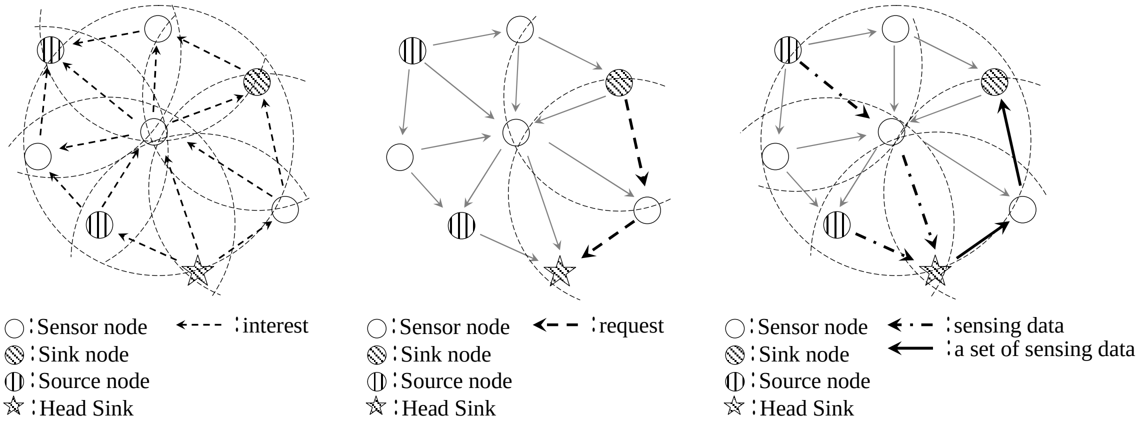
In two-phase pull diffusion and one-phase pull diffusion, each sink node firstly broadcasts a message (a query) which specifies what it wants throughout the network, and afterward it gathers sensing data from each source node capable of meeting its query. In push diffusion, on the other hand each source node firstly broadcasts a message which specifies what it has measure and can provide throughout the network, and afterward it transmits sensing data to each sink node that wants sensor information included in its message. Pull types, which are two-phase pull diffusion and one-phase pull diffusion, adapt themselves to cases where the number of source nodes is more than the number of sink nodes, and push diffusion adapts itself to their contrary cases. In cases where communication between sink nodes and source nodes dynamically changes, therefore, it is difficult to use directed diffusion effectively. Directed diffusion includes the following problems.

1. Since flooding is frequently used for disseminating messages (or queries), each sensor node is loaded with loads of energy consumption.
2. Since the function for autonomously selecting the effective protocol from the above protocol family according to the situations of communication is not arranged, directed diffusion can not always achieve efficient communication in changing communication environments.
3. The communication load of each sensor node is not sufficiently balanced

3 PROPOSED PROTOCOL

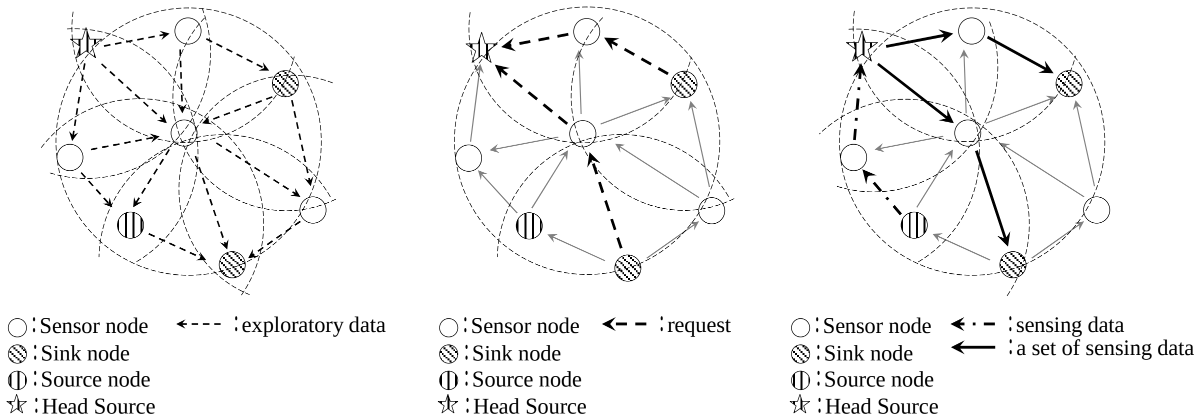
The proposed protocol, which is an adaptive communication protocol for a ubiquitous sensor network, is devised for improving the above-mentioned problems included in directed diffusion. In the proposed protocol, the first node that disseminated a query in sink nodes, called *head sink*, functions for efficient data gathering, and the first node that disseminated a message, the contents of which is outlined in section 2, in source nodes, called *head source*, functions for efficient data providing in the same way. In addition, the mechanism of autonomous load-balancing communication[13] is introduced in the proposed protocol. By realizing efficient and load-balancing communication between sink nodes and source nodes, the proposed protocol can prolong the lifetime of a ubiquitous sensor network.

The proposed protocol is composed of two protocol family: sink-oriented communication protocol and source-oriented communication protocol. In the proposed protocol, each node has a connective value named *value to self*, which is not updated by transmitting and/or receiving messages or sensing data, and this is used for autonomous load-balancing communication between sink nodes and source nodes, where parts on autonomous load-balancing communication in the proposed protocol is outlined in the following subsections. The mechanism is detailed in Utani et al.[13].



1) Interest propagation 2) Request transmission 3) Data delivery

Fig.1. Flow of communication based on sink-oriented communication protocol.



1) Exploratory data propagation 2) Request transmission 3) Data delivery

Fig.2. Flow of communication based on source-oriented communication protocol.

3.1. Sink-Oriented Communication Protocol

The flow of communication based on sink-oriented communication protocol consists of the following steps. In **Fig.1**, the communication flow is illustrated.

1) A sink node broadcasts a message (a query) which includes what it wants named *interest* and its own *value to self* throughout the network with hop counts updated, where this node, which is the first sink node that broadcast a query in sink nodes, becomes the head sink. Each node that repeatedly receives this message stores the connective values computed from *value to self*, "hop counts" and "residual energy" in the matching neighborhood node fields of its own routing table. In each node, the connective values updated by "residual energy" are used as the only index to evaluate the relay destination value of each neighborhood node.
2) Each sink node, which wants to gather the same sensing data (sensor information) as what the head sink wants, transmits a message named *request* to the head sink according to the above connective values which are the only route information. Therefore, the path between the head sink and each sink node is constructed.
3) Each source node, which has measure and can provide sensing data (sensor information) specified in *interest* that is propagated by the head sink, transmits sensing data to the head sink according to the above connective values, and then the head sink transmits a set of data consisting of sensing data gathered from source nodes to each sink node along the constructed path.

3.2 Source-Oriented Communication Protocol

Next, the flow of communication based on source-oriented communication protocol is described. In **Fig.2**, the communication flow is similarly illustrated.

1) A source node broadcasts a message which includes what it has measure and can provide named *exploratory data* and its own *value to self* throughout the network with hop counts updated, where this node, which is the first source node that broadcast a message in source

nodes, becomes the head source. Each node that repeatedly receives this message stores the connective values computed from *value to self*, "hop counts" and "residual energy" in the matching neighborhood node fields of its own routing table. As in the above-mentioned sink-oriented communication protocol, the connective values updated by "residual energy" are used as the only index to evaluate the relay destination value of each neighborhood node in each node.

2) Each sink node, which wants to gather sensing data (sensor information) specified in *exploratory data* that is propagated by the head source, transmits a message named *request* to the head source according to the above connective values which are the only route information. As in step 2) of sink-oriented communication protocol, therefore, the path between the head source and each sink node is constructed.

3) Each source node, which has measure the same sensing data (sensor information) as what the head source can provide, transmits sensing data to the head source according to the above connective values, and then the head source transmits a set of data consisting of its own sensing data and sensing data transmitted from the other source nodes to each sink node along the constructed path.

4 SIMULATION EXPERIMENT

Through simulation experiments on a large scale and dense ubiquitous sensor network, the performance of the proposed protocol, i.e., the adaptability of the proposed protocol in a changing communication environment, is investigated in detail to verify its effectiveness.

4.1. Conditions of Simulation

A ubiquitous sensor network composed of many static sensor nodes with global positioning system placed in a large scale square field was assumed. The conditions of the simulation which were used in the experiments performed are shown in **Table1**, where a thousand static sensor nodes were randomly arranged in the set simulation area as in **Fig.3**. The *value to self* of each node and the connective value attenuation factor accompanying hop[13] for autonomous load-balancing communication were set to 100.0 and 0.5 from a preliminary investigation, respectively. As in Intanagonwiwat et al.[14], messages which include *interest* were modeled as 36-byte packets, and messages which include *exploratory data* as 64-byte packets, where the size of sensing data of each node was set to 10 byte. The battery capacity of each node was modeled as 0.5J, and energy consumption was computed as in Heinzelman et al.[17]. In the following experimental results reported, the proposed protocol is evaluated through a comparison with "one-phase pull diffusion" and "push diffusion" in directed diffusion.

Table1. Conditions of simulation.

Simulation size	2,400[m]×2,400[m]
Operation time	1,000[s]
Number of sensor nodes	1,000
Range of ratio wave	150[m]
Value to self of each node	100.0
Connective value attenuation factor	0.5
Interest message	36-byte packet
Exploratory data message	64-byte packet
Size of sensing data	10[bytes]
Battery capacity of each node	0.5[J]

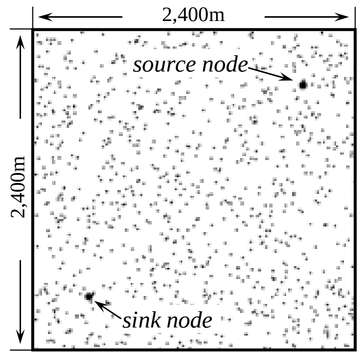


Fig.3. Arrangement of sensor nodes in the set simulation area.

4.2. Experimental Results

In the first experiment, it was assumed that the sink node marked in **Fig.3** transmitted the data packet with sensing data measured to the source node similarly marked in **Fig.3**, where the data packets were periodically transmitted every 10sec and the network operation duration was 1,000sec. The routes used by applying the proposed protocol are shown in **Fig.4**. Of the 100 data packets transmitted from the sink node, the routes used by the first 25 data packets are illustrated in **Fig.4**(1), those used by the 50 data packets are in **Fig.4**(2), and those used by a total of 100 data packets are in **Fig.4**(3). **Fig.4** indicates that the proposed protocol enables the autonomous load-balancing transmission of data packets using multiple routes. By this autonomous load-balancing communication, to prolong the network lifetime can be expected.

Next, the sustainability of the proposed protocol was evaluated in a changing communication environment. Here, it was assumed as a changing communication environment that sinks to sources was periodically transformed from *one-to-one* to *one-to-ten*, from *one-to-ten* to *ten-to-one*, and from *ten-to-one* to *ten-to-ten* every 250sec, where all sink nodes and all source nodes were randomly selected from a total of 1,000 nodes shown in **Fig.3**. In the same way as in the above experiment, all data packets were periodically transmitted every 10sec and the operation duration was 1,000sec. In **Figs.5** and **6**, the transition of total energy consumption of all nodes arranged in the set simulation area is shown, and total energy consumption in applying the proposed protocol is compared with it in directed diffusion. From **Figs.5** and **6**, it can be confirmed that the proposed protocol always realizes efficient communication between one or more sink nodes and source nodes accompanying the variety of types of communication. In **Figs.7** and **8**, the transition of the average data delivery ratio of fifty trials is shown, and the network lifetime in a changing communication environment is compared. From **Figs.7** and **8**, it can be confirmed that the proposed protocol achieves a longer-term operation of a ubiquitous sensor network than directed diffusion because it improves and balances the load of each node by the communication load reduction for network control and data gathering, and the load-balancing communication. Through simulation experiments, it was verified that the proposed protocol is substantially advantageous for the long-term operation of an ubiquitous sensor network.

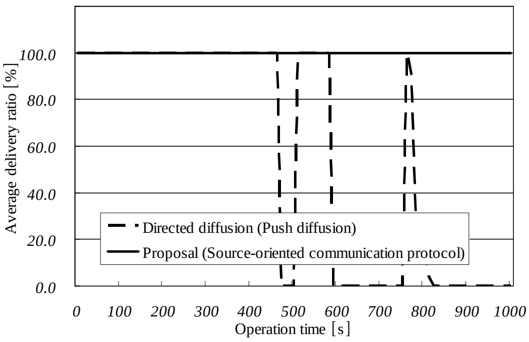

Fig.8. Transition of average data delivery ratio (Source-oriented protocol).

5. CONCLUSIONS

In this paper, a new adaptive communication protocol for a wireless sensor network, which adapts itself to the variety of types of communication, has been proposed. The proposed protocol can improve several problems in directed diffusion, which is the existing representative protocol for adaptive communication in a wireless sensor network. In simulation experiments performed, the performances of the proposed protocol were compared with those of directed diffusion. The experimental results indicate that the proposed protocol is superior to directed diffusion from the viewpoint of the long-term operation of a ubiquitous wireless sensor network, and has the development potential as a promising one. Future work includes a detailed evaluation of the adaptability of the proposed protocol in dramatically changing communication environments.

Abstract: Wireless sensor networks have great potential as a means of realizing a wide range of applications, such as natural environmental monitoring, environmental control in residential spaces or plants, and object tracking. As a frame to actualize these sensor applications, this study assumes a monitoring-oriented wireless sensor network, which periodically gathers their sensing data from all sensors placed in a service area. This paper proposes an autonomous decentralized control scheme with data aggregation technique to prolong the lifetime of monitoring-oriented wireless sensor networks. This is a novel scheme devised by considering the application environment of a wireless sensor network as a typical example of a complex system where the adaptive adjustment of the entire system is realized from the local interactions of components of the system. We evaluate our scheme using simulation experiments, and also discuss its development potential.

Keywords: Monitoring, Wireless sensor networks, Multiple sinks, Autonomous decentralized control, Data aggregation.

1 INTRODUCTION

Various communication services are currently considered. They include environmental monitoring or control by static sensors, ad-hoc communication between mobile nodes, and inter-vehicle communication in intelligent transport systems. As a means of facilitating these advanced communication services, autonomous decentralized networks, such as wireless sensor networks [1,2], mobile adhoc networks [3-6], and wireless LAN mesh networks [7], have been intensively studied with great interests. Especially, a wireless sensor network, which is a key network to construct ubiquitous information environments, has great potential as a means of realizing a wide range of applications, such as natural environmental monitoring, environmental control in residential spaces or plants, object tracking. Recently, there is growing expectation for a new network service by a novel wireless sensor network consisting of a lot of static sensors arranged in a service area and a few mobile robots as a result of the strong desire for the development of advanced systems that can flexibly function in dynamically changing environments [8].

As a frame to actualize the above-mentioned sensor applications, this study assumes a monitoring-oriented wireless sensor networks composed of many static sensors with global positioning system, which periodically gathers their sensing data from all sensors placed in a service area. In a general monitoring-oriented wireless sensor network, hundreds or thousands of sensors with limited resources, which are compact and inexpensive, are placed in a large scale service area, and the sensing data from each node is gathered to a sink node by inter-node wireless multi-hop communication. Each sensor node consists of a sensing function to measure the status of an observation point or object, a limited function of information processing and a simplified wireless communication function, and it generally operates on a resource with a limited power-supply capacity such as a battery. Therefore, a data gathering scheme and/or a routing protocol capable of meeting the following requirements is needed to prolong the lifetime of wireless sensor networks made up of hundreds or thousands of sensors with limited resources.

1. Efficiency of data gathering
2. Balance of communication load among sensor nodes
3. Adaptability to network topology changes

For the long-term operation of wireless sensor networks, clustering-based schemes [9,10], gradient-based routing protocol [11] and synchronization-based schemes [12-14] are under study, but not all the above requirements are sufficiently satisfied. Recently, bio-inspired routing algorithms, such as ant-based routing algorithms, have attracted a significant amount of interest from plural researchers. In ant-based routing algorithms [15,16], the routing table of each sensor node is updated by applying the process in which ants build routes between their nest and food by chemical substances (pheromones). The advanced ant-based routing algorithm proposed as an example that satisfies the three requirements above is an efficient route-learning algorithm which shares route information between ants (control messages) [17]. In contrast to conventional ant-based routing algorithms, this can suppress the communication load of each sensor node and adapt itself to network topology changes. However, this does not positively ease the communication load concentration on specific sensors, which is the source of problems in the long-term operation of sensor networks. Intensive data transmission to specific sensors results in concentrated energy consumption by them, and causes them to break away from the sensor network early. This makes long-term observation by a wireless sensor network difficult.

In wireless sensor networks, the communication load is concentrated on sensors around a sink node during the operation process. In cases where sensors are not evenly placed in a service area, the communication load is concentrated on sensor nodes placed in a range of low node density. To solve this communication load concentration problem, recent approaches have been to introduce multiple sinks in a wireless sensor network [18,19]. In the fundamental scheme [18], each sensor node sends the sensing data to the nearest sink node. In comparison with the case of one-sink wireless sensor networks, the communication load of sensors around a sink node is reduced. In each sensor node, however, the destination sink node cannot be selected autonomously and adaptively. Therefore, the load of load-concentrated nodes is not sufficiently balanced. The pheromone-oriented routing protocol, which belongs to the category of ant-based routing algorithms, achieves autonomous load-balancing data transmission to multiple sinks, but requires the periodical update of routing table of each sensor node by ants (control messages) dispersed in a wireless sensor network [19]. In monitoring-oriented wireless sensor networks, the nearest sink data transmission scheme in [18] achieves a longer-term operation of the network than the pheromone-oriented routing protocol in [19].

In the previous study [20], we devised a novel autonomous decentralized control scheme and evaluated its fundamental performance through simulation experiments. This scheme needs no special communication for network control, but enables autonomous load-balancing data transmission to multiple sinks. The load of each sensor node is autonomously balanced. In monitoring-oriented wireless sensor networks, however, the efficiency of data gathering should be improved. In this paper, we propose an autonomous decentralized control scheme with data aggregation technique for the long-term of monitoring-oriented wireless sensor networks, and evaluate the proposed scheme using simulation experiments in detail. The rest of this paper is organized as follows. First, in Sec.2, the proposed scheme is detailed, and its novelty and superiority are described. In Sec.3, the experimental results are reported in detail, and the effectiveness of the proposed scheme is demonstrated by comparing its performances with those of the existing scheme. Finally, we give the overall conclusion and future problem of this study in Sec.4.

2 PROPOSED SCHEME

To facilitate the long-term operation of an actual sensor network service, recent approaches have been to introduce multiple sinks in a wireless sensor network. In wireless sensor networks with multiple sinks, the sensing data of each node is generally allowed to gather at any of the available sinks. The proposed scheme devised by considering the application environment of a wireless sensor network as a typical example of a complex system where the adaptive adjustment of the entire system is realized from the local interactions of components of the system is a novel data gathering scheme based on this assumption, which can be expected to produce a remarkable effect in monitoring-oriented wireless sensor networks with multiple sinks.

2.1 Construction of a data gathering environment

Each sink node has a connective value named a "value to self", which is not updated by transmitting a control packet and receiving data packets. In the initial state of monitoring-oriented wireless sensor network with multiple sinks, each sink node broadcasts a control packet containing its own ID and "value to self", and hop counts ($=0$). This control packet is rebroadcast throughout the sensor network with hop counts updated. By receiving the control packet from each sink node, each sensor node can grasp the "value to self" of each sink node, and the IDs and the hop counts from each sink node of its own neighboring nodes.

Initial connective value of each sensor node, which is the connective value before starting data transmission, is generated by using the "value to self" of each sink node and the hop counts from each sink node. The procedure for computing initial connective value of a node (i) is as follows:

1. The value [$v_{ij}(0)$] on each sink node ($j = 1, \dots, S$) of node (i) is first computed according to the following equation

$$v_{ij}(0) = vo_j \times dr^{hops_{ij}} \qquad (j = 1,\dots,S) \tag{1}$$

   where vo_j ($j = 1, \dots, S$) is the "value to self" of sink node (j), $hops_{ij}$ is the hop counts from sink node (j) of node (i). dr represents the value attenuation factor accompanying the hop determined within the interval [0,1].

2. Then, the initial connective value $[v_i(0)]$ of node (i) is generated as follows

$$v_i(0) = \max v_{ij}(0) \qquad (j = 1, \ldots, S) \tag{2}$$

where this connective value $[v_i(0)]$ can be also conducted from the following equation

$$v_i(0) = vm_i(0) \times dr \tag{3}$$

In(3), $vm_i(0)$ represents the greatest connective value before starting data transmission in the neighborhood nodes of node (i).

Before starting data transmission, each sensor node computes the initial connective value of each neighborhood node according to the above (1) and (2), and stores the computed connective value, which is used as the only index to evaluate the relay destination value of each neighboring node, in each neighborhood node field of its own routing table. Therefore, the routing table of each sensor node, which is made up of the IDs and initial connective values before starting data transmission to neighboring nodes, is constructed.

2.2 Data transmission and connective value update

For data transmission, each sensor node selects the neighboring node with the greatest connective value from its own routing table as a relay node, and transmits the data packet to this selected node. In cases where more than one node shares the greatest connective value, however, the relay node is determined between them at random. The data packet in each sensor node is not sent to a specified sink node. By repetitive data transmission to the neighboring node with the greatest connective value, data gathering at any of the available sinks is completed. In the proposed scheme, the connective value of each sensor node is updated by considering residual node energy. Therefore, by repetitive data transmission to the neighboring node with the greatest connective value, the data transmission routes are not fixed.

To realize autonomous load-balancing data transmission, the data packet from each sensor node includes its own updated connective value. Here, we assume that a node (l) receives a data packet at time (t). Before node (l) relays the packet, it replaces the value in the connective value field of the data packet by its own renewal connective value computed according to the following connective value update equation

$$v_l(t) = vm_l(t) \times dr \times {e_l(t)}/{E_l} \tag{4}$$

where $vm_l(t)$ is the greatest connective value at time (t) in the routing table of node (l), and $e_l(t)$ and E_l represent the residual energy at time (t) of node (l) and the battery capacity of node (l), respectively.

In our scheme, the data packet addressed to the neighboring node with the greatest connective value is intercepted by all neighboring nodes. This packet includes the updated connective value of the source node based on (4). Each neighborhood node that intercepts this packet stores the updated connective value in the source node field of its own routing table. **Fig.1** shows an example of data packet transmission and its accompanying connective value update. In this example, node (l) refers to its own routing table and addresses the data packet to node (r), which has the greatest connective value $[vm_l(t)]$. When this data packet is intercepted, each neighboring node around node (l) stores the updated connective value $[v_l(t)]$ included in the data packet in the node (l) field of its own routing table.

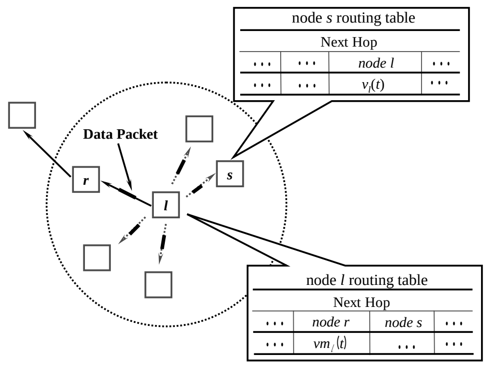

Fig.1. Data transmission and connective value update

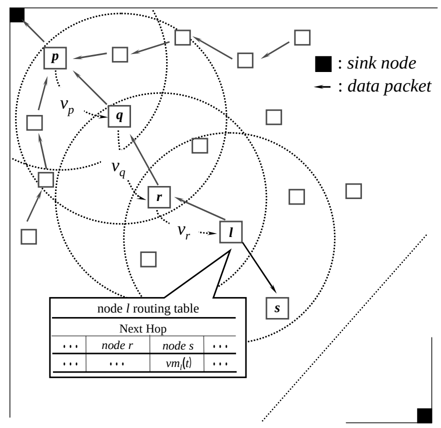

Fig.2. Autonomous load-balancing data transmission to multiple sinks

The proposed scheme requires the construction of a data gathering environment in the initial state of wireless sensor networks with multiple sinks, but needs no special communication for network control. The above-mentioned simple mechanism alone achieves autonomously adaptive load-balancing data transmission to multiple sinks, as in **Fig.2.** It can be expected that the lifetime of wireless sensor networks is extended by reducing the communication load for network control and solving the node load concentration problem.

2.3. Autonomous data aggregation technique

To improve the efficiency of data gathering, an autonomous data aggregation technique is newly introduced in our scheme. This data aggregation technique matches our autonomous decentralized control scheme. Generally, data aggregation-based schemes improve the efficiency of data gathering in a wireless sensor network, but some of them facilitate the communication load concentration on specific sensors and/or limited routes [2]. Since our scheme has the mechanism to realize autonomous load-balancing data transmission to multiple sinks using many routes, however, it can be considered that to introduce a data aggregation technique in our autonomous decentralized control scheme is effective.

The data aggregation to improve the efficiency of data gathering is autonomously actualized without special communication in the operation process of a wireless sensor network. In our data aggregation technique, the node that first transmits the original data packet or the data packet from the other sensor node to the neighboring node with the greatest connective value in the node itself and its own neighboring nodes becomes a data aggregation node called *head node*, and functions for efficient data gathering. Here, the neighboring node that intercepts the data packet from a head node becomes the member of the head node in cases where it is not the member of any of the other head nodes, and the connective value of the head node is greater than its own connective value. When the node that is the member of a head node transmits the data packet to any of its own neighboring nodes, it addresses the data packet to the head node. **Fig.3** shows an example of efficient data gathering by our data aggregation technique. In **Fig.3**, node (l) and node (r) are head nodes, and node (s) is the member of head node (l). In this example, node (l) transmits the data aggregation packet containing the sensing data from each member to the node (r) with the greatest connective value in its own neighboring nodes.

In addition, the function to ease the continuous communication load concentration to head nodes is introduced in our data aggregation technique. The node that is the member of a head node breaks away from the member when the connective value of the head node became less than its own connective value in the network operation process, and it becomes a new head node, and newly functions for efficient data gathering in cases where the other head node, the connective value of which is greater than its own connective value, does not exist in its own neighboring nodes. On the other hand, it becomes the member of the other head node with the greatest connective value in cases where the other head nodes, the connective values of which are greater than its own connective value, exist in its own neighboring nodes. **Fig.4** illustrates an example of this additional function. In **Fig.4**, node (l) and node (r) are head nodes, as in **Fig.3**. In this example, node (s) breaks away from the member of head node (l) because the connective value of head node (l) became less than its own connective value. Here, node (s) becomes a new head node when the connective value of head node (r) is less than its own connective value, as shown in **Fig.4**(a), and becomes the member of node (r) when the connective value of head node (r) is greater than its own connective value, as shown in **Fig.4**(b).

3 SIMULATION EXPERIMENTS

Through simulation experiments on monitoring-oriented wireless sensor networks, the performances of our autonomous decentralized control scheme with data aggregation technique is investigated in detail to verify its effectiveness.

In a large scale and dense wireless sensor network with multiple sinks made up of many static sensors placed in a large scale square field, it is assumed that each sensor node constructing the network transmits the data packet with the measurement data periodically. The conditions of the simulation which were used in the experiments performed are shown in **Table1**. In the initial state of the simulation experiments, many static sensors are randomly arranged in the set experimental area, and two sinks are placed on the corners of this area. An example of the arrangement of sensors in the set experimental area is illustrated in **Fig.6**. In the experiments performed, the value attenuation factor accompanying hop (*dr*) and the "value to self" of each sink node introduced in the proposed scheme were set to 0.5 and 100.0, respectively. The sizes of the control packets were set to 36 bytes and the sizes of the data packets were set to $40+10\times n$ bytes, where the size of sensing data of each node was set to 10 bytes, and n represents the number of sensing data in each data packet. The battery capacity of each sensor node was modeled as 0.5J, and the energy consumption of each sensor node was computed as in [9].

Table 1. Conditions of simulation

Simulation size	*2,400 m × 2,400 m*
Number of sensor nodes	*1,000*
Range of radio wave	*150 m*
Number of sinks	*2*

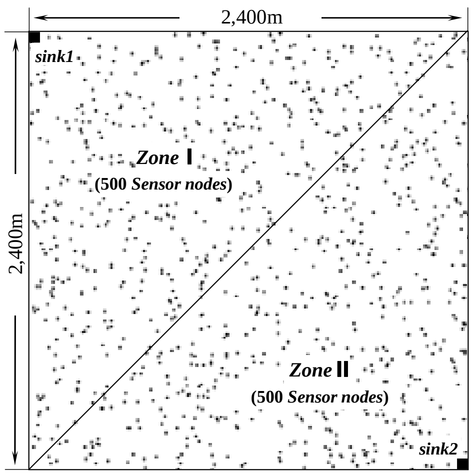

Fig.5. Arrangement of sensors in the set experimental area (Case1)

The proposed scheme is evaluated through a comparison with the existing one [18], which describes representative data gathering for wireless sensor networks with multiple sinks. In the experimental results reported, the scheme in [18] is denoted as "Nearest Sink". First, the experimental results on the arrangement of sensors (Case1) illustrated in **Fig.5** is shown. **Fig.6**(a) and (b) illustrate the routes used by applying Nearest Sink and the proposed scheme, where the bold lines in these figures indicate the routes frequently used. From **Fig.6**, it is confirmed that the proposed scheme can balance and improve the load of each sensor node by the autonomous load-balancing data transmission mechanism and the data aggregation technique newly introduced. **Fig.7** shows the transition of the delivery ratio of the total number of sensing data periodically transmitted from each sensor node. In **Fig.7**, our scheme without data aggregation is denoted as "Proposal A", and our scheme with data aggregation technique is as "Proposal B". From **Fig.7**, it can be confirmed that the proposed scheme achieves a longer-term operation of a monitoring-oriented wireless sensor network than Nearest Sink, and the effect of our scheme is facilitated by the autonomous data aggregation technique newly introduced in this study.

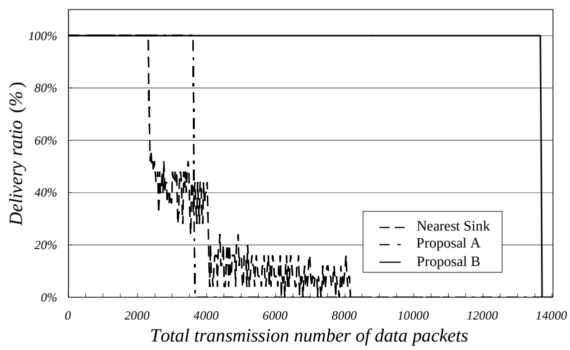

Fig.7. Delivery ratio (Case1)

Next, we assume the cases where sensors are not evenly placed in the set experimental area, as in **Figs.8**(Case2). **Fig.9** shows the transition of the delivery ratio of the total number of sensing data periodically transmitted from each sensor node, as in **Fig.7**. Through the experimental results, it can be also confirmed that our scheme with data aggregation technique is substantially advantageous for the long-term operation of monitoring-oriented wireless sensor networks with multiple sinks.

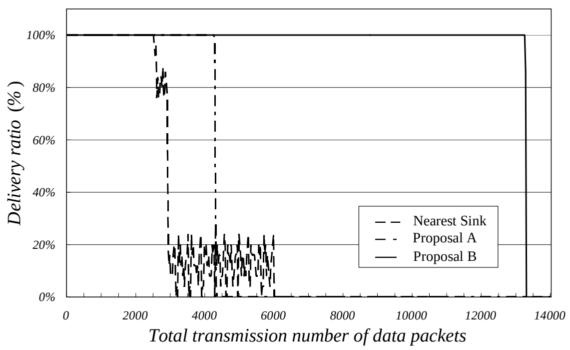

Fig.9. Delivery ratio（Case2）

4 CONCLUSION

In this paper, an autonomous decentralized control scheme with data aggregation technique that adaptively reduces the load of load-concentrated sensors and facilitates the long-term operation of monitoring-oriented wireless sensor networks with multiple sinks has been proposed. This is a novel scheme devised by considering the application environment of a wireless sensor network to be a typical example of a complex system where the adjustment of the entire system is adaptively realized from the local interactions of components of the system. In simulation experiments, the performances of the proposed scheme were compared with those of the existing one. The experimental results indicate that the proposed scheme is superior to the existing one from the viewpoint of the long-term operation of monitoring-oriented wireless sensor networks. Future work includes a detailed evaluation of the proposed scheme in various network environments.

Abstract: This paper presents an ecological vehicle platooning control system that aims in reducing overall fuel consumption of the vehicles in a platoon. A centralized linear quadratic regulator system for controlling the vehicles in the platoon has been developed considering the aerodynamic characteristics of the vehicle and the resistance due to the road slope. The proposed control system is simulated on a highway with up-down slopes for high speed driving. Its fuel saving performance is compared with a conventional decentralized vehicle platooning control system. Computer simulation results reveal the significant improvement in fuel economy by the proposed control system.

Keywords: Aerodynamic characteristics, centralized control, ecological driving, linear quadratic regulator theory, platooning, road shape information.

1 INTRODUCTION

In recent years, global warming and ozone depletion have been gotten widespread international attention. Since the energy consumption of vehicles accounts for a substantial amount of all the energy consumption, it is considered that so-called "eco-driving" by vehicles is important to solve such environmental issues. Eco-driving can be characterized by a fuel-efficient driving style to match various road-traffic situations. The fuel consumption caused by the aerodynamic drag during high speed driving can be reduced by platooning. As shown in Fig.1, a number of vehicles run with short spacing in a line. The aerodynamic drag of each vehicle is reduced owing to the improved airflow profile around the platoon [1]. Therefore, fuel consumption of each vehicle caused by the aerodynamic drag can be reduced. Automated control of the vehicles has been introduced for such platooning. Various conventional methods mainly focused on the platoon formation and achievement of the string stability [2] [3] [4]. On the other hand, automated driving control system for energy saving of two vehicles has been proposed [5]. However, fuel saving by synchronized driving behavior of more vehicles was not considered. To build an ecological vehicle platooning (EVP) control system, it is considered that centralized controller is efficient in synchronizing motion of the vehicles by using driving information of all the vehicles in the platoon.

In this paper, a centralized linear quadratic regulator (LQR) system for the ecological vehicle platooning is proposed to reduce the overall fuel consumption of the vehicles in the platoon. The dynamical model of the platoon including the varying aerodynamic drag coefficient depending on vehicles' spacings and the road shape has been developed. This model is linearized around the target driving situation. The fuel consumption model based on the engine efficiency characteristics is constructed. Computer simulations considering high speed driving on a typical highway with up-down slopes were conducted. The fuel-saving performance of the proposed control system was compared with a conventional decentralized vehicle platooning control system (CVP). Significant improvement in fuel economy by the proposed control system was verified.

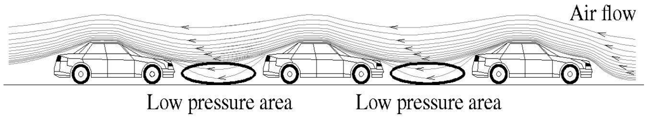

Fig. 1. Air flow profile around a platoon

This paper is structured as follows. In Section 2, control for an ecological vehicle platooning is proposed. In Section 3, computer simulation results demonstrate the effectiveness of the proposed control system. In Section 4, conclusions are discussed.

2 CONTROL METHOD FOR ECOLOGICAL VEHICLE PLATOONING

2.1 Vehicle model

A platoon consisting of three vehicles is shown in Fig.2. Longitudinal movement of a vehicle in the platoon can be

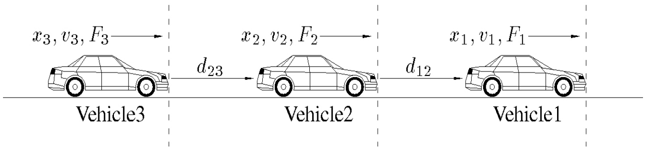

Fig. 2. A platoon consists of three vehicles

represented by the following equations:

$$\begin{aligned}
&\dot{x}_i(t) = v_i(t) \ , \\
&m_i \dot{v}_i(t) = F_i(t) - f_{ai}(t) - f_{gi}(t) - f_{\mu i} \ , \\
&f_{ai}(t) = \frac{1}{2}\rho A_i C_i(d_{12}(t), d_{23}(t)) v_i^2(t) \ , \\
&f_{gi}(t) = m_i g \sin\theta(x_i(t)) \ , \\
&f_{\mu i} = \mu_i m_i g \ , \\
&d_{12}(t) = x_1(t) - x_2(t) - l_1 \ , \\
&d_{23}(t) = x_2(t) - x_3(t) - l_2 \ , \qquad (1)
\end{aligned}$$

where, subscript i is an integer which indicates the i-th vehicle (i=1,2,3) counted from the leading vehicle in the platoon. Parameters ρ, g, m_i, A_i, μ_i, and l_i are the air density, the gravity acceleration, the mass, the projected frontal area, the coefficient of all the other friction resistances, and the length of the i-th vehicle, respectively. Variables x_i, v_i, F_i, d_{12}, and d_{23} are the position, the velocity, the traction force or the brake force of the i-th vehicle, and the spacing between the neighbor vehicles, respectively. Functions f_{ai}, f_{gi}, and $f_{\mu i}$ denote the aerodynamic drag, the grade resistance, and all the other friction resistances of the i-th vehicle, respectively. $C_i(d_{12}, d_{23})$ is the aerodynamic drag coefficient that depends on the spacing. $\theta(x_i)$ is the road gradient that depends on the position of each vehicle. The time delay from input command to the traction force or the brake force is assumed to be represented by the first order lag:

$$\dot{F}_i(t) = -\frac{1}{\tau_i}F_i(t) + \frac{1}{\tau_i}u_i(t) \ , \qquad (2)$$

where, τ_i and u_i are the time delay constant and the control input command of the traction force or the brake force of the i-th vehicle, respectively.

Around the target driving situation, the model of the vehicle' longitudinal equations are linearized. Each deviation of the velocity δv_i, the traction force or the brake force δF_i, the control input δu_i, and the spacings are represented by

$$\begin{aligned}
&\delta v_i(t) = v_i(t) - v^* \ , \\
&\delta F_i(t) = F_i(t) - f_{ai}^* - f_{gi}(t) - f_{\mu i} \ , \\
&\delta u_i(t) = u_i(t) - f_{ai}^* - f_{gi}(t) - f_{\mu i} \ , \\
&\delta d_{12}(t) = d_{12}(t) - d^* \ , \\
&\delta d_{23}(t) = d_{23}(t) - d^* \ , \\
&f_{ai}^* = \frac{1}{2}\rho A_i C_i(d^*, d^*) v^{*2} \ , \qquad (3)
\end{aligned}$$

where, v^* and d^* are the target velocity and the target spacing. A state equation used in the centralized LQR control system is represented as

$$\begin{aligned}
&\dot{x}(t) = Ax(t) + Bu(t) \ , \\
&x(t) = \left[\ \delta v_1\ \ \delta F_1\ \ \delta d_{12}\ \ \delta v_2\ \ \delta F_2\ \ \delta d_{23}\ \ \delta v_3\ \ \delta F_3\ \right]^T \ , \\
&u(t) = \left[\ \delta u_1\ \ \delta u_2\ \ \delta u_3\ \right]^T \ , \qquad (4)
\end{aligned}$$

\end{bmatrix} .$$

$$\begin{aligned}
&\alpha_i = \left.\frac{\partial f_{ai}}{\partial v_i}\right|_{v_i=v^*, d_{12}=d^*, d_{23}=d^*} \\
&\beta_i = \left.\frac{\partial f_{ai}}{\partial d_{12}}\right|_{v_i=v^*, d_{12}=d^*, d_{23}=d^*} \\
&\gamma_i = \left.\frac{\partial f_{ai}}{\partial d_{23}}\right|_{v_i=v^*, d_{12}=d^*, d_{23}=d^*} \ ,
\end{aligned}$$

where, α_i, β_i, and γ_i are parameters of Taylor expansion of f_{ai} that ignore the terms over second-order.

2.2 Centralized control system using LQR

The performance index using LQR is formulated as

$$J = \int_0^\infty \left(x^T Q x + u^T R u\right) dt \ , \qquad (5)$$

where, Q is positive semidefinite matrix, and R is positive definite matrix. The control input is calculated by

$$u_{LQR} = -R^{-1} B^T P x(t) \ , \qquad (6)$$

where, P is the solution of the following equation:

$$A^T P + PA - PBR^{-1}B^T P + Q = 0 \ . \qquad (7)$$

3 COMPUTER SIMULATION

In the computer simulations, a typical vehicle equipping continuously variable transmission (CVT) was selected. The parameters of the vehicles were $m_i = 1480$ [kg], $A_i = 2.87$ [m^2], $l_1 = l_2 = 4.3$ [m], and $\tau_i = 0.1$. The driving condition were $\rho = 1.2$ [kg/m^3] and $\mu = 0.01$. To construct the function C_i, a set of data that represents the relationship of C_i, d_{12}, and d_{23} obtained from wind tunnel experiments [1] was adopted. The approximation results of C_i are shown in Fig.3 and Fig.4. The fuel consumption of the vehicle was

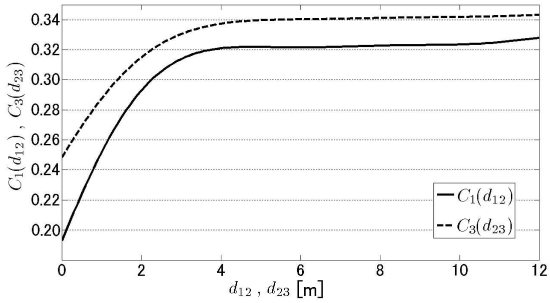

Fig. 3. Approximation results of C_1 and C_3

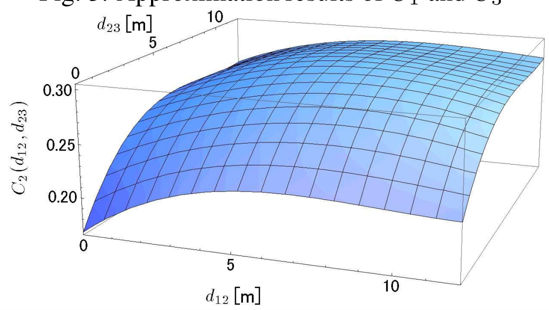

Fig. 4. Approximation result of C_2

estimated as

$$f_{uel\ i}(t) = \begin{cases} \dfrac{P_i(t)}{\eta_i(P_i(t))Q} & \text{for} \quad u_i \geq 0 \\ 0 & \text{for} \quad u_i < 0 \end{cases},$$

$$\begin{aligned} P_i(t) &= \big(m_i \dot{v}_i(t) + f_{ai}(t) + f_{gi}(t) + f_{\mu i}\big)v_i(t) + P_c \\ &= F_i(t)v_i(t) + P_c\ , \end{aligned} \tag{8}$$

where, f_i is the fuel consumption per unit time, P_i is the engine power output needed for driving a vehicle, η_i shown in Fig.5 is the maximum efficiency based on the engine characteristics map [6], $Q = 34.5$ [MJ/L] is the calorific value of gasoline, $P_c = 845.825$ [W] is the constant power required when the vehicle is idling. This equation was matched with the fuel consumption rate of the selected vehicle on the Japan 10-15 mode test.

At the initial time ($t = 0$), $v_1(0) = 95$ [km/h], $v_2(0) = 90$ [km/h], $v_3(0) = 85$ [km/h], $d_{12}(0) = d_{23}(0) = 10$ [m]. The desired driving situation was set as $v_i^* = 100$ [km/h] and $d_{12}^* = d_{23}^* = 2$ [m]. Altitude and slope of the road shapes used here are shown in Fig.6. $\sin\theta$ was approximated as $\sin\theta \approx \theta$ since the road slope is very small. The matrices Q and R are defined as

$$\begin{aligned} Q &= \text{diag}[\ 340 \quad 80 \quad 12 \quad 360 \quad 80 \quad 12 \quad 380 \quad 80\ ]\,, \\ R &= \text{diag}[\ 380 \quad 390 \quad 400\ ]\,. \end{aligned} \tag{9}$$

The sampling period was set as 0.01 [s]. To evaluate the performance of the proposed EVP control system, its computer simulation results were compared with a CVP control system. In the CVP control system [2], the control inputs of

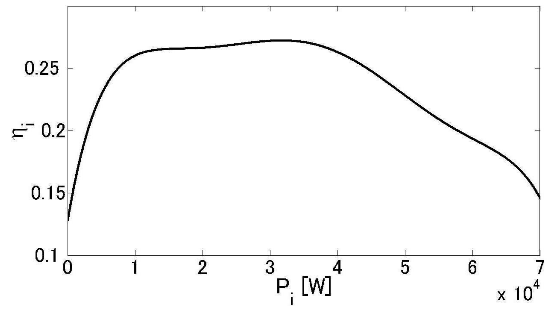

Fig. 5. Approximate engine efficiency η_i

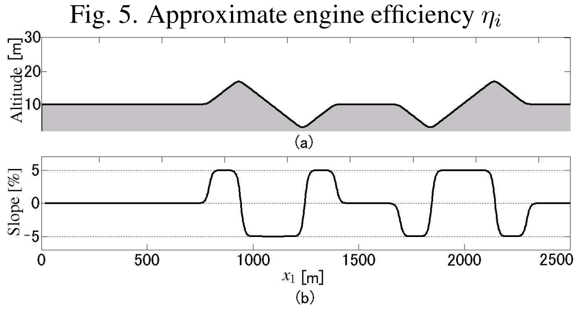

Fig. 6. Road shapes (a) altitude, (b) slope

the traction force or the brake force of the vehicles are represented as follows:

$$\begin{aligned} u_{CVP\ 1}(t) &= k_a\big(v^* - v_1(t)\big) + \int_0^t k_p\big(v^* - v_1(t')\big)dt', \\ u_{CVP\ 2}(t) &= k_1\big(v_1(t) - v_2(t)\big) \\ &\quad -k_2\big(hv_2(t) + \delta_{min} - d_{12}(t)\big), \\ u_{CVP\ 3}(t) &= k_1\big(v_2(t) - v_3(t)\big) \\ &\quad -k_2\big(hv_3(t) + \delta_{min} - d_{23}(t)\big), \end{aligned} \tag{10}$$

where, $k_a = 1184$, $k_p = 296$, $k_1 = 29600$, $k_2 = 2960$, $\delta_{min} = 0.5$, and $h = 0.05$ are constant parameters. To confirm the advantage of the platoon driving, the solitude driving (SOL) of a vehicle without the platooning ($u_{SOL} = u_{CVP\ 1}$) was also simulated. The initial velocity of this vehicle was the same as the velocity of the lead vehicle of the CVP.

The fuel consumption of the vehicles of the EVP, the CVP and the SOL at a distance of 2500 [m] are shown in Fig.7. Here, the improvement rates mean that the fuel consumption of the i-th vehicle of the EVP is compared with those of the CVP and the SOL. It is clear that the vehicles of the EVP further reduce the fuel than the CVP, and the platoon driving can save more fuel than the SOL.

The computer simulation results shown in Fig.8 and Fig.9 indicate that: During the early time period (0-25 [s]), the lead vehicle of the EVP accelerated slightly while the middle vehicle and the tail vehicle accelerated. This maneuver indicated that the EVP synchronously controlled the vehicles, the fast convergence in their spacings was achieved. The control inputs were small owing to the low acceleration of the vehicles. The vehicles of the CVP accelerated independently

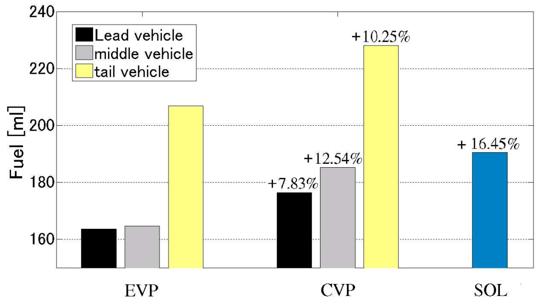

Fig. 7. Fuel consumption in 0–2500 [m]

since each vehicle of the CVP did not use the information of the other vehicles. By this maneuver, the slow convergence in their spacings was observed, and the control inputs were very large because of the high acceleration of the vehicles. During the uphill-downhill driving (25-90 [s]), the vehicles of the EVP tried to keep a low speed during uphill driving and a high speed during downhill driving. The amplitude of the control inputs was small owing to these driving policies. The vehicles of the CVP tried to keep the desired speed. This driving policy needed the large control inputs during the uphill driving, and wasted the kinetic energy of the vehicles during the downhill driving.

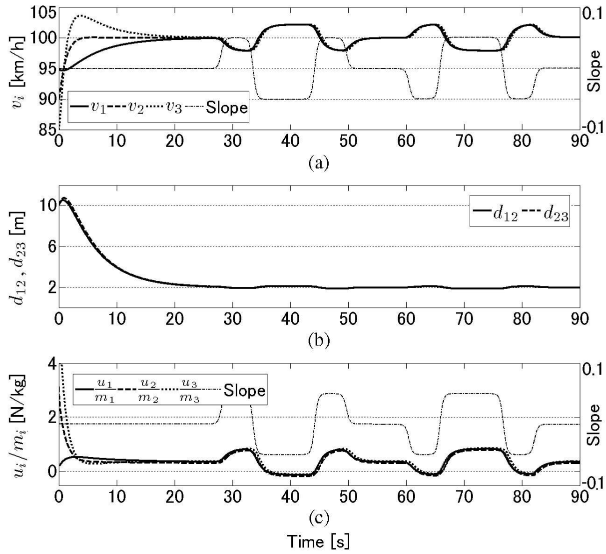

Fig. 8. The computer simulation results of the EVP

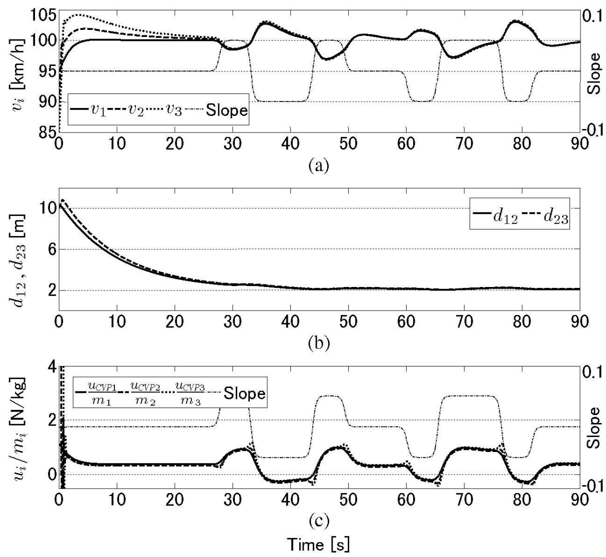

Fig. 9. The computer simulation results of the CVP

4 CONCLUSIONS

A centralized linear quadratic regulator system for ecological vehicle platooning considering the aerodynamic drag varied by the spacing and the road shape has been presented. The performance of the proposed control system was confirmed by the computer simulations. The synchronized driving obtained by the centralized control has provided the fast convergence of the spacings. The excessive acceleration and deceleration during the uphill and downhill driving have been avoided. The results revealed the significant improvement in fuel economy by using the proposed control system in comparison with those of a conventional vehicle platooning.

Abstract: Many applications (such as search and rescue or planetary exploration) require robots to characterize an environment that they have little or no initial information about. In this type of a scenario, a team of heterogeneous robots can be used to perform discovery and characterization activities. Unlike a collection of homogeneous robots which can be controlled without regards to the particular abilities possessed (e.g., using many common swarm techniques), the effective use of heterogeneous teams requires dynamic assignment based on constantly changing needs, available skills and robot locations. This paper discusses one such control technique that is demonstrated via a collection of small robots with very limited – but heterogeneous – sensing capabilities.

Keywords: heterogeneous robot team control, robot group communications, robotic control techniques.

1 INTRODUCTION

Task assignment to a collection of heterogeneous robots is an ill posed problem that also presents the complexity of continuous change. Assignment algorithms commonly consider distance from a target, closeness of fit for a given task and other metrics in considering which robot or robots to assign. Various assignment approaches are presented in the literature including self-assignment, central-assignment and swarm-based assignment. This paper proposes a feedback-trained task assignment mechanism which is demonstrated via a foraging application.

Obstacles of different heights were placed in the testing area; robots with sensors mounted at different height levels seek to generate a range measurement for the obstacles. A minimum of two robots is required to identify the height of an object (if it is taller than the highest sensor, for example). A second appropriately equipped robot must confirm each classification. Practically, several robots with different height measurement capabilities will be required to determine the lower and upper bound of the height. Then robots with corresponding height measurement capabilities will be required to confirm these findings. This experimental setup mirrors a variety of real-life conditions where alternate sensor types may be required (for example, sensors focusing on an adjacent range of light spectrum, etc.) to complete a task.

In this application, robots begin by searching for targets of interest and return to this when not assigned an alternate task. When a target is found the robot determines whether it is able to adequately assess it and then either issues a request for confirmation of its assessment or a request for an alternately equipped robot to be sent.

A central planner that runs on a selected robot (any robot with sufficient capabilities can potentially take this role) receives all confirmation or alternate robot requests and tasks a robot based on a combination of existing task-load, closeness to the target and closeness of task fit. The assigned robot receives the task and incorporates it into its task list based on path optimization. The central planner occasionally polls all of the robots for movement and task completion times. This data is used to update the controller's time-cost estimates via a weighted feedback incorporation technique. Updated estimates are sent out to all robots which incorporate the new data (weighed against local condition data) in to their internal costing values.

2 BACKGROUND

Collaborative robotic group control has a myriad of prospective applications. Three of these are particularly relevant to the research that has been conducted and the proposed control techniques: planetary exploration, reconnaissance and search-and-rescue.

It has been proposed, by Fink [1, 2, 3], to perform collaborative planetary exploration (inclusive of Earth science) through the use of a multi-tier robotic group. This concept presents an obvious collection of heterogeneous robots. They are differentiated by their movement type (orbital, flying or ground-based) and their particular function within the group. This mission architecture takes a top-down approach to task assignment. Orbital tier members (with great scope of coverage but limited resolution) identify targets of interest for exploration by aerial tier members which direct the efforts of (and may deploy) ground-based robots.

The multi-tier architecture presented for planetary exploration purposes is also highly relevant for reconnaissance. Work on sensornets [e.g., 4] is a demonstration of collaborative control of multiple heterogeneous robots. While many sensornets do not control the actual actions of their component sensors (robots), they do control the interaction between the data consumer and various sensors for the particular application. The sensornet concept can be looked at as a special case of the multi-tier mission architecture which may focus only on a particular subset of tiers and evidence only limited control.

Terrestrial search and rescue applications are also similar to the aforementioned applications. While this effort may be occurring in what was previously a well-known space, there is no guarantee that its configuration is as-previously-known and no guarantee that any particular infrastructure will be available. In fact, urban search and rescue presents a particular challenge as the environment may contain both physical and electromagnetic hazards to collaborative robotic operation. Robots deployed into search and rescue applications must be self-sufficient and be prepared to encounter electromagnetic interference to group communications and a changing array of hazards. They must also operate under a level of time pressure that is not present in many other robotic applications.

3 COLLABORATIVE CONTROL

To simulate the real-world conditions typical of the operation of heterogeneous group robot operations, each robot in the experimental group is controlled by a separate process that communicates with other robot control processes via message passing. Due to onboard processing limitations of the very basic robot hardware that was used for this experiment and the desire to capture performance information in real time, these processes were all physically located on a single computer that communicates with the robots via Bluetooth. This wireless protocol has limited range, but it was sufficient for the experimental environment used – specifically a small classroom-sized room. The experimental area was a rectangle approximately 10 feet by 20 feet. Three robots were operated concurrently in this area; they searched for and characterized pseudo-randomly placed obstacles.

The robots each begin in exploration mode, but will switch in to exploring traversal mode when another robot detects an object of interest and requests assistance to characterize it. When a robot is in close proximity to an object (or the believed position of an object) it switches into characterization mode. Once the robots have characterized the area completely (no area with a radius greater than a specified value remains unexplored) they switch in to terminal mode.

3.1 Exploration Mode

In exploration mode, the robot moves in a search pattern that is determined based on the presence of known and unknown areas surrounding it. The robot will avoid known obstacles, but prefers unknown (no pheromone) grid locations to those with known (positive pheromone) traverse-cost values. The robot will move will move to maximize its expected utility; however, in this mode, unknown grid locations will be treated as having +10 pheromone, impassible ones will be treated as having -100 and known locations will be treated has having -1 pheromone. The robot will continue in a utility maximizing search pattern until an uncharacterized obstacle is identified, the grid space is completely explored or another robot requests characterization assistance that it is well positioned to offer.

3.2 Exploring Traversal Mode

When a robot receives a suitable request, it evaluates the closeness and priority of the request relative to others that it is presently processing. If the new request has a lower combined (importance weighted against distance and current completion progress) selection value, it is queued; otherwise, the robot begins moving to the new location.

$$SEV = a\bullet I_t - b\bullet D_t - c\bullet C_{cur} \quad (1)$$

A robot that is in exploration mode will service any request that it is suitable to service (that is, it meets the instrumentation requirement and is not beyond the maximum traversal distance away from). Once a robot selects a request, it enters exploring traversal mode. In this mode, the robot selects the lowest-cost route. Unknown grid locations are assigned a cost of zero while those which slow movement (which was not a condition that was tested in this experiment) or contain an obstacle are considered based on their assigned negative utility value. The robot also continues its exploration activities along the path. If an object of interest is detected, it will compare the need to characterize this new object (that it is obviously in close proximity to) to the combined selection metric for its current task. Based on this, it may characterize this newly discovered object or queue it for later revisiting.

3.3 Characterization Mode

When the robot is in close proximity to an object that it has discovered and decided to characterize or one for which it has received a characterization or verification request, it will enter characterization mode. Characterization mode has two goals. First, the robot attempts to perform the characterization or verification activity required. Secondarily, it aims to align its grid with that of any previous robots that have visited this obstacle.

The robot moves around the obstacle and attempts to locate (trigger the bump sensor) from various directions. Through this, the robot characterizes the size of the object (i.e. how many and which grid squares it occupies). This is stored and transmitted to the central control process. If a previous robot has visited, the shape, size and location are compared and the correlation matrix between the grids of the robots are updated.

3.1 Terminal Mode

The robot enters terminal mode when it believes that its exploration area is completely characterized and there are no pending characterization assistance or verification requests remaining. In terminal mode, the robots return to their starting location and attempt to locate each other (through bump sensor triggering). This step is used to perform a final alignment on the grid correlation matrix between robots and once the robots locations are known to each other, they return to their ending formation.

4 COMMUNICATIONS

A simplified version of the communications architecture presented in [5] was used for message passing between the robot control processes and the central controller. Three message types (and their respective response) were used: object located, object characterized and request. Messages are processed by the central controller and forwarded out (containing the ID of the initiating robot, which is important for grid matching use) to the other robots to update their internal state database.

4.1 Object Located Message

The object located message is used to send a preliminary point obstacle to the central control process for distribution to the rest of the robots. This allows other robots to consider the presence of this obstacle when planning their routes during the characterization process. It also communicates that characterization of this object is in process and will prevent another robot that detects the same object during the characterization process from beginning to characterize it.

4.2 Object Characterized Message

When an object has been characterized (or verified) completely (i.e., from all directions), the object characterized message is sent to the central controller. This message contains all grid spaces that the object has been identified to occupy. When the central controller receives this message, it will send the preliminary data to all of the other robots and automatically generate characterization assistance or verification messages (depending on whether the characterization by the current robot was definitive – or simply determined that an alternately configured robot is required for further characterization).

4.3 Request Message

The request message is sent by the central controller once it receives an initial characterization completion notification (via the object characterized message). It will then, if this characterization was definitive (i.e., no other robot is required to characterize the object) issue a verification request; if further characterization is required it will issue a characterization request stating the required characterization capabilities (e.g., sensor above 2.2 cm, etc.). All request messages contain the grid location or locations of the object that requires the robot's characterization efforts and the reporting robot (for grid matching purposes).

4.3 Current State Message

The current state message is sent regularly by each robot to the central controller. The central controller distributes this message to any other robots that are operating in close proximity to the sending robot. This message is designed to allow robots to be aware of each other to prevent collisions.

Fig. 1. Picture of one of the robots that was used for testing the system. This robot has its second bump sensor set at the lowest setting (directly above the lower sensor). Other robots had their sensors at higher settings.

5 COMBINED SYSTEM OPERATIONS

The robotic control in this system is event driven. Once a path is selected for robot exploration or traversal, the control software will continue to execute the movement actions required to follow the designated route until interrupted by the detection of an obstacle, arrival in proximity to a characterization or verification target, receipt of a request that exceeds the selection value of the present task, or the determination that the entire exploration area has been completely explored.

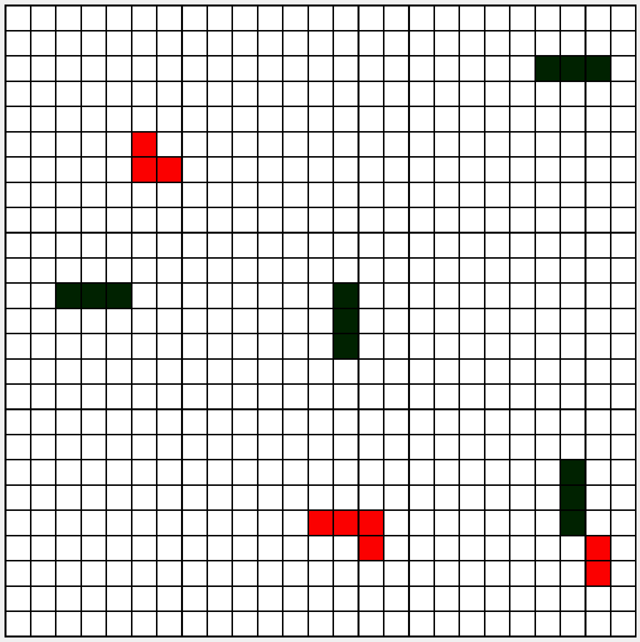

Fig. 2. Partial grid of exploration area showing obstacles (red / light) and demonstrated-traversable areas (green / dark)

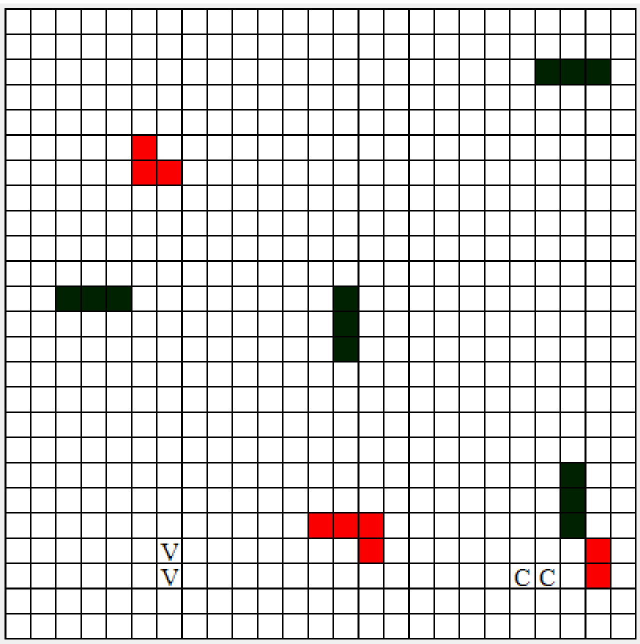

Fig. 3. Partial grid of exploration area showing obstacles, demonstrated-traversable areas and areas that need to be verified (V) or characterized (C)

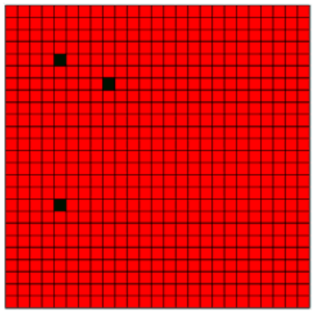
The system determines the speed of robot movement based on the current mode that the robot is in and the nature of the grid locations that it is traversing. In exploring traversal mode, the robot will increase speed across regions of well-known (demonstrated-traversed) grid locations; however, it will slow when preparing to enter an unknown region or approaching the target to be characterized. The effect of different speed settings was not tested; however, this is an area that learning techniques (which will be discussed in the following section) could possibly be used to increase system performance in future research.



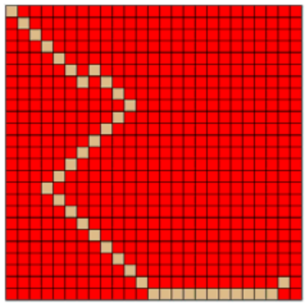


Fig. 4 & 5. Left: Partial grid of exploration area with initial -10 setting for all uncharacterized grid locations (red / light) and three characterized demonstrated-traversable locations (green / dark). Right: Partial grid of exploration area showing how high utility grid locations (as shown in Fig. 4.) impact routing

5.1 Path Planning

Path planning is utility and pheromone driven. The routing engine will make selections based on the lowest cost route that it perceives. Locations with known obstacles will have high negative utility values while those that have been demonstrated to be passable without issue on several occasions will have moderate positive utility values. A modified version of the A* path-finding algorithm is used. The route with the lowest total cost is selected.

6 LEARNING

The system relies on several constant values that are used to guide system operation. These values include the maximum target separation distance for accepting a task, the radius that determines when exploration is complete (when there is no region of this radius left unexplored, exploration is deemed complete) and the values that are used for positive and negative pheromone when regions are deemed impassible or well-traveled-enough to be demonstrated-traversable.

A learning algorithm based on testing incremental changes and evaluating their outcome has been developed and limited testing has been conducted. Minor changes to these values have been shown to have minimal effect; however, future research may focus on changing these values in conjunction. Additionally, correlation of particular value sets to preferential performance in various scenario types should be investigated.

7 EXPERIMENTAL SETUP

For testing, three robots were built which could be transformed into a variety of configurations. For characterization testing, the robots were set up with three different height levels for the upper bump sensor. For verification testing, two robots were assigned the same height level and the third was assigned a level that would only trigger characterization help requests (its upper sensor was shorter than the other group and also shorter than all obstacles).

A variety of obstacles were placed in the exploration area prior to each test; there location was measured so that the robotic results could be compared to the actual placement of obstacles. Obstacles were all heavy enough to avoid being moved by robot impact and no changes were made during each testing run.

The robots were placed in a central location facing in different directions. Once the test begun, the robots all moved off in their initial direction and begun random search activities.

Several scenarios were created which differed primarily in the density of obstacles present. The starting location of the robots was also varied as they were placed arbitrarily each time; however, the initial formation-placement of the robots was always very similar.

8 PERFORMANCE EVALUATION

The system was demonstrated to perform exceptionally well. In all test scenarios presented, the system identified all obstacles present in the exploration area. Additionally, this was done with virtually no manual involvement (in a few limited instances the robot dislodged one of its bump sensors requiring manual reattachment; however, this is a construction issue and not a control one). Despite having no mechanism for detecting side or rear impacts, the robots managed to successfully their exploration activities after rear collisions or side-swipes. Settings that allowed only short rearward movements for backing away from an obstacle worked as intended. The occasional non-bump-sensor-triggering collision (i.e., a collision with the front treads, etc.) or side swipe would temporarily cause a divergence of the robot's internal state believed-position and its actual position; however, this was generally resolved reasonably quickly by encountering an obstacle or wall and 'snapping' back to the grid based on this.

The small exploration area and high-traction carpet that it was covered with were undoubtedly factors in this performance. If the robot were more prone to slipping (or even could be spun by an impact) it is likely that re-snapping would have taken significantly longer or not occurred. The sensor configuration onboard the robots makes them have an exceptionally low tolerance for capture-and-place activities as they must physically explore a large area and encounter several known obstacles to reorient their internal position state.

9 CONCLUSION

The research conducted has demonstrated that limited communication and a set of well-defined behaviors are sufficient for characterizing an unknown environment. The robots in this experiment were purposefully simplistic in sensing capabilities and intentionally did not have any way to determine their true position (e.g., GPS). They demonstrated that with a reasonable level of relative movement knowledge, robots could assist each other in characterizing an environment that each could not sufficiently characterize on its own.

The control techniques demonstrated in this experiment are highly applicable to a variety of real world applications. Additional research, however, is required to validate their suitability and to identify required application-specific algorithm augmentations and constant values. A variety of general enhancements are also of research interest. These include adaptive learning (where constant values are updated based on performance in near-real-time by the evaluation system) and enhancements to deal with sensor data of varied levels of accuracy (i.e., visually sensed data versus bump-sensed data).

ACKNOLEDGEMENT

Thanks is given to the University of North Dakota Computer Science Department, especially Tom Stoke and Dr. Ronald Marsh, for providing the components that were used in this research.

Abstract: A magnetic levitation technique has a potential to realize a non-contact object manipulation. As a result, it is expected that a lot of problems caused by contacts can be evaded. Then, the authors developed a magnetic levitation system that was able to manipulate a magnetically levitated hand by non-contact. In this system, four electromagnets are assigned on a horizontal plane for 3-D positioning of the hand. However, it had been examined only about the movement of three directions so far.

In this paper, a new controller was presented which was developed to suppress the rotation around z axis, and its effectiveness was conformed through magnetic levitating experiments.

Keywords: Magnetic levitation, Adaptive Control, Positioning, Manipulation, Sensor

1 INTRODUCTION

Problems sometimes occur from the contacts between actuators and objects. Among various actuator systems, a magnetic levitation technique that levitates a hand by an electromagnetic force with no contact has a potential ability of achieving non-contact object manipulations. Therefore, the non-contact object manipulations would be a solution for the above described problems.

Thus, the magnetic levitation technologies have been in practical uses in some fields [1, 2, 3, 4] such as in a wind-tunnel test [5], and have been studied by applying various control theories such as the model reference adaptive control system (MRACS), H-infinity control [6, 7, 8, 9] to improve control characteristics. As for the multidegree-of-freedom systems, Fulford et al. [10] and Kim et al. [11] have studied on the magnetic levitation control where the air gap to the levitated object were very thin and the work spaces were restricted in very small range: the work spaces of translation was from nanometer to several millimeters, and that of rotation was from micro-radian to milliradian. Although Craig et al. [12] employed a magnetic levitation system that have as much wide work-spaces of several centimeters as our system, they studied only on the three-DOF positional control technique, but didn't take up the rotational control.

The authors have also developed a magnetic levitation system. In the system, four electromagnets are assigned on a horizontal plane for 3 dimensional (3-D) positioning of the hand as well as the work by Khamesee [13]. Yet we have also developed various 3-D positional control schemes such as the model reference adaptive control system (MRACS) heretofore [14], there has been remaining a problem of controlling orientations. Especially, unexpected rotational oscillation occurred around the vertical axis, which was a pressing issue for the system. Thus, we have studied on the oscillation-suppressing controller. The detail of the study for developing the controller was presented in this paper. Experimental apparatus including a sensor system to measure the rotational angle is described in Chapter2. Next, after showing a finding that the magnetic flux sum value has a dominant effect on the rotational oscillation, we present a way of designing oscillation-suppressing controller, i.e., a controller for stabilizing the magnetic-flux sum, in Chapter 3. Then, the effectiveness of the proposed method is confirmed by magnetic levitation experiments using a trial controller in Chapter 4. Finally, Chapter 5 concludes this paper.

2 EXPERIMENTAL APPARATUS

2.1 Magnetic levitation system

Schematic view of a magnetic levitation system used in this work is shown in Fig. 1and Fig. 2. In the system, as shown Fig. 3 and Fig. 4, four electromagnets are assigned on a horizontal plane for 3 dimensional (3-D) hand positioning. The electric circuits for the four electromagnets are independently controlled by FET amplifier circuits. The hand is levitated at an arbitrary position by controlling the currents flowing into the four electromagnets where the hand position is utilized as feedback information (Fig. 5). Fig. 6 shows an appearance of the levitated hand that is carrying a transistor. The permanent magnet in the driving unit is used to achieve the zero-power control: the zero-power control decreases the necessary power for the electromagnetic by compensating the hand gravity. As for the hand, the mass is approximately 6 g, and the weight capacity is approximately 1 g in the space of 20 mm × 20 mm × 20 mm cubic, and the spacing between the hand and the electromagnets is approximately 50 mm. The magnetic fluxes below the electromagnets are measured with the hall elements (THS119, Toshiba Corporation) that are attached at the electromagnets one-by-one.

2.2 Rotation measurement system

This section describes a sensor system to measure the rotational angle around the axis in the longitudinal direction of the levitating hand.

As for a preparatory for developing the system, we had to examine the behavior of the levitated hand, and had to quantitatively evaluate the rotational oscillation. Here, since non-contact sensing system for measuring rotation to be applied to our levitation system was not available, we contrived a rotational measurement system. As shown in Fig. 8 and Fig. 9, by chipping off the lower part of the hand, we carved the bottom face into the spirally elevated slope. Then, the vertical distance between the slope and a distance sensor that was located down below varies with the rotation around the vertical axis as well as the 3-D positional change. As for the distance sensor, we employed a positional sensor (LB-040, Keyence): the measurable range is 35 to 45 mm, and the resolution is 2 μ m.

To confirm the effectiveness of the proposed rotation measurement system and to get an angle-distance conversion coefficient, rotational angle measurement experiments were carried out. While rotating the hand by a motor, the distance between the bottom of the hand and the positional sensor was measured.

Taking the medium height of the measured one as the origin, the averaged value of ten times of distance measurement is plotted along with the time in Fig. 10. While the hand rotating 360 ° in 0.8 seconds, the hand position decreased from 3.78 to -3.78. It gives the angle-to-distance conversion coefficient of 0.021mm/°. Here, note that, if the hand changes its 3-D position, the positional change causes an offset of the hand-sensor distance. Therefore, given the hand position, we should subtract the offset. Thus, the distance can be transformed into the rotation angle.

3 DESIGN OF CONTROLLER

3.1 Positional control of magnetically levitated hand

This section describes the positional control method of the magnetically levitated hand.

The 3-D position of the hand is controlled by manipulating the currents i_1, i_2, i_3,and i_4, each of which is to be input into the corresponding electromagnet: based on the following equations, we can determine i_1, i_2, i_3,and i_4 from $\boldsymbol{u_p} = [u_x, u_y, u_z]$ except that one of the four currents is determined arbitrarily.

$$\begin{aligned} &\Sigma_{j=1,4}\, i_j = u_z \\ &i_1 - i_3 = u_x, \\ &i_2 - i_4 = u_y \end{aligned} \tag{1}$$

Utilizing the positional sensor information as a feedback signal, we applied a feed-forward PID control to the hand position control. That is, the nonlinear compensators from the levitating position X, Y, Z to the manipulated variables $\boldsymbol{u_p} = [u_x, u_y, u_z]$ were represented by the second order approximate equations, and were utilized for feed-forward signals. The approximate equations had been obtained by a preparatory experiment: while changing the levitating position X, Y, Z, the relationships between the levitating position X, Y, Z and the manipulated variables $\boldsymbol{u_p} = [u_x, u_y, u_z]$ were measured.

Let $\boldsymbol{e}_p$ denote the deviation of the present position $\boldsymbol{p}_p = [p_{px}, p_{py}, p_{pz}]$ from the desired position $\boldsymbol{r}_p = [r_{px}, r_{py}, r_{pz}]$. If we denote the gains with respect to the position by K_{pp}, K_{ip}, and K_{dp}, and denote the nonlinear compensation with respect to the position by $\boldsymbol{u}_{fp} = [u_{fpx}, u_{fpy}, u_{fpz}]$, the manipulated variable in the horizontal direction, $\boldsymbol{u_p} = [u_x, u_y, u_z]$ is given by

$$\boldsymbol{u}_p = K_{pp}\boldsymbol{e}_p + K_{ip}\int \boldsymbol{e}_p dt + K_{dp}\dot{\boldsymbol{e}}_p + \boldsymbol{u}_{fp} \tag{2}$$

3.2 Magnetic flux control (MF control)

As for the hand's positional control in the horizontal plane, a magnetic flux control loop using hall elements was embedded into the inside of the positional control loop. Here, note that, because the electromagnets interfere with each other, it is difficult to control the magnetic fluxes independently. Therefore, as well as the horizontal positional control method described in the section 3.1, we took the differences between the fluxes emitted from the opposing electromagnets to control them.

We constituted a magnetic flux vector $\boldsymbol{p}_f = [p_{fx}, p_{fy}, 0]$ from the magnetic fluxes b_1, b_2, b_3, b_4: they are measured by the hall elements that are attached at the electromagnets. That is,

$$p_{fx} = b_1 - b_3$$
$$p_{fy} = b_2 - b_4 \tag{3}$$

As well as 3.1, let $\boldsymbol{e}_f$ denote the deviation of the present magnetic flux $\boldsymbol{p}_f$ from the desired magnetic flux $\boldsymbol{r}_f$. If we denote the gains with respect to the magnetic flux by K_{pf}, K_{if}, and K_{df}, and denote the nonlinear compensation with respect to the magnetic flux by $\boldsymbol{u}_{ff} = [u_{ffx}, u_{ffy}]$, the manipulated variable in the horizontal direction, $\boldsymbol{u}_f = [u_x, u_y, u_z]$ is given by

$$\boldsymbol{u}_f = K_{pf}\boldsymbol{e}_f + K_{if}\int \boldsymbol{e}_f dt + K_{df}\dot{\boldsymbol{e}}_f + \boldsymbol{u}_{ff} \tag{4}$$

where

$$\boldsymbol{e}_f = \boldsymbol{r}_f - \boldsymbol{p}_f$$
$$\boldsymbol{r}_f = K_{pp}\boldsymbol{e}_p + K_{ip}\int \boldsymbol{e}_p dt + K_{dp}\dot{\boldsymbol{e}}_p + \boldsymbol{u}_{fp}$$
$$\boldsymbol{e}_p = \boldsymbol{r}_p - \boldsymbol{p}_p$$

The nonlinear compensators are represented by approximate equations that were obtained by a preparatory experiment: while changing the manipulated variable values, that is, the levitating position X, Y, Z and the control currents i_1, i_2, i_3, i_4, we measured the magnetic fluxes $\boldsymbol{b} = [b_1, b_2, b_3, b_4]$.

The block diagram of the magnetic flux controller before-improvement is shown in Fig. 11. The block of [CONV2] in the block diagram represents the transformation from $\boldsymbol{b}$ into $\boldsymbol{p}_f$ by Eq.(3). And, the block of [CONV1] represents the transformation from $\boldsymbol{u}_f$ into i_1, i_2, i_3, i_4 as in the followings.

$$\Sigma_{j=1,4}\, i_j = u_z$$
$$i_1 - i_3 = u_x,$$
$$i_2 - i_4 = u_y \tag{5}$$

where $\boldsymbol{u}_f = [u_x, u_y, u_z]$

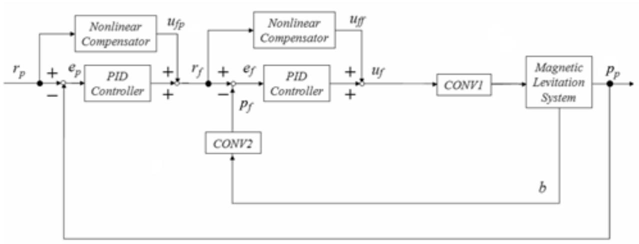

Fig. 11. Block diagram of MF control

3.3 Rotation suppressing control

The authors introduced a control method to suppress the unwilled rotational oscillation around the vertical axis in the magnetic levitating system.

We found an important behavior from experimental data: when hand suffering rotation oscillation, the rotational oscillation was in phase with the perturbation of the sum value of four pieces of the magnetic flux emitted from the four electromagnets. It means that the magnetic flux sum value has a dominant effect on the rotational oscillation, and it suggested us the necessity of suppressing the perturbation of the sum value. Taking sum of the magnetic fluxes in the X-direction, and that in the Y-direction, we apply a PID control for the rotation suppression: the desired value of the sum in the X-direction is denoted by r_{sx}, and that in the Y direction is by r_{sy}, and the measured value of the sum in the X-direction is denoted by p_{sx}, and that in the Y direction is p_{sy}. If the deviation of r_{sx} from r_{sy} is denoted by r_s and that of p_{sx} from p_{sy} is by p_s, they are shown by

$$r_s = r_{sx} - r_{sy}$$
$$p_s = p_{sx} - p_{sy}, \quad p_{sx} = b_1 + b_3, \quad p_{sx} = b_2 + b_4 \tag{6}$$

If the deviation of r_s from p_s is denoted by e_s, and if the gains with respect to the magnetic flux are K_{ps}, K_{is}, and K_{ds}, the manipulated variable in the horizontal direction, $\boldsymbol{u}_s = [u_x, u_y, u_z]$, is given by the following PID control.

$$\boldsymbol{u}_s = K_{ps}\, e_s + K_{is} \int e_s dt + K_{ds}\, \dot{e}_s \qquad (7)$$

By adding $\boldsymbol{u}_s$ of Eq. (7) to $\boldsymbol{u}_f$ of Eq. (4), the input for the [CONV1] in the block diagram, $\boldsymbol{u}_f'$ shown in Fig. 12 is given by

$$\boldsymbol{u}_f' = K_{pf}\boldsymbol{e}_f + K_{if} \int \boldsymbol{e}_f dt + K_{df}\dot{\boldsymbol{e}}_f + \boldsymbol{u}_{ff} + \boldsymbol{u}_s \qquad (8)$$

The block diagram of the proposed magnetic flux control is shown in Fig. 12 where the sampling time of the positional control loop was set at 4 ms, and that of the magnetic flux control loop 1 ms.

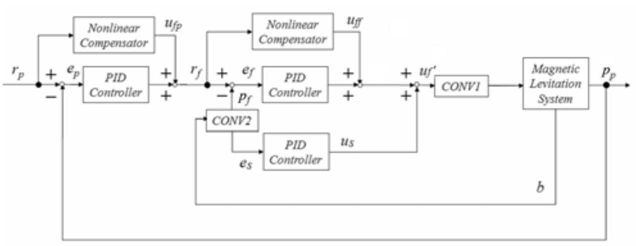

Fig. 12. Block diagram of proposed MF control with rotation suppressing control

4 EXPERIMENT

To confirm the effectiveness of the proposed method, the authors implemented the above-described controller, and carried out some magnetic levitation experiments.

First of all, to make clear the problem of the existing method that is represented by Eq. (4), a result of before-improvement p_s is shown in Fig. 13 where the hand was levitated at the height of Z=5 mm. Next, to make clear the effectiveness of the proposed rotational measurement system, the measured values after the hand's Z positional correction, the converted hand's rotational angles are shown in Fig. 14. Contrary to Fig.13 and Fig. 14, after-improvement result of p_s is shown in Fig. 15 where the proposed controller by Eq. (8) is implemented, and the corrected hand's rotational angle is also shown in Fig. 16.

As you can see from Fig. 13 and Fig. 14, they were found that the magnetic flux p_s has a strong correlation with the hand's rotational angle, and that the hand oscillates periodically within the range of -110 degree ~ +110 degree. The findings support the validity of the principle of the rotation-suppressing-control described in the section 3.3. Next, from Fig. 15 and Fig. 16, by virtue of the proposed controller, the periodic oscillation in the magnetic flux p_s has been markedly suppressed, and the consequently occurring periodic oscillation in the hand's rotational angle has also been effectively suppressed within the range of -15 degree ~ +15 degree.

As a result, it can be concluded that the proposed method effectively decreased the unwilled rotation around Z-axis much more than the existing method.

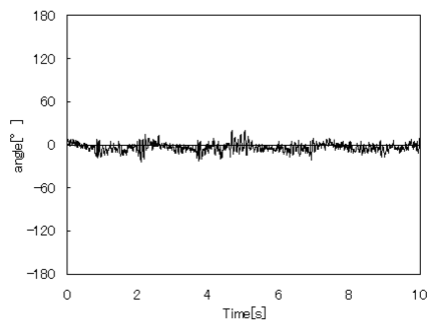

Fig. 16. Rotation angle by proposed controller

5 CONCLUSION

A controller to suppress the oscillation around the vertical axis was presented in this paper. The main points are as follows:

(1) Carrying out some magnetic levitating experiments, we have found an interesting behavior: the rotational oscillation was in phase with the perturbation of the sum value of four pieces of the magnetic flux respectively emitted from the four electromagnets. It means that the magnetic flux sum value has a dominant effect on the rotational oscillation, and it suggested us the necessity of suppressing the perturbation of the sum value.

(2) Considering this necessity, we designed a controller for stabilizing the magnetic-flux sum, and developed a trial system of the controller.

(3) We carried out some magnetic levitating experiments:the perturbation of the sum of four pieces of the magnetic flux was markedly decreased, and the ill rotational oscillation around the vertical axis was successfully suppressed. As a result, the effectiveness of the proposed method was confirmed.

In the future, based on the rotational oscillation suppression technique, we are directed to enhance the control characteristics of the magnetic levitating system: if we can arbitrarily control the rotation around the vertical axis, the system would be applied to more wide range of areas.

Abstract: The studies of model based fuzzy control system are concentrating on regulator problem. But in real system, the output of the system needs to be regulated to the desired reference output which is not only zero. Servo system can regulate the output to desired reference output without steady state error against unknown disturbance. In this paper, application of fuzzy servo control for stabilizing inverted pendulum system will be discussed. The inverted pendulum system is a simple system consists of pendulum and cart but has strong nonlinearity and inherent instability. The simulations are done and the result shows that the proposed method can stabilize the system.

Keywords: Davison-Smith method, Fuzzy control, Inverted pendulum system, Nonlinear servo system

1 INTRODUCTION

The studies of model based fuzzy control system are concentrating on regulator problem, which is involved with the design of the controller that can drive all the initial condition to zero as required by the design specification. In real system, the output of the system needs to be regulated to the desired reference output which is not only zero. Servo system can regulate the output to desired reference output without steady state error against unknown disturbance. In this paper, application of fuzzy servo control for stabilizing inverted pendulum system will be discussed. The inverted pendulum system is a simple system consists of pendulum and cart but has strong nonlinearity and inherent instability. It is used as benchmark problem for study the performance and effectiveness of new control method. The idea behind of this control method is to divide the operating region of nonlinear system into small area, and to treat as a collection of local linear servo systems by using Davison-Smith method. The control rule of each local linear servo systems is calculated using pole assignment method proposed by Hikita. Fuzzy method is applied to each local linear servo system and combines it as new control rule. The simulations have been done and the results shown that proposed can stabilize the system. As shown in the result, the output of the system follows the reference given and converges to the reference value as desired.

2 SYSTEM DESCRIPTION

Let the original system S be a nonlinear system one as

$$\dot{x} = f(x,u) + d \tag{1}$$
$$y = g(x) + d_o \tag{2}$$

Where, $x \in R^n$ is state vector, $u \in R^m$ is control input, $y \in R^l$ is control output, $d \in R^n$ is state disturbance and $d_o \in R^l (m \geq l)$ is output disturbance. n, m and l are dimensions of state, input and output of the system. Assume the trajectory of nonlinear system around operating point of the system(x_i, u_i) as

$$\delta x = x - x_i \tag{3}$$
$$\delta u = u - u_i. \tag{4}$$

Where δx and δu represent the small quantity of state and input variable respectively.The system can be linearized by applying Taylor expansion to (1) and (2) around operating point (x_i, u_i), where

$$\begin{aligned} \delta\dot{x} &= \frac{\partial}{\partial x^T} f(x_i,u_i)\,\delta x + \frac{\partial}{\partial u^T} f(x_i,u_i)\,\delta u \\ &\quad + f(x_i,u_i) + d \end{aligned} \tag{5}$$
$$y = \frac{\partial}{\partial x^T} g(x_i)\,\delta x + g(x_i) + d_o. \tag{6}$$

The linear approximated system S_i can be represented as,

$$\dot{x} = A_i x + B_i u + d_{xi} \tag{7}$$
$$y = C_i x + d_{oi} \tag{8}$$

where,
$A_i = \frac{\partial}{\partial x^T} f(x_i,u_i), B_i = \frac{\partial}{\partial u^T} f(x_i,u_i), C_i = \frac{\partial}{\partial x^T} g(x_i), d_{xi} = f(x_i,u_i) - A_i x_i - B_i u_i + d, d_{oi} = g(x_i) - C_i x_i + d_o$.
Let error of the system be as following

$$\dot{v} = y - r. \tag{9}$$

Derive the augmented system from (7),(8) and (9).

$$\begin{aligned} \frac{d}{dt}\begin{bmatrix} x \\ v \end{bmatrix} &= \begin{bmatrix} A_i & 0 \\ C_i & 0 \end{bmatrix}\begin{bmatrix} x \\ v \end{bmatrix} + \begin{bmatrix} B_i \\ 0 \end{bmatrix} u \\ &\quad + \begin{bmatrix} d_{xi} \\ d_{oi} - r \end{bmatrix} \end{aligned} \tag{10}$$

Equation(10) can be re-written as

$$\dot{z} = A_{zi}z + B_{zi}u + d_{zi} \tag{11}$$

where,
$z = \begin{bmatrix} x \\ v \end{bmatrix}, A_{zi} = \begin{bmatrix} A_i & 0 \\ C_i & 0 \end{bmatrix}, B_{zi} = \begin{bmatrix} B_i \\ 0 \end{bmatrix},$
$d_{zi} = \begin{bmatrix} d_{xi} \\ d_{oi} - r \end{bmatrix}.$
The system that has ability to follow the given reference is called as servo system.This system in (11) is controllable if controlability condition satisfies.

$$rank \begin{bmatrix} B_{zi} & A_{zi}B_{zi} & A_{zi}^2 B_{zi} & \cdot\cdot & A_{zi}^{n+l-1} B_{zi} \end{bmatrix} = n+l. \tag{12}$$

This condition is equivalent to the next one.

$$rank \begin{bmatrix} B_i & A_iB_i & A_i^2 B_i & \cdots\cdot & A_i^{n-1}B_i \end{bmatrix} = n, \quad rank \begin{bmatrix} A_i & B_i \\ C_i & 0 \end{bmatrix} = n+l \tag{13}$$

3 FUZZY SERVO SYSTEM

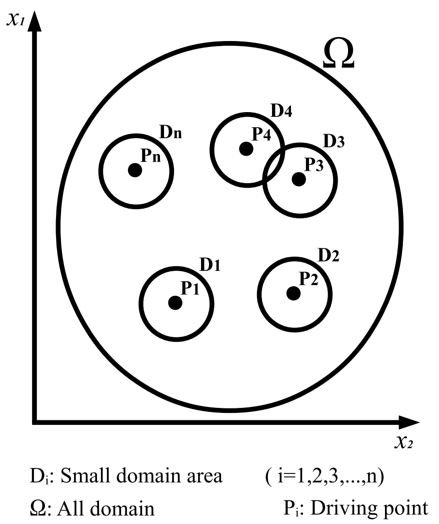

Fig. 1. Partition of driving domain Ω

In this section we apply fuzzy method to develop the control rule for the nonlinear system. First, nonlinear variable for system in (1) and (2) will be determined. Let, the element of nonlinear variable for x in funtion $f(x, u), g(x)$ as x_{ej} and can be determine as

$$\frac{\partial}{\partial x_{ej}} f\,(x, u) \neq const. \tag{14}$$

This definition also can be use for output equation u. The origin point $(0, 0)$ are used as linear driving point. Let, the vector of the set of nonlinear variable x and u for $f(x, u), g(x)$ as $x_n \in R^{n_{xn}}$ and $u_n \in R^{n_{un}}$. The relationship between x, u and x_n, u_n can be shown as

$$x_n = C_{xn}x \tag{15}$$
$$u_n = C_{un}u \tag{16}$$

$C_{xn} \in R^{n_{xn} \times n} and C_{un} \in R^{n_{un} \times m}$ are the matrix of which its elements are 1 or 0. Define the vector for all nonlinear variable as $z_n \in R^{n_{zn}}, n_{zn} = n_{xn} + n_{un}$, the relatioship between the variable can be represent as

$$z_n = \begin{bmatrix} x_n \\ u_n \end{bmatrix} = \begin{bmatrix} C_{xn} & 0 \\ 0 & C_{un} \end{bmatrix} \begin{bmatrix} x \\ u \end{bmatrix} = C_n \begin{bmatrix} x \\ u \end{bmatrix}. \tag{17}$$

Where $C_n \in R^{n_{zn} \times (n+m)}$. Next, we divide the region of nonlinear variable z_n,into small area D_i around driving point P_i. Fuzzy method has been apply to each local linear system and combines it and treated as a collection of local linear servo systems (Fig.1). The fuzzy rule R_i can be define as

$$R_i : \quad IF \;\; z_n \in D_i \;\; THEN \;\; S \;\; is \;\; S_i. \tag{18}$$

Where, the fuzzy rules are $-N \leq i \leq N$. Let ω_i define as Gaussian type fuzzy membership function (Fig.2) as following.

$$\omega_i = e^{-(z_n - z_{ni})^T Q_n (z_n - z_{ni})} \tag{19}$$
$$Q_n = {Q_n}^T > 0 \tag{20}$$

ρ_i can be define as,

$$\rho_i = \frac{\omega_i}{\sum_{i=-N}^{N} \omega_i}. \tag{21}$$

The Fuzzy Servo System can be re-write as,

$$\dot{z} = \sum_{i=-N}^{N} \rho_i \left(A_{zi}z + B_{zi}u + d_{zi} \right). \tag{22}$$

In order to stabilized the system in (22), the control input u can be defines as

$$u = -\sum_{i=-N}^{N} \rho_i K_i z. \tag{23}$$

K_i is the feedback coefficient matrix of the input for small area D_i. This matrix calculated using Hikita method [3] based on servo system proposed by Davison-Smith[2]. Let

$$\begin{aligned} f_{ij} &= -(\lambda_{ij}I - A_{zi})^{-1} B_{zi} g_{ij} \\ (j &= 1, 2, 3, ...n + l), \\ g_{ij} &\in R^m, f_{ij} \in R^{n+l}. \end{aligned} \tag{24}$$

λ_{ij} be the eigenvalues, g_{ij} be non-zero vector and f_{ij} be eigenvector of the system. The feedback co-efficient matrix can be represented as

$$K_i = \begin{bmatrix} g_{i1} & \ldots & g_{i(n+l)} \end{bmatrix} \begin{bmatrix} f_{i1} & \ldots & f_{i(n+l)} \end{bmatrix}^{-1} \quad (-N \leq i \leq N) \tag{25}$$

The input u in (23) are applied to system in (1) and (2).

4 SIMULATION AND RESULTS

The inverted pendulum used in this simulation is shown in Fig.3. It consists of cart and a pendulum. The cart is free to move the horizontal direction when the force F applies to it. We assume that the mass of the pendulum and cart are homogenously distributed and concentrated in their center of the gravity and the friction of the cart is proportional only to the cart velocity and friction generating by the pivot axis is proportional to the angular velocity of the pendulum. The parameters used for simulation are shown in Table 1.The mathematical model of inverted pendulum system can be described as the following.

$$(M+m)\ddot{x}+mlcos\theta\ddot{\theta}+D\dot{x}-mlsin\theta\dot{\theta}^2=F \tag{26}$$

$$mlcos\theta\ddot{x}+\frac{4}{3}ml^2\ddot{\theta}-mglsin\theta+C\dot{\theta}=0 \tag{27}$$

With output as

$$y=x_1 \tag{28}$$

Define an error of the system as

$$\dot{v}=e=y-r. \tag{29}$$

Table 1. Parameters of Inverted Pendulum System

Parameter	Description	Value
Mass of the cart	M	0.165kg
Mass of the pendulum	m	$0.12kg$
Distance from pivot to center of mass of the pendulum	l	$0.25m$
Gravitational constant	g	$9.80m/s^2$
Co-efficient of friction for pivot	C	$0.01kgm/s$
Co-efficient of friction for cart	D	$4.0kg/s$

Re-arranged the equation in term of $x_1=x, x_2=\dot{x}, x_3=\theta, x_4=\dot{\theta}$ and $F=u$. The new equation for inverted pendulum are shown in (30), (31),(32) and (33).

$$\dot{x_1} = x_2 \tag{30}$$

$$\begin{aligned}\dot{x_2} = {} & 3cosx_3\,(mglsinx_3-Cx_4) \\ & -4l\left(u-Dx_2+mlsinx_3x_4^2\right)/ \\ & \left\{4l(m+M)+3mlcosx_3^2\right\}\end{aligned} \tag{31}$$

$$\dot{x_3} = x_4 \tag{32}$$

$$\begin{aligned}\dot{x_4} = {} & -3\,\{(m+M)(mglsinx_3-Cx_4) \\ & -mlcosx_3(u-Dx_2+mlsinx_3x_4^2)\}/ \\ & \left[ml^2\left\{-4(m+M)+3mcosx_3^2\right\}\right]\end{aligned} \tag{33}$$

The nonlinear variable for the system are calculated using (14). In this example the nonlinear variable are x_2, x_3, x_4 and u. The linearization has been done to mathematical model of the inverted pendulum system using Taylor expansion as shown in (5) and (6) around of the driving points for nonlinear variables x_2, x_3, x_4 and u. Where,

$$\delta x_2 = x_2 - x_{2i} \tag{34}$$

$$\delta x_3 = x_3 - x_{3i} \tag{35}$$

$$\delta x_4 = x_4 - x_{4i}. \tag{36}$$

$$\delta u = u - u_i. \tag{37}$$

The linearization has been done and the linear servo system can be represent as

$$\dot{z} = A_{zi}z + B_{zi}u + d_{zi}. \tag{38}$$

The controllability of the servo system of inverted pendulum system has been investigated using (12). In this case, the output of system has been setting as shown in (28) because of the controllability problem. Let,

$$Q_n = \begin{bmatrix} q_2 & 0 & 0 & 0 \\ 0 & q_3 & 0 & 0 \\ 0 & 0 & q_4 & 0 \\ 0 & 0 & 0 & q_5 \end{bmatrix} \tag{39}$$

and the nonlinear variables x_2, x_3, x_4 and u can be represent as

$$z_n = \begin{bmatrix} x_2 \\ x_3 \\ x_4 \\ u \end{bmatrix}, C_n = \begin{bmatrix} 0 & 1 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 0 & 1 \end{bmatrix} \quad (40)$$

The fuzzy membership function ω_i can be represent as

$$\begin{aligned} \omega_i &= e^{-(z_n - z_{ni})^T Q_n (z_n - z_{ni})} \\ &= e^{-q_2(x_2 - x_{2i})^2 - q_3(x_3 - x_{3i})^2 - q_4(x_4 - x_{4i})^2 - q_5(u - u_i)^2} \end{aligned} \quad (41)$$

So that,

$$\rho_i = \frac{\omega_i}{\sum\limits_{i=-N}^{N} \omega_i}. \quad (42)$$

The fuzzy servo system for inverted pendulum system is,

$$\dot{z} = \sum_{i=-N}^{N} \rho_i \left(A_{zi} z + B_{zi} u + d_{zi} \right). \quad (43)$$

The set of poles used is $\lambda = [-1.2 - 1.3 - 1.4 - 1.5 - 1.6]$ .The feedback coefficient matrices K_i are calculated using Hikita Method. The input of the system is

$$u = -\sum_{i=-N}^{N} \rho_i K_i z. \quad (44)$$

with $x_{2i} = h_2 i(-N_2 \leq i \leq N_2), x_{3i} = h_3 i(-N_3 \leq i \leq N_3), x_{4i} = h_4 i(-N_4 \leq i \leq N_4), u_i = h_5 i(-N_5 \leq i \leq N_5), N_2 = 5, N_3 = 5, N_4 = 5, N_5 = 5, N = (N_2) \times (N_3) \times (N_4) \times (N_5) = 625$, increment $h_2 = 0.1, h_3 = 0.01, h_4 = 0.1, h_5 = 0.1$. The initial condition is $z_0 = [0\ 0\ \theta\ 0\ 0]^T$ with value of angle, θ is 33^o.The simulation are done for three different values of Q_n. Where, in simulation 1: $q_2 = 1.0, q_3 = 1.0, q_4 = 1.0, q_5 = 1.0$, simulation 2: $q_2 = 14.0, q_3 = 14.0, q_4 = 14.0, q_5 = 14.0$ and simulation 3: $q_3 = 0.1, q_3 = 0.1, q_4 = 0.1, q_5 = 0.1$.

The graph in Fig.4 and Fig.5 are the results for the simulation. The result shows that not only the output of system $y = x_1 = x$, but the value of $x_3 = \theta$ also converges to zero. The effect of varying the value of matrix Q_n also can be observe in the result. The simulation shows that the fuzzy servo control can stabilize inverted pendulum system.

5 CONCLUSION

In this paper, we discuss about the application of the fuzzy servo control on inverted pendulum system. The theory used have been explained in detail and the simulations have been done. As shown in the result, the output of the system follows the reference given and converges to the reference value as desired. For future work, study of characteristic of the proposed method will be done by doing the simulation using other system together with the study of the stability issue.

Abstract: To support disabled people using remote controllers, biological signals have been applied to. We propose a lightweight sensing method extracting the tooth-touch without a sophisticated signal processing to eliminate the normal audio sound. Proposal uses a shock wave (i.e. ultrasonic wave) which is generated when the upper and lower tooth hit each other, instead of the sound wave of tooth-touch. By our method, the signal processing has only to perform a high-pass filter eliminating lower frequency domain than the ultrasonic domain. Through the preliminary experiment with a conventional microphone, we show that the tooth-touch has the larger power than the voice sounds in the ultrasonic region. Then, we design the filtering hardware to implement a small and cheap SoC. Through the implementation to the FPGA, and the simulation, we show that our hardware is small and has the enough performance for a real-time operation.

Keywords: Disable people, Supporting system, Remote control, Tooth-touch, Ultrasonic

1 INTRODUCTION

Since the remote controllers for the house appliances are becoming complex, a method supporting disabled people to use them is very important for providing more efficient social life. To tackle such problem, the biological signals such as voice, eye blinks, chin operated control sticks, mouth sticks [1], and brain computer interfaces [2, 3] have been applied to the supporting systems.

The tooth-touch sound is one of the simplest biological signals, i.e. the simplest human actions. It can be easily sensed by the trivial sensors such as electret condenser microphone. In general, to realize the remote controller by the tooth-touch sound, the sequences of the tooth-touch sounds are converted to the operation code sequences [4]. However, since the tooth-touch sound is mixed with the normal audio sound, the sophisticated signal processing to extract only the tooth-touch sound is needed [4]. In order to spread the supporting system using tooth-touch sound to many disabled people, the system must be very cheap, small and low-power consumption for the battery. That is, the signal processing has to be simple and mature enough to realize a low-cost hardware module which can be mounted to a cheap system-on-chip (SoC).

This paper proposes a lightweight sensing method extracting the "**tooth-touch**" that does not need a sophisticated signal processing to eliminate the normal audio sound. This method uses an shock wave (i.e. ultrasonic wave) which is generated when the upper tooth and the lower tooth hit each other, instead of the sound wave of tooth-touch. Conventional microphones such as electret condenser microphone have a sensitivity to the ultrasonic wave. By our proposed method, the the signal processing extracting the tooth-touch has only to perform a well-known filter eliminating lower frequency domain than the ultrasonic domain.

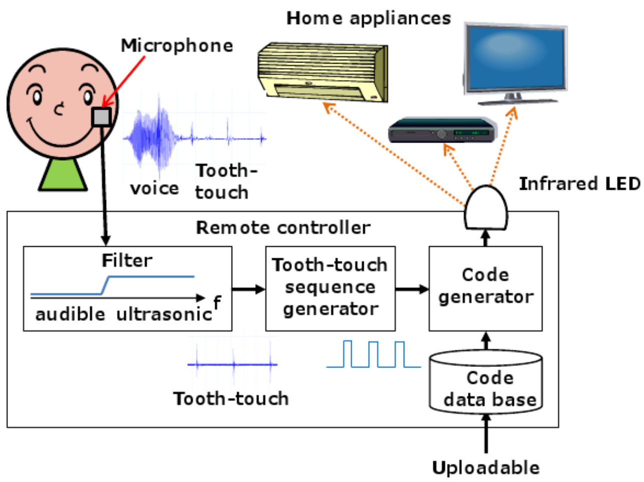

Fig. 1. System Overview.

The rest of this paper is organized as follows. Section 2 describes the system overview which employs our proposed method. Section 3 confirms that the ultrasonic wave can be detected by the conventional microphone, while hitting the upper tooth and the lower tooth. Section 4 designs the filtering hardware based on the above analysis by the conventional FFT and IFFT pair [5]. Then, Section 5 shows the performance and the hardware size of our filter hardware. Finally, Section 6 concludes this paper.

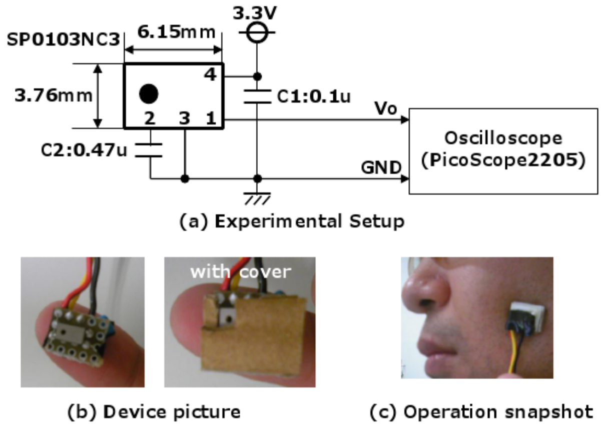

Fig. 2. Prototype Hardware.

2 SYSTEM OVERVIEW

Fig. 1 shows a system overview employing our proposed method. A microphone which has sensitivity to the ultrasonic region is attached to the cheek of the user. This is because if the microphone resides in front of the mouth, it may disturb the user's talking, eating, drinking and so on.

The shock wave is generated when one material strikes another material [8]. That is, when the upper tooth strikes the lower tooth, the ultrasonic wave that is equal to the shock wave may also be generated. However, this case would need to strike them rather strongly compared with the normal chewing. In general, many cheap and trivial microphones can generate some output to the ultrasonic wave [6, 7]. Thus, a special and expensive microphone is not needed to sense the ultrasonic wave.

The waveform from the microphone includes the voice and the tooth-touch. To leave only the ultrasonic wave of the tooth-touch from the waveform, it is input to a highpass filter with the cutoff frequency near the entrance of the ultrasonic region.

To make the command sequence from the tooth-touch sequence, the waveform including only the ultrasonic wave is rectified to the pulse wave. Considering of the number, the time duration and the time interval of pulses, the command sequence is generated [4]. Finally, the remote controlling code is generated by matching the generated command sequence with the registered it in the data base.

The data base can be updated arbitrarily. By using the data base, the differences among the makers and the products of the same maker can be hidden.

3 WAVEFORM ANALYSIS

3.1 Experimental Setup

To confirm that the ultrasonic wave can be detected by the conventional microphone, while hitting the upper tooth and the lower tooth, we have developed a prototype hardware shown in Fig. 2.

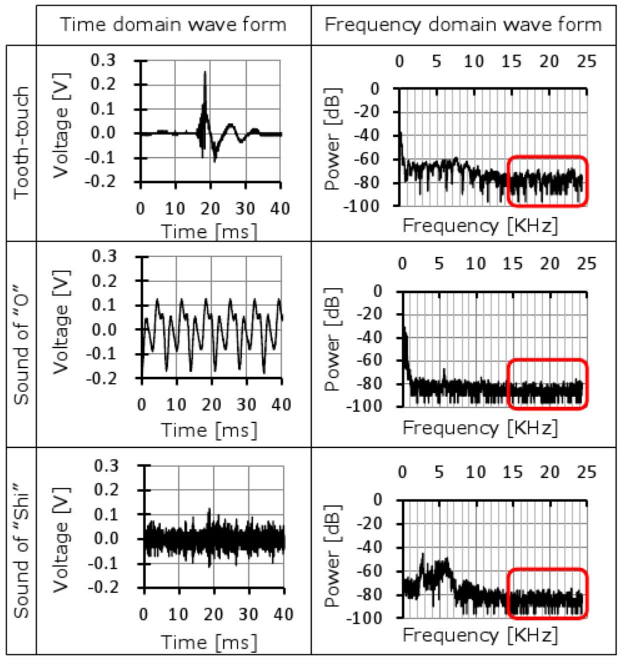

Fig. 3. Waveform Analysis.

The microphone used is the SP0103NC3 of Knowles Acoustics co. which has the wide sensitivity ranging from 100Hz to 10KHz or more [6]. The microphone is given 3.3V power. The capacitor of C1 in Fig. 2 (a) is a bipass condenser. This microphone includes an amplifier. The capacitor C2 is used to make its gain 10 times. Fig. 2 (b) is the pictures of the device we have developed. We also have made a cover of the corrugated cardboard so that the microphone does not contact directly to the cheek. When measuring, the microphone with the cover is attached to the user's cheek as shown in Fig. 2 (c).

We have probed the output voltage of the microphone by the oscilloscope, PicoScope2205 [9]. Via this oscilloscope, the waveform is acquired into the personal computer. The acquired waveforms are analyzed by the FFT we have developed by C language at the frequency domain. The rectangular window is used in this analysis. The time frame is about 42 ms and the number of data points is 2048. Thus, the sampling period is 20.5 us and the sampling frequency is 48 KHz. Consequently, the FFT can analyze the frequency ranging from 0 Hz to 24 KHz, with the resolution of about 23 Hz.

3.2 Result and Discussion

The waveforms of the time and frequency domains are shown in Fig. 3. As shown in Fig. 3, the tooth-touch has the larger power than that of the voice sounds, in the ultrasonic region from 15 KHz to 24 KHz. The difference between them reaches about 10 dB. This fact indicates that a conventional microphone can actually sense the shock wave generated by

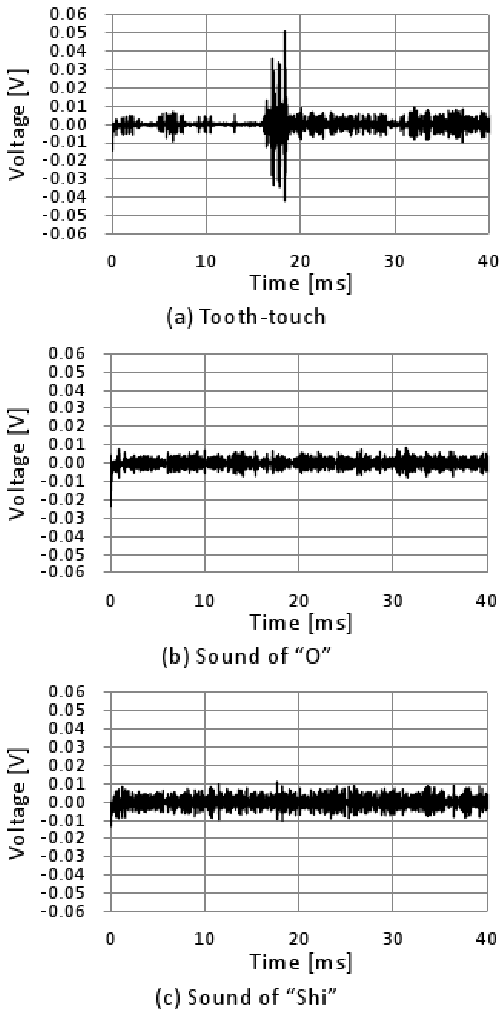

Fig. 4. Filtered Waveform by FFT–IFFT Pair.

the tooth-touch that the voice sounds never include.

Through the analysis mentioned above, the highpass filter with the cutoff frequency of 15 KHz is built by using FFT–IFFT pair [5]. This filter pads 0 from DC to 15 KHz on the waveform of the frequency domain generated by the FFT. Then, the filtered wavform of the time domain is regenerated by IFFT to this padded waveform of the frequency domain. This result is shown in Fig. 4. The waveform of the tooth-touch shows obviously larger peaks than those of the voice sounds. Thus, by the simple method setting the appropriate voltage threshold, the tooth-touch can be detected except for the voice sounds.

4 HARDWARE DESIGN

Fig. 5 is an FFT filter hardware we have designed. It has 6 pipelined stages. This hardware employs the decimation-in-frequency (DIF) radix-2 FFT. The width of the real number and the imaginary number is 16 respectively. That is, the value is the fixed-point number with 16bit width. The decimal point is set to the 1bit lower point from MSB. Thus, the input data must be normalized to [-1,1).

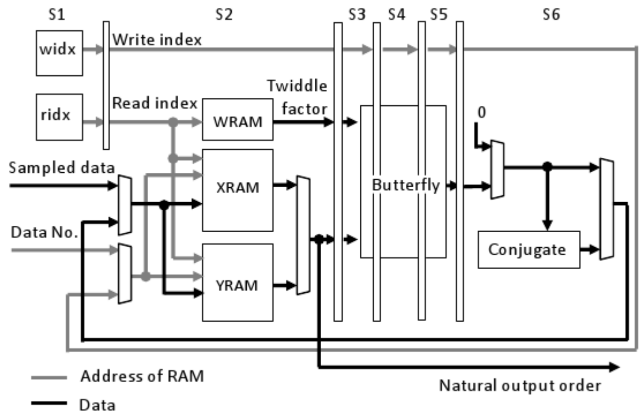

Fig. 5. Pipelined FFT Filter Hardware.

The sampled data comes from an AD converter to the data RAM (initially XRAM) according to the sampling rate used. Once the data RAM is filled with the sampled data, this hardware starts the pipelined execution. The FFT is constructed by log2(number of data points) stages. Our hardware executes the pipelined execution at each stage in the FFT. Thus, the continuous stages in the FFT are sequentially executed.

In each FFT stage, this hardware outputs the intermediate results calculated at the current stage to the temporary RAM (initially YRAM). Until the forward FFT finishes, this hardware uses the data RAM and temporary RAM, flipping their role per stage. In the final stage of the forward FFT, this hardware conjugates the complex number and stores the temporary RAM in order to execute the inverse FFT (IFFT) next. At the same time, the result with the index less than the index corresponding to the cutoff frequency is set to 0 in order to play the role of the highpass filter.

Once the forward FFT finishes, the IFFT starts immediately using the processed data in the internal RAM. Since all input data of IFFT has already been conjugated, the IFFT has only to perform the same execution as the FFT. After the IFFT, the filtered data in the data RAM are outputted sequentially to a DA converter according to the sampling rate.

This hardware consumes the $(6 + N)$ clocks in each FFT stage. The 6 clocks are for filling the pipeline with the data. The N is the number of data points. Thus, the forward and inverse FFT takes the $(2 \times log2(N) \times (6 + N))$ clocks for the completion of the FFT filter.

5 HARDWARE EVALUATION

5.1 Size and Clock Speed

To evaluate the amount of hardware and the achievable clock speed, we have implemented our hardware and the conventional FFT hardware to FPGA. The used tool is ISE13.2 and the used FPGA is spartan 6. The conventional hardware is generated by the Xilinx IP generation tool (Core-

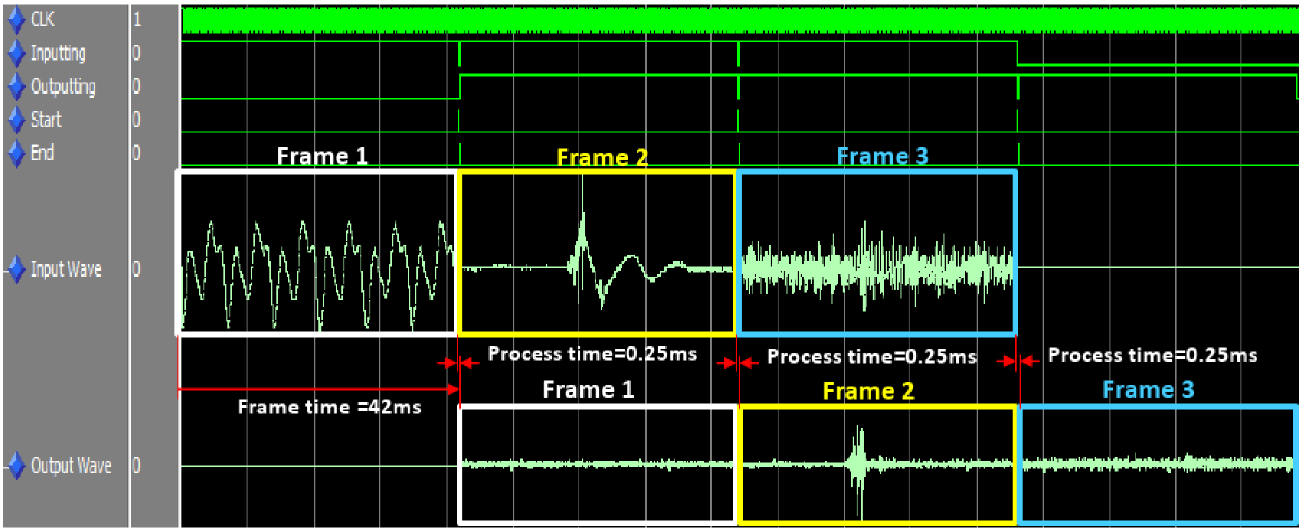

Fig. 8. Execution Snapshot.

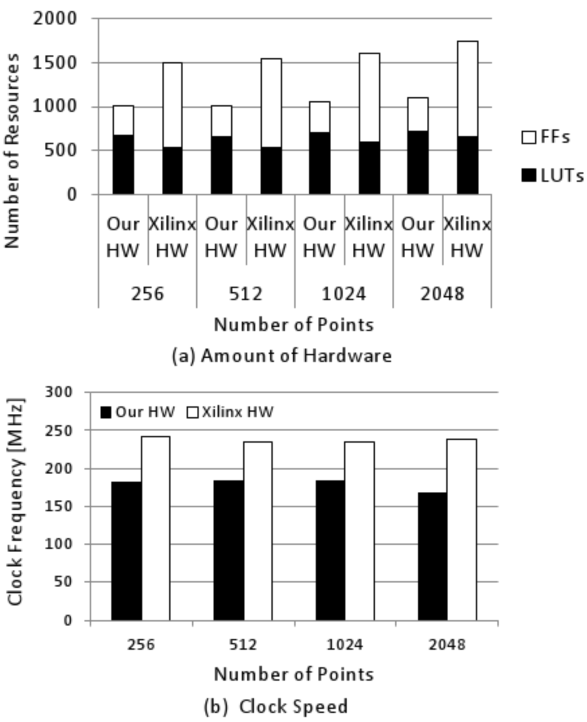

Fig. 6. Result of Hardware Evaluation.

Gen) [10]. The Xilinx FFT can switch the forward and reverse operations by the input signal. The parameters of the conventional FFT hardware generated by the CoreGen have been chosen where the hardware architecture of each other becomes equivalent.

Fig. 6 shows the result of implementation. Our hardware is smaller than the Xilinx FFT. However, the achievable clock speed of our hardware is less than the Xilinx FFT. This is because the Xilinx FFT may have deeper pipeline of the butterfly calculation than our hardware. That is, the Xilinx FFT consumes more flip-flops (FFs) than us to improve the

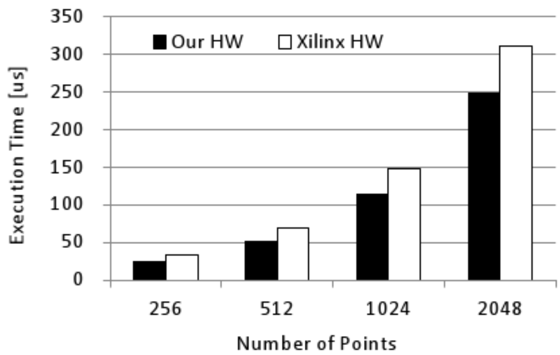

Fig. 7. Performance Evaluation.

clock speed. The hardware generated by the CoreGen is not the hardware description language (HDL) program but the netlist highly optimized to the target device. Thus, the Xilinx FFT cannot be ported to other FPGAs. In contrast, our hardware can be ported without any modification since it is described only by the generic features of HDL. In addition, the our hardware has room to optimize the pipeline structure to improve clock speed more.

5.2 Performance

Fig. 7 shows the result of the performance evaluation. We have used the ModelSim SE 10.0b as a logic simulator. The clock period is set to 10 ns; the clock frequency is 100MHz. Our hardware can improve the performance compared with the Xilixn FFT. In the Xilinx FFT, all data processed by the FFT have to be loaded from the internal output memory before IFFT. Then, the loaded data is re-inputted into the internal input memory for the Xilinx FFT setting the functionality to reverse operation. In contrast, our hardware immediately executes the IFFT using the processed data in the internal memory once the FFT finishes. The execution time that is less than 250us may be neglectable to the frame time of 42 ms as mentioned in Section 3.

Fig. 8 depicts the snapshot that our hardware actually operates in the environment that is same as Section 3. This result indicates that the execution time of our hardware is actually neglectable to the frame time. That is, our hardware has enough performance such as not to affect the realtime operation.

6 CONCLUSION

This paper has proposed a lightweight sensing method extracting the tooth-touch that does not need a sophisticated signal processing to eliminate the normal audio sound. This method uses an shock wave (i.e. ultrasonic wave) which is generated when the upper tooth and the lower tooth hit each other, instead of the sound wave of tooth-touch. By our proposed method, the the signal processing extracting the tooth-touch has only to perform a well-known filter eliminating lower frequency domain than the ultrasonic domain.

Through the preliminary experiment by using the prototype hardware with a conventional microphone, we have confirmed that the tooth-touch has the larger power than that of the voice sounds, in the ultrasonic region from 15 KHz to 24 KHz. Based on the above analysis, we have designed the filtering hardware by the conventional FFT and IFFT pair. Through the implementation to the FPGA, and the simulation near the actual environment, it has been confirmed that our hardware is small and has the enough performance for a realtime operation.

As future work, we will develop the total system as shown in Fig. 1. Then, we will perform the operation test by some testees.

Abstract: In this research, the merging problem is considered in the two-dimensional space instead of the one-dimensional space. In this paper, we set up the mathematic model of the system, formulate the two-dimensional merging problem as an optimization problem and solve it by model predictive control (MPC). To compare the simulation results with the practical situation, three typical cases were researched. In order to be more practical, the initial conditions of the cases were set according to the data obtained through analyzing the helicopter-shot video. The results represent that the MPC-controlled merging maneuver carried out safely and smoothly, and the relative positions after merging is also the same with the practical results in all the three representative conditions considered in this research. The absolute values of the accelerations of the vehicles are all below 3m/s^2, which are quite practical as well. The simulation results also represented the importance of the adjustment in driving during merging. By adjusting these vehicles, this control algorithm would generate the merging path that could avoid merging accident even in the very severe condition.

Keywords: automotive control, merging, model predictive control, optimal control, path generation.

1 INTRODUCTION

As motorization grows, it is becoming more and more important to realize a safe and ecological driving. From Ohashi et al [1] and Takayama et al [2] we could know that one of the riskiest maneuvers that a driver has to perform is to merge into the traffic, especially for the beginners and the aged people. It would take a lot courage and attention for them to conduct the maneuver. Iguchi et al [3] tells that merging is also one of the reasons for traffic congestion at the same time. The traffic throughput is often reduced at the merging part.

As a result, many researchers are now working on this subject. Jula et al [4] worked on collision avoidance merging through calculating the safe region. However, this paper does not represent the exact merging way for the vehicles. It will still be a difficult problem for the driver to merge into the traffic. Lu et al [5] worked on automated vehicle merging, and provided the 'adaptive solution', but the ecological requirement was not considered.

This paper presents an algorithm for merging path generation, in which the two-dimensional merging problem was formulated as a nonlinear optimization problem. The initial conditions were set according to the helicopter-shot video data. The input constraints, and the performance function, which realizes ecology and safety, were also set realistically. With all these elements chosen, the optimization problem was solved by the C/GMRES method proposed in Otsuka [6]. To investigate the effectiveness of the control algorithm, three representative cases were researched. The computer simulation results show that in all the three conditions the algorithm could generate smooth merging and the relative positions of the two vehicles are also practical. The results of the case, which have a quite severe initial condition, also represent the function of trajectory adjustment of this algorithm, what we think is also the key point during merging. If a vehicle merges automatically under the control of this algorithm, the driver would not feel any pressure during the merging maneuver, and the ecological requirement could also be satisfied at the same time.

The rest part of this paper is arranged as follows. In the section 2 we describe the formulation of the merging problem. The simulation results and analysis are shown in the section 3. The section 4 gives some conclusions of the whole paper.

2 MERGING PROBLEM FORMULATION

Due to the difficulty of merging and the time varying nature of the traffic situation, it is essential to predict the future situation of the traffic. Taking these aspects into account, we choose nonlinear model predictive control to solve the merging problem. As shown in **Fig. 1.**, in this research, only one vehicle on the merging lane, and one vehicle on the main lane, are considered. The vehicle on the merging lane is denoted as Vehicle1, and the vehicle on the main lane is denoted as Vehicle2 in the following parts of this paper. The merging problem is formulated as the following optimization problem.

$$\min_{a} J = \int_{t}^{t+T} L(x(\tau), a(\tau), \tau) d\tau \quad (1)$$

subject to the input constraints and the vehicle dynamics.

Here, x denotes the state variables, and a denotes the input of the system, respectively. The expression of function L is described in Subsection 2.3.

The optimal control input is updated at each time step by solving the above optimal control problems during the prediction horizon T. Only the first element of the optimal control sequence is applied to the system as the actual input. The process is repeated at each time step.

2.1 Vehicle model

To save the calculation time, a simplified vehicle dynamics is used. Instead of the actual three-dimensional movement, only the horizontal motion is considered. In this paper it is assumed that the main lane can be approximated to be straight and the width of the main lane is quite a small number compared to the length of it. Then the lateral movement of Vehicle2 is omitted. We assume that Vehicle2 always moves on the middle line of the main lane. This means that the coordinate, the velocity and the acceleration of Vehicle2 in the Y-axis direction are all 0.

Under these assumptions, the state equation of the system is as follows.

$$\dot{x} = \begin{bmatrix} \dot{x}_{hx} \\ \dot{x}_{hy} \\ \dot{x}_m \\ \dot{v}_{hx} \\ \dot{v}_{hy} \\ \dot{v}_m \end{bmatrix} = \begin{bmatrix} v_{hx} \\ v_{hy} \\ v_m \\ 0 \\ 0 \\ 0 \end{bmatrix} + \begin{bmatrix} 0 \\ 0 \\ 0 \\ a_{hx} \\ a_{hy} \\ a_m \end{bmatrix} \quad (2)$$

where

$$x = [x_{hx} \;\; x_{hy} \;\; x_m \;\; v_{hx} \;\; v_{hy} \;\; v_m]^T$$
$$a = [a_{hx} \;\; a_{hy} \;\; a_m]^T$$

Here, x_{hx} and x_{hy} denote Vehicle1's coordinate in X-axis and Y-axis respectively. v_{hx} and v_{hy} denote the velocities, and a_{hx} and a_{hy} denote the accelerations of Vehicle1 in the X-axis and Y-axis respectively. The x_m, v_m and a_m denote the coordinate, the velocity and the acceleration of Vehicle2 in X-axis respectively.

During merging, the two vehicles have to adjust their velocities. Therefore the brake and the accelerator are involved. The acceleration and the deceleration have upper bounds. It is assumed that the system has the following input constraints.

$$\begin{cases} -a_{hxmax} \le a_{hx} \le a_{hxmax} \\ -a_{hymax} \le a_{hy} \le a_{hymax} \\ -a_{mmax} \le a_m \le a_{mmax} \end{cases} \quad (3)$$

Where a_{hxmax}, a_{hymax}, and a_{mmax} are the upper bounds of the absolute value of a_{hx}, a_{hy}, and a_m, respectively.

2.2 Expression of the road shape

Fig. 1. shows the figure of the merging part of the helicopter-shot roads and the initial position of the two vehicles. The ○ represents the initial position of Vehicle1 and the × represents the initial position of Vehicle2.

Fig. 1. The merging part of the roads

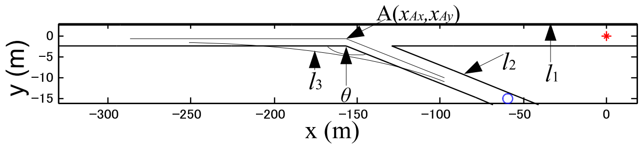

Fig. 2. The approximation results of the roads

To simplify the calculation we approximate this typical roads' figure with two straight lines and a hyperbola. The result is shown in **Fig.2.**. Choose the initial position of Vehicle2 as the origin of the coordinate system, the driving direction of Vehicle2 as the X-axis positive direction, the expressions of the lines are as follows:

$$l_1 = x_{hy} - \frac{1}{2}d = 0 \quad (4)$$

$$l_2 = kx_{hx} + x_{hy} + c = 0 \quad (5)$$

$$l_3 = 1 + \frac{(-\sin\frac{1}{2}\theta(x_{hy} - x_{Ax}) + \cos\frac{1}{2}\theta(x_{hy} - x_{Ay}))^2}{k_d(\tan\frac{1}{2}\theta)^2} - \frac{(\cos\frac{1}{2}\theta(x_{hx} - x_{Ax}) + \sin\frac{1}{2}\theta(x_{hy} - x_{Ay}))^2}{k_d} = 0 \quad (6)$$

The meanings of the variables are shown in Table 1. To keep safe, point A is set at the upper right side of the intersection point of the left side of the merging lane and the main lane.

Table 1. Variables in l_1, l_2, and l_3

d	the width of the main lane
k	the slope of the merging lane
c	a constant of the road shape
θ	the angle between the main lane and the merging lane
x_{Ax}	abscissa of the point A
x_{Ay}	ordinate of the point A
k_d	a constant of the shape of the hyperbola

2.3 Performance function

Subject to the input constrains, there are also many requirements which must be considered during the merging maneuver. These requirements are realized by the performance function as equation 1. The expression of function $L(x(\tau), a(\tau), \tau)$ is as follows.

$$\begin{aligned} L \;=\; & \frac{\omega_1}{r^2} - \omega_2 \log(l_1) - \omega_3 \log(l_2) - \omega_4 \log(l_3) \\ & + \omega_5 (v_{hx} - v_m)^2 + \omega_6 a_{hx}^2 + \omega_7 a_{hy}^2 + \omega_8 a_m^2 \\ & + \omega_9 (v_{hx} - v_i)^2 + \omega_{10} (v_m - v_i)^2 + \omega_{11} x_{hy}^2 \quad (7) \end{aligned}$$

Where ω_1, ω_2, ω_3, ω_4, ω_5, ω_5, ω_6, ω_7, ω_8, ω_9, ω_{10}, and ω_{11}, represent the weight of every term respectively, r is the relative distance of the two vehicles, defined in equation 8, and v_i is the desired value of the velocity.

$$r = ((x_{hx} - x_m)^2 + x_{hy}^2)^{\frac{1}{2}} \quad (8)$$

The cost function L consists of 11 terms. The first term is the cost due to the relative distance r. The second term, the third term and the forth term are the barrier functions to represent the road shape. Among them, the second term represents the restriction of the line l_1, which is shown in **Fig. 2.**, the third term represents the restriction of the line l_2, and the forth term represents the restriction of the line l_3. All the barrier functions are chosen as minus logarithm functions, because the restrictions of the road shape could never be violated, or there will be an accident. The fifth term describes the cost due to relative velocity, because running at the same speed would generate smooth merging. The terms from the sixth one to the eighth one describe the requirements of ecology. They minimize the accelerations and decelerations to save unnecessary fuel consumption. The ninth term and the tenth term make the two vehicles run as closely as possible at the desired value of the velocity v_i. The eleventh term is used to reduce the overshoot of Vehicle1.

3 SIMULATION RESULTS AND ANALYSIS

To investigate the effectiveness of the control algorithm, three representative cases are researched. The computer simulation was conducted with the time step $h = 0.01$s, and the prediction horizon is $T = 1$s. The values of the parameters are chosen suitably as follows: $\omega_1 = 4.0$, $\omega_2 = 0.01$, $\omega_3 = 0.01$, $\omega_4 = 0.01$, $\omega_5 = 0.01$, $\omega_6 = 0.03$, $\omega_7 = 0.01$, $\omega_8 = 0.01$, $\omega_9 = 0.01$, $\omega_1 0 = 0.01$, $\omega_1 1 = 0.01$, $d = 5$m, $k = -0.16$, $c = 24$, $\theta = 3.0$rad, $x_{Ax} = -160$m, $x_{Ay} = -2.0$m, $k_d = 0.01$, $v_i = -17$m/s (about 60km/h), $a_{hxmax} = a_{hymax} = a_{mmax} = 3$m/s^2.

3.1 Case 1

The initial conditions of the two involved vehicles in this case were set according to the data drawn from the helicopter-shot video. The obtained initial conditions are as follows: $(x_{hx}, x_{hy}) = (-59\text{m}, -15\text{m})$, $x_m = 0$m, $v_{hx} = -9.9$m/s, $v_{hy} = 1.6$m/s, $v_m = -20$m/s, $a_{hx} = 0$m/s^2, $a_{hy} = 0.03$m/s^2, $a_m = -0.05$m/s^2. The actual merging trajectories of this situation is shown in **Fig. 3.**, while the simulation result is shown in **Fig. 4.**. In **Fig. 3.** the ◯ represents the position of Vehicle1 and the × represents the position of Vehicle2 of every time respectively. In **Fig. 4.** The ∘ represents the position of Vehicle1 and the ∗ represents the position of Vehicle2 of every time respectively. The time in these two figures is: $t_0 = 0$s, $t_1 = 4$s, $t_2 = 8$s, $t_3 = 12$s, $t_4 = 16$s respectively. **Fig. 5.** shows the variation of the variables during the merging maneuver.

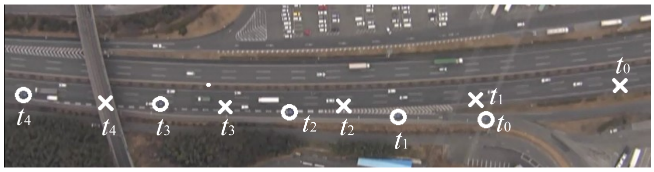

Fig. 3. The actual merging result of the case 1

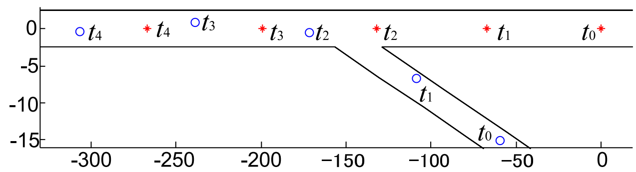

Fig. 4. Merging trajectories of the two vehicles of the case 1

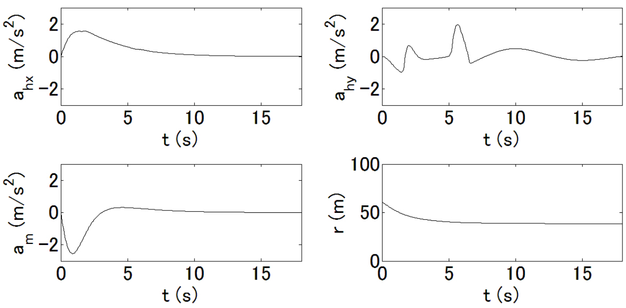

Fig. 5. Variation of the variables in the case1

We could see from **Fig. 4.** that Vehicle1 merged into the main lane without hitting any side of the main lane and the merging lane, and ran in front of Vehicle2 after merging. The time-history of r is shown in the second diagram in the second row of **Fig. 5.**. From it we could see that during the merging maneuver Vehicle1 kept an appropriate distance with Vehicle2. We could also see from **Fig. 5.** that all accelerations were kept below 3m/s^2.

3.2 Case 2

The initial condition of the two vehicles were set as follows: $(x_{hx}, x_{hy}) = (-59\text{m}, -15\text{m})$, $x_m = -59$m, $v_{hx} = -9.9$m/s, $v_{hy} = 1.6$m/s, $v_m = -20$m/s. Accelerations are all the same with the case 1. Since $x_{hx} = x_m$, $|v_{hx}| < |v_m|$, and accelerations are very small, without control, Vehicle1 would go to the behind of Vehicle2 and follow it. The simulation results, shown in **Fig. 6.** and **Fig. 7.**, represented that Vehicle1 merged to the behind of Vehicle2 successfully just as it was supposed to be.

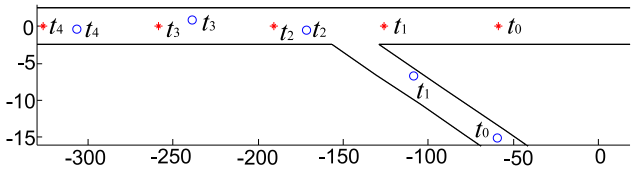

Fig. 6. Merging trajectories of the two vehicles of the case 2

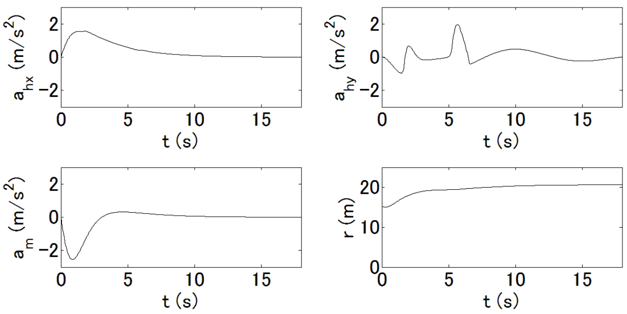

Fig. 7. Variation of the variables in the case 2

We could see from **Fig. 7.** that Vehicle1 kept an appropriate distance with Vehicle2 too. Accelerations are always below 3m/s^2 as well.

3.3 Case 3

As it was considered in the two dimensional space, x_{hy} could be involved in the calculation of r. This enables an extreme condition, that is: $(x_{hx}, x_{hy}) = (-59\text{m}, -15\text{m})$, $x_m = -59\text{m}$, $v_{hx} = -16\text{m/s}$, $v_{hy} = -1.6\text{m/s}$, $v_m = -16\text{m/s}$, $a_{hx} = 0\text{m/s}^2$, $a_{hy} = -0.03\text{m/s}^2$, $a_m = 0\text{m/s}^2$. Since $x_{hx} = x_m$, $v_{hx} = v_m$, $a_{hx} = a_m$, if no adjustment of trajectories is employed, the two vehicles will collide with each other. However the simulation results shown in **Fig. 8.** and **Fig. 9.** represented that Vehicle1 merged successfully to the behind of Vehicle2, and kept an appropriate distance. The accelerations were kept below 3m/s^2. The relative distance was more than 2m, hence the collision was avoided successfully.

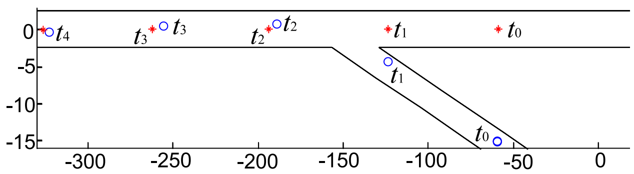

Fig. 8. Merging trajectories of the two vehicles of the case 3

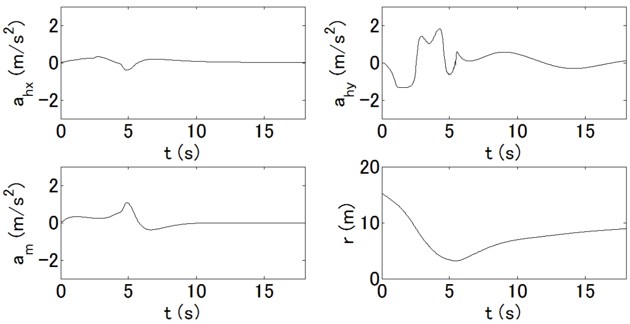

Fig. 9. Variation of the variables in the case 3

4 CONCLUSION

With the algorithm proposed in this paper, in all the three representative conditions the trajectories of the two vehicles showed that the merging vehicle merged successfully. The distance between the merging vehicle and the main lane vehicle is kept long enough during the merging maneuver as well. So the requirement of safety is satisfied. Besides, both the absolute values of the accelerations of the two vehicles can be kept below the specified value. Furthermore, the relative positions of the two vehicles in the simulation results are the same with the actual situations. That is, in the case 1 Vehicle1 became the preceding vehicle, which is the same with the helicopter-shot result, and in the case 2 Vehicle1 became the following vehicle as it should be. Remarkably, in the case 3 Vehicle1 slowed down a little to keep the safe distance between Vehicle2 and itself, instead of colliding with Vehicle2. This clearly shows the function of trajectory adjustment of this algorithm, which we think is also the key point of merging. The simulation results of the three cases show that the proposed algorithm enables smooth merging. Under the control of this algorithm, the two vehicles could merging smoothly by adjusting with each other.

Abstract: This paper presents a model predictive control (MPC) approach for the energy management problem of a power-split hybrid electric vehicle (HEV) system. The MPC is suggested to optimally share the road load to the engine and the battery. By analyzing the configuration of the power-split HEV system, we developed a simplified model for better implementation of MPC. The MPC problem is solved using numerical computation method: continuation and generalized minimum residual (C/GMRES) method. The computer simulation results showed that the fuel economy was improved using the MPC approach than the ADVISOR rule based approach over three driving cycles respectively. We conclude that the MPC approach is effective for the application of power-split HEV systems energy management and has the potential for real-time implementation. The simplified modeling method of the power-split HEV system configuration can be applied to other configurations of HEV.

Keywords: energy management, hybrid electric vehicle, model predictive control

1 INTRODUCTION

In recent years, HEV has become a research hotspot due to rising cost of fossil fuels and environmental problems. HEV has an electrical power source and it can downsize the engine, optimize the engine operating point and recuperate braking energy, which helps to improve fuel economy, and reduces emissions Serrao [1].

The key technology of HEV is its energy management. A lot of works have been published on the energy management problem of HEV systems. These approaches are typical in a family of optimal control techniques. And they can be subdivided into four categories: numerical optimization, analytical optimal control theory, instantaneous optimization, heuristic control techniques Serrao [1]. The most representative of numerical optimization is dynamic programming (DP) Serrao [1] and Liu et al [2] . However DP is based on known driving cycle which is impossible to get in reality. A kind of analytical optimal control techniques is Pontryagin's minimum principle Kim et al [3]. It gives necessary conditions that the optimal solution must satisfy. It also needs to know the entire driving cycle in prior. The instantaneous optimization includes the equivalent consumption minimization strategy (ECMS) Serrao [1]. It is based on instantaneous optimization and is easy to implement in real time. However it can not garantee the optimality over the whole driving cycle. Heuristic control techniques like rule based control strategies are robust but they are impossible to guarantee the optimality.

Although MPC Borhan et al [4] is also in numerical optimization class, its advantage is its predictive nature which can use vehicle-road-traffic information in the near future Deguchi et al [5] and Kamal et al [6] and be applicable to unknown driving cycles Kaku et al [7]. Based on a simple and accurate model of the system, MPC can provide real time control for the system.This paper examines energy management problem of a power-split HEV system over known and unknown driving cycles. Because the power-split HEV system has functionality of both series and parallel HEV systems, it has more modes to operate the energy management system for better fuel economy. The simplified modeling method by introducing contraints to reducing the system degrees of freedom is presented.

The rest of this paper is organized as follows: In Section 2, simplified model of the power-split HEV system and MPC algorithm are presented. Section 3 gives comparative simulation results between the MPC approach and the ADVISOR Wipke et al [8] rule based approach over three different driving cycles. Section 4 provides conclusions.

2 MODELING OF THE POWER-SPLIT HEV SYSTEM

The configuration of the power-split HEV system is shown in **Fig. 1.**. FD rerespents the final drive. The power split device (PSD) is the key component of the power-split HEV system and has both functionality of speed coupler and continuously variable transmission (CVT). There are five dynamic components: the engine, the battery, two motor/generators (M/G), and the wheels in this power-split HEV system, the only dynamic state to be considered in the optimal control problem based on known driving cycle is the battery state of charge (SOC) which can simplify the MPC algorithm for implementation. This simplification is possible because we introduce four constraints: the road load, the torque and speed relationship of the speed coupler, the power flow relationship among the five components, and the engine optimal operating line (OOL) using CVT. We divided the optimal control problem into two levels. The high level controller determines the optimal battery power and the low level controller determines the optimal torque and speed of the engine and the motor/generators. In this paper we focus on the high level controller.

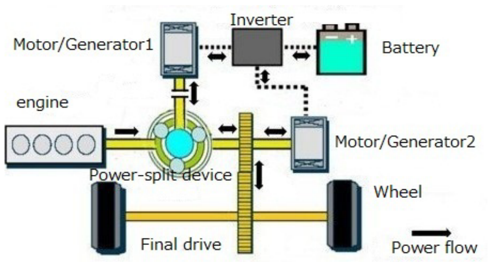

Fig. 1. Configuration of the power-split HEV system. Diagram adapted from Liu et al [2]

The torque and speed relationship of the speed coupler can be expressed as Ehsani et al [9]:

$$\begin{aligned} \tau_{eng}(t) &= -(1+\frac{R}{S})\tau_{M/G1}(t) \\ \tau_{eng}(t) &= -(1+\frac{S}{R})(\tau_{M/G2}(t) - \frac{\tau_{req}(t)}{g_f}) \\ S\omega_{M/G1}(t) &+ R\omega_{M/G2}(t) - (S+R)\omega_{eng}(t) = 0 \end{aligned} \tag{1}$$

where S and R are the number of sun gear and ring gear teeth respectively, $\tau_{M/G1}$, $\tau_{M/G2}$, τ_{req}, and τ_{eng} are the torques of the M/G1, M/G2, the road load and the engine respectively, $\omega_{M/G1}$, $\omega_{M/G2}$ and ω_{eng} are the angular speeds of the M/G1, the M/G2, and the engine respectively.

The power flow relationships among the five components at the inverter and the power split device in **Fig. 1.** are given as:

$$\begin{aligned} P_{batt}(t) &= P_{M/G1}(t) + P_{M/G2}(t) \\ P_{req}(t) &= P_{M/G1}(t) + P_{M/G2}(t) + P_{eng}(t) \end{aligned} \tag{2}$$

where P_{batt}, $P_{M/G1}$, $P_{M/G2}$, P_{eng}, and P_{req} are the power of the battery, the M/G1, the M/G2, the engine, and the road load.

We assume that the engine always works along its OOL using CVT which can also be considered as a constraint. When the engine power is known, by looking up the table of OOL, the engine speed and torque can be obtained.

We evaluate the fuel consumption using Willans line method to reduce the complexity of the engine fuel consumption model. It was found that good approximation are obtained using the Willans line method Serrao [1]. The fuel consumption can be expressed as:

$$\dot{m}_f(t) = \dot{m}_f(P_{req}(t) - P_{batt}(t)) \approx c_f(P_{req}(t) - P_{batt}(t)) \tag{3}$$

where c_f is a constant.

The road load which are the vehicle speed and the required power at the wheels is known when the driving cycle is known. From the configuration of the power-split HEV system, the M/G2 speed is also known as:

$$\omega_{M/G2}(t) = \frac{g_f}{r_w} v_{req}(t) \tag{4}$$

where $\omega_{M/G2}$ is the speed of the M/G2, g_f is the final drive gear ratio, r_w is the wheel radius, v_{req} is the required vehicle speed by the driving cycle.

When the drivng cycle is known, the system dynamics is reduced to the battery dynamics. The optimization objective is only the fuel economy. The only state variable is the battery SOC, x_{SOC}, and the control input is the battery power. The battery model can be expressed as Kim et al [3]:

$$\dot{x}_{SOC} = -\frac{V_{OC} - \sqrt{V_{OC}^2 - 4P_{batt}R_{batt}}}{2R_{batt}Q_{batt}} \tag{5}$$

where V_{OC}, R_{batt}, and Q_{batt} are the open circuit voltage, the internal resistance, and the capacity of the battery.

When the driving cycle is unknown, the system dynamics includes the battery and the vehicle dynamics. Both the fuel economy and the driving profile are optimized. The system model is then represented by

$$\dot{x} = \begin{bmatrix} v \\ w - \frac{1}{2}\rho C_D A v^2/m - g\mu - g\sin(\theta(p)) \\ k_p(u_1 - w) \\ -\frac{V_{OC} - \sqrt{V_{OC}^2 - 4P_{batt}R_{batt}}}{2R_{batt}Q_{batt}} \end{bmatrix} \tag{6}$$

$$\begin{aligned} x &= [p\ v\ w\ x_{SOC}]^T \\ u &= [u_1\ P_{batt}]^T \end{aligned} \tag{7}$$

where p, v, and w are the vehicle position, speed, and acceleration or deceleration converted from the traction force or brake force. ρ, C_D, A, m, g, μ, and $\theta(p)$ are the air density, the air drag coefficient, the frontal area of the vehicle, the vehicle mass, the gravity acceleration, the rolling resistance coefficient, and the road grade. u_1 and k_p are the vehicle acceleration or deceleration control input and the delay constant.

Due to the simplified modeling method derived from the power relationship among the engine, the battery and the road load which is general in the HEV configurations, it can be applied to other HEV configurations.

3 MODEL PREDICTIVE CONTROL

The optimal control problem based on known driving cycle is defined as:

$$\text{Min. } J_{known} = \int_t^{t+T} L_{known}(x_{SOC}(\tau|t), P_{batt}(\tau|t))d\tau \tag{8}$$

$$\begin{aligned} \text{Subject to:} \quad & SOC_{min} \le x_{SOC}(\tau|t) \le SOC_{max} \\ & P_{battmin} \le P_{batt}(\tau|t) \le P_{battmax} \end{aligned} \tag{9}$$

where T is the prediction horizon, $_{min}$ and $_{max}$ denote the minimum and maximum bounds of battery SOC and power.

The objectives of this optimal control problem is to minimize the fuel consumption, meanwhile, the battery SOC is maintained between the thresholds. This is achieved by minimizing the cost function L_{known} including three terms: the fuel use, the engine use and the mechanical brake use, and the deviation of battery SOC from the reference value. The cost function L_{known} is defined as follows:

$$\begin{aligned}L_{known} &= w_1 c_f (P_{req} - P_{batt})/(1 + e^{-\beta(P_{req} - P_{batt})}) \\ &+ w_2 (P_{req} - P_{batt})^2 + w_3 (x_{SOC} - SOC_d)^2 \\ &+ w_4 (-\ln(x_{SOC} - SOC_{min}) - \ln(SOC_{max} - x_{SOC})) \quad (10)\end{aligned}$$

where SOC_d is the desired SOC value. w_1, w_2, w_3 and w_4 are the weights.The sigmoid function is chosen to evaluate the vehicel brake fuel comsumption. The log barrier function is used as a penalizing term for violations of state contraints.

The optimal control problem based on unknown driving cycle is defined as:

$$\text{Min. } J_{unknown} = \int_t^{t+T} L_{unknown}(x(\tau|t), u(\tau|t)) d\tau \quad (11)$$

$$\begin{aligned}\text{Subject to: } \quad & SOC_{min} \le x_{SOC}(\tau|t) \le SOC_{max} \\ & P_{battmin} \le P_{batt}(\tau|t) \le P_{battmax} \\ & u_{1min} \le u_1(\tau|t) \le u_{1max} \quad (12)\end{aligned}$$

The cost function $L_{unknown}$ is defined as follows:

$$\begin{aligned}L_{unknown} &= w_x L_x + w_y L_y + w_z L_z + w_d L_d + w_e L_e + w_f L_f \\ L_x &= (w - \frac{1}{2}\rho C_D A v^2 / m - g\mu)^2 \\ L_y &= (v - v_d)^2 \\ L_z &= c_f (mwv - P_{batt})/(1 + e^{(-\beta(mwv - P_{batt}))}) \\ L_d &= (x_{SOC} - SOC_d)^2 \\ L_e &= (mwv - P_{batt})^2 \\ L_f &= -\ln(x_{SOC} - SOC_{min}) - \ln(SOC_{max} - x_{SOC}) \quad (13)\end{aligned}$$

where w_x, w_y, w_z, w_d, w_e, and w_f are the weights, v_d is the desired vehicle speed. The first term of $L_{unknown}$ indicates the acceleration and braking cost.

At each time t, the optimal control input is computed by solving the above optimal control problems during the prediction horizon T. Only the first element of the optimal control sequence is applied. At the next time step, the prediction horizon moves forward, and the process is repeated.

4 COMPUTER SIMULATION

4.1 Simulation conditons

In this simulation, vehicle parameters are obtained from ADVISOR 2002. **Fig. 2.** gives the engine OOL of the power-split HEV system. The vehicle parameters are m=1368 [kg], ρ=1.23 [kg/m³], C_D=0.3, A=1.746 [m³], g=9.8 [m/s²], μ=0.015, V_{OC}=307.85 [V], R_{batt}=1.004 [Ω] and Q_{batt}=6 [Ah], c_f=0.0874. The control parameters are β=0.5, SOC_d=0.7, SOC_{min}=0.6, SOC_{max}=0.8, k_p=10, $P_{battmin}$=-20 [kW], $P_{battmax}$=20 [kW], u_{1min}=-3 [m/s^2], u_{1max}=3 [m/s²], v_d=50 [km/h], w_1=4000, w_2=5000, $w_3 = 3.5 \times 10^7$ and $w_4 = 10^5$, w_x=10, w_y=20000, w_z=40000, $w_d = 9 \times 10^7$, w_e=2200 and w_f=100. The MPC problem is solved using a numerical computation method: continuation and generalized minimum residual (C/GMRES) method Ohtsuka et al [10].

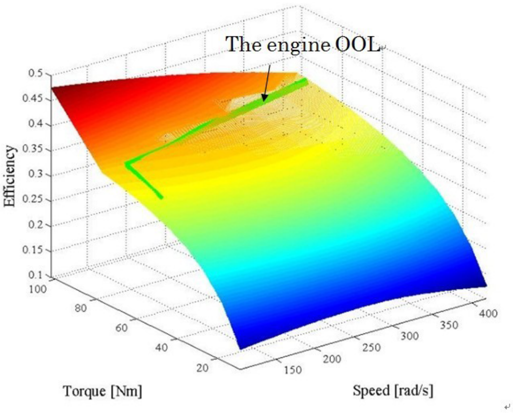

Fig. 2. The engine OOL of the power-split HEV system

Driving cycle 1 included acceleration, deceleration, and cruise scenario (see the first row of **Fig. 3.**). Driving cycle 2 was the standard driving cycle: Japan 10-15 (see the first row of **Fig. 4.**). Driving cycle 3 was an unknown driving cycle with road slopes (see the first and second row of **Fig. 5.**).

4.2 Simulation results

Driving cycle 1:

The simulation results of driving cycle 1 were presented in **Fig. 3.** using the ADVISOR simulation results as comparison. We observed from these results that the MPC algorithm performed better than the ADVISOR rule based algorithm. In the case of MPC, the battery assisted vehicle driving and recuperated vehicle braking power properly.

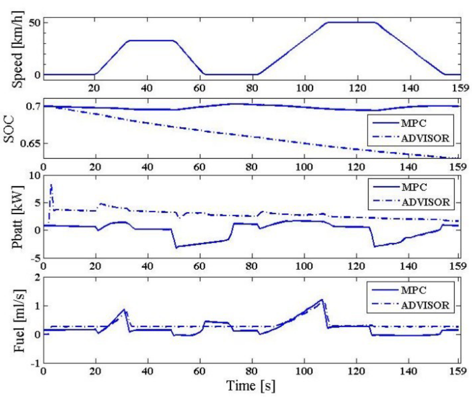

Fig. 3. Performance of the MPC algorithm and the ADVISOR rule based algorithm over driving cycle 1

Driving cycle 2:

Japan 10-15 simulation results (see **Fig. 4.**) showed that the MPC algorithm performed similarly as driving cycle 1.

Driving cycle 3:

The unknown driving cycle simulation results (see **Fig. 5.**) showed that the MPC algorithm could also use the road slope information well to reduce the fuel consumption. The vehicle accelerated before the upslope to make use of the kinetic energy. The battery recuperated vehicle braking power during the vehicle downslope driving. Since over this low road load

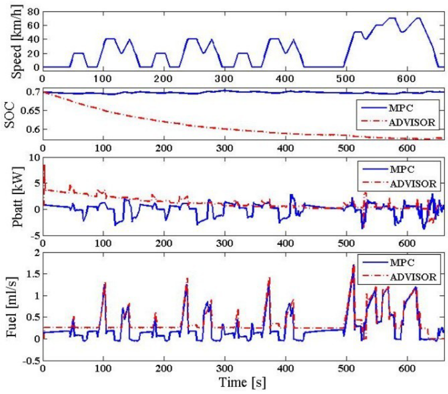

Fig. 4. Performance of the MPC algorithm and the ADVISOR rule based algorithm over driving cycle 2

driving cycle the ADVISOR rule-based algorithm used the motor assist driving mode, the fuel consumption reduction by MPC was not evident.

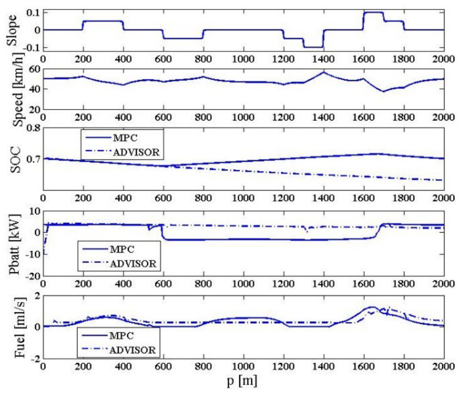

Fig. 5. Performance of the MPC algorithm and the ADVISOR rule based algorithm over driving cycle 3

The overall fuel economy results over the three driving cycles were presented in **Table. 1.**. We can see that the MPC approach can impove fuel economy significantly and keep the final SOC near the initial SOC compared to the ADVISOR approach over the three driving cycles. Although the ADVISOR approach considers the idling, accessories losses, battery efficiency and motor/generator efficiency, it performs poorly according to the road load, which results in the large deviation of the battery SOC. Therefore the MPC approach results are optimistic because of not considering those losses, but the results are still reasonablely better compared with the ADVISOR approach.

5 CONCLUSION

MPC of a power-split HEV system was presented. The simplified system model was developed. The simulation results of the MPC algorithm using known and unknown driving cycle revealed a significant improvement of the fuel economy compared to the ADVISOR rule based algorithm. Because the MPC algorithm uses simplified system model and can be applied to unknown driving cycle, it has the potential for the real-time implementation. The simplified modeling method of the power-split HEV system configuration can also be applied to other configurations of HEV.

Table 1. Fuel economy comparison results

Method	Cycle	Initial SOC	Final SOC	Fuel (km/l)
MPC(known)	Cycle1	0.7	0.6997	26.40(+33.64%)
ADVISOR	Cycle1	0.7	0.6302	17.52
MPC(known)	Cycle2	0.7	0.6995	23.97(+32.87%)
ADVISOR	Cycle2	0.7	0.5745	16.09
MPC(unknown)	Cycle3	0.7	0.7000	38.49(+16.19%)
ADVISOR	Cycle3	0.7	0.6312	32.26

Abstract: In recent years, Web searching on mobile devices with a touchscreen has increased. However, a search query using a mobile phone is not easy as that using a PC. In this study, we propose a search support system that provides user search queries and Web pages to suit the user's situation. This system continually records the user's location, time, Web search log and call log. Since the system does not have a server, the user's mobile phone records everything and provides search assistance to the users based on the recorded information.

Keywords: Mobile Phone, Web Serch, Query, Search Intention

1 INTRODUCTION

The increase of smartphones with a Web Browser has resulted in an icreasing need to view Web pages created for a PC using a mobile terminal rather than for mobile phones. Nevertheless, the labor required for searching is a major issue for mobile devices using touchscreens, unlike PCs where data can be entered from the keyboard. In order to solve such problems, a method recommending useful search queries and web pages from the search history, Web page information recorded when the user searches the Web, has been proposed. Whereas, they are focused on activities in the user's web search. However, little research on Web page recommendations has focused on the user's behavior in the real world.

Our goal is to recommend appropriate Web pages to users and to determine their search intentions with mobile phones depending on their situation. Their search intentions are related to the content that they utilize on their mobile phones , not rather than being limited to their user's Web search history. Call and mail contents are rich with keywords of interest to the user. Recently, smartphones have becomes popular. Therefore, with the user's permission, it is easy to collect Web search history and call history beyond the user's location. However, the risk of leaking user's private information to others has increased. Also related to the issue of personal privacy is the fact that the proposed system uses call logs.

The purpose of this study is to recommend Web pages that users can easily visit and search queries that users are expected to use, in order to eliminate the need for user input and to allow quick access to the desired page. For this reason, this system recommends Web pages and search queries based on the user's situation e.g., latitude and longitude, time, call log, and Web search log from the mobile phone.

In this paper, Section 2 discusses the motivation for this study. Section 3 describes the design of the proposed syste. Section 4 describes the implementation of the proposed design. Section 5 concludes this paper.

2 MOTIVATION

Mobile phones are used in many different situations. Therefore, research has focused on gathering information that can be observed with mobile phones and added sensors, and the use of the collected information to suit the user 's situation. For example, Uesaka et al. observed actual daily mobile phone user operations with minimal interference for six months [1]. As a result, they demonstrated that Machine learning could be used predict operation from the collected information. Additionally, Uesaka et al. proposed a system to recommend applications, according to the situation, based on collected information and application usage [2]. In studies using sensors in mobile phones, Minamikawa et al. proposed a system that indicates calories burned by the user by estimating the user movement with an accelerometer in the phone [3]. Yamamoto et al. proposed to a system to recommend contents using a GPS sensor in a mobile phone[4]. The system in the present study searches for the overlap between context of the content to be recommended and context in the user's Web page by recording Web page browsing history, location information, and time. Moreover, the system recommend a wide range of information. The difference between the system and this system is to decide to delivery information and to recommend contents which Web pages are viewed by the user.

Mobile phones involve many physical constraints such as the difficulty of entering information as compared to a PC. It is studies on the support that has been searching for many studies. Letizia by Lieberman automatically recommends links based on the user's browsing behavior[5]. FIXIT by Hart et al. searches repair information from copier manuals, associating keywords related to the symptoms of the failure[6]. Uchiyama et al. proposed an information search system in the user's clearance time, by using mobile phones that recommend queries extracted from the browsing history on the user 's PC[7]. Y!Q by Kraft et al. searches related pages, analyzing the Web pages content[8, 9]. For example, when a user searches news articles related to browsing news articles, the system extracts only the keywords that the user selects the area of care from the area of interest. Hattori et al. proposed a system that presents queries that meets the user's search request by gestural manipulation after the user specifies a range of the word that would be[10]. Nishio et al. proposed a recommendation system that automatically extracts words that are likely to be used as a search query from Web pages that the users views[11]. Their studies recommend queries that are expected to be available to users within a Web page. In contrast, the present system recommends search queries based on the user's current location.

3 SYSTEM DESIGN

This section describes the processing flow and a system overview of search support that reduces input effort by reaching its goal of a user's page.

3.1 System overview

The purpose of the proposed system is to reduce the user's input in a search. Therefore, the user's input must not be inhibited when this system is collecting necessary information. This information must be collected automatically when the user acts (e.g., searches). Furthermore, the information collected and removed should be ready for utilization, and the user's privacy must be protected. Screens to help users find prepare recommended Web Page screen and recommended search query screen. A screen recommends Web pages in a list format, in descending order based on points assigned by this system. The information on each page includes the title, some excerpts from the text in the body, and frequently appearing keywords. In addition, each page has a related- view button. Thus, even if the desired page is not presented, the user can find some input by pressing the related-view button to close the related page. A screen also recommends search queries in a list format, in descending order based on points assigned by this system, and each query has a related-view button. Two screens were prepared for the following reasons. To reduce the user 's input, it is better to recommend Web pages than to recommend search queries. However, a Web page provides more information than a search query does. Therefore, the method of recommending a search query can be more widely applied than the method of recommending Web pages. Thus, the search query screen supplements the Web Page screen.

3.2 Processing flow

This section describes information processing (e.g., Web browsing history, call log and location).

Location information

The mobile device records position (latitude and longitude) information on a regular basis, and it guesses the user 's movement. Latitude and longitude information is based on GPS information when a GPS is available. When a GPS is not available, latitude and longitude information is received as a unit area of 300m by acquiring radio signals from the base station. We want to collect latitude and longitude information in short intervals in order to estimate the user 's movement. Here, latitude and longitude information is acquired every 600sec, due to battery power[12]. The user is classified as either stationary or moving, based on the speed calculated using latitude and longitude information obtained from the mobile phone. If the mobile terminal indicates lack of movement, Web search history and call history in the error range of latitude and longitude information from the current position are recognized in the same stationary period. If the mobile phone indicates movement, it refers to the Web search history on the move rather than the current position. In addition, the location information is also recorded in the Web browsing history and call history.

Web Browsing Logs

Each time the user searches, Web browsing logs are collected as follows. In general, the users who wants to search for information enters a query into a search engine and then presses the search button. The search results page appears, and the user selects the desired page.

This system detects that the page has changed and collects information about the user's location and the query that the user entered when the search button is pressed. No information about the page that appears in the search engine results list is extracted; this system collects information on the page that the user selects from the search results (e.g., the user 's start time of viewing that page, the URL of the page, keywords appearing on a page, and location information at that time). When the user closes the browser or moves to a different page, this system records the time just be-

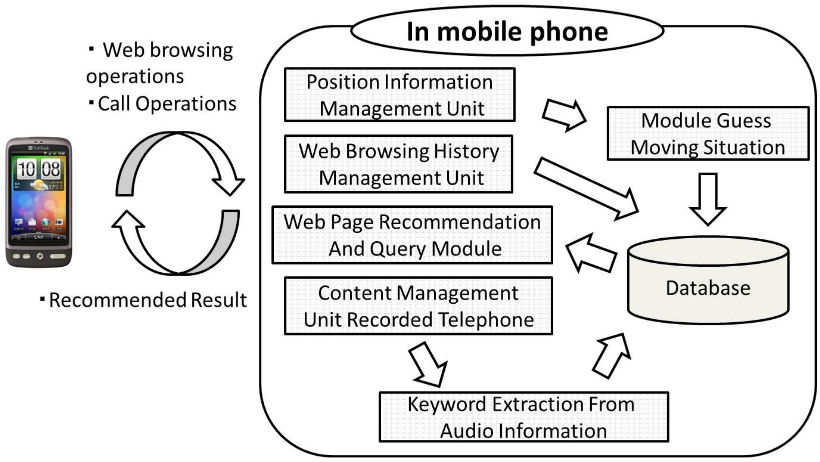

Fig. 1. System configuration

fore the page you were viewing. Thus, the time during which the user was looking at the page is recorded. This is one indicator of whether or not the user was interested in that page.

Call Logs

Each time the user calls, the call log is collected as follows. The system detects that the user's mobile phone is in initiating a call. At that time, this system collects current time and location information, as well as the content of the calls (e.g., what the user said during the call) and keywords from it. When the system detects that the call has ended, it stops grecording the content and extracting keywords. In this case, only the user's voice information is recorded since the called or calling party has not consented to the recording of his or her voice.

This system always records the user 's location information, Web browsing history, and call history. It weights Web pages and search queries using the information collected and recommends Web pages and search queries depending on the user's location and the time when the user starts the system.

4 IMPLEMENTATION

This system is implemented on an HTC Desire SoftBank X06HT equipped with Android 2.2. Getting location information uses locaton package(android.location) in AndroidSDK[13]. GPS that can be used outdoors is better than to obtain the signal strength from base station, so that this system primarily uses GPS. In case that this system does not use only GPS, it uses to obtain the signal strength from base station. Jump detection during Web browsing uses webkit package(android.webkit) in AndroidSDK. In feature extraction from Web Pages, JavaScript extracts HTML sources. The full text is extracted with tagsoup. Feature extraction from the full text of Web Pages uses WebAPI(e.g., Yahoo! keyphrase extraction). The process documenting of call of content uses speech package(android.speech) in AndroidSDK. Feature extraction from call contents is also performed. This system processing almost completely on a mobile phone to protect privacy. Fig. 1 depicts the configuration. From the same viewpoint, algorithm(e.g., Collaborative filtering) does not use, because others do not use the information recorded in the user's mobile phone.

5 CONCLUSION

This study proposes a search support system for a mobile phone with a touchscreen. This system records the user 's Web browsing history, call history, and location and automatically collects information based on the user's daily operations. By utilizing these information, A system to close to help users conduct searches implements. To protect the user's privacy, data is recorded in only the user's mobile device, and the user can view and remove the data. A system to help users conduct searches implements by varying the contents of Web pages and search queries recommendation to the user depending on the user's moving situation and location information.

Since evaluation indicates a time is delay for reading a Web page that users access on a daily basis, it is necessary to review the procession of keyword extraction. Specifically, it is necessary to reduce keyword extraction, or to perform keyword extraction when the user is' not operating his or her mobile phone.

Future tasks include reflecting the user's search, increasing the information collected in the PC Web Browsing History, reducing keyword extraction time, improving the relevancy of recommendations and processing when recording data is little.

Abstract: We develop a sentiment analysis system for domain-specific texts. The sentiment analysis estimates a polarity of a text, for example positive or negative. To develop such a system a dictionary, which consists of words and their polarities, is needed. The dictionary reflects specialists ' knowledge and affects a sentiment analysis precision. Hence, it is important to construct an appropriate dictionary. And making a dictionary needs much human cost generally. As a good dictionary is constructed, the human cost must be decreased. To achieve the goal our proposed approach uses a bootstrap method to decrease human cost and a χ^2 statistic to estimate a polarity of a word correctly. To evaluate a performance of the proposed approach we carried out an evaluation experiment using real stock market news, T&C news. We confirmed that the proposed approach could construct a dictionary but had some problems which were inappropriate words and that the dictionary did not have enough words.

Keywords: Sentiment Analysis, Bootstrap, Natural Language Processing

1 INTRODUCTION

Many reviews are posted in shopping sites and opinion sites and shared in the Internet. The reviews include opinions of users and are read by many users and affect a consumer activity. Hence, opinion mining and sentiment analysis is paid attention by many researchers. Turney[1] reported because there often were positive words around a positive word, a polarity of a word was determined using a cooccurrence frequency. Hatzivassiloglou et al[2] determined a polarity of a word using a conjunction. Nasukawa et al[3] estimated a polarity of a word using context coherence. Pan et al[4] focuses domain-specific words and domain-nonspecific words and developed a cross-domain sentiment classifier.

In the paper we focus a sentiment analysis for domain-specific texts. The domain-specific texts include a lot of technical terms because only users shared with the same interests read them. Hence, to develop the sentiment analysis system we must deal with the technical terms effectively. However, it is difficult to determine polarities for the terms because specialists for the specific domain need to determine them. This means that the specialists pay much effort to construct a dictionary that represents polarities of the technical terms. To solve the problems a dictionary construction approach must decrease human costs.

Previous works used a cooccurrence frequency to determine a polarity that a word has not attached yet. It is important what kind of evaluation criterion is used to evaluate how often the word occurs with positive words or negative words. The simple cooccurrence frequency includes much noise and is not a reliable criterion. Hence, a new evaluation method, which is hard to be disturbed by noise, must be proposed.

The χ^2 statistic is one of criteria that evaluates a bias of an occurrence probability. As the χ^2 statistic is big, it means that occurrence of the word has statistical significant. Hence, if words have the bigger χ^2 statistic than a threshold that is enough big, a pseudo cooccurrence can be neglected. Using the χ^2 statistic, we construct a dictionary that includes many words attaching correct polarities.

In the paper we presents a dictionary construction approach that uses a bootstrap method and a χ^2 statistic to evaluate the polarity of a word. The bootstrap method starts a dictionary construction from a small dictionary and expands it using predefined rules. Hence, the initial small dictionary must be constructed manually but human costs are decreased because of the small number of words in the initial dictionary.

Finally we check our proposed approach using real stock market news, T&C news. At first the polarity dictionary is constructed using all the articles in T&C news. We discuss the dictionary constructed with our proposed approach and found some characteristics.

1. The dictionary consists of the similar number of positive and negative words.

2. The dictionary includes words attaching correct polarities form the viewpoint of human judgment.

3. The dictionary includes some inappropriate words. For example, some words have opposite polarities.

4. The number of words in the dictionary is too small comparing with the number of all adjectives in all the articles.

In the next section we describe the proposed approach and the details of our approach are presented. In Section 3 we explain experiment and discuss the proposed approach. And we conclude our work in Section 4.

2 PROPOSED METHOD

We explain a dictionary construction method using a bootstrap method and χ^2 statistic for domain-specific texts. To determine a polarity for a domain-specific text it is important to use technical terms appropriately. For example, though "hooked" is often appeared in video game reviews[4] and is a positive word, it is a neutral word in some cases and a negative word in other cases. So it is important to construct a specific dictionary that assigns correct polarities with words.

In making the dictionary it is important to decrease human cost. Because a dictionary is constructed using a lot of specialists' knowledge generally, it denotes that making a dictionary needs a lot of human costs. Hence, we develop an automatic dictionary construction method using the least human costs.

To achieve our aim we use a bootstrap approach to construct a dictionary. The bootstrap approach stars from a small dictionary where some words are registered according to specialists' knowledge. A dictionary construct cost is very small because the initial dictionary is small. The approach expands the dictionary using rules that are used to select words that are assigned with polarities. In a proposed approach we use a cooccurrence frequency with words that have positive or negative polarities. We show a bootstrap flow below.

1. Select seed words and assign their correct polarities manually.
2. Count cooccurrence frequency with polarity-attached words.
3. Select words that polarities are estimated using the cooccurrence frequencies.
4. Retuen step 2 if a polarity is assigned with a new word in step3.

In the flow it is important what kind of criterion is used. Words that occur frequently with positive words are assigned with positive polarities. Hence, we must evaluate a bias of the cooccurrence frequency. The proposed approach uses a χ^2 statistic to evaluate the bias because a raw cooccurrence frequency is so noisy. Equation (1) shows how to calculate χ^2 statistic from cooccurrence frequencies.

$$\chi^2(w) = \sum_{w^s \in D_s} \frac{(\mathrm{freq}(w^s, w) \quad \frac{\mathrm{freq}(w^s)\mathrm{freq}(w)}{N})^2}{\frac{\mathrm{freq}(w^s)\mathrm{freq}(w)}{N}} \tag{1}$$

The $\mathrm{freq}(w_1, w_2)$ is cooccurrence frequency in a sentence and the $\mathrm{freq}(w)$ is occurrence frequency in a text corpus. The N denotes the number of all the sentences in the text corpus and the D_s denotes a set of seed words.

In this approach we use the χ^2 statistic to evaluate how often a word occurs with positive words or negative words. In constructing a dictionary the number of words attached with positive polarities are different from the number of words attached with negative polarities. Because the number of polarity-attached words have an affect on the χ^2 statistic, we must deny the affect in calculating the χ^2 statistic. The improved χ^2 statistics is defined below.

$$\chi_P^2(w) = \frac{1}{|D_S^P|} \sum_{w^s \in D_s^P} \frac{(\mathrm{freq}(w^s, w) \quad \frac{\mathrm{freq}(w^s)\mathrm{freq}(w)}{N})^2}{\frac{\mathrm{freq}(w^s)\mathrm{freq}(w)}{N}} \tag{2}$$

$$\chi_N^2(w) = \frac{1}{|D_S^N|} \sum_{w^s \in D_s^N} \frac{(\mathrm{freq}(w^s, w) \quad \frac{\mathrm{freq}(w^s)\mathrm{freq}(w)}{N})^2}{\frac{\mathrm{freq}(w^s)\mathrm{freq}(w)}{N}} \tag{3}$$

The D_S^P and the D_S^N are a set of words with positive polarities and a set of words with negative polarities respectively.

The bigger a χ^2 static of a word is, the more reliable a polarity of the word is. Hence, when the χ^2 static is over a threshold, which are defined previously, the word is registered in the dictionary.

$$w = \begin{cases} \text{positive} & (\chi_P^2(w) > \text{threshold}) \\ \text{negative} & (\chi_N^2(w) > \text{threshold}) \end{cases} \tag{4}$$

As the threshold is big, it is difficult to register new words in the dictionary and to expand the dictionary. On the other hand, as the threshold is small, new words are registered easily and the dictionary includes many meaningless words. Hence, because we must adopt the appropriate threshold.

We describe a sentiment analysis using the constructed dictionary. Because the dictionary consists of words and their polarities, a polarity of an article is determined according to how many positive or negative words are included. The above judgement uses a assumption that is that negative articles include many negative words and positive articles include many positive words. Hence, when an article includes more positive words than negative words, the article is estimated as a positive one. One the other hand, when an article includes more negative words than positive words, the article is estimated negative one. When there are the same number of positive words and negative words in a article or there are no polarity-attached word in a article, the article is estimated as neutral one.

The proposed approach does not consider negation and adversative conjunction at all. This decreases a performance of the proposed approach. This improvement is a future work.

3 EXPERIMENT

3.1 Data Set

In this experiments we used T&C news, which was one of stock market news delivery services, as data for dictionary construction. T&C news is written in Japanese and consists of 62,478 articles in 2010, which are stock price news, business performance reports, comments of specialists and so on.

We used all articles to construct a dictionary including word polarities. Using some articles to evaluate a performance of the proposed method is not a severe drawback, although the articles is shared in a construction step and an evaluation step. Because the proposed approach does not need labels of articles, which denotes whether the articles is positive or negative.

We extracted sentences from the all articles. The T&C news includes many tables and charts to explain a stock market situation for readers. The non-sentence elements tend to overestimate statistics to determine whether words are registered in a dictionary. After this preprocess we got 2,084,105 sentences from our data set. Hence, we made a polarity dictionary using all the sentences.

To construct the dictionary we used only adjectives in the sentences because adjective includes stronger polarity than other part of speech, for example, noun, verb, and adverb. In this experiment we used MeCab, which is a morphological anlyzer for Japanese, to extract adverbs from the sentences.

3.2 Dictionary Construction

We constructed a dictionary, which define words' polarities, using the all sentences, which are extracted from T&C news.

The proposed approach needs seed words to make the dictionary with a bootstrap method. Table 1 shows the seed words in this experiment. In this case we used 5 negative polarity words and 5 negative polarity words. Because the seed words are selected manually according to domain knowledge, they are correct polarities.

Table 1. Seed words to construct the dictionary

Positive polarity	Negative polarity
powerful	obscure
accessible	heavy
strong	low
successful	poor
positive	difficult

Using the seed words, we carried out the proposed method and constructed the dictionary. In this process we decreased the threshold, which was used to determine whether new words were registered in the dictionary. At first the registration criterion is so strict but the criterion is not strict finally. Because polarity-attached words are few At the beginning of the process, χ^2 statistic is not reliable, the threshold should be high. On the other hand after the polarity-attached words are enough, we can trust χ^2 statistic. So the threshold is small at the end of process. In this experiment the threshold was equal to 300.0 and is discounted at the rate of 0.95 times per loop.

Table 2 shows the number of words that are registered in the dictionary after executing the propose approach. Because there are 1,166 unique adjectives in T&C news, we think the number of words is so small. It is future work to increase the number of words that polarity we can estimate. The number of word with positive polarity is similar to the number of words with negative polarity. We found it was favorable that the number of positive words was similar to the number of negative words. If we use a dictionary that included more negative words, almost all articles are judged as negative article in a sentiment analysis step because negative words occurs in almost all articles easily. So the dictionary constructed in the experiment has a good feature.

Table 2. The number of positive polarity words and negative polarity words in the dictionary

Words with positive polarity	48
Words with negative polarity	47

We discuss the words that are registered in the dictionary using the propose method. Table 3 shows polarity-attached words in the dictionary. Some words, for example "appropriate" and "inappropriate", "necessary" and "unnecessary", "unstable" and "hard", and "thick" and "hard", has correct polarities. The "appropriate" and the "necessary" are common words and their polarities are estimated easily. The "thick" and "hard" is not common words but technical terms in stock market. It is difficult to estimate their polarities without using stock market news. Hence, the proposed approach is good because it can adapt easily using domain-specific texts and human load is small.

Table 3. The dictionary constructed with the proposed method

Words with positive polarity	Words with negative polarity
appropriate	inappropriate
necessary	unnecessary
unstalbe	stable
thick	hard
annoying	comfortable

The proposed approach has some drawbacks. In Table 3 some words are incorrect opposite to human judgement. The "annoying" is usually a negative word and the "comfortable" is usually a negative word. Because the proposed method does not consider negation and adversative conjunction in a sentence, the problems happen. It is a future work to improve the proposed method considering negation and adversative conjunction. Now we illustrate a problem on adversative conjunction. An article includes a sentence, "it is positive in C-duration and it is negative in D-duration." The sentence does not include adversative conjunction but the former clause is opposite to the latter clause. It is difficult to solve the problem from viewpoint of syntax level processing.

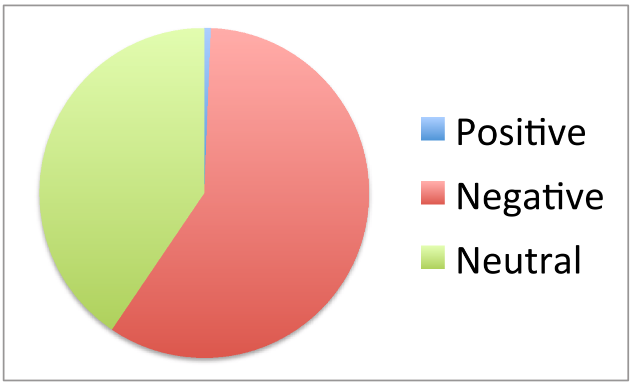

Fig. 1. The distribution of sentiment in all articles

Figure 1 shows the distribution of positive articles, negative ones, and neutral ones, which are not assigned with polarities. This figure shows negative articles occupy over half of articles. Because the articles are created after Lehman Shock, they include many negative articles. The number of positive articles, however, is too small in the result. Hence, the dictionary constructed with the proposed approach is difficult to capture sentiments of articles. There are many neutral articles in the result. This means that the number of words in the dictionary is too small.

4 CONCLUSION

We proposed a dictionary construction method to estimate correct polarities for domain-specific texts. The proposed approach has some features: (1)low human costs, and (2)easy adaptation for specific domain. The approach uses (1)a boostrap method and (2)a χ^2 statistic to construct the dictionary automatically. We confirmed that the proposed approach could make a dictionary in assign correct polarities with few words manually in an evaluation experiment.

The proposed approach, however, needs some improvements. The approach can not assign polarities with enough words in a data set. To improve the drawback we must discuss a χ^2 statistic and a criterion, which determine whether a word is registered in a dictionary or not. The approach assign incorrect polarities with some words. To improve the drawback we must consider negation and adversative conjunction in a sentence.

ACKNOWLEDGEMENT

We thank Centillion Co. for giving us data sets and many supports.

Abstract: This paper proposes a new localization method for smart phones using an accelerometer. Although the global positioning system (GPS) is applied in various fields, it has a disadvantage in that it cannot be used effectively in indoor environments. To overcome this problem, many localization methods in indoor environments exploiting Wireless LANs have been proposed, but few systems achieve high accuracy. On the other hand, the smart phones with many sensors and powerful CPUs are becoming wide spread. We examined a localization method specialized for smart phones, and evaluated our proposed method by implementing a prototype system and conducting experiments with it.

Keywords: localization, smart phone, accelerometer, Wireless LAN

1 INTRODUCTION

Currently, the Location-Based Services (LBS) are spreading widely. Using GPS is one way to obtain position information, and it is being used for variety of LBS, including car-navigation systems. However, this approach is difficult to use in indoor environments where electromagnetic waves cannot reach. Then, many systems utilizing variety of wireless equipment for indoors have been proposed[1][2], but they require constructing an infrastructure specifically for the service. Therefore, they may not be the best policy because of the cost. Some systems using existing Wireless LAN(WLAN) access points to solve that problem. If a WLAN is used for localization, a simple and widely used way to estimate distance is based on Received Signal Strength Indicator (RSSI), which do not require complex hardware. Unfortunately, RSSI is environment-dependent, and the wireless channel is very noisy in indoor environments. A radio frequency signal can suffer from reflection, diffraction, and multipath effects, making the signal strength a complex function of the distance. Therefore, the many existing methods exploiting RSSI cannot provide results high accuracy.

On the other hand, over the last few years, smart phones with many sensors have become widely distributed and are expected to increase in the future. Nevertheless, almost all existing localization methods for mobile phones are for non-smart phones, there are few or no methods specialized for smart phones.

Based on this background, we propose a localization method achieving greater accuracy with smart phones by making the best use of the its advantage. The smart phone has features such as usability, powerful computing ability and many sensors. We attempted to use the accelerometer in smart phone for localization. In this study, we exploit existing wireless access points for localization to avoid the cost of custom system.

2 LOCALIZATION METHOD

In this study, we use the RSSI received by a smart phone for position estimation using existing WLAN access points. Generally, the RSSI value will vary in the same place because the radio signal emanating from an access point is affected by shadowing and multipath fading. Therefore, it is hard to accurately estimate distance or position based on the RSSI . Assuming an office environment as the situation requiring the LBS, users will be stationary most of the time. If the user is not moving, it is reasonable to use all signals during the period the user remains stationary to estimate the position rather than using only the last signal. In general, the signal strength follows a Gaussian distribution, so we can improve overall accuracy by using the average value in our estimation.

2.1 Models for localization

The system estimates the user's position using the RSSI from WLAN access points. As the localization algorithm, we use least-squares approach, which is the most common and easiest using RSSI.

2.1.1 Distance estimation using RSSI

We assume a localization model comprising a set of access points as anchors $A \ni a_i$, which have well-known positions on the map and are identified by the pair (x_i, y_i), a smart phone designated as the target T and a localization server. Generally, a smart phone can obtain RSSI from WLAN access points. As mentioned above, though the RSSI value is very noisy, when defining d_i as the true distance between a_i

and T, the variation in RSSI can be well modeled with the following[3]:

$$\overline{P}_i = \alpha d_i \tag{1}$$

where $\overline{P}_i$ denotes the average signal power received at the ith access point, and α and β are two channel parameters representing the attenuation factor and the power decay factor, which are uniquely determined by the location estimation area.

2.1.2 Localization model

Generally, the localization model using least-squares approach is defined by the following[4]:

$find\ \varphi = (x, y)\ which\ minimizes$

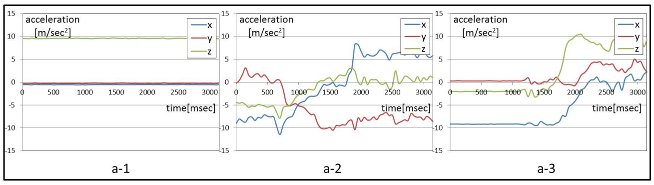
$$E(\varphi) = \sum_{a_i \in A} w_i^2 \left(\hat{d}_i \quad d_i(\varphi)\right)^2 \tag{2}$$

where $\hat{d}_i$ is the estimated distance between a_i and T, or in other words between the ith access point and the smart phone using the model in Eq. (1), and $d_i(\varphi)$ is the distance between a_i and a coordinate (x, y). the w_i term represents the weight applied to each equation. For simplicity we assume that $w_i = 1$. This equation allows us to find a coordinate (x, y) that minimizes $E(\varphi)$ and exhibits a non-linear continuous function about φ. As a result, the localization problem can be viewed as a problem of minimizing a non-linear continuous function with no constraints.

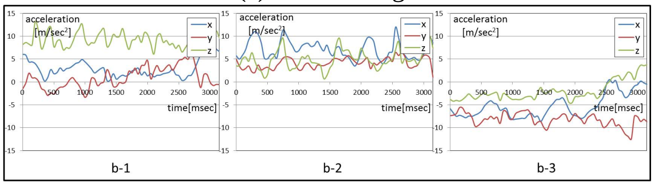
However, in many cases, distance $\hat{d}_i$ estimated by RSSI is unreliable because of large amount of noise, made worse by using only a single RSSI measurement. Since $\overline{P}$ in the model of Eq. (1) denotes an average of RSSIs, we need to measure many times and calculate the average for a proper estimation. Clearly the more measurement made the more accurate $\hat{d}_i$ will be. The best approach is to have the system calculate the average from all RSSIs during periods the user does not move.

2.2 Movement detection

In order to detect whether or not user is moving, specifically whether or not the user is walking in this study, we utilize information from the accelerometer in the smart phone. The accelerometer must always be running while the position is being estimated, raising the issue of battery drain. However, for examining the effectiveness of using the accelerometer for localization, we are not concerned with this. Almost all smart phones can obtain acceleration data in three dimensions, but it is impossible to calculate the distance that a user has moved from this data because of the amount of noise. To detect whether the user is walking based on noisy acceleration data, the system needs to check the data directly and its time frequency. For example, if the user shakes his legs while his smart phone is in his pocket, the system must determine that he is not in fact walking. Fig. 1. presents examples of acceleration while a user is walking and not walking. There seems to be a slight difference between (a) and (b) in that when the user is walking the acceleration changes at a constant frequency. We transformed the composite acceleration data into its frequency components using the Fast Fourier Transform (FFT) , and this clearly shows the difference (Fig. 2.). In generating a classifier based on the transformed data, we found it inadvisable to classify simply according to a threshold and determined that we should utilize supervised learning because of the diversity of situations. We subsequently generated a classifier using a K-nearest neighbor algorithm (K-NN) for the detection.

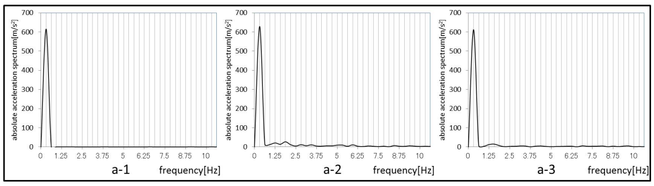


(a) Not walking

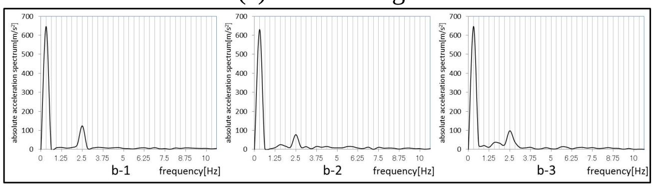


(b) Walking

Fig. 1. Examples of acceleration



(a) Not walking



(b) Walking

Fig. 2. Examples of spectrum

Acceleration data obtained at intervals of 50[ms] by a smart phone and transformed into frequency components, which are classified once 64 data have been stored. Therefore the system indicates whether or not a user is walking at intervals of 3.2[s]. The classifier is generated from 200 samples used as a training data set, and evaluated by 200 other samples used as a test data set. Fig. 3. presents the results of this test. According to the K-NN algorithm, an unclassified sample is assigned to the class represented by a majority of its k nearest neighbors in the training data set. With $k = 5$, we achieve a precision of 100.0[%] and recall of 94.0[%] for

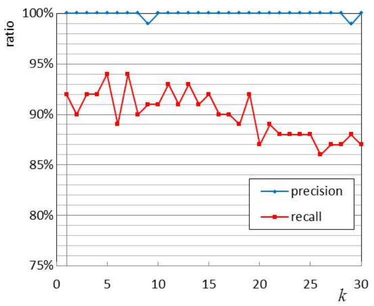


Fig. 3. Precision and recall ratio vs. k

classification of whether or not a user is walking, using the accelerometer in a smart phone.

2.3 Proposed system model

The system estimates position using this classifier and the model of Eq. (2). Consider the set $\mathbf{P}_i$, defined as the set of significant RSSI. $\mathbf{P}_i$ is updated by the following steps:

1. measure RSSI of the ith access point at time $t :\stackrel{\text{def}}{=} p_t$
2. if the classifier determines the user is moving, $\mathbf{P}_i = \{\emptyset\}$
3. $\mathbf{P}_i = \mathbf{P}_i + \{p_t\}$

The number of elements $|\mathbf{P}_i|$ thus varies dynamically, and the average value $\overline{P}_i$ of Eq. (1) is given by

$$\overline{P}_i = \frac{1}{|\mathbf{P}_i|} \sum_{p_t \in \mathbf{P}_i} p_t \quad . \tag{3}$$

Furthermore, $\hat{d}_i$, defined as the distance estimated by RSSI, is

$$\hat{d} = exp\left(\frac{1}{\beta} ln\left(\frac{\bar{P}}{\alpha}\right)\right) \tag{4}$$

by deformatting Eq. (1). Therefore, the localization problem is given by the following:

$$find\ \varphi = (x, y)\ which\ minimizes$$

$$E(\varphi) = \sum_{a_i \in A} w_i^2 \left(\hat{d}_i \quad d_i(\varphi)\right)^2$$

$$where$$

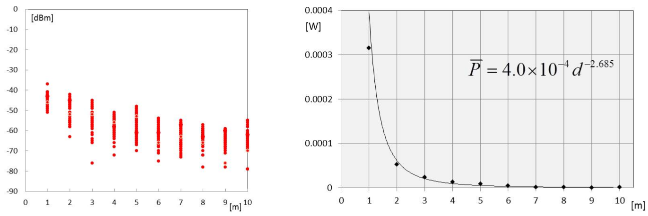
$$\hat{d} = exp\left(\frac{1}{\beta} \ln\left(\frac{\frac{1}{|\mathbf{P}_i|}\sum_{p_t \in \mathbf{P}_i} p_t}{\alpha}\right)\right) \tag{5}$$

3 IMPLEMENTATION FOR EVALUATION

We implemented a localization system using the model given above.

3.1 System configuration

The system consists of a module in the smart phone and a localization server. The smart phone measures the RSSI from multiple access points at even intervals, while in parallel obtaining acceleration information from its accelerometer. The obtained acceleration data are transformed, and then a classifier determines whether or not a user is moving based on data taken at regular intervals by the smart phone. The smart phone sends the RSSI data for multiple access points along with the result of the determination of whether or not the user is moving to the localization server. The server estimates the smart phone's position from the received data using the proposed method and displays the result on the screen.



(a) RSSI measurement (b) RSSI propagation model

Fig. 4. RSSI measurement

3.2 Preparatory experiment

We measured the RSSI 100 times at each 1[m] intervals to determine the constants of Eq. (1), . Fig. 4.(a) presents the result. Using the average value for each distance, we determine the constants by the least-squares method after converting the units form dBm to W. In this case, we obtained $\alpha = 4.0 \quad 10^{\ 4}$ and $\beta = 2.685$.

3.3 Solution for least-squares problem

As mentioned above, the localization problem can be viewed as a problem of minimizing a non-linear continuous function with no constraints, or what is called least-squares problem. Several algorithmic solutions for this problem have been proposed, and in this study, we use the Levenberg-Marquardt algorithm[5]. This is a cross between the Gauss-Newton direction and the steepest descent direction, and is the most popular method for least-squares. We need to note, however, that it may not converge to a best fit solution if the initial value is far from the optimum value.

4 EXPERIMENT AND EVALUATION

4.1 Outline of experiment

We conducted an experiment with the system in order to evaluate the effectiveness of the proposed method. In this experiment, we compare the proposed method and the classical method using RSSI that simply uses the last signal to estimate distance. The room in which the experiment was conducted is a space of 8.75[m] by 9.4[m], and there are many desks in the room. Imagine a user sitting at his desk, the system estimates his position 500 times in two different ways. The experiment was conducted at three positions in the room.

4.2 Result and evaluation

Fig. 5. presents the graphical result of the experiment. The triangle indicates the true position in the room, and the black and red circles indicate the estimated position by the classical and proposed methods. These observations may suggest that the proposed method has a smaller variance than the classical method. In fact, we see from Fig. 6. that the more times the system estimates the position, the smaller the share of error in the position estimated by the proposed

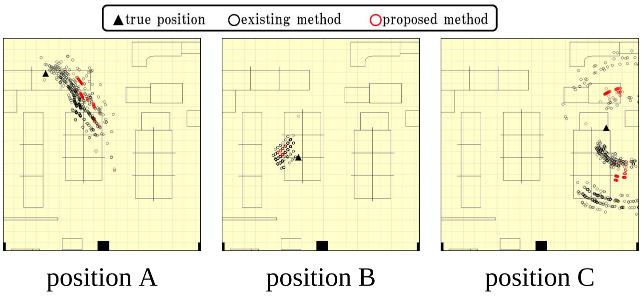


Fig. 5. Graphical result

method becomes. It is reasonable to assume that the influence of any one distance measurement on the estimation becomes small and that the estimation result becomes more accurate as a result of using more measurement data. Note that a position estimated by the proposed method uses only the average value of the overall RSSIs measured before, and not the average position from among all the positions estimated before. Therefore the error in Fig .6. is not an average of overall precious performance either. Something else notable is the earliest few values in the graphs of positions B and C. The values are very high, but this is caused by the Levenberg-Marquardt algorithm. As mentioned in Section 3.3, the initial value is significant for this algorithm, and if it is far from the optimum value, the result may converge to a local optimal solution. We set the initial value of the first estimation to the center of the room and designed the system so that the initial value after the first one is the last estimated value, but it is nevertheless likely that earliest few values converge to a local optimal solution.

In addition, we use the Root Mean Square Error (RMSE) as a numerical measure for evaluation. RMSE is a frequently used measure of the difference between true values and values which are actually observed in the environment being modeled and estimated. Looking at Table 1.,the RMSE of the proposed method is smaller than that of the classical method in all positions, and therefore the proposed method is superior to the classical method, which simply uses the last signal for position estimation.

Table 1. RMSE

	classical	proposed
position A	1.90[m]	1.75[m]
position B	1.01[m]	0.95[m]
position C	1.93[m]	1.74[m]

5 CONCLUSION

This paper proposes a new indoor localization method for smart phones which are becoming more popular. We focused on the fact that smart phones feature an accelerometer, and introduced a classifier that detects whether or not a user is moving into a classical localization method using least-squares. Our experiment clearly demonstrates that the proposed method is superior to the classical method from an RMSE standpoint.

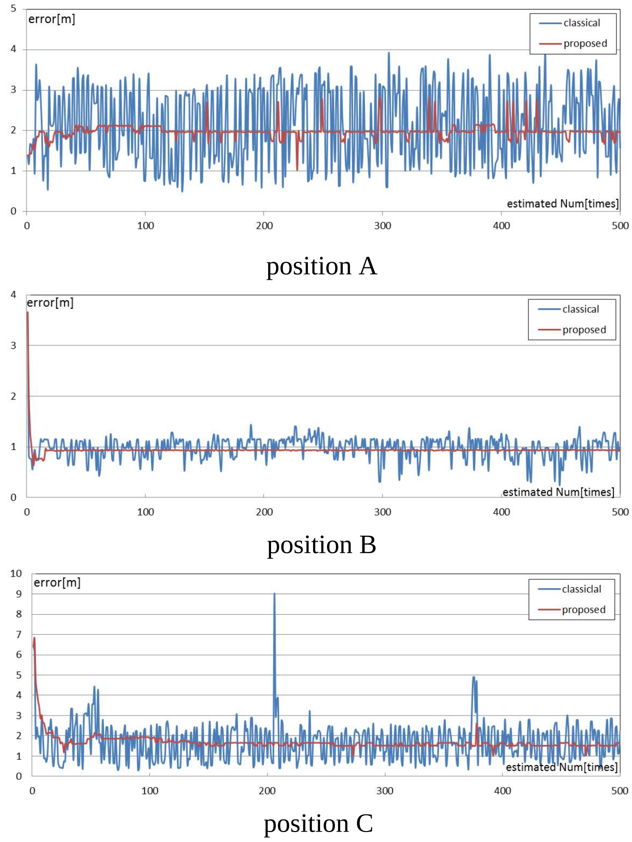

Fig. 6. Comparing error between classical and proposed methods

A future study will combine this classifier with a "finger printing" approach in order to achieve greater accuracy. In this study we used the least-squares approach for indoor localization, but generally, this approach is not so accurate. In fact, though the proposed method achieved greater accuracy than the classical method in our experiment, it did not achieve the required accuracy. Therefore, we need to use another approach superseding the least-squares, e.g. a "finger printing" approach, for indoor localization with smart phones.

Abstract: When new transactions are inserted into an original database, the existing rules may be change. An incremental association rule mining is an approach to deal with such problem. This paper proposes an algorithm for mining incremental association rules, called batch fast update (BFUP). The proposed algorithm improves the performance of FUP algorithm by reducing a number of scanning times of an original database. The experimental results show that an execution time of BFUP is much faster than that of FUP.

Keywords: Incremental association rules mining, Association rule mining, Data mining

1. INTRODUCTION

An association rule mining, one of the important tasks in data mining, is a well-known research topic that many researchers propose a large number of algorithms for solving association rule discovering problems. This problem was first presented by Agrawal et al [1] which analyzes the behavior of customer purchasing to help business make a decision. The results show co-occurrence buying items called frequent patterns, which can generate interesting rules. From that research, the problem statement of an association rule mining is defined as follows.

Let I = $\{I_1,I_2,\ldots,I_m\}$ be a set of literal items. DB is a database which contains transactions. Each transaction T is a set of items where $T \subseteq I$. Given X is an item and $X \subseteq I$. Each transaction contain X if and only if $X \subseteq T$. Let X and Y are an item where $X \subseteq I$, $Y \subseteq I$ and $X \cap Y \neq 0$. Each set of items , itemsets, is called a frequent itemset if and only if its support is greater than or equal to support threshold s%. It calculates from a number of transactions in DB that contain $X \cup Y$. An association rule can be shown in $X \Rightarrow Y$ form. Each frequent itemset can be made the association rule if and only if it is satisfied by confidence threshold c% which calculates from a number of transactions in DB that contain X and also contain Y. Both s% and c% are specified by user.

After an association rule mining was revealed, it motivated many researchers to extend this research area in a lot of issues. An incremental association rule mining is the one of an association rule mining issue which maintains association rules when new transactions are appended to an original database.

One research issue of an incremental association rule mining is reducing running time of the algorithms by minimizing the number of times to scan an original database. This paper also works on this issue. An algorithm for mining incremental association rules, called batch fast update (BFUP), is proposed. This algorithm has only one original database scanning.

The paper is organized as follows. The literatures of an association rule mining and an incremental association rule mining are reviewed in section 2. The problem statement of an incremental mining on association rule in dynamic database and FUP algorithm are detailed in section 3. The proposed algorithm and its experiment are presented in section 4 and 5 respectively. The paper conclusion and future work are briefed in section 6.

2. RELATED WORK

Mining association rules was first proposed by Agrawal et al [1] which finds a correlation between itemsets in a transaction database. The algorithm has 2 steps: finding frequent itemsets (sometimes they are called large itemsets) and generating rules. Subsequent years, Apriori [2], the most popular algorithm, was proposed to discover frequent itemsets.

When a database, called a dynamic database, is inserted new transactions, frequent itemsets can be changed after inserting new transactions into the dynamic database. Therefore, an association rule discovery algorithm for a dynamic database has to maintain frequent itemsets when new transactions are inserted into the dynamic database.

One approach to find the new frequent itemsets is to rerun Apriori algorithm for the whole transactions of the dynamic database. This approach is not efficient because all the computation done initially at finding out the old large itemsets are wasted and all large itemsets have to be computed again from scratch [3].

Cheung et al [3] proposed fast update algorithm, FUP, to solve a rules maintenance problem by using the previous knowledge to find frequent itemsets in updated database. The concept of FUP is re-using frequent itemsets of previous mining to update with frequent itemsets of an incremental database. Although FUP can decrease a number of candidate itemsets for scanning original database, it still needs to scan an original database k times when new frequent itemsets are found. This can degrade the performance of FUP algorithm.

In our observation, the advantage of FUP are re-using frequent itemsets of a previous mining to prune itemsets which cannot be a frequent itemset in updated database and reducing candidate itemsets to scan in an original database.

However, the disadvantage of FUP is the algorithm needs to scan an original database equal to a size of k frequent itemsets, e.g., if maximum size of k frequent itemsets is k=5, FUP needs to scan an original database for 5 times.

From this problem, this paper proposes an incremental association rule mining algorithm to improve the performance of FUP algorithm by reducing a number of scanning times of an original database.

3. INCREMENTAL ASSOCIATION RULES MINING

3.1 Problem statement

In a dynamic database, new transactions are appended to a database; accordingly, the previous valid rules may be invalid. The problem statement for an incremental association rule is defined as follows.

Let DB is an original database. An increment database db is the new transactions which are inserted into DB. Updated database UD is the combining between original database and increment database, i.e, $UD = DB \cup db$. A number of transactions of an original database, an increment database and an updated database are |DB|, |db| and |UD| = |DB|+|db| respectively.

Before updating activity, L is the frequent itemsets in DB if and only if X.support $\geq s \times |DB|$. After updating activity, L' is the frequent itemsets in updated database if and only if X.support $\geq s \times |UD|$.

According to Tsai et al [4], when news transactions are insert into an original database, an itemset, i.e. X, can be categorized into 4 cases:

Case 1: X is a frequent itemset in both DB and UD

Case 2: X is a frequent itemset in DB and an infrequent itemset in UD

Case 3: X is an infrequent itemset in DB and a frequent itemset in UD

Case 4: X is an infrequent itemset in both DB and UD

Form these cases of itemsets are mentioned above, it is easy to discovered updated frequent itemsets for the itemset of case 1 and 2 because their count in DB and UD are known, therefore, an updating activity is a trivial task. The itemset in case 4 is unimportant because it cannot change an association rule. The most serious case is the 3rd because it needs to rescan an original database for updating its count. Thus, discovering itemsets in case 3 is the most important problem in an incremental association rule mining. In section 3.2, the method to solve that problem is reviewed and section 4, batch fast update algorithm is presented how to improve a performance of FUP.

3.2 FUP algorithm

Apriori [2] is successful for finding frequent itemsets in a database. However, it is unsuitable for mining in dynamic database. Cheung et al [3] have been proposed an incremental algorithm which has a good performance for mining association rules in dynamic database. The concept of FUP is reviewed briefly in this section.

The operation of FUP has 2 phases: 1-iteration and k-iteration where $k \geq 2$. In the first phase, an increment database is scanned for finding candidate 1-itemsets C_1 and its count. After that loser and winner itemsets are found. Finding loser and winner itemsets, C_1 are divided into 2 types: a member and not a member of previous frequent itemsets in an original database. The first type is updated its count and pruned loser itemsets if its updated count is less than s*|UD|. The second type is scanned to an original database if and only if it is a frequent itemset (winner) in an increment database, i.e., its count is greater than or equal to s*|db|. Both types which satisfy by them threshold can be frequent 1-itemsets in updated database L_1'(winner).

The second phase has 3 steps: filtering out loser itemsets, generating candidate k-itemsets $C_{k\geq 2}$ and finding new frequent itemsets. Firstly, FUP filters out losers from L_k (L_k in DB). Given $Y \in L_k$ and $X \in L_{k-1} - L_{k-1}'$, Y is a loser iff $X \in Y$. For the remaining L_k, they are scanned to an increment database and updated their count. Then they are checked for finding a winner or loser itemset similar to the first phase.

Secondly, C_k is generated by using Apriori-gen. Any C_k is pruned if and only if $Y \in C_k$ where Y is the loser from L_k. This step is a key to reduce a number of C_k before scanning an original database. Finally, new frequent itemsets L_k' are found with the same method as the first phase.

4. BATCH FAST UPDATE ALGORITHM

In this section, an algorithm for mining incremental association rules, batch fast update (BFUP) is presented. The proposed algorithm is assumed that two thresholds, minimum support s% and minimum confidence c%, are static. This algorithm needs only one original database pass and infrequent itemsets are not required. The notation used in this section is defined in Table 1.

Table 1. The notation for Batch fast update algorithm

notation	meaning
DB	original database
db	increment database
UD	updated database
s	minimum support
L_k^{DB}	frequent k-itemset in DB
L_k^{UD}	frequent k-itemset in UD
C_k	candidate k-itemset
|DB|	a number of transactions in DB
|db|	a number of transactions in db
|UD|	a number of transactions in UD
X.count	a support of an itemset
Temp_scanDB	itemsets which are scanned in DB

The algorithm has 2 phases: an increment updating phase and a re-scanning original database phase. The first phase is shown in figure 1. At each iteration, an increment database is scanned to find candidate itemsets, i.e., C_k, and their support counts. Basically, candidate itemsets are divided into 2 types: a member and not a member of previous frequent itemsets of an original database. Candidate itemsets of the first type becomes updated frequent itemsets, i.e., L_k^{UD}, if and only if their updated support count is greater than or equal to s*|UD|. Candidate itemsets of the second type are kept in temp_scanDB for rescanning in an original database if and only if their count plus |DB|-1 is greater than s*|UD|. On the other hand, Candidate itemsets of the second type are pruned if and only if their count plus |DB|-1 is less than s*|UD|.

For generating candidate itemset C_k, Apriori-gen is applied. Apriori generates C_k with L_{k-1}*L_{k-1}, whereas BFUP generates C_k with L_k^{UD} * temp_scanDB$_k$.

The second phase of BFUP algorithm is shown in figure 2. After an increment updating phase is ended, all itemsets in temp_scanDB are re-scanned in an original database and updated their support count. Then, all itemsets in temp_scanDB are checked to find updated frequent itemsets. Let X ∊ temp_scanDB, X can be an updated frequent itemset, i.e., L_k^{UD}, if and only if X.count ≥ s*|UD|.

Algorithm 1 An increment updating phase ()

```
Input : db,s,L_k^DB,C_1^DB,|DB|

5. EXPERIMENT

The proposed algorithm in this paper aims to improve the performance of FUP. To evaluate the performance of batch fast update (BFUP) algorithm, this algorithm is implemented and tested on a PC with a 2.93 GHz Intel Core i7 and 3 GB main memory. The experiment is tested with 2 synthetic datasets which are generated by using technique in Agrawal [1]. The first dataset is T10I4D100K which has 100,000 transactions. The second dataset is T10I4D50K which has 50,000 transactions. Both datasets are appended by an increment database that has 1,000 transactions.

For the first original database, i.e., T10I4D100K, the experiment is conducted with 0.1%, 0.3% and 0.5% minimum support thresholds. The average of an execution time is shown in table 2 and figure 3 respectively. For comparison, the results are compared with FUP.

Table 2. Average of Execution time for I10T4D100K

min sup	algorithm	execution time (sec.)	a number of frequent itemset	maximum frequent itemset (size of k)
0.1%	FUP	175890.2901	17,127	L_{10}
	BFUP	43580.3014		
0.3%	FUP	19645.1002	1,991	L_7
	BFUP	11678.5801		
0.5%	FUP	9771.1612	862	L_2
	BFUP	9105.8170		

For the second original database, i.e., T10I4D50K, the experiment is conducted with 0.2%, 0.3% and 0.4% minimum support thresholds. The average of an execution time is shown in table 3 and figure 4 respectively.

From the results of the both datasets, they are shown that an execution time of BFUP is much faster than that of FUP. Furthermore, we observe that the more size k is increasing, the execution time between FUP and BFUP is more different.

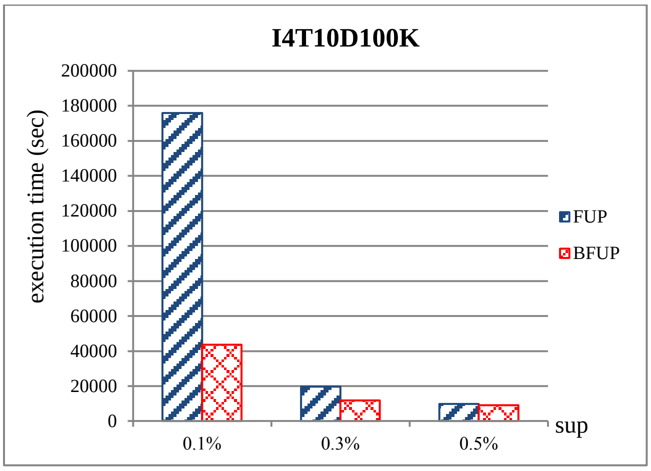

Fig. 3. Execution time comparison for I10T4D100K

Table 3. Average of Execution time for I10T4D50K

min sup	algorithm	execution time (sec.)	a number of frequent itemset	maximum frequent itemset (size of k)
0.2%	FUP	36012.0041	5,307	L_{10}
	BFUP	15402.0908		
0.3%	FUP	17695.8894	1,995	L_7
	BFUP	12906.0013		
0.4%	FUP	12363.9417	1,051	L_3
	BFUP	10866.7162		

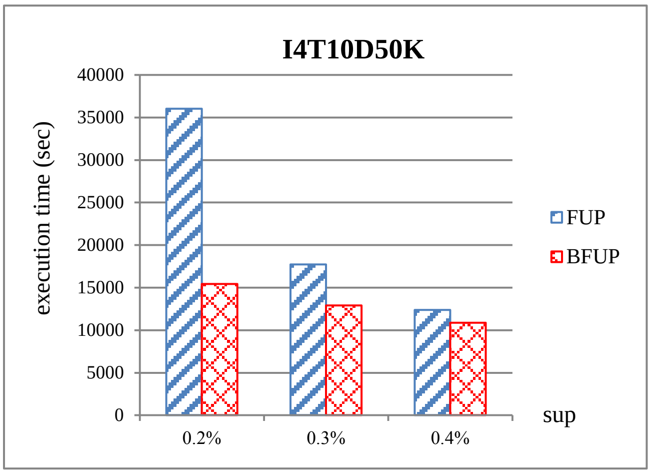

Fig. 4. Execution time comparison for I10T4D50K

6. CONCLUSION

An incremental association rules mining algorithm called batch fast update (BFUP), is proposed. The concept of this algorithm is based from Apriori and FUP algorithm. Although batch fast update algorithm has an execution time better than that of FUP, a large number of temp_scanDB are kept. In the future research, the algorithm for reducing temp_scanDB will be proposed.

Abstract: In this study, we collected and analyzed tweets on "Twitter" to classify information of categories related to the location to systematically provide information about the location. This method extracts keywords of a high occurrence ratio (location-related words) appearing in tweets from a set of tweets generated at one location. We hypothesized that tweets including location-related words (location-dependent information) contained information related to the location, and classified the information accordingly. This method enables classifying the information related to the location and providing it to users even from information without an address or location.

Keywords: Twitter, location information, location-related word

1 INTRODUCTION

This century is said to be the era of an advanced information society, in which information technology has been developed, such as computers and networks. With the spread of high-performance mobile devices such as smart phones in recent years, we have become able to transmit and receive information anytime, and anywhere. We are thus able to transmit information easily now but have difficulty extracting and obtaining only the information we want from the vast amount of information available. Therefore, we need the ability to identify information proactively, judge its value, and use it suitably. The high-performance mobile devices mentioned above also have a GPS capability, so we can now transmit and receive location information. However, with this GPS capability, even more information has become available to us, so it is even more important that we selectively acquire only the appropriate information. But we hereby have been more needed to acquire appropriate information from the information became more extensive. In the past, we could acquire appropriate information using a keyword search and link structure. But regarding information related to the location, the intensive and provision has not been systematic currently. However, location information has not been widely provided. Although location information is an important factor in categorizing search results, the supply and demand for information is not sufficiently balanced. In this study, we propose a new method of providing location information. We use "Twitter" as a source that includes location information and classify only the tweets that depend on one location from the number of tweets generated. "Twitter"[1] is used as the information because it is able to provide a number of strings with location information attached, strings are obtained from a broad strata of users, and the freshness of the information is good. In 2010, Arakawa et al. proposed methods of acquiring the standard deviation of latitude and longitude for a tweet group, measuring the locational dependence of keywords from the degree of variation in the tweet group, and performing a two-dimensional depth-first search to extract the area with more than a certain percentage of tweet and extracting some locational dependence for the keyword[2]. That enables quantifying the location dependence of the keyword. In the same year, they conducted research on analyzing the string obtained from the location and time information of tweets, and revealed a correlation between the string and the actual input string[3]. Geocoding is a technique for converting geographical information such as station name and address or place name into latitude and longitude coordinates. Using this technique enables obtaining coordinates from information including place names in the text and linking the textual information and coordinates. As an example, there are services such as "maplog"[4] that enables searching the latest blog posts which are written about the range of the map to display. Also, a method to classify messages by category and aggregate similar messages using spatiotemporal information has been proposed by Yamanaka et al[5].

2 SYSTEM DESIGN

Using the geocoding techniques described in the previous section, the categories of information that can be obtained are limited to geographical information. However, there are other categories of information related to the location such as buildings, traffic, and weather. This study attempts to provide only the information of categories related to the location. In this study, the keywords with a high occurrence ratio (location-related words) are extracted from a number of tweets generated on "Twitter" at one location, and location-related words are registered in the database on the server together with location information. We hypothesized that, based on the database created, tweets including location-related words in the text (location-dependent information) contained other information related to the location. Additionally, by repeating the procedure of extracting location-related words and classifying location-dependent information, we thought that extra information (non-location-related words) would be excluded, the number of missed words would be reduced, and the latest information would be provided while responding to location-related words and location-dependent information that varies with time. Also, information is provided by displaying tweets (location-dependent information) in the range of the map for users of this system to display in the browser on the map. The following describes in detail the proposed method for each procedure. In this study, words that have not been determined to be location-related words yet or words for which it is still been unclear whether they are location-related words are referred to as candidate location-related words.

2.1 Extracting location-related words

In this method, tweets including location information are collected. The tweets of Twitter users are collected continuously (can designate a collection area) and are registered in the database together with location information. At the same time, each tweet is morphologically analyzed, and several morphemes generated from a single tweet are registered in the database. Keywords with a high incidence are extracted from a number of tweets generated at one location, and are registered as location-related words in the database. Thus, it is possible to determine location-related words for each area. In addition, location-related words are expected to continue to change constantly with the behavior of Twitter users. However, it is always possible to respond to changing location-related words by constantly repeating the steps from collecting tweets to extracting location-related words, and using only tweets generated in a certain time period. The problem here is how to determine which location tweets are expressed.

2.1.1 Determining the area to which tweets belong

This section describes how to determine which location tweets are indicating. For example, we will consider the situation in Fig. 1. If tweet a was generated at Point X, the tweet could be determined to be indicating Landmark A. A landmark here is a reference point on the map and refers to the name of a station, government office, school, hospital, or post office. In this case, it is possible to identify the area by performing reverse geocoding. Reverse geocoding is a technique to convert the latitude and longitude coordinates for geographical information such as station name and address or place name. However, if it is unclear which location the tweet is indicating like Point Y, it is necessary to know how to resolve the ambiguity. In this method, the area around the tweet generation spot is defined as the area to which the tweet belongs. If the tweet is generated at the red dot in Fig. 2, the range inside the blue circle around the red dot is the tweet area. If the tweet area is partially determined, it is also possible to define the area which an individual morpheme is extracted from the tweet belongs to is equal to the area which the tweet belongs to. Thus, the tweet area is defined by using reverse geocoding and our proposed method together. One more matter must be defined. The tweet area has been determined, but we must determine how to identify location-related words and the area to which they belong from morphemes extracted from several tweets (candidate location-related words).

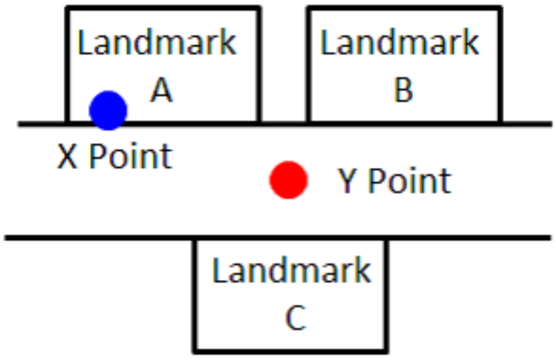

Fig. 1. Subject of tweets: Point X is clear; Point Y is unclear.

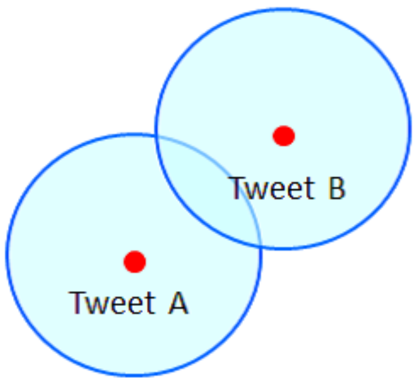

Fig. 2. Area to which tweets belong

2.1.2 Determining location-related words and the area to which they belong

This section describes how to determine the area to which location-related words belong. Even if tweets contain certain location-related words, they can not be location-independent unless they are tweets generated in the area to which location-related words belong. Therefore, how to determine the area to which location-related words belong is important. We will consider focusing on one keyword. The area to which tweets belong is described in the above section. Here, in an area to which a certain location-related word inherently belongs, the tweets including the location-related word should be somewhat dense. Conversely, in an area to which the location-related words inherently should not belong to, generated tweets including the location-related word are few and sparse. If these sparse tweets are removed, the area to which the location-related word belongs can be specified to some extent. For example, assume that tweets including a certain keyword are generated by many users in the positions depicted in Fig. 3. In the area to which a certain location-related word inherently belongs, some of the areas encompassing individual tweets including the location-related word will overlap. In an area to which the location-related word inherently should not belong, there should be few such overlaps. Therefore, only tweets with a specified threshold number of overlaps with other tweets (tweets in the green area in Fig. 3) are adopted, and the tweets with fewer overlaps are removed. Thus, the area is determined by the density of certain candidate location-related words. Pay attention to still being candidate location-related words at phase to have determined the area. When the area is determined, a set of areas composed of several tweets is found (the set of green circles in Fig. 3). If the number of individual tweets composing this set (Fig. 3; three in this example) exceeds a certain number, the word is determined to be a location-related word. Thus, after determining the area in the candidate location-related words phase, the words are determined to be location-related words depending on the number of tweets composing the area. The next section describes how to classify location-dependent information with these location-related words.

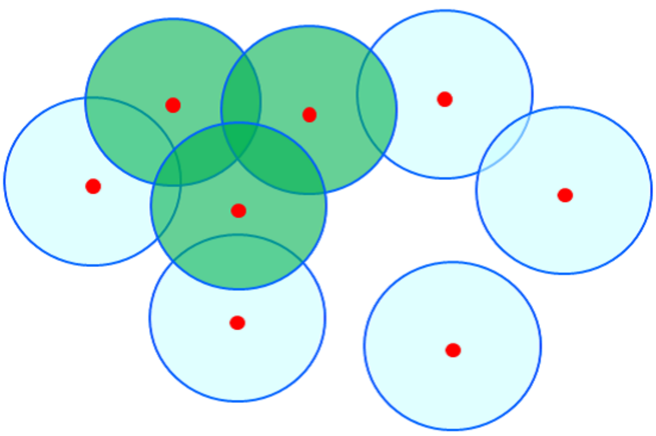

Fig. 3. Area to which location-related words belong

2.2 Classification of location-dependent information

Location-dependent information is classified based on location-related words described in the above section. On the theory that, based on the database created, tweets including keywords determined to be location-related words in the location in the text contained information related to the location, the tweets are acknowledged as location-dependent information. However, this classification rule causes a problem. It can be easy to image that the words expressing a place name and location also become candidate location-related words. In "Twitter," too many tweets express only their own place, such as the Japanese word "nau." Because words expressing a place name and location are also registered as location-related words, tweets expressing only their own place are also acknowledged as location-dependent information. Thus, it is necessary to remove unwanted information from the tweets including location-related words by classifying by means. In this way, location-dependent information is determined from tweets including location-related words in the location in the text by removing unwanted information.

3 IMPLEMENTATION

In this study, Apache is used as a Web server and MySQL is used as the database for the server. The Web server-side programs is implemented using php; the browser-side program, which is a client, is implemented using JavaScript. Tweets on "Twitter" are collected using Twitter API, and location-dependent information is provided to a browser using Google Maps API. Fig. 4 illustrates the system processing flow.

Tweets containing Twitter user location information are collected and registered in the database together with other location information (①). Morphemes generated from the tweets are also registered in the database with location information (②). Location-related words are determined from a set of generated morphemes by the method described in Section 2.1 (③, ④). Using the results, a set of tweets that are already registered in the database is classified (from tweets in the area to which location-related words belong) according to whether it contains location-related words (⑤). Unwanted information described in Section 2.2 is removed from classified tweets by means (⑥). Classification of location-dependent information is complete at this stage, and tweets which include location-dependent information are provided for users of this system by displaying tweets on the map with location information (⑦, ⑧). Fig. 5 presents an example.

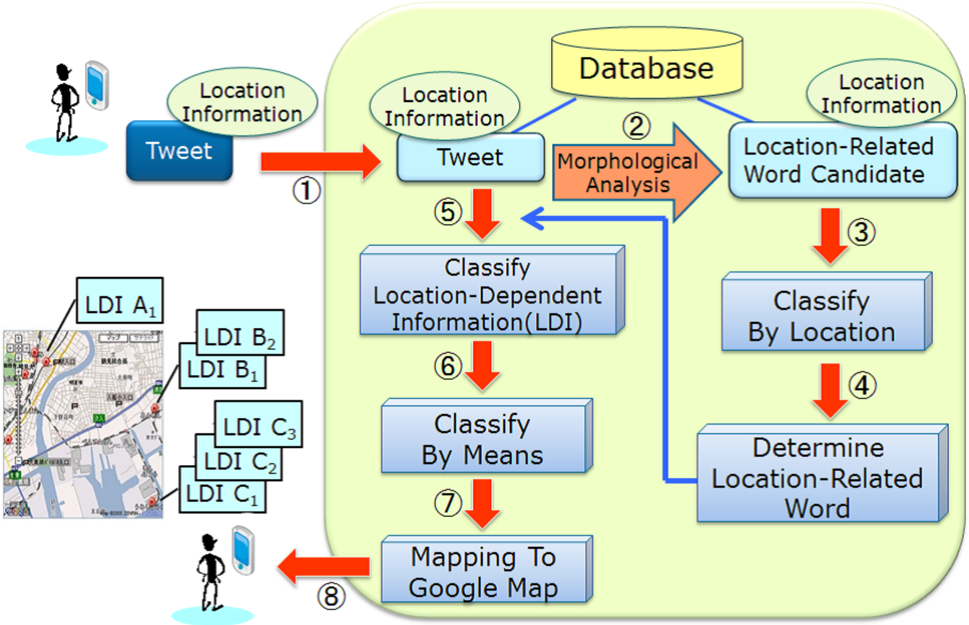

Fig. 4. System flow

This system can be used even from a PC or a smartphone using a browser.

Fig. 5. Example

4 CONCLUSIONS

In this study, we sought to classify only the information of categories related to the location as a systematic method of providing information related to the location. This enables us to classify the information related to the location even from information that cannot be found by conventional methods such as geocoding, not including geographical information such as the address or location. Location-related words change due to changes in the behavior of Twitter users, but if the system is running, this method is able to update location-related words and provide fresh information without the need for analysis. In the future, we will consider extending our method to determine information that users need depending on the content of tweets and location information of Twitter users and to provide location-dependent information focused on the users. We would like to pursue the usefulness of this method further by repeating these extensions of the system.

Abstract: Morphological computation is the concept for which a well-designed hardware can bear part of the computational cost required for robot's control and perception. So far, many musculoskeletal robots have been developed by taking inspiration from human's one and shown superior motion performances. The use of pneumatic artificial muscles (PAMs) has been the key to realize these high performance. Additionally, PAMs have the possibility of being used as sensors for environmental information because they are flexible and backdrivable. In this research, we focus on clarifying how PAMs can contribute to morphological computation of robots driven by these actuators. In particular, we propose an analysis method based on transfer entropy and apply this method to the experimental data acquired by a musculoskeletal robot that opens a door.

Keywords: musculoskeletal robot, pneumatic artificial muscle, transfer entropy

1 INTRODUCTION

Creating a robot inspired from biological systems has been an attractive approach for many researchers in robotics. Especially, human's musculoskeletal system has been often focused because it was optimized to realize intelligent motions during the whole evolutionary history of humans. So far, many musculoskeletal robots that exploit information processing provided by well-designed musculoskeletal structures were proposed. This information processing is called morphological computation and it is one of the key words that symbolize the field of the artificial intelligence paying attention to the embodiment[1].

Artificial pneumatic muscles (PAMs) have been one of most suitable actuators to develop musculoskeletal robots. Thanks to useful features proper of PAMs such as flexibility, backdrivability and high power-to-weight ratio, musculoskeletal robots driven by PAMs have successfully shown superior motion performances[2][3]. Additionally, PAM's state have sometimes been used as a sensor[4] that provides information on the external world and on the state of the robot. This information can be interpreted as proprioceptive information of the musculoskeletal robot and we think that this point is notably important to understand morphological computation in robot's perception. However, in previous researches, the PAM (among the robot's numerous PAMs) that contains important information on the external world was required to be known beforehand and the air-flow to/from such PAM had to be set to zero during the sensing process.

In this research, we focus on morphological computation of musculoskeletal robot's perception using flexibility of PAMs. In particular, in this paper, we aim to show that acquiring environmental information is possible even while the PAM is being driven. Additionally, we don't specify which PAM notably contains environmental information in advance and figure out which PAM is important from the data of all PAMs available in the robot. To this end, we use a musculoskeletal robot arm able to easily open a door by exploiting the morphological computation provided by the flexibility of PAMs. Additionally, we propose an analysis method based on transfer entropy to investigate whether or not PAMs driving the robot arm can contain environmental information. Finally, we apply the proposed method to the data taken in a door-opening task and discuss the analysis results.

2 MUSCULOSKELETAL ROBOT ARM

In this research, we use a musculoskeletal robot arm developed in our research group. This robot arm is driven by PAMs and has several sensors to control and observe the states.

2.1 Hardware design

Fig.1 shows the developed musculoskeletal robot and the configuration of its degrees of freedom. This robot has 7 degrees of freedom(DOF) in its skeletal structure and the configuration is schematically similar to the human's one. For example, the robot arm employs a radioulnar joint and an ellipsoidal joint in the forearm and the wrist, respectively[5]. Fig.2 shows the layout of the PAMs in the robot. The robot is equipped with 17 groups of PAMs for driving its skeletal structure. Because the PAMs have flexibility and backdrivability, the arm can change the posture accordingly to excerting external force. The layout of the PAMs presents similarity with human muscles as well. For example, most of PAMs are configured in the form of antagonistic pairs and there are not only monoarticular muscles but also biarticu-

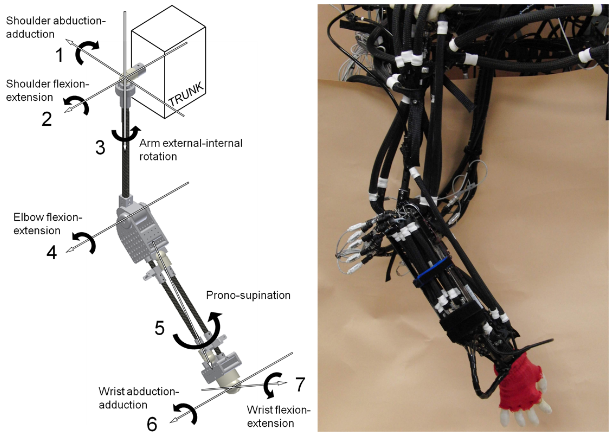

Fig. 1. The 7-DOF musculoskeletal robot arm. The structure is schematically similar to the one of humans and it is driven by PAMs.

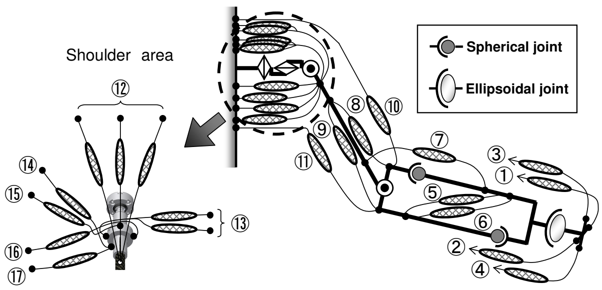

Fig. 2. PAMs layout of the developed pneumatic robot arm. There are 17 different groups of PAMs in the robot arm. Muscles having the same muscle ID are controlled as if they were a single muscle

lar muscles[5]. Additionally, the robot mounts a robot hand driven by PAMs at the end of the arm[6].

In order to investigate whether or not acquiring environmental information from PAMs is possible even if PAMs are being driven, the robot arm was equipped with several kinds of sensors. Since analytical models of PAM's statics have three variables, namely pressure, tension and length, it is obvious that at least two of three variables have to be measured to know the static state[7] of the PAM. In the musculoskeletal robot arm, pressure and tension sensors are available for all PAMs and all PAMs except the robot hand, respectively.

2.2 Control system

So far, many researches have focused on controlling PAMs and the statics was modeled accurately[7]. However, since the analytical models are very complex, it is very difficult to fully consider these models to generate motions of musculoskeletal robots driven by PAMs. Therefore, simple pressure feedback control has been often used[8][9]. In this research, we also adopt a pressure feedback system based on PID control.

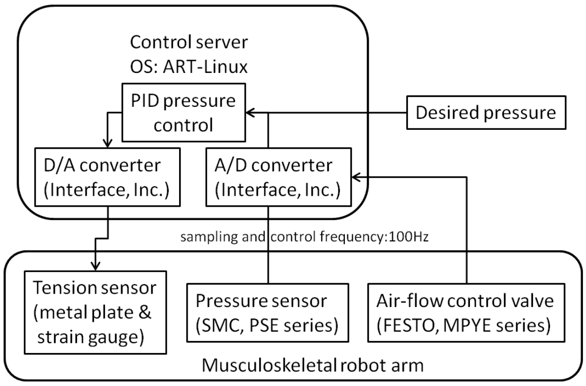

Fig. 3. Control system of the developed musculoskeletal robot.

Fig.3 shows the control system of the robot. Note that all the sensor information and control signal can be recorded during an experiment. For the control server, ART-Linux[1] is employed to ensure realtime data sampling and control. Because the control system shown in Fig.3 needs only the pressure information from all PAMs, the tension sensor information is recorded only for analysis purposes. Actually, the tension sensor information is very important for the analysis because the robot can assume different postures with the same pressures depending on the tensions.

3 MOTION ANALYSIS OF MUSCULOSKELETAL ROBOT

When a musculoskeletal robot is controlled by a time-series of desired pressures, the obtained sensor data has a lot of information about the desired pressures. Therefore, it is required to analyze the differences caused by changes of external force exerted by physical contact and dynamics of the robot. In this research, we focus on transfer entropy to extract these differences.

3.1 Transfer entropy

Transfer entropy is a measure which can quantify nonlinear relationships among stochastically generated time-series of data and a stochastic variable. Intuitively speaking, transfer entropy quantifies dynamic information flow, by measuring how large the influence from a stochastic variable to a time-series of data is.Additionally, transfer entropy can quantify the information flow correctly even in the cases where the two stochastic variables are influenced by another stochastic variables. Recently, transfer entropy has been exploited in

[1] A realtime operating system based on Linux developed by National Institute of Advanced Industrial Science and Technology in Japan: http://www.dh.aist.go.jp/en/research/humanoid/ART-Linux/

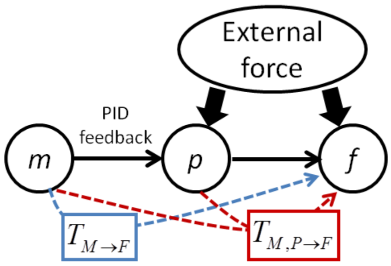

Fig. 4. The schematic relationship among M, P, F and the external force .

the robotics field to find out causalities among robot sensor data[10].

Transfer entropy between two discrete stochastic variables I and J can be defined as:

$$T_{J\to I} = \sum_{i_{n+1},i_n,j_n} P(i_{n+1}, i_n, j_n) \log \frac{P(i_{n+1}|i_n, j_n)}{P(i_{n+1}|i_n)} \quad (1)$$

Where n is a discrete time. This indicates that the transfer entropy is similar to Kullback-Leibler divergence between a probability distribution assuming I has Markov property and a probability distribution assuming I is a subject to J.

3.2 Analysis method

Considering the ideal condition of pressure feedback control, in which the desired pressure M is exactly corresponding to the actual pressure P, the subsidiarity of F to M or P can be expressed by using transfer entropy written as following:

$$\begin{aligned} T_{M\to F} &= \sum_{f_{t+1},f_t,m_t} P(f_{t+1}, f_t, m_t) \log \frac{P(f_{t+1}|f_t, m_t)}{P(f_{t+1}|f_t)} \\ &= T_{P\to F} \quad (2) \\ &= T_{M,P\to F} \end{aligned}$$

As explained in the beginning of this section, the aim of the analysis is investigating the difference caused by changes of external force exerted by physical contact and dynamics of the robot. To this end, we evaluate the difference by using the ideal condition Eq.2 as the baseline.

In order to consider the qualitative meaning of $T_{M\to F}$ and $T_{M,P\to F}$ in the actual condition, we show the relationship among M, P, F and the external force schematically in Fig.4. In the actual condition, the error on the pressure feedback control has to be caused by external force derived from physical contact with the environment and by the dynamics of the robot. As a result, $T_{M\to F}$ and $T_{M,P\to F}$ have to be different. Considering how $T_{M\to F}$ and $T_{M,P\to F}$ change compared to the ideal condition, $T_{M,P\to F}$ is larger than $T_{M\to F}$ in most cases since the M, P will has larger information on the external force than the M alone.

In this paper, we evaluate the difference $T^C_{M,P\to F} = T_{M,P\to F} - T_{M\to F}$ as a measure on how the dynamics of the robot and physical contacts with the environment influence the PAM's states. This measure can be interpreted as the fact that it is possible to subtract the effect of the M because both $T_{M\to F}$ and $T_{M,P\to F}$ contain the information flow from the M to the F.

The $T_{M,P\to F}$ can be written as following:

$$T_{M,P\to F} = \sum_{f_{t+1},f_t,m_t,p_t} P(f_{t+1}, f_t, m_t, p_t) \log \frac{P(f_{t+1}|f_t, m_t, p_t)}{P(f_{t+1}|f_t)} \quad (3)$$

Subtracting $T_{M\to F}$ from Eq.3, $T^C_{M,P\to F}$ can be written as following:

$$\begin{aligned} &T^C_{M,P\to F} = \\ &T_{M,P\to F} - T_{M\to F} = \quad (4) \\ &\sum_{f_{t+1},f_t,m_t,p_t} P(f_{t+1}, f_t, m_t, p_t) \log \frac{P(f_{t+1}|f_t, m_t, p_t)}{P(f_{t+1}|f_t, m_t)} \end{aligned}$$

As explained above, this measure $T^C_{M,P\to F}$ should indicate how external force influences the PAMs. Note that $T^C_{M,P\to F}$ does not have theoretical validity although similar method can be found in related research[10]. Additionally, we note that $T^C_{M,P\to F}$ is applied individually for all PAMs in the robot arm without specifying which PAM should be focused.

4 EXPERIMENT

In this research, we focus on a door-opening task as an example of task in which both exerting and changing external force are present. At first, we will explain about the door-opening task used in the experiment, which can be attained by using the morphological computation of the musculoskeletal robot shown in Fig.1. In the following, we apply the proposed analysis method based on transfer entropy to the data obtained in the door-opening task.

4.1 Door-opening task

The door-opening task is a task in which a robot arm reaches a doorknob, grasps it and opens the door. For the musculoskeletal robot shown in Fig.1, the door-opening task is one of most suitable task to exploit its morphological computation because of the flexibility and backdrivability offered by the PAMs.

Fig.5 shows the sequential snapshots of the robot's motion during door-opening task. The sequence of desired pressures was designed through a trial-and-error process. However, the process is not very complex because it is possible to safely come in contact to the doorknob and move according to the physical constraints imposed by the doorknob easily due to the flexibility of the PAMs. For instance, the rotating and

Fig. 5. The execution of the door-opening task. The developed musculoskeletal robot arm can adaptively grasp and rotate the door knob, and open the door by exploiting its morphological computation.

the opening can be accomplished by inaccurate control because the physical constraints of the door hardly limits the robot motions and guides them to the few available motions when the robot hand is fixed on the doorknob. Since the door-opening consists in a reaching, rotating and opening phase as shown in Fig.5, it is a good example in which the differences previously explained are caused by changes of external force exerted by physical contacts and by the dynamics of the robot.

In addition to the three phases in the door-opening task, we add following three conditions of the task:

1. normal condition (successful trial)
2. locked condition (the door does not open)
3. uncontact condition (failure in reaching the doorknob)

In this paper, we analyze the data obtained in these three conditions. In particular, we investigate how different the $T^C_{M,P\to F}$ are in the three phase of the door-opening task and in the three different conditions.

4.2 Result

For the analysis, 10 trials data were collected for each three conditions. In each trials, the robot arm starts reaching in 0.9 seconds from the beginning of the trial, grasps and rotates the doorknob at 1.0 seconds and pulls it for 3.0 second after the rotation. In comparison with the first condition, the second condition will differ in the second phase and the third condition will be differ after touching the doorknob. It can be assumed that these differences among three conditions and three phases will be observed by $T^C_{M,P\to F}$.

Fig.6 shows the average of $T^C_{M,P\to F}$ value in ten trials of each conditions. The error bar indicates the standard deviation. The left of Fig.6 shows the $T^C_{M,P\to F}$ value for each PAMs in the reaching phase. In the reaching phase, there is no difference among the three conditions except that for the third condition the contact with the doorknob does not occur at the end of the phase. Small differences can be observed in muscle 1, 2, 3 and 4 which drive the wrist of the robot arm as shown in Fig.2. Therefore, the analysis results are reasonable for the reaching phase.

The middle of Fig.6 shows the result for the rotating phase. In this phase, the third condition is very different from the others because it is not physically constrained by the door. From the result, it can be observed that there is a large difference in muscles 6, 7 and 16 between the third condition and the others. Considering the physical meaning of why these $T^C_{M,P\to F}$ values are larger in the third condition, we note that these muscles will get a large reaction force from the know when this is grasped and rotated, if the robot hand is actually fixed on the doorknob. In other words, in the first and the second conditions, the robot motions have to obey the physical constraints imposed by the door. As a consequence, we can assume that the $T^C_{M,P\to F}$ value captured the environmental information reflected in muscle 6, 7 and 16 for the third condition.

The right of Fig.6 shows the results for the opening phase. In this phase, the second condition provides large resistance in moving the arm because the door is locked and does not open. Therefore, the $T^C_{M,P\to F}$ value will be increased in the second condition because the change of the pressure will be more directly easily reflected in the change of the tension. In the right of Fig.6, it can be seen that the $T^C_{M,P\to F}$ values for almost muscles in the second condition are larger than the same values in the first condition. In the third condition, the $T^C_{M,P\to F}$ values of some muscles, such as muscle 8 and 10, are larger than the value for the same quantities in the

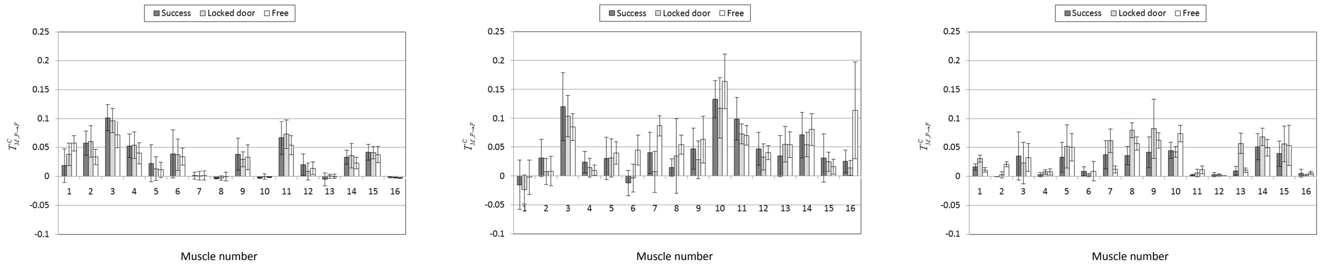

Fig. 6. The $T^C_{M,P\to F}$ in three conditions and three phases.

first condition. This indicates that physical constraints sometimes reduce the resistance of gravity because muscle 8 and 10 mainly bear the weight of the arm in this posture.

Through this experiment, it is qualitatively confirmed that PAMs driving the robot arm can be exploited to extract environmental information such as external force derived from physical contacts with the environment and from the dynamics of the robot. However, this is still a preliminary result that needs to be validated in order to confirm the main concept of this research. Future works will deal with more extensive experiments to validate our hypothesis, supported by the current preliminary results.

5 DISCUSSION AND CONCLUSION

In this research, we focused on morphological computation in a robot's perception that exploits the PAM's features. In particular, we focused on the possibility of PAMs to contribute to morphological computation of robots driven by these actuators. To this end, we proposed an analysis method based on transfer entropy and applied this method to the data taken from an experiment in which a musculoskeletal robot opens a door. As a consequence, it was qualitatively confirmed that the PAMs actuating the musculoskeletal robot arm can be used to obtain environmental information such as physical contacts and the dynamics of the robot even when these are actively actuated. Additionally, it was verified that the analysis method can be applied without specifying beforehand which PAMs should be focused.

The result in this paper can be used for finding out which PAM are useful to learn or improve the musculoskeletal robot's motions. In fact, one of biggest problems to control complex musculoskeletal robots driven by PAMs is the high dimensionality of the state and the motor command spaces derived from the structural complexity. The experiment showed the possibility that few PAMs could be able to generate the robot's motion appropriately and could be used as sensors to extract information on the surrounding environment.

However, the result obtained in this research is still very preliminary. Therefore, it will be necessary to investigate both of the robot's structure and the analysis method for clarifying morphological computation offered by musculoskeletal structures.

Abstract: To save home energy, we have proposed indirect control based on awareness. One of issues for indirect control is to classify users based on their life style which affects on the transaction of energy consumption. Designing pair-wise comparison among six kinds of value senses (convenience, housework support, healthy life, secure living space, comfort, sustainable environment), this paper proposes the method how to make clusters and then how to clarify the features of cluster in the context of value senses. Using the responses for questionnaire, this paper also describes how the proposed method works.

1 INTRODUCTION

The energy consumption has been a big issue before the miserable disaster of earthquake and tsunami occurred in Japan. Although the industry departments in Japan have paid much attention on this issue since thirty years ago for saving energy and decreasing the volumes of energy consumption, the home energy consumption has been increased because many people prefer comfortable life.

To achieve sustainable development in society, everybody should consider how to save energy in office and at home and public area. There are some ways to bring about a fundamental improvement in energy consumption. For example: 1) to develop intelligent home appliances, 2) to develop new materials for insulated house. Today not only engineers but also consumers are required to bring forth new ideas for saving energy.

One of currently noticeable approach is applying HEMS (Home Energy Management System) under indirect control [1]. Monitoring the status of energy consumption, HEMS tries to raise consumer's awareness of self-control. The Google power meters [2] and the Microsoft hohm [3] are typical examples of HEMS which show graph referring to energy transaction volumes. We have also designed the knowledge management system [4] and the advising method which are under indirect control [5]. The proposal premised on that the similar homes consume about the same amount of energy.

Then how to find out the similar homes? There are some ideas: classifying by consumer/ family property, house property and their life style. Calculating the entropy by the attributes can classify in terms of heavy, general and light consumers which previous research has proposed [6]. However, it cannot find objective boundary between consumers.

This paper focuses on value senses in our daily life. The leverages we used to analysis the responses of questionnaire include pairwise comparison between value senses and energy transaction volumes.

First, we review the background of this research in Chapter 2. Then in Chapter 3 we propose our approach and in Chapter 4 we will describe numerical experimentation. Finally, in Chapter 5 we will conclude our approach and discuss the future work.

2 RELATE WORKS AND PROBLEM DESCRIPTION

2.1 Indirect Control for Saving Energy

First, let us show the statistics of energy consumption. In Japan, as shown in Fig. 1, the volume of energy consumption at industry has been decreasing since thirty years ago. It is because there are variety of regulation and technology innovation.

However, the volume of energy consumption at home has not been decreased but gradually increased even though technology innovation.

It is because people prefer comfortable life and do not pay attention to their consumption: whether they consume energy much or not.

The premise under our research goal is that people change their lifestyle once they are aware of that they consume more energy than others who are similar to them. To save energy, it is expected that they may switch off home appliance if not needed. They may decrease the frequency of bathing. Such action driver is called indirect control [1].

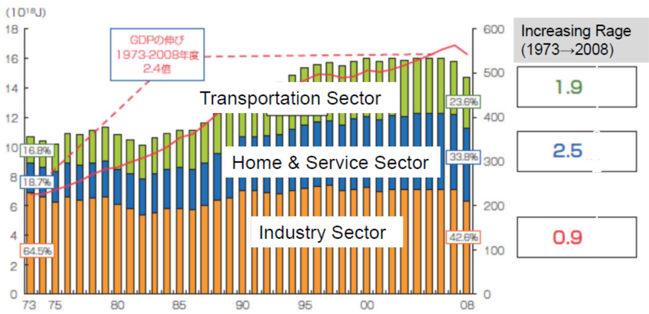

Fig. 1 Trend of Energy Consumption in Japan

As the first step to achieve indirect control, Google power meter [2] and Microsoft hohm [3] are trying to provide the data of their real-time consumption volume by line graph or bar graph to home residents who use them. The smart meter monitors the electric consumption in interval of an hour or sends the central server their consumption at least daily back. However, they do not propose the volume of other energy such as gas and kerosene. Even if one is aware that he consumes much energy than others, he has no chance to know how to improve his life.

On the other hand, the previous research [4] proposed diagnosis system based on knowledge management model. The story for indirect control is as follows:

(1) Collect volumes of recent home energy consumption data with home property including their life environment and life style. Example property includes location, house construction method, frequency of bathing, hour of rising and bedtime.

(2) Classify sample data with their variance by home property. If a classification has a small variance, it becomes useful for notification.

(3) Show consumers their status of energy consumption in the same category homes by visualization technique such as box chart.

(4) Some are notified that they consume energy much. We expect them to improve their daily activity. On the other hand, we expect others who save energy to disclose their idea, motivation, introspection as well as device or artifice.

(5) After the proposed indirect energy load control works well, new sample data should be collected for further energy saving.

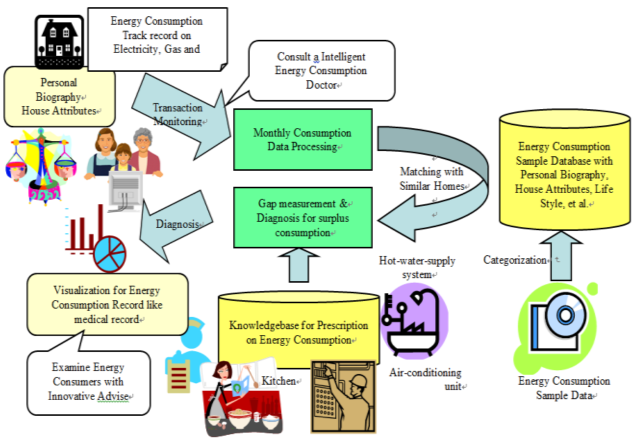

Fig. 2 Overview of KNOTES: Knowledge & Transaction based domestic energy saving support system

We have already designed knowledge management system for second generation of indirect control called KNOTES (Knowledge & Transaction based domestic energy saving support system) [5]. The overview of KNOTES is shown in Fig2.

2.2 Bandwidth of Home Energy Comsumption

In order to make KNOTES work better, the variance of the consumed energy in the same category should be small. To examine if the similar home consume almost the same amount of energy or not, we have collected transaction from two thousands and five hundreds homes with their property [4].

Then main concern is "what is similar?" There are home property such as the family size, generation and occupation. There are also house property such as construction method and size. Further, there is variety of life-style.

Using information entropy theory, we have tried to find out the attributes which affect consumption volume [6]. However, we have not yet gotten clear similarity. Rather it has shown that there are really varieties of homes on energy consumption even if their home property and house property are the same.

In our samples, there are pair-wise comparisons of value sense preference. The prepared value senses are six: convenience, housework support, healthy life, secure living space, comfort, sustainable environment. Therefore, the number of combination is fifteen (6C2). In the following, we will describe how to use the value senses to make category for consumers.

3 VALUE SENSE BASED TREND ANALYSIS

3.1Value Sense Based Cluster Analysis

The pair-wise comparison of value sense is processed as follows: Which is more important for your life: convenience or housework support? The option of answer is 0 (former) or 1 (latter). Then the value senses can be represented by fifteen-dimensional vector whose element is either 0 or 1.

For the vectors, we can apply cluster analysis. Although there is variety of distance functions, we use Euclidean distance. The most similar two samples are combined into one cluster and the same combination is repeated until all samples are combined. It is a kind of hierarchical clustering.

3.2Visualization for Value Sense

In order to clarify the feature of cluster, we propose the VS (Value Sense)-map. VS-map consists of nodes and lines for the preference strength and relations among value senses [7]. Size of node expresses the magnitude of preference. The arrow expresses the priority on preference between nodes.

If there is no priority, the line does not have direction. If there is strong bias between value senses, the line is bold. The flow of drawing up VS-map is illustrated in Fig. 3.

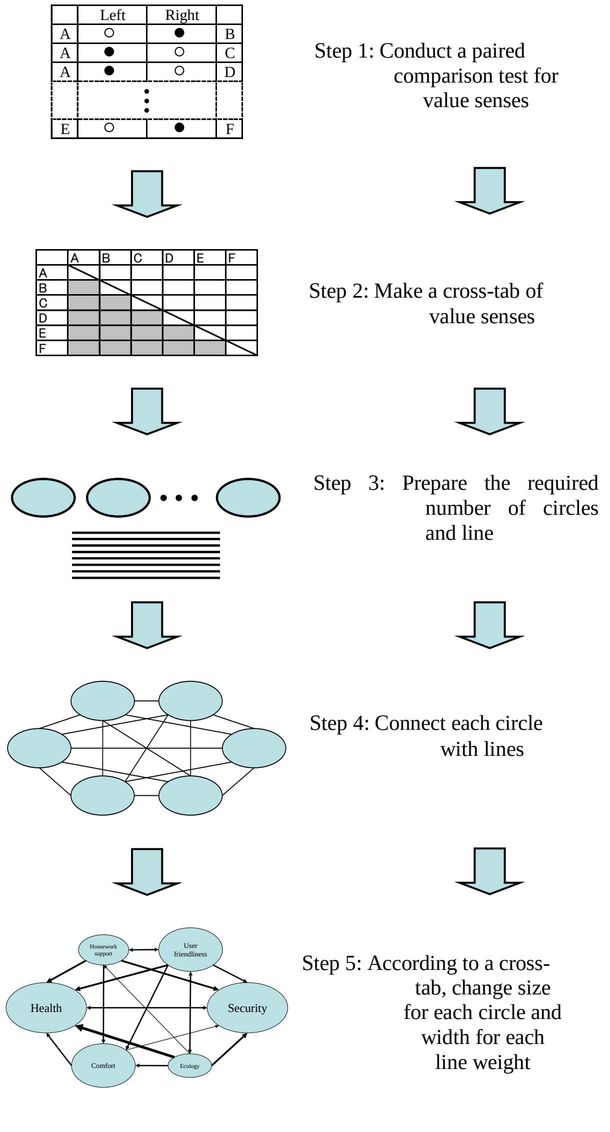

Fig. 3 Flowchart of Creating Value Map

4 NUMERICAL EXPERIMENTATION

4.1 Dataset and Cluster Analysis

To collect at least 13 months transaction data between January, 2007 and December, 2008, we asked 100,000 monitors preliminary if they could disclose them with personal biography, house attributes and life style in January, 2009. Then, we found 2,500 responders who had interest in disclosing their data in a couple of days [4]. The questionnaire consists of thirty categories of questions including energy consumption transaction for 24 months, personal biography and their life style.

Screening the size of family, we have 1,268 samples where more than three persons live in a house. The result of cluster analysis (the number of cluster is ten) is shown if Fig. 4. The basic statistics of clusters are also summarized in Table 1.

The table shows that standard deviation of cluster variance is smaller than that for all samples (2,925.7). It means that value sense based cluster analysis works well for decreasing bandwidth diversity of home energy consumption. It also shows that more than fifty percent of samples are in cluster E14.

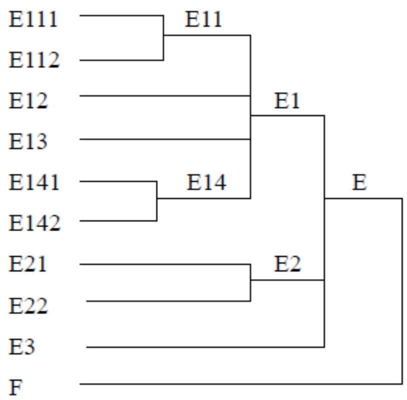

Fig. 4 Cluster Diagram

Table 1 Basic Statistics for Clusters(consumed Joule/year)

Cluster	E111	E112	E12	E13	E141
n	128	144	19	8	284
mean	4,605.1	4,644.4	4,784.2	5,322.4	4,738
Std.	1,959.9	2,295.2	2,234.6	2,616.4	1,912.6
Cluster	E142	E21	E22	E3	F
n	453	52	72	60	48
mean	4,989.6	4,072	4,492.1	4,290	4,031.1
Std.	2,176.9	1,738.2	1,569.8	1,813.7	1,420.4

Total: n=1,268, mean=5,089.2, std.=2,925.7

4.2 Value Map based Discussion

Let us check Fig. 4 again. Hierarchy implies that cluster F is exceptional because there is no subclass. We also found that the average consumption of cluster F(4,031.1) and its standard deviation (1,420.2) are smaller than others as shown in Table 1. It means that the value senses in this cluster relates to the volume of energy consumption in this cluster.

Next, let us check cluster E13 because the average consumption of cluster E13 (5,322.4) is the largest in clusters. Although the number of cluster E13 (8) is smallest, the standard deviation (2,616.4) is largest. It means that the cluster can be also regarded as exceptional and the expected volume of energy consumption in this cluster may be beyond value senses.

Finally, let us check cluster E21 because the average of energy consumption (4,072) is smallest in cluster E. Our concern is how value senses in cluster E21 differs from those in all samples.

The VS-map for all samples, clusters E13, E21 and F are shown in Fig. 5-8. Then we are aware of the followings:

(1) Healthy life is generally preferred over clusters.

(2) Value senses in cluster F is opposite around secure living space. The home which does not take care of secure living space tends to save energy.

(3) Value senses in cluster E13 is not consistent because the directions of arrows are complicated. Then person who does not clear preference among value senses tends to consume much energy.

(4) Person in cluster E21 prefers secure living space as well as sustainable environment. At the same time he does not take care of convenience or housework support.

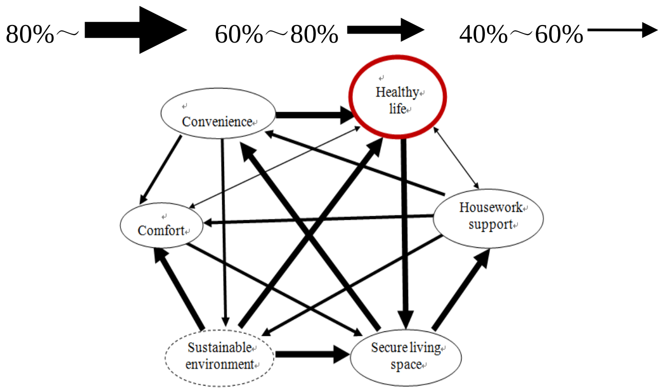

Fig. 5 VS-Map for Typical Clusters (clusters E13)

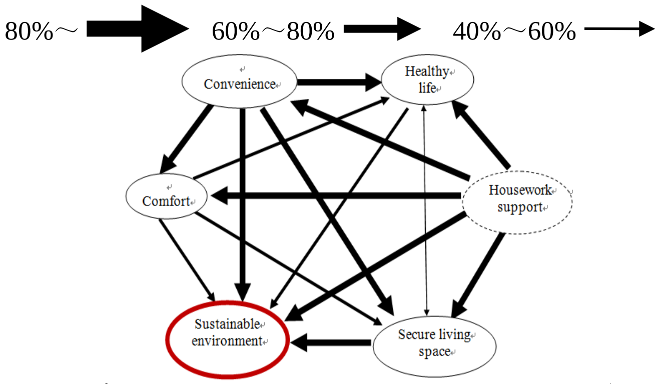

Fig. 6 VS-Map for Typical Clusters (clusters E21)

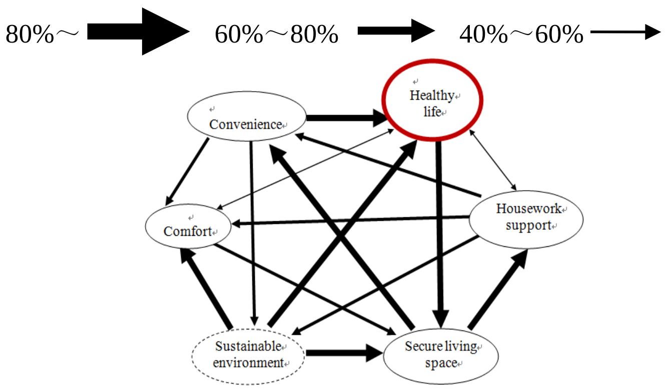

Fig. 7 VS-Map for Typical Clusters (clusters F)

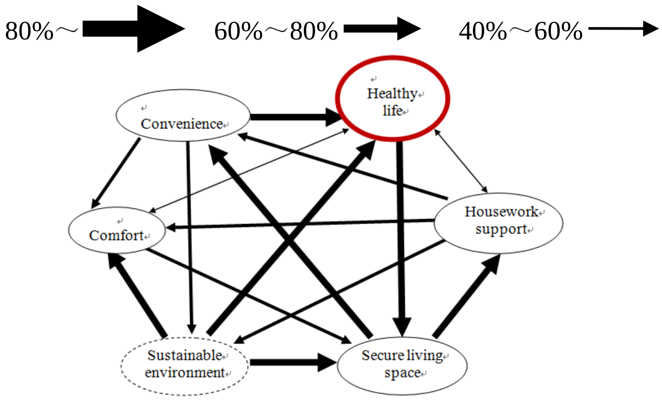

Fig. 8 VS-Map for Typical Clusters (clusters all samples)

5 CONCLUSION

This paper has described indirect control for saving home energy based on awareness. To classify the users, this paper proposed cluster analysis by value senses and introduces the method which visualized the features of the clusters. In our numerical experimentation, there were ten clusters where users in one cluster consumed much energy and those in another cluster consumed less energy.

The features of clusters were visualized by VS-map which shows what kinds of users consume much energy or less. We will develop a knowledge management system which gives awareness and advises for improving our daily life in the near future.

Abstract: In this work, an ordinal optimization based evolution algorithm (OOEA) is proposed to solve for a good enough target inventory level of the assemble to order (ATO) system. First, the ATO system is formulated as a combinatorial optimization problem with integer variables that possesses a huge solution space. Next, the genetic algorithm (GA) is used to select *N* excellent solutions from the solution space, where the fitness is evaluated with the radial basis function (RBF) network. Finally, we proceed with the OCBA technique to search for a good enough solution. The proposed OOEA is applied to an ATO system comprising 10 items on 6 products. The good enough target inventory level obtained by the OOEA is promising in the aspects of solution quality and computational efficiency.

Keywords: ordinal optimization, genetic algorithm, radial basis function, optimal computing budget allocation, assemble to order system.

1 INTRODUCTION

Assemble to order (ATO) systems refer to a production strategy in which the customer must first order specified products before the item is manufactured [1]. The main advantage of ATO systems is that customers can quickly receive products customized to meet their requirements. Since the optimal inventory policies for the general ATO systems are not known, heuristic policies such as independent base-stock policies or batch-ordering policies are often used in practice to manage the component inventories. However, there is an exponential growth in the huge solution space as the number of items increases. The huge solution space makes the considered problem very hard for conventional heuristic methods to find near-optimal base-stock policy in a reasonable time.

To overcome the drawback of consuming much computation time for complex ATO systems, we propose an ordinal optimization based evolution algorithm (OOEA) to solve for a good enough target inventory level within a reasonable amount of time. The key idea of the OOEA is to narrow the solution space stage by stage or gradually restrict the search through iterative use of ordinal optimization (OO) theory [2]. The OO theory has been successfully applied to cope with the NP-hard optimization problems such as the wafer probe testing process [3], the cyclic service of the centralized broadband wireless networks [4], and resource allocation of grid computing system [5]. The ATO system operating with a continuous-review base-stock policy can be formulated as a combinatorial optimization problem that possesses a huge solution space and is most suitable for demonstrating the validity of the OOEA.

Therefore, the purpose of this paper is to determine a good enough target inventory level using limited computation time such that the expected total profit per period is maximized. The developed mathematical formulation and simulation procedure can be used for any distributions of arrival processes and production times. The proposed OOEA consists of diversification stage and intensification stage. A radial basis function (RBF) network [6] is firstly treated as a surrogate model to roughly evaluate the objective value of an inventory level. In the diversification stage, the genetic algorithm (GA) [7] is utilized to efficiently select *N* excellent solutions from the solution space where the fitness is evaluated with an RBF network. In the intensification stage, we proceed with the optimal computing budget allocation (OCBA) method [8], which allocates the computing resource and budget by iteratively and adaptively selecting the excellent solutions.

We organize our paper in the following manner. In Section 2, we present a mathematical formulation of a general ATO system. In Section 3,we illustrate the proposed OOEA. In Section 4, the proposed OOEA is applied to an ATO system that comprises 10 items on 6 products. Finally, we draw a conclusion in Section 5.

2 ASSEMBLE TO ORDER SYSTEMS

2.1 Problem Statement

The ATO system consists of a set of h key items and m non-key items from which n products are assembled [9]. Orders for each of n different products arrive according to independent Poisson processes with constant arrival rates $\lambda_i, i = 1,\ldots,n$. Products are made up of a collection of items of different types. Items are either key items or non-key items. If any of the key items are out of stock, then the product order is lost. If all key items are in stock, the order is assembled from all key items and the available non-key items. Product *i* requires $a_{i,j}$ items of type *j*, where *j* ranges from 1 to (*h*+*m*). Each item sold brings a profit p_j, and each item in inventory has a holding cost per unit time of h_j, $j=1,\ldots,h+m$. There are inventory capacities C_j for each item, so that $0 \le x_j \le C_j$, where x_j is the inventory level of item *j*, $j=1,\ldots,h+m$. The production time for each item is truncated normally distributed with mean μ_j and variance σ_j^2, $j=1,\ldots,h+m$, lower bound 0 and upper bound ∞ and is independent of the products' arrival processes.

The ATO system operates with a continuous-review base-stock policy under which each item has a target base stock x_j, $j=1,\ldots,h+m$, and each demand for an item triggers a replenishment order for that item. There are (*h*+*m*) machines, each producing a single type of item. Items are produced one at a time on dedicated machines. We wish to maximize the expected total profit per unit time by selecting the target inventory level for a given arrival rate.

2.2 Mathematical Formulation

The ATO system under the assumed arrival rates for each order can be formulated as follows:

$$\max_{\mathbf{x}\in\Omega} E[f(\mathbf{x})]$$
$$0 \le x_j \le C_j,\ x_j \in Z,\ j=1,\ldots,h+m. \quad (1)$$

where $\mathbf{x}=[x_1 \cdots x_{h+m}]$ denote the vector of inventory level, $E[f(\mathbf{x})]$ denotes the expected total profit per unit time of $\mathbf{x}$. The inequality constraint for each x_j is $0 \le x_j \le C_j$, where the upper bound ensures that we will not go over capacity. Apparently, the solution space is

$$\Omega = \{\mathbf{x}=(x_1,\cdots,x_{h+m}) \mid 0 \le x_j \le C_j,\ x_j \in Z,\ j=1,\ldots,h+m\} \quad (2)$$

where Ω consists of $(C_j+1)^{h+m}$ possible $\mathbf{x}$. Suppose that $h=8$, $m=2$ and $C_j=20$ for $j=1,\ldots,10$, the size of Ω will be 21^{10}, which is very huge. The relationship between inputs and output of ATO stochastic simulated procedures is described in Fig. 1, in which $\mathbf{x}$ and $\boldsymbol{\lambda}$ are the input variables, $f(\mathbf{x})$ is the output objective value, T_w denotes the warm-up period, and $T_{\max}$ denotes the predetermined measurement of time. Each simulation replication should start from a fully stocked system with no orders in production, have a warm-up period of T_w time units, and then capture statistics for the next $T_{\max}-T_w$ time units of operation.

In practice, it is impossible to perform an infinitely long simulation. Thus, the sample mean of the stochastic simulation for a given value of $\mathbf{x}$ is defined as

$$\bar{f}(\mathbf{x}) = \frac{1}{L}\sum_{l=1}^{L} f_l(\mathbf{x}) \quad (3)$$

where L is the total number of simulation replications, $f_l(\mathbf{x})$ denotes the objective value of the lth simulation replication. The $\bar{f}(\mathbf{x})$ is an approximation to $E[f(\mathbf{x})]$, and $\bar{f}(\mathbf{x})$ is asymptotically close to $E[f(\mathbf{x})]$ as L increases. Thus, let $L_e=10^4$ represent the sufficiently large L. In the sequel, we define the exact model of (1) as when $L=L_e$. For the sake of simplicity in expression, we let $\bar{f}_e(\mathbf{x})$ denote the objective value of a given $\mathbf{x}$ computed by exact model.

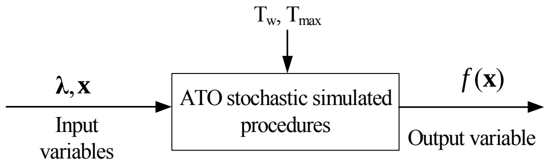

Fig. 1. Relationship between the inputs and the output of ATO stochastic simulated procedures

3 SOLUTION METHOD

3.1 RBF network

The RBF networks are three layer networks including input source nodes, hidden neurons with basis functions, and output neurons with linear activation functions, as shown in Fig. 2 [6].

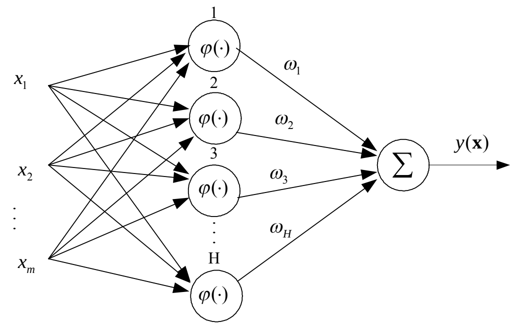

Fig. 2. Structure of an RBF network

An RBF network with a single output can be expressed as follows:

$$y(\mathbf{x}) = \sum_{h=1}^{H} \omega_h \varphi(\|\mathbf{x}-\mathbf{z}_h\|) \quad (4)$$

where $y(\mathbf{x})$ is the objective value of a given $\mathbf{x}$, H is the number of hidden nodes, $\mathbf{z}_h$ are the centers of RBF network, $\varphi(\cdot)$ is a set of RBF, ω_j are weight coefficients, and $\|\cdot\|$ is usually the Euclidean norm. In this work, the Gaussian function is used as the RBF. Once the centers have been chosen and fixed, we use the given *M* samples to find the $\boldsymbol{\omega}=[\omega_1,\ldots,\omega_H]$ by setting up the M equations:

$$\begin{aligned}
&\omega_1\varphi(\|\mathbf{x}^{(1)}-\mathbf{z}_1\|)+\omega_2\varphi(\|\mathbf{x}^{(1)}-\mathbf{z}_2\|)+\ldots+\omega_H\varphi(\|\mathbf{x}^{(1)}-\mathbf{z}_H\|)=y^{(1)}\\
&\omega_1\varphi(\|\mathbf{x}^{(2)}-\mathbf{z}_1\|)+\omega_2\varphi(\|\mathbf{x}^{(2)}-\mathbf{z}_2\|)+\ldots+\omega_H\varphi(\|\mathbf{x}^{(2)}-\mathbf{z}_H\|)=y^{(2)}\\
&\qquad\vdots \qquad\qquad\qquad\qquad\qquad\qquad \vdots\\
&\omega_1\varphi(\|\mathbf{x}^{(M)}-\mathbf{z}_1\|)+\omega_2\varphi(\|\mathbf{x}^{(M)}-\mathbf{z}_2\|)+\ldots+\omega_H\varphi(\|\mathbf{x}^{(M)}-\mathbf{z}_H\|)=y^{(M)}
\end{aligned} \quad (5)$$

The above equations can be solved using the least squares error as long as the vectors $\mathbf{x}^{(i)} \neq \mathbf{x}^{(j)}$, for $i \neq j$. Once we have the weight coefficients and centers, we can evaluate the RBF network at a new sample by using (4) as a guide. We let $F(\mathbf{x}, \boldsymbol{\omega})$ denote the functional output of the trained RBF network of a given $\mathbf{x}$.

3.2. The Genetic Algorithm

GA is a stochastic search algorithm based on the mechanism of natural selection and natural genetics. By the aid of the above effective objective value evaluation model, we can select N excellent solutions from Ω using GA. Assuming an initial random population produced and evaluated, genetic evolution takes place by means of three basic genetic operators: (a) parent selection; (b) crossover; (c) mutation [7]. The chromosome in GA terminology represents a solution $\mathbf{x}$, and each chromosome is encoded by a string of 0s and 1s. Parent selection is a simple procedure whereby two chromosomes are selected from the parent chromosome based on their fitness values. Solutions with high fitness values have a high probability of contributing new offspring to the next generation. The selection rule we used in our approach is a simple roulette-wheel selection. Crossover is an extremely important operator for the GA. It is responsible for the structure recombination and the convergence speed of the GA and is usually applied with relatively high probability denoted as p_c. The chromosomes of the two parents selected are combined to form new chromosomes that inherit segments of information stored in parent chromosomes. The crossover scheme we employed is the single-point crossover. Mutation is the operator responsible for the injection of new information. With a small probability, random bits of the offspring chromosomes flip from 0 to 1 and vice versa and give new characteristics that do not exist in the parent chromosome. In our approach, the mutation operator is applied with a relatively small probability denoted as p_m to every bit of the chromosome.

We randomly selected I chromosomes from Ω to be the initial populations of the GA. The GA is iterated until the maximum iteration count $k_{\max}$ is reached. After reaching the stop criterion, we rank the final generation of these I chromosomes based on their fitness values and pick the top N chromosomes, which form the N excellent solutions.

3.3. The OCBA technique

First, a small number of simulation replications denoted by n_0 is applied to calculate the means and variances of the sample mean of objective value for the N excellent solutions. Let T denote the allowable computing budget for selecting the best solution and n_i denote the number of simulation replications allocated to the i th solution from T. We increase the computing budget by Δ for each iteration, and the criteria of the OCBA technique is to optimally allocate T to n_1, n_2, …, n_N with $n_1 + n_2 + \cdots + n_N = T$, such that the probability of selecting the best solution is maximized. The value of the allowable computing budget is determined by $T = (N \times L_e)/s$, where s is a speed-up factor for corresponding N using the OCBA technique. The OCBA technique can be stated in the following [8].

Step 0. Perform a small number of simulation replications n_0 for all N excellent solutions. Set $l = 0$, $n_1^l = n_0, \ldots, n_N^l = n_0$, and set the value of Δ and T.

Step 1. If $\sum_{i=1}^{N} n_i^l \geq T$, stop and output the best solution $\mathbf{x}^*$ with the maximum number of simulation replications; else, go to Step 2.

Step 2. Increase Δ additional number of simulation replications to $\sum_{i=1}^{N} n_i^l$, and compute the new allocation of simulation replications by $n_j^{l+1} = (\sum_{i=1}^{N} n_i^l + \Delta)/(1 + \alpha_b^l + \sum_{i=1, i \neq j \neq b}^{N} \alpha_i^l)$, $n_b^{l+1} = \alpha_b^l n_j^{l+1}$, and $n_i^{l+1} = \alpha_i^l n_j^{l+1}$ for all $i \neq j \neq b$, where $\alpha_i^l = \left(\frac{\delta_i^l \times (\bar{f}_b^l - \bar{f}_j^l)}{\delta_j^l \times (\bar{f}_b^l - \bar{f}_i^l)} \right)^2$, $\alpha_b^l = \delta_b^l \sqrt{\sum_{i=1, i \neq b}^{N} (\frac{\alpha_i^l}{\delta_i^l})^2}$, $\bar{f}_i^l = \frac{1}{n_i^l} \sum_{k=1}^{n_i^l} f_k(\mathbf{x}_i)$, $\delta_i^l = \sqrt{\frac{1}{n_i^l} \sum_{k=1}^{n_i^l} \left(f_k(\mathbf{x}_i) - \bar{f}_i^l \right)^2}$, $\mathbf{x}_i$ represents the i th excellent solution, $f_k(\mathbf{x}_i)$ denotes the objective value of $\mathbf{x}_i$ at the k th simulation replication, and $b = \arg \max_i \bar{f}_i^l$.

Step 3. Perform additional $\max(0, n_i^{l+1} - n_i^l)$ simulation replications for the i th excellent solution, $i = 1, \ldots, N$. Set $l = l + 1$ and go to Step 1.

3.4 The OOEA

Now, the proposed OOEA can be stated as follows.

Step 1: Randomly select M $\mathbf{x}$'s from Ω. Compute the corresponding $\bar{f}_e(\mathbf{x})$ for each $\mathbf{x}$. Train an RBF network and calculate its $\boldsymbol{\omega}$ using the obtained M input-output pairs, ($\mathbf{x}$, $\bar{f}_e(\mathbf{x})$)'s. Let $F(\mathbf{x}, \boldsymbol{\omega})$ denote the functional output of the trained RBF network.

Step 2: Randomly select I $\mathbf{x}$'s from Ω as the initial population. Apply the GA to these individuals assisted by RBF network, $F(\mathbf{x}, \boldsymbol{\omega})$. After the GA converges, we rank all the final I $\mathbf{x}$'s based on their approximate fatnesses and select the top N $\mathbf{x}$'s to be the excellent solutions.

Step 3: Use the OCBA technique to select the best $\mathbf{x}$ from the N excellent solutions, and this $\mathbf{x}$ is the good enough solution that we seek.

4 TEST RESULTS

To gain more attention from broad readers, we set up a similar example provided in [10] as the application example. The ATO system has six types of product orders (n=6) and ten items including eight key items (h=8) and two non-key items (m=2). Different types of product orders come into the system as Poisson arrival processes with different rates, $\lambda_i, i = 1, \ldots, 6$, and each of them requires a set of key items and a set of non-key items. Each item sold brings a profit, p_j, and each item in inventory has a holding cost per period, h_j, $j = 1, \ldots, 10$. There are inventory capacities for each item, C_j,

$j = 1,\ldots,10$, such that $0 \le x_j \le C_j$, and the production time for each item is normally distributed with mean μ_j and variance σ_j^2, $j = 1,\ldots,10$, truncated at 0. All parameters used are included in Tables 1 and 2. The measurement of time is assumed to start T_w=20 up until $T_{\max}$=70.

Table 1. Parameters related to ten items

Item	1	2	3	4	5	6	7	8	9	10
p_j	1	2	3	4	5	6	7	8	9	10
h_j	2	2	2	2	2	2	2	2	2	2
μ_j	0.15	0.40	0.25	0.15	0.25	0.08	0.13	0.40	0.08	0.13
σ_j	0.0225	0.06	0.0375	0.0225	0.0375	0.012	0.0195	0.06	0.012	0.0195
C_j	20	20	20	20	20	20	20	20	20	20

4	2.4	0	0	1	1	0	1	0	1	1	0
5	1.8	0	0	1	0	1	1	1	0	0	1
6	1.2	0	1	1	1	0	1	0	1	0	0

To construct the surrogate model, we use an RBF network consisting of 10 neurons in input layer, 20 neurons in hidden layer, and 1 neuron in output layer. The 10 neurons in the input layer are for $\mathbf{x}$, and the single output neuron is for $E[f(\mathbf{x})]$. The spread of Gaussian function is set to $\sigma = 1$. The system's condition is the six arrival rates of product orders, $\lambda_i, i = 1,\ldots,6$, which are given in Table 2. For a given system condition, we train the RBF network by randomly selecting M=9604 $\mathbf{x}$'s from the discrete solution space Ω first, then evaluate the corresponding $\bar{f}_e(\mathbf{x})$. We use the above 9604 pairs of $(\mathbf{x}, \bar{f}_e(\mathbf{x}))$'s as the input and output pairs to train the BRF network by calculating its weight coefficients. Once the RBF network is trained, the approximate objective value of $E[f(\mathbf{x})]$ for a given $\mathbf{x}$ can be obtained from the output of RBF network.

We have simulated the OOEA for two cases of N with N=100 and 50. The following parameters are used in GA: I=1000, $p_c = 0.8$, $p_m = 0.03$, and $k_{\max} = 30$. The following parameters are used in OCBA: n_0=20, Δ=20, and $L_e = 10^4$. Since s=25 and 20 corresponding to N=100 and 50, respectively, the parameters T used in OCBA are different in the two cases: T= 40000 and 25000 for N=100 and 50, respectively. The good enough target inventory level $\mathbf{x}^*$, the corresponding $\bar{f}_e(\mathbf{x}^*)$, and the consumed CPU times for the two cases are presented in Table 3. Apparently, as N increases, the corresponding $\bar{f}_e(\mathbf{x}^*)$ increases, however the consumed CPU time also increases. Above all, the CPU times consumed in all cases are within two minutes, which are very fast.

Table 3. The good enough target inventory level $\mathbf{x}^*$, the corresponding $\bar{f}_e(\mathbf{x}^*)$, and the consumed CPU times for the two cases of N

N	s	T	Good enough target inventory level $\mathbf{x}^*$	$\bar{f}_e(\mathbf{x}^*)$	CPU times (minute)
100	25	40000	[3 4 4 13 7 4 4 2 5 8]	237.83	1.91
50	20	25000	[3 7 5 14 9 4 4 2 8 9]	236.06	1.66

5 CONCLUSION

In this work, we have proposed an OOEA to solve for a good enough target inventory level of an ATO system using reasonable computation time. By the aid of the RBF network, the objective value of an inventory level can be roughly evaluated without consuming much computation time. Via stochastic simulation optimization, the arrival processes and production times of ATO system can be from any distributions, and the dimension of the problem can be high.

Abstract: This paper is concerned with DNA sequencing by hybridization. An algorithm that Max-Min Ant System and Genetic Algorithm (MMASGA) is proposed to solve the computational field of sequencing resulting from hybridization experiment. For avoiding the local minimum, MMASGA is based on Max-Min Ant System (MMAS), into which Genetic Algorithm (GA) is added. Before getting into the maximum iteration of MMAS, GA takes place in MMAS. In the numerical evaluation, with the iteration mounting up, the summation of the DNA probe appearance frequency turns more. The accuracy of the solution gotten by MMASGA is higher than MMAS.

Keywords: DNA sequencing, sequencing by hybridization, Max-Min Ant System and Genetic Algorithm.

1 INTRODUCTION

Bioinformatics is the application of computer science and information technology to the field of biology and medicine. DNA sequencing is one of the research objects of the bioinformatics. One of the sequencing methods is sequencing by hybridization (SBH). It is concerned with the computational part of the SBH in this paper. In the case of ideal hybridization experiment, an original DNA sequence can be reconstructed. SBH whose errors are under consideration is regarded as integer program problem and has been formulated. The application of Branch-and-Bound Algorithm for seeking the optimized solution has succeeded, but if there are many errors or the DNA sequence is long, it will take an immense amount of time and the optimized solution cannot be gotten [1].

For seeking the optimized solution Ant Colony Optimization (ACO) has been proposed. ACO is a probabilistic technique for solving computational problems which can be reduced to finding good paths through graphs. Being based on ACO, Max-Min Ant System (MMAS) is proposed and has been applied to the combinatorial optimization problem such as traveling salesman problem (TSP), quadratic assignment problem (QAP), vehicle routing problem (VRP), and internet packet switching.

This paper is concerned with DNA sequencing and Max-Min Ant System and Genetic Algorithm is proposed to solve the computational field of sequencing by hybridization. For avoiding the local solution, the proposed MMASGA is based on MMAS and GA is added into MMAS. Furthermore, by the performance evaluation test, the accuracy of the proposed method is better than the traditional method.

2 Sequencing by Hybridization

2.1 About DNA Sequencing

DNA is a nucleic acid that contains the genetic instructions used in the development and functioning of all known living organisms. The four bases founded in DNA are adenine (A), cytosine (C), guanine (G) and thymine (T). Sequencing by Hybridization is a class of methods for determining the order in which nucleotides occur on a strand of DNA, typically used for looking for small changes relative to a known DNA sequence. The binding of one strand of DNA to its complementary strand in the DNA double-helix is sensitive to even single-base mismatches when the hybrid region is short or if specialized mismatch detection proteins are present. This is exploited in a variety of ways, most notable via DNA chips or microarrays with thousands to billions of synthetic oligonucleotides found in a genome of interest plus many known variations or even all possible single-base variations [3].

In molecular biology, a hybridization probe is a fragment of DNA or RNA of variable length, which is used in DNA or RNA samples to detect the presence of nucleotide sequences (the DNA target) that are complementary to the sequence in the probe. The probe thereby hybridizes to single-stranded nucleic acid whose base sequence allows probe-target base pairing due to complementarity between the probe and target. The labeled probe is first denatured into single stranded DNA (ssDNA) and then hybridized to the target ssDNA immobilized on a membrane [3].

If the gained DNA sequence is ACTCTGG in the hybridization experiment and the probes whose length l is 3 are used, the set of all the probes is {AAA, AAC, AAG… TTT} and the amount of elements is 4^3=64. According to

DNA hybridization, {ACT, CTC, TCT, CTG, TGG} are necessary, as shown in the **Fig.1** [4].

```

```

Fig. 1. Example of sequencing.

2.2 Formulation

If all the probes aren't recognized, the alphabets below *l*– 1 must overlap in the adjacent probes. And if the wrong probe is not found, several probes must be taken out in the SBH. To deal with all the errors, Blazewics etc. formulated the maximum cardinality found in the SBH below as integer linear programming problem. It is also known as the NP-hard combinatorial optimization problem.

Maximize

$$\sum_{i=1}^{m}\sum_{j=1}^{m} x_{ij} + 1 \qquad (1)$$

Subject to

$$\sum_{i=1}^{m} x_{ik} \le 1, k = 1, \dots, m \qquad (2)$$

$$\sum_{i=1}^{m} x_{ki} \le 1, k = 1, \dots, m \qquad (3)$$

$$\sum_{k=1}^{m}\left(\left|\sum_{i=1}^{m} x_{ki} - \sum_{j=1}^{m} x_{jk}\right|\right) = 2 \qquad (4)$$

$$\sum_{s_k \in s'}\left(\sum_{s_i \in s'} x_{ik} \cdot \sum_{s_j \in s'} x_{ki}\right) < |s'| \qquad (5)$$

$$\forall S' \subset S, S' \neq 0$$

$$\sum_{i=1}^{m}\sum_{j=1}^{m} c_{ij}\, x_{ij} \le n - l \qquad (6)$$

Where m is a cardinality of spectrum, S is a set of probes of cardinality of m, $x_{ij,}$ is a Boolean variable (it is equal 1 if an probe joining vertices i and j is included in the solution; otherwise it is equal to 0), c_{ij} is a cost of a probe joining vertex i with vertex j, and n-*l* is a maximum allowed cost.

Equation (1), to be maximized is equivalent to the number of probes selected. Equation (2) and Equation (3) ensure that each probe included in the solution has at most one immediate successor and one immediate predecessor in the solution path, respectively. Equation (4), the path cannot be the circuit construction. Equation (5), the same probe cannot be used more than twice. Equation (6), a cost connected with the solution is not greater than a given value (equal to n-*l*) [1].

The problem above is one of the kinds that the visited nodes are maximized at the limited distance. For the SBH, distance is the length of the DNA sequence and the nodes are the probes. If the visited nodes get most, the path will be ACT→CTC→TCT→CTG→TGG [4].

3 Ant Colony Optimization and Genetic Algorithm

3.1 Ant Colony Optimization Algorithm

Ant Colony Optimization (ACO) is a population based approach which has been successfully applied to several fields. As the name suggests, ACO has been inspired by the behavior of real ant colonies, in particular, by their foraging behavior. One of its main ideas is the indirect communication among the individuals of a colony of agents, called artificial ants, based on an analogy with trails of a chemical substance, called pheromone, which real ants use for communication. The artificial pheromone trails are a kind of distributed numeric information which is modified by the ants to reflect their experience accumulated while solving a particular problem.

The original idea comes from observing the exploitation of food resources among ants, in which ants' individually limited cognitive abilities have collectively been able to find the shortest path between a food source and the nest. The first ant finds the food source, via any way, then returns to the nest, leaving behind a trail pheromone Ants indiscriminately follow several possible ways, but the strengthening of the runway makes it more attractive as the shortest route. Ants take the shortest route; long portions of other ways lose their trail pheromones. In a series of experiments on a colony of ants with a choice between two unequal length paths leading to a source of food, biologists have observed that ants tended to use the shortest route [5].

The algorithm involves the movement of a colony of ants through the different states of the problem. Thereby, each such ant incrementally constructs a solution to the problem. When an ant completes a solution, or during the construction phase, the ant evaluates the solution and modifies the trail value on the components used in its solution. This pheromone information will direct the search of the future ants.

3.2 Max-Min Ant System

Max-Min Ant System (MMAS) is one kind of the common extensions of ACO. MMAS is that when the pheromones of are updated, the pheromone trails are limited. The added maximum and minimum amounts are $[\tau_{max}, \tau_{min}]$. MMAS thought is the most accurate extension of ACO. MMAS differs in three key aspects from ACO [2].

I. To exploit the best solutions found during an iteration or during the run of the algorithm, after each iteration only one single ant adds pheromone. This ant may be the one which found the best solution in the current iteration (*iteration-best* ant) or the one which found the best solution from the beginning of the trial (*global-best* ant).

II. To avoid stagnation of the search the range of possible pheromone trails on each solution component is limited to an interval [τ_{max},τ_{min}].

III. Additionally, we deliberately initialize the pheromone trails to τ_{max}, achieving in this way a higher exploration of solutions at the start of the algorithm.

The scheme of MMAS algorithm is shown in the **Fig.2.**

procedure MMAS algorithm:
  Set parameters, initialize pheromone trails,
    upper and lower limit of pheromone trails
  while (termination condition not met) **do**
    Construct Solutions
    Apply Local Search
    Update Trails
    Limit Trails
  end
end

Fig.2. The scheme of MMAS algorithm.

3.3 Genetic Algorithm (GA)

A genetic algorithm (GA) is a search heuristic that mimics the process of natural evolution. This heuristic is routinely used to generate useful solutions to optimization and search problems. GAs belong to the larger class of evolutionary algorithms (EA), which generate solutions to optimization problems using techniques inspired by natural evolution, such as inheritance, mutation, selection, and crossover.

GAs are adaptive heuristic search algorithm premised on the evolutionary ideas of natural selection and genetic. The basic concept of GAs is designed to simulate processes in natural system necessary for evolution, specifically those that follow the principles first laid down by Charles Darwin of survival of the fittest. As such they represent an intelligent exploitation of a random search within a defined search space to solve a problem [6].

First pioneered by John Holland in the 60s, Genetic Algorithms has been widely studied, experimented and applied in many fields in engineering worlds. Not only does GA provide an alternative method to solving problem, it consistently outperforms other traditional methods in most of the problems link. Many of the real world problems involved finding optimal parameters, which might prove difficult for traditional methods but ideal for GAs. However, because of its outstanding performance in optimization, GAs have been wrongly regarded as a function optimizer. In fact, there are many ways to view genetic algorithms. Perhaps most users come to GAs looking for a problem solver, but this is a restrictive view

4 Improvement of Max-Min Ant System

It is possible for MMAS to lapse into the local best solution. To raise the precision of MMAS, the problem addressed in this paper is concerned with DNA sequencing and Max-Min Ant System and Genetic Algorithm (MMASGA) is proposed to solve the computational field of sequencing by hybridization. The proposed MMASGA is based on MMAS and GA is added into MMAS. Firstly initial solutions are gotten by MMAS. Then initial solutions of MMAS are treated as the initial solutions of GA in order not to lapse into the local solution. And the method of pheromone secretion is also improved. Only the pheromone of the path of the good solution is raised. After that, inheritance, mutation, selection, and crossover take place and repeat until the termination conditions are fulfilled. Before getting into the maximum search iteration of MMAS, GA takes place in MMAS. The algorithm of MMASGA is shown below. (**Fig.3.**)

procedure MMASGA algorithm:
  Set parameters, initialize pheromone trails,
    upper and lower limit of pheromone trails
  while (termination condition not met) **do**
    Construct Solutions
    Apply Local Search
    while (generation not maximum) **do**
      Inheritance
      Selection
      Crossover
      Mutation
    end
    Update Trails
    Limit Trails
  end
end

Fig.3. The scheme of MMASGA algorithm.

The flow of MMASGA is described below:

I. Initialize the parameters: the maximum iteration T_{max}, the iteration t←0, the initial scatter list, and the initial pheromone trails.

II. The paths are formed randomly and the searched paths are putted into the scatter list. At the same time, a record of the scatter list is made. The initial solutions are made to be the initial generation population of individuals of GA.

III. Until the maximum generation, inheritance, selection, crossover and mutation take place among the individuals.

IV. The probes are calculated and the maximum value is saved.

V. The pheromone trails that construct the solutions are limited and updated. A new record of the scatter list is made.

VI. Set t←t+1. If t = T_{max}, the program terminates, otherwise the program goes to the step Ⅱ.

5 Experimental Results

The parameters of MMASGA are shown in the following description. The set of probes is {CTC, TCT, ACT, TGG, CTG}, the amount of agents is 50, the maximum iteration is 50, the mutation rate is 0.7, and the crossover rate is 0.6.

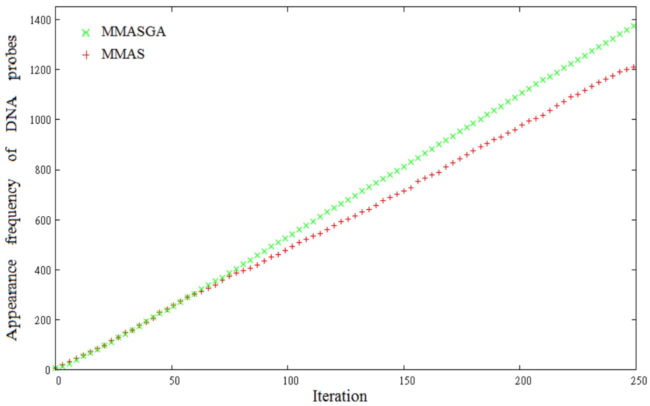

Fig.4. the comparison of performance to MMAS and MMASGA

Table 1. Experimental Results by MMAS and MMASGA

Iteration	MMAS	MMASGA
250	1184	1405
500	2401	3227
1000	4741	6181
10000	47829	79363

The evaluation result is shown above until the iteration counts 250 (**Fig.4.**). The line of × is the result of calculation by MMASGA. The line of + is the result of calculation by MMAS. With the iteration mounting up, the summation of the DNA probe appearance frequency turns more (**Table 1.**). Through the evaluation of the calculation, the accuracy of the solution gotten by proposed MMASGA is higher than MMAS. When the visited nodes get most, the path turns to be ACT→CTC→TCT→CTG→TGG.

6 Conclusion

In the paper, the Max-Min Ant System and Genetic Algorithm for solving a computational phase of the DNA sequencing by hybridization method has been proposed. The algorithm can handle the DNA sequencing with great accuracy. The presented algorithm has been extensively tasted on real, thus computationally hard, DNA sequences. Parameters n (the length of a reconstructed sequence) and l (the length of hybridizing oligonucleotides) chosen for test purposes, had the values used in real experiments. The tests have shown a good performance of the algorithm in presence. With the application of the global search of GA, the precision of MMAS is raised. Future examinations should allow for a further evaluation of the scope of applications of the sequencing approach with the algorithm proposed in this paper with great accuracy.

Abstract: In many engineering applications (engineering design problems), since the environment and/or situation of applications may change, it is important to detect plural acceptable solutions (plural acceptable means). As a technique of detecting not a single global optimum solution but plural acceptable solutions, this paper proposes a new optimization algorithm based on advanced Artificial Bee Colony (ABC) algorithm that has the good performance on large scale optimization problems. We evaluate the proposed algorithm through numerical experiments on well-known benchmark functions, such as Rastrigin function and Schwefel function, and discuss its development potential. In numerical experiments, the performances of the proposed algorithm are compared with those of the existing optimization one based on Particle Swarm Optimization (PSO) algorithm for detecting plural acceptable solutions.

Keywords: plural acceptable solutions, swarm intelligence algorithms, artificial bee colony algorithm.

1 INTRODUCTION

The minimization of multimodal functions with many local and global minima is a problem that frequently arises in diverse scientific fields and numerous engineering design problems. This problem is NP-hard in the sense of its computational complexity even in simple cases. As techniques of computing a global minimum of the objective function, many meta-heuristics, which are search algorithms for optimization based on heuristic knowledge, have been proposed. Some well-known representative meta-heuristics are simulated annealing and tabu search which are the traditional optimization algorithms, genetic algorithms and immune algorithms which are classified as evolutionary computation techniques, and ant colony optimization algorithms and particle swarm optimization algorithms [1] which belong to the category of swarm intelligence algorithms.

In meta-heuristics, genetic algorithms and immune algorithms, classified as evolutionary computation techniques, are generally techniques for combination optimization problems. In genetic algorithms and immune algorithms, the variables of continuous type are frequently translated into those of discrete (genetic) type. If there is a dependency between variables, therefore, a promising solution may be destroyed during the solution search process (genetic operation) and the solution search performance may deteriorate. To the contrary, particle swarm optimization algorithm [1] can directly handle the variables of continuous type. Even when there is a dependency between variables, therefore, an efficient and effective solution search can be realized. Recently, particle swarm optimization algorithm is intensively researched because it is superior to the other algorithms on many difficult optimization problems. The ideas that underlie particle swarm optimization algorithm are inspired not by the evolutionary mechanisms encountered in natural selection, but rather by the social behavior of flocking organisms, such as swarms of birds and fish schools. Particle swarm optimization algorithm is a population-based algorithm that exploits a population of individuals to probe promising regions of the search space. The algorithm is simple and allows unconditional application to various optimization problems. However, it has been confirmed that the performance of particle swarm optimization algorithm on large scale optimization problems is not always satisfactory. Therefore, we have proposed a new optimization algorithm based on Artificial Bee Colony (ABC) algorithm [2] that has the good performance on large scale optimization problems [3]. However, in many engineering applications (engineering design problems), since the environment and/or situation of applications may change, it is important to detect plural acceptable solutions (plural acceptable means).

As a technique of detecting not a single global optimum solution but plural acceptable solutions, this paper proposes a new optimization algorithm based on advanced ABC algorithm [3]. We evaluate the proposed algorithm through numerical experiments on well-known benchmark functions, such as Rastrigin function and Schwefel function, and discuss its development potential. In numerical experiments performed, the performances of the proposed algorithm are compared with those of the existing optimization one. The rest of this paper is organized as follows. In Section 2, the proposed algorithm based on advanced ABC algorithm is outlined. In Section 3, the results of numerical experiments are reported. Finally, the paper closes with conclusions in Section 4.

2 PROPOSED ALGORITHM

In the original ABC algorithm, the colony of artificial bees contains three groups of bees: employed bees, onlookers, and scouts. Half of the bees that construct artificial bee colony consist of the employed bees and the rest constitute the onlookers. At the initial state of ABC algorithm, multiple solution search points are randomly set in multidimensional solution search space. For every solution search point, there is only one employed bee, i.e., the number of employed bees is equal to the number of solution search points.

Each employed bee updates its own allocated solution search point in the solution search process. Each onlooker selects one solution search point from the probability based on the fitness value of each solution search point and updates the solution search point chosen. The employed bee of the solution search point that is not undated during the set search iterations becomes a scout and starts to search a new solution search point randomly.

The original ABC algorithm is summarized as follows:

Step 1 (Initialization)

Generate and evaluate the population of solution search points ($\boldsymbol{x}_i$, i=1, ... , SN), where i indicates the solution search point's index. SN is the number of solution search points.

Step 2 (Update of search points by employed bees)

1. Produce and evaluate the new solution search point ($\boldsymbol{v}_i$) on each solution search point ($\boldsymbol{x}_i$) according to the following formula

$$v_{ij} = x_{ij} + \phi_{ij}(x_{ij} - x_{mj}), \quad i = 1,\ldots,SN \tag{1}$$

where $m\in\{1, 2, \ldots, SN\}$ represents randomly chosen solution search point's index and $j\in\{1, 2, \ldots, D\}$ represents randomly chosen variable's index. D is the number of optimization variables. Although m is determined randomly, it has to be different from i. ϕ_{ij} is a random number, uniformly distributed within the interval [-1,1].

2. Apply the greedy selection process between $\boldsymbol{x}_i$ and $\boldsymbol{v}_i$.

Step 3 (Update of search points chosen by onlookers)

1. Compute the probability (P_i) of each solution search point ($\boldsymbol{x}_i$) according to the following formulas

$$fit_i = \begin{cases} \dfrac{1}{1+f(\boldsymbol{x}_i)}, & f(\boldsymbol{x}_i) \geq 0 \\ 1+abs(f(\boldsymbol{x}_i)), & f(\boldsymbol{x}_i) < 0 \end{cases} \quad (i = 1,\ldots,SN) \tag{2}$$

$$P_i = fit_i \Big/ \sum_{n=1}^{SN} fit_n \tag{3}$$

where $f(\boldsymbol{x})$ is the objective function. Each onlooker selects one solution search point ($\boldsymbol{x}_i$) depending on the probability (P_i).

2. Produce and evaluate the new solution search point ($\boldsymbol{v}_i$) on the solution search point ($\boldsymbol{x}_i$) chosen by each onlooker, as in Step2.
3. Apply the greedy selection process between $\boldsymbol{x}_i$ and $\boldsymbol{v}_i$.

Step 4 (Update of solution search points by scouts)

If the solution search point that is not undated during the set search iterations exists, replace it with randomly produced solution search point within solution search space.

Step 5 (Update of best solution)

Memorize the best solution search point.

Step 6 (Judgment of end)

Finish the search when the end condition is satisfied. Otherwise, return to Step 2.

The algorithm of [3] is an advanced ABC algorithm. To detect a global optimum solution effectively, ABC algorithm is improved as follows:

1. Improvement of Eq.(2) to compute fitness value (fit_i)
   To improve the adaptability to various engineering design problems, in the proposed algorithm, the fitness value (fit_i) of each solution search point is computed as follows:

$$fit_i = \begin{cases} \dfrac{1}{f(\boldsymbol{x}_i) - f_{bound}}, & f(\boldsymbol{x}_i) - f_{bound} \geq f_{accuracy} \\ \dfrac{1}{f_{accuracy}}, & f(\boldsymbol{x}_i) - f_{bound} < f_{accuracy} \end{cases} \quad (i = 1,\ldots,SN) \tag{4}$$

   where f_{bound} represents the boundary value of $f(\boldsymbol{x}^+)$ on $\boldsymbol{x}^+$ acceptable as a solution for every problem and $f_{accuracy}$ indicates the exactness of convergence to f_{bound}.
2. Improvement of search point selection by onlookers
   To improve the performance of global solution search, in the proposed algorithm, the solution search is divided into two stages. Each onlooker selects one solution search point out of the high-order α solution search points of fitness value (fit_i) randomly during the first stage of the search.
3. Improvement of reference point (m) in Eq.(1)

To improve the update frequency of each solution search point, the reference point (m) in Eq.(1) is randomly chosen out of the high-order α solution search points of the fitness value (fit_i) during the first stage of the search and is chosen by the roulette selection based on the probability (P_i) of each solution search point $(\boldsymbol{x}_i)$ during the second stage of the search.

In addition, Step 4 (Update of search points by scouts) in the original ABC algorithm is not executed in the algorithm of [3] because the performance of global solution search is improved by the above 2 (Improvement of search point selection by onlookers).

In the proposed algorithm, multiple colonies (swarms) search multiple (plural) acceptable solutions competitively, as in [4].

3 EXPERIMENTAL RESULTS

Through numerical experiments on the following D dimensional benchmark functions, the performances of the proposed algorithm are investigated in detail to verify its effectiveness on large scale optimization problems.

- Rastrigin function

$$\text{min.}\ f_1(\boldsymbol{x}) = \sum_{j=1}^{D} \left\{ x_j^2 - 10 cos(2\pi x_j) + 10 \right\}$$

$$\text{subj. to}\ -5.12 \le x_j \le 5.12, \quad j = 1,...,D$$

$$\boldsymbol{x}^* = (0,...,0), \quad f_1(\boldsymbol{x}^*) = 0$$

- Schwefel function

$$\text{min.}\ f_2(\boldsymbol{x}) = 418.98288727\,D + \sum_{j=1}^{D} - x_j sin(\sqrt{|\,x_j\,|})$$

$$\text{subj. to}\ -512 \le x_j \le 512, \quad j = 1,...,D$$

$$\boldsymbol{x}^* = (420.968750,...,420.968750), \quad f_2(\boldsymbol{x}^*) = 0$$

where $\boldsymbol{x}^*$ of each benchmark function represents a global optimum solution. In **Fig.1**, the landscapes of multimodal functions are illustrated. In the experimental results reported, the proposed algorithm is evaluated through a comparison with the existing optimization one, where the desired number of solutions (m) is set to 3.

First, the fundamental performance of the proposed algorithm is verified through the experimental result on Schwefel function $(D = 2)$. **Fig.2** shows the solution search points on Schwefel function $(D = 2)$. From **Fig.2**, it can be confirmed that three acceptable solutions which include one global optimum solution is accurately detected.

The experimental results obtained by applying the Particle Swarm Optimization algorithm for computing Plural Acceptable Solutions (PSO-PAS) of [4] and the proposed algorithm are arranged in **Tables 1** and **2**. From these experimental results, it can be confirmed that the proposed algorithm is substantially advantageous.

4 CONCLUSION

In this paper, as a technique of detecting not a single global optimum solution but plural acceptable solutions, a new optimization algorithm based on advanced artificial bee colony algorithm [3] has been proposed. In numerical experiments performed on some well-known representative benchmark functions, such as Rastrigin function and Schwefel function, the performances of the proposed algorithm were compared with those of the existing optimization one for detecting plural acceptable solutions [4]. The experimental results indicate that the proposed algorithm is superior to the existing optimization one for detecting plural acceptable solutions [4] and has the development potential as an effective and promising one for many engineering applications (engineering design problems).

Abstract: Car navigation systems of the modern vehicles are equipped with an optimal path selection (OPS) unit. The OPS unit is responsible for finding the shortest paths between any source and destination nodes in the road network. In Electric Vehicles (EVs), the purpose of the OPS unit is to find multi-objective shortest paths (MOSP) w.r.t.: (i) Recharging Time, (ii) Distance, and (iii) Travelling Time. This work presents a memory efficient Simulated Evolution (SimE) based algorithm for solving the MOSP problem in EVs. The proposed algorithm uses innovative representation of the solution, and problem-specific goodness and allocation operations. Two different techinques for selecting the recharging stations are also proposed. The performance of the proposed algorithm is compared with NSGA-II, which is a popular population based heuristic for solving the multi-objective optimization problem. The comparsion results show that the proposed algorithm achieves the performance equal to NSGA-II while it requires 2.22 times lesser memory than any population based heuristic.

Keywords: Multi-Objective Optimization, Electric Vehicles, Simulated Evolution

1 INTRODUCTION

Car navigation systems of the modern vehicles are equipped with an optimal path selection unit. The optimal path selection unit is responsible for finding the shortest paths between any source and destination nodes in a road network. The optimization objectives in the internal combustion engine (ICE) based vehicles are: minimizing the distance, travelling time, traffic, etc. The Electric Vehicles (EVs) are also gaining popularity [1]. The optimal path selection in EVs should include minimization of the recharging time. The recharging time of the EVs can generally vary from 10 minutes to 30 minutes and therefore, it is an important factor to be considered in optimal path selection.

The main obstacles in the popularity of the EVs are: (i) Limited battery life, the EVs can travel until the time duration which is equal to the time limit of their batteries without recharging. A general value for the time limit is 2 hours. However, the time limits of the EVs are very small as compared to the ICE based vehicles. (ii) Lack of the infrastructure for the recharging stations. The recharging stations should be placed at regular intervals to ensure that the EVs can travel without any recharging problem. (iii) The recharging time of the EVs is also important. The recharging of the EVs should be performed in minimum possible time like 10 minutes. Many researchers have investigated the feasibility and positioning of the recharging stations [1, 2, 3, 4]. The results of the previous research showed that portable or fixed recharging stations could be placed at suitable places along the road, which ensured that the majority of the EVs could travel without any problem [7]. The rapid recharging technology has enabled full recharging of the EV in 10 minutes. Besides rapid recharging, battery swapping technology is also available which has recharging time as low as 5 minutes. However, battery swapping is expensive to implement than recharging.

The problem of finding optimal path between a source and destination node in the road network is a multi-objective shortest path (MOSP) problem. In this work, the MOSP problem has the following objectives: (i) Minimizing the recharging time, (ii) Minimizing the travelling distance, and (iii) Minimizing the travelling time. The MOSP is an NP-hard discrete optimization problem [5, 6]. The objectives in any multi-objective optimization problem are often contradictory therefore, no one solution can be optimal in all objectives. Therefore, a set of Pareto optimal solutions is found for the multi-objective optimization problem. The Pareto optimal set contains the non-dominated solutions. Evolutionary computation (EC) algorithms have been predominately used to solve multi-objective optimization problems. In many EC algorithms the calculation in any iterations does not depends on the previous iteration. Therefore, they are robust to dynamic changes in the parameter values of the road network like changes in traffic, waiting delay at the recharging stations, etc. The performance of any EC is measured by the number of Pareto optimal solutions it returns and the diversity of the solutions. For practical applications other properties of the EC algorithms like computation time and memory requirements are also very important. The research work in this paper, focused on developing a memory and time efficient EC algorithm for solving the MOSP problems in Electric Vehicles. The objectives of the MOSP problem, can be in contradiction with each other based on the traffic situation or the queues at the recharging stations. For example, when the shortest paths becomes congested then the travelling time on them can exceed the other paths. The proposed algorithm can find MOSP despite the changing traffic conditions. Simulated Evolution (SimE) [9] is a popular EC algorithm which works on only one solution at a time and is therefore, memory efficient than the other population based algorithms like Genetic Algorithms (GA), etc.

This paper proposed a SimE based multi-objectives optimization algorithm for solving the MOSP problem in EVs. The proposed SimE based algorithm has innovative goodness and allocation operations which are tailored for solving the MOSP problem. The performance of the proposed algorithm is compared with a famous heuristic: Non-dominated Sorting Genetic Algorithm (NSGA) -II [8]. The NSGA-II is a population-based algorithm for solving the multi-objective optimization problems. The simulation results show that the proposed algorithm can provide results equal to or better than the NSGA-II while it requires lesser memory than NSGA-II.

This paper is organized as follows: Second section shows the formal description of the problem. Third section contains the detail of the proposed algorithm. Fourth section contains the simulation results and comparison of the proposed algorithm with the other algorithms. The last section contains the conclusion.

2 DESCRIPTION OF THE PROBLEM

2.1 System Overview

In the car navigation system, the driver selects the source and destination nodes of his/her journey. The navigation system finds one or more optimal paths between the source and destination nodes. The navigation systems of the modern vehicles comprise of an embedded system which has interface to the GPS (Global Positioning System). The selection of the optimal path can either be performed independently by each vehicle or the optimal path selection is performed at any centralized station for a group of vehicles.

This work assumes that the optimal path selection is performed independently by the vehicles. Therefore, optimal path selection is performed in the embedded system of the car navigation system and it uses the updated information related to the road network from the GPS. The GPS system can provide the information related to the location of recharging stations and their recharging times to the EVs. The block diagram of the Optimal Path Selection (OPS) unit of an EV is shown in Fig. 1. The figure shows that the OPS unit receives inputs from the GPS and source and destination nodes from the driver. The OPS searches the optimal path based on the provided information and yields one or more optimal paths

Table 1: Properties associated with edges, recharging stations and electric vehicles

Element	Symbol	Description
edge ($e_i \in E$)	$e_i.l$	Length of the edge
	$e_i.S$	Average speed of the EVs
recharging station	$r_j.R_{delay}$	Recharging time per EV
($r_j \in R$)	$r_j.W_{delay}$	Waiting delay per EV due to queuing in it
	$r_j.e$	$e \in E$, s.t. r_j lies along the edge e
	$r_j.p$	Distance of the r_j from the start of $r_j.e$
	$r_j.D$	Travelling time of r_j from the source node
electric vehicle	t_{LIMIT}	The maximum time which the EV can
(EV)		travel without recharging
	s	Source node of the journey
	d	Destination node of the journey
	B_s	The battery level at the source node

to the display unit of the car navigation system.

2.2 Description of the Road Network

Let us consider that in the OPS unit, the electric vehicle is represented as EV and the road network is represented by an undirected graph (G), which is represented as: $G = (V, E, R)$, where V is the set of all vertices or intersections in the road network, E contains the road segments which join the intersections and R contains the recharging stations which exist in the road network. When the road network contains a total of N nodes and M edges, then $V = \{n_0, n_1, ..., n_{N-1}\}$ and $E = \{e_0, e_1, ..e_{M-1}\}$. Any edge $e_i \in E$, $e_i = (n_x, n_y)$, where $n_x \neq n_y$ and $n_x, n_y \in V$. n_x and n_y are the starting and ending nodes of the edge e_i. When the road network contains a total of m recharging stations, then the set R is represented as: $R = \{r_0, r_1, ..., r_{m-1}\}$. The properties associated with the edges, recharging stations and the electric vehicle are shown in Table. 1.

2.3 Description of the Multi-objective Optimization Problem

Let us consider that the solution in the OPS unit is represented as: $P = \{P^A, P^B\}$. P^A stores the edges from E which form a path from the source to the destination node and is represented as: $P^A = \{e_i, e_j, .., e_k\}$, $e_i = (s, n_x)$ and

Input: nodes: u, & v, G=(V,E), N_e= Number of elements in E
Output: Q: A path from u to v nodes.

1: $W = random(M)$
2: Q= Apply Dijkstra's Algorithm (u, v)
3: **return** Q

Fig. 2: Method to find paths: $form\_path(u, v)$.

$e_k = (n_y, d)$, and $s, n_x, n_y, d \in V$. P^B stores the recharging stations from R on which EV should be recharged in order to complete its journey on the path P^A.
The optimization performed in the OPS unit aims to find the paths which are optimized w.r.t. three functions: (i) $f_1(P^B)$, which corresponds to the total recharging time. (ii) $f_2(P^A)$, which corresponds to the total distance and (iii) $f_3(P^A)$, which is the total travelling time. The values of the functions can be computed as follows:

$$f_1(P^B) = \sum_{r_j \in P^B} (r_j.R_{delay} + r_j.W_{delay}) \quad (1)$$

$$f_2(P^A) = \sum_{e_i \in P^A} e_i.l \quad (2)$$

$$f_3(P^A) = \sum_{e_i \in P^A} \frac{e_i.l}{e_i.S} \quad (3)$$

The objective function can be represented as: $Obj(P)$= $Minimize(f_1(P^B), f_2(P^A), f_3(P^A))$. The minimization is performed through the proposed SimE-based algorithm.

3 PROPOSED ALGORITHM

Simulated Evolution (SimE) [9] is a general search strategy for solving a variety of combinatorial optimization problems. The SimE optimization loop consists of the following steps: (i) Evaluation, in which goodness of each element in the population is evaluated. (ii) Selection, in which up-to $n_s\%$ elements in the current solution or P^A having lower goodness values are selected into the set S. (iii) Allocation, in this step the elements in the set S will undergo through the allocation process. The optimization iterations are continued until the stopping criteria which can be the maximum time is reached. This work proposes a design of SimE which has innovative goodness and allocation operations which are tailored for the proposed multi-objective optimization problem. The proposed algorithm stores all non-dominated solutions found during the optimization iterations, which forms its set of Pareto optimal solutions. However, storing only one non-dominated solution which has the maximum value of the hypervolume is sufficient for the proper execution of the proposed algorithm.

In the following the proposed goodness and allocation operations are described in detail. First a method of building a random path from nodes u to v is shown which will be used to build a random path between any two nodes. The algorithm is shown in Fig. 2 and is represented by the function $form\_path(u, v)$. In line 1, W stores M randomly generated integers between $[1, 1000]$. The elements in W are used to assign weights to the edges in E. The Dijkstra's Algorithm finds shortest path w.r.t. the weights assigned to edges in line 1.

3.1 Goodness Function

In SimE, the goodness is defined as the ratio of the estimated minimum cost to the actual cost of the elements. In this work, the solution is represented as $P = \{P^A, P^B\}$. In the Evaluation step, the goodness of all elements in the set P^A is determined. The P^A comprises of a set of edges, and the starting node of the first edge in it is the source node and the ending node of the last edge in it is the destination node. Before goodness calculation is performed, the weights (w_1, w_2, w_3) are assigned to all edges in E. The procedure to assign weights to any edge $e_i \in E$ is shown in Fig. 3.

The weight w_1 corresponds to the average of the recharging and waiting delays of all the recharging stations which exists along the edge e_i. The term in the denominator indicates the total number of recharging stations on any edge [7], which is used to calculate the average. The weight w_2 corresponds to the length of the edge and w_3 corresponds to the travelling time on the edge. The proposed procedure to find the goodness of any edge is shown in Fig. 4. In Fig. 4, the goodness of the edge $e_i \in P^A$ is calculated. The variable r_1 holds the number of edges in P^A which have w_1 value lesser than $e_i.w_1$. Similarly, the variables r_2 and r_3 holds the number of edges in P^A which have w_2 and w_3 values lesser than $e_i.w_2$ and $e_i.w_3$ respectively. At the end, the average of the r_1, r_2 and r_3 variables is calculated.

Input: Any edge $e_i \in P^A$, $P = \{P^A, P^B\}$
Output: $e_i.w_1$, $e_i.w_2$, $e_i.w_3$

$e_i.w_1 = \frac{\sum_{r_j \in R \& r_j.e=e_i} (r_j.R_{delay}+r_j.W_{delay})}{0.05 \times e_i.l}$
$e_i.w_2 = e_i.l$
$e_i.w_3 = \frac{e_i.l}{e_i.S}$
return $\{e_i.w_1, e_i.w_2, e_i.w_3\}$

Fig. 3: Procedure for the assignment of the weights to any edge $e_i \in P^A$.

3.2 Allocation

The selection operation populates the set S by selecting up-to $n_s \times s$ elements from P^A. $n_s \in [0, 1] \in R^+$. The selection operation selects the elements from P^A which are not already selected and have lowest goodness value with probability P_s and any randomly selected element with probability

Input: Any edge $e_i \in P^A$, $P = \{P^A, P^B\}$
Output: $g(e_i)$: goodness of the edge e_i

$r_1 = 0, r_2 = 0, r_3 = 0$
n =Number of elements in P^A
for $j = 0; j < n; j++$ **do**
  if $P^A[j].w_1 > e_i.w_1$ **then**
    r_1++
  end if
  if $P^A[j].w_2 > e_i.w_2$ **then**
    r_2++
  end if
  if $P^A[j].w_3 > e_i.w_3$ **then**
    r_3++
  end if-[]
end for
$g(e_i) = \frac{r_1+r_2+r_3}{3}$
return $g(e_i)$

Fig. 4: Goodness Function $g(e_i)$, $(e_i \in P^A)$.

$P_s - 1$. The allocation operation is applied after the selection operation and it uses the elements in S.

The proposed allocation operation is shown in Fig. 5 using the pseudo code. The variable P_{min} is initialized to P^A. As shown, the allocation operation consists of doubly nested for loops. The outer-most loop executes for N_s number of times and the inner loop executes for each element in S. In the inner loop, an element from S is selected in each iteration. A random sub-path which exists from the starting node of the selected edge to the destination node is created. Then the sub-path is concatenated with the portion of the original solution (i.e., P^A) from the first edge to the edge which lies just before the edge selected from S. The resultant of the sum of the weights (or the square root of the sum of the squares of the three weights) of the new path is calculated and if the value is lesser than the P_{min} then P_{min} is updated to the new solution. At the end of the doubly nested for loops, the path which has minimum value of the resultant of the sum of the weights is returned and P^A is updated.

3.3 Mutation

The mutation operation is applied with probability M_b, In the mutation operation, the complete path which is stored in P^A is replaced by another path from source to destination. The new path is formed using the $form\_path$ function.

3.4 Selection of the Recharging Stations

The travelling limit (t_{LIMIT}) of the EV is the maximum time until which the EV can travel without recharging. Therefore, the EV requires periodic recharging during its journey. The set P^B in P stores the recharging stations on which the EV should be recharged. This subsection

Input: $S = \{x, y, ..., z\}$, $P = \{P^A, P^B\}$, $N_s \in Z^+$
Output: P^A (which is the path after the allocation operation)

s = Number of elements in S, $P_{min} = P^A$
n = Number of elements in P^A
for $i = 0; i < N_s; i++$ **do**
  for $j = 0; j < s; j++$ **do**
    $snode = P^A[S[j]].startnode$, $enode = P^A[n-1].endnode$
    $t1 = FormPath(snode, enode)$
    $t = concatenate\{P^A[0...S[j]-1], t_1\}$
    $v_1 = \sum_{e_i \in t} e_i.w_1$, $v_2 = \sum_{e_i \in t} e_i.w_2$, $v_3 = \sum_{e_i \in t} e_i.w_3$
    $R_1 = \sqrt{v_1^2 + v_2^2 + v_3^2}$
    $v_4 = \sum_{e_i \in P_{min}} e_i.w_1$, $v_5 = \sum_{e_i \in P_{min}} e_i.w_2$, $v_6 = \sum_{e_i \in P_{min}} e_i.w_3$
    $R_2 = \sqrt{v_4^2 + v_5^2 + v_6^2}$
    if $R_1 < R_2$ **then**
      $P_{min} = t$
    end if
  end for
end for
$P^A = P_{min}$
return P^A

Fig. 5: Allocation Operation.

shows the methods of selecting recharging stations for P^B. The proposed methods assumed that P^A is already formed and is not null. Before the recharging stations are selected, the travelling time of all recharging stations which lie along the edges in P^A is determined. For any recharging station $r_j \in P^B$, its travelling time from the source node (s) is stored in $r_j.D$. Equation (4) shows the calculation of the $r_j.D$ value. The equations assumes that r_j lies along e_i and function $pos(e_x)$ returns the position of any edge in the set P^A. $pos(e_x) < pos(e_i)$, if e_x lies before e_i in P^A.

Let us consider: $r_j.e = e_i$, then

$$r_j.D = \sum_{e_x \in P^A \& pos(e_x) < pos(e_i)} \frac{e_x.l}{e_x.S} + \frac{r_j.p}{e_i.S} \tag{4}$$

The proposed work uses two different approaches to select the recharging stations. The first approach is the Last Station Strategy (LSS) and the second approach is the Random Selection Strategy (RSS). In LSS, the recharging station which has travelling time (or D value) closest but not greater than the time which the EV can travel without recharging is selected. The LSS approach is shown using flow chart in Fig. 6(a). In the RSS approach, a recharging station is randomly selected from among the candidate recharging stations. The RSS approach is shown using flow chart in Fig. 6(b). To

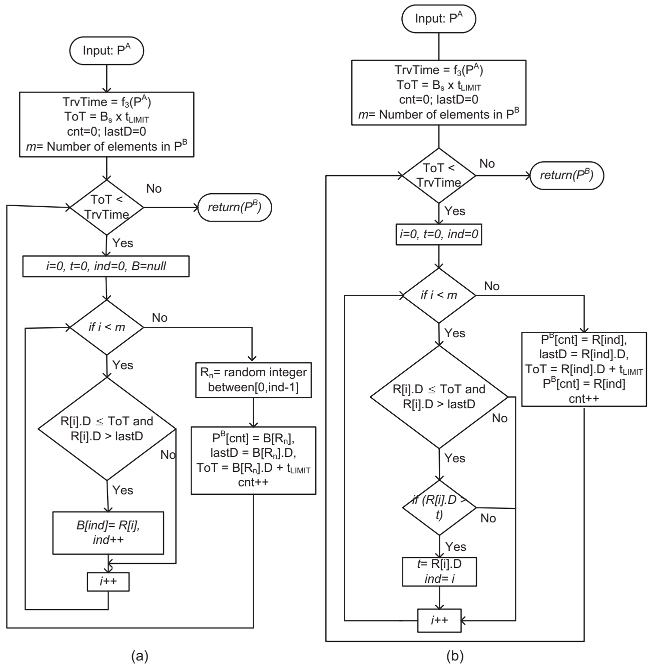

Fig. 6: Selection of recharging stations

populate the set P^B, the proposed algorithm applies both the LSS and RSS techniques. Let us consider that the result from the LSS is P^B and the result from the RSS is P^B.

3.5 Estimation of the Memory Requirements

The SimE works on only one solution. The proposed algorithm creates additional paths which include: Storing a solution which has minimum value of the product: $f_1(P^B) \times f_2(P^A) \times f_3(P^A)$. The allocation operation creates two new paths (t and P_{min}). In the techniques for the selection of recharging stations, the LSS creates one path and RSS creates two paths. The calculation of the number of paths which should be stored in the memory is as follows:
Let us consider that P^A or P^B requires δ units of memory. The maximum memory required is: $mem_{proposed}$= Memory required by the current solution (2δ) + Memory required by the allocation operation (2δ) + Memory required in storing a non-dominated solution (2δ) + memory required in selecting the recharging stations (3δ). Therefore, the total memory requirement is equal to 9δ. For comparison purposes, the minimum memory required by any GA (Genetic Algorithm) is also calculated. The GA stores a population of N elements, and therefore requires: mem_{GA}= $N \times 2\delta$ units of memory. The ratio $\frac{mem_{GA}}{mem_{proposed}} = \frac{2N}{9}$. In GA, the population size i.e. N $\geq$ 10 [8].

4 SIMULATIONS

The proposed algorithm is implemented using Java and its performance is compared with Non-dominated Sorting Genetic Algorithm - II (NSGA-II). The NSGA-II also optimizes paths w.r.t. the recharging time, distance and travelling time. NSGA-II uses the LSS scheme for selecting the recharging stations. The NSGA-II was implemented with population size (N) equal to 10. The ratio $\frac{mem_{GA}}{mem_{proposed}}$= 2.22. In NSGA-II, the population size is 2N, therefore, the ratio becomes 4.44. The proposed algorithm was implemented with parameter values: N_s= 5, i.e., the loop im the Allocation operations executes for five times, and M_b, which is the mutation probability is set to 0.60. The maximum time for the optimization loop is set to 10 seconds in both the proposed algorithm and in NSGA-II. Four road networks $(RG1, RG2, RG3, RG4)$ of different complexities are generated using a research tool [10]. The complexity of the road networks are as: RG1 having 1800 edges and 600 nodes, RG2 having 900 edges and 300 nodes, RG3 having 3400 edges an 1000 nodes, and RG4 having 4700 edges and 1400 nodes. The values to road lengths are randomly assigned to integers between [1, 400] km. The average speed on the edges are assigned to randomly selected integers between [40,120]. The waiting and recharging delay at the recharging stations varies randomly between $[10, 20] \in R$. The maximum time which the EV can travel without recharging is considered to be 2 hours. In any test case the source and destination nodes are randomly selected and the algorithm are used to find the optimum paths between them. On each graph, up-to 20 test problems are executed. In each test problem, the Pareto sets are obtained from both algorithms.

Table 2: Results of the Wilcoxon Rank-Sum tests.

Road Network	p	h	Remarks
$RG1$	0.9031	0	The Hypervolume distributions are same.
$RG2$	0.9676	0	The Hypervolume distributions are same.
$RG3$	0.4567	0	The Hypervolume distributions are same.
$RG4$	0.0858	0	The Hypervolume distributions are same.

The 3D Hypervolume calculation is performed by using the tool [11], which was proposed by Carlos Fonseca et al.. The tool calculates the Hypervolume for the minimization problems. In the Hypervolume calculation, the bounds for the maximum values are considered more than the values in the Pareto Optimal sets. The larger Hypervolume value represents that the Pareto optimal set consists of better solutions. The results are shown using Box-and-Whisker plots in Fig. 7. The box-and-whisker plots, the whiskers are drawn between the minimum and maximum values. The central mark is the median, the edges of the boxes are at the 25th and 75th percentiles. The Wilcoxon Rank Sum test [12] is used to test the null hypothesis, which shows that the Hypervolume distributions obtained from the two algorithms are same. The rank sum test returns p and h values. If $h = 0$, which means that the two distribution are same. p indicates the probability that an element from the first distribution is equal to

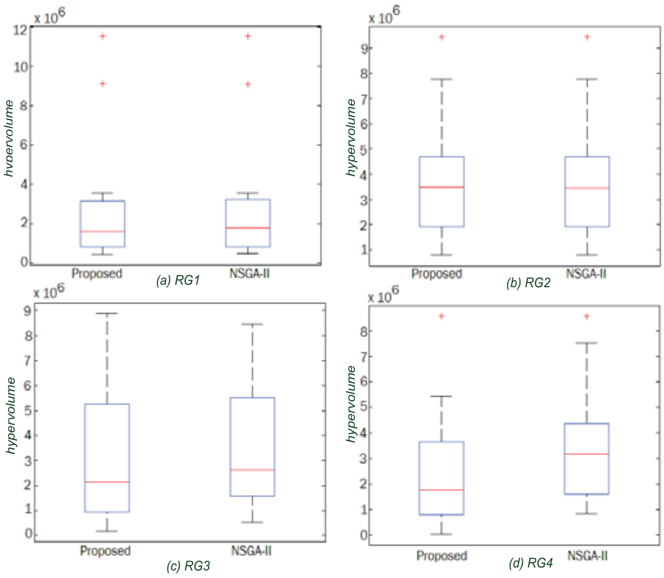

Fig. 7: Box-and-Whisker Plots of the Hypervolumes on different graphs.

the element from the second distribution. The MATLAB's $ranksum$ function is used to apply the rank sum test. The results are shown in Table 2, which shows that the Hypervolumes obtained fromthe proposed algorithm and NSGA-II on different graphs are same. Therefore, the Pareto Optimal solutions obtained from the proposed algorithm are as good as obtained from the NSGA-II.

5 CONCLUSION

In this work, the multi-objective route optimization problem for the Electric Vehicles (EVs) is solved by using the Simulated Evolution (SimE) based algorithm. The optimization objectives are: recharging time, distance and travelling time. Innovative and problem specific Goodness and Allocation operations are being used to achieve better performance. The comparison of the proposed algorithm with NSGA-II, which is a popular GA based heuristic for the multi-optimization problems shows that the proposed algorithm achieves same results as NSGA-II. However, the proposed algorithm requires memory which is 2.2 times lesser than any GA or population based algorithm. This memory size reduction is effective for implementing an embedded hardware.

Abstract: The resource constrained project scheduling problem (RCPSP) is an NP-hard optimization problem. RCPSP is one of the most important and challenging problem in the project management field. In the past few years, many researches have been proposed for solving the resource constrained project scheduling problem. The objective of this problem is to schedule the activities under the limited amount of the resources so that the project makespan is minimized. This paper proposes a new algorithm for solving RCPSP that combines the concepts of the biological immune system, the simulated annealing algorithm (SA), the tabu search algorithm (TS) and the genetic algorithm (GA) together. The performance of the proposed algorithm is evaluated and compared to the current state of the art metaheuristic algorithms. In this study, the benchmark data sets used in testing the performance of the proposed algorithm are obtained from Project Scheduling Problem Library (PSPLIB). The performance is measured in terms of the average percentage deviation from the critical path lower bound. The experimental results show that the proposed algorithm outperforms the state of the art metaheuristic algorithms on all standard benchmark data sets.

Keywords: Resource constrained project scheduling problem, Metaheuristic, Evolutionary algorithm

1 INTRODUCTION

The resource constrained project scheduling problem (RCPSP) is an NP-hard optimization problem. RCPSP is one of the most important and challenging problem in the project management field. The methods for solving the RCPSP have ranged from exact methods, to heuristic methods, to metaheuristic methods. In recent years, due to the need for solving large realistic project instances, the trend of the research has shifted toward the metaheuristic approaches. The objective of the RCPSP is to schedule the activities under the limited amount of the resources so that the project makespan is minimized [1]. Some metaheuristic methods for solving the RCPSP are reviewed in the following paragraph.

Debels et al [2] proposed a new metaheuristic which combines the scatter search with the electromagnetism optimization heuristic. Tseng and Chen [3] presented a hybrid metaheuristic, named ANGEL, for solving the RCPSP. ANGEL combines ant colony optimization, genetic algorithm and the local search strategy together. A new heuristic algorithm based on filter and fan method has been proposed in [4]. A hybrid metaheuristic algorithm based on the scatter search approach was developed by Ranjbar and Kianfar [5] to solve the RCPSP. Chen et al [6] proposed a hybrid algorithm, called ACOSS, for solving the RCPSP in real-time. The ACOSS algorithm combines a local search strategy, ant colony optimization, and a scatter search in an iterative process.

In this paper, a new hybrid evolutionary algorithm for the RCPSP is proposed. This proposed algorithm combines the concepts of the biological immune system, the simulated annealing algorithm (SA), the tabu search algorithm (TS) and the genetic algorithm (GA) together.

The rest of this paper is organized as follows: Section 2 is the problem definition of the RCPSP. Section 3 presents the proposed algorithm. A brief description of the test sets and the experimental results are given in Section 4. Finally, Section 5 is the conclusion.

2 PROBLEM DEFINITION

The resource constrained project scheduling problem (RCPSP) involves the scheduling of the project activities subject to precedence relations as well as the resource constraints in order to minimize the project duration.

The RCPSP can be stated as follows: A project consists of a set of N activities. Each activity j ($j \in N$) has duration of d_j and requires r_{jk} units of the resource type k. The resource type k has a limited capacity of R_k at any point in time. This means that the sum of the resource requirements for the resource k in any time period cannot exceed R_k. While the activity j is processed, the activity j requires r_{jk} units of the resource type k during every time instant of its non-preemptive duration d_j. In addition, the precedence relation between activities must also be taken into account, not just the resource restrictions.

Fig. 1 is an example of a project which consists of 6 activities (N = 6). Activities 0 and 5 are the dummy activities which represent the start and the end of the project respectively. Activities 1, 2, 3, and 4 are the real activities which require 3, 7, 6, and 2 units of the resource type k.

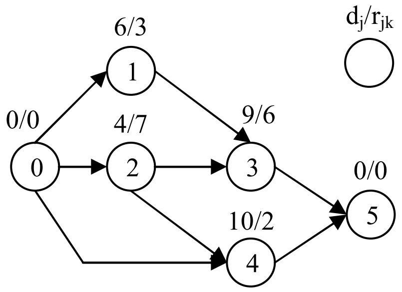

Fig. 1. An example of a project

3 PROPOSED ALGORITHM

The proposed algorithm is based on the concepts of the biological immune system, the simulated annealing algorithm (SA), the tabu search algorithm (TS) and the genetic algorithm (GA). The detailed procedure of the proposed algorithm (Fig. 2) is described as follows:

First, the initial population is generated by using the schedule generation scheme (SGS). The SGS consists of N stages, where N is the number of activities in the project. In each stage, one activity is selected and scheduled at its earliest possible time within the precedence and resource constraints. The SGS process stops when all activities are scheduled.

Second, the negative selection mechanism, to be discussed in Subsection 3.1, is employed to filter out the worst 10 percent of the whole population while the best 90 percent of the population are kept for the crossover process. The crossover operator used in this paper is the permutation encoding crossover (Fig. 3).

Third, the filtered-out chromosomes are forwarded to the TS-SA search algorithm, to be discussed in Subsection 3.2. After performing the TS-SA search, the new chromosomes obtained from the TS-SA search are combined with the new offspring obtained from the crossover operation.

Fourth, the mutation operation is performed on the combined population. The insertion mutation operator proposed by Fogel [7] is employed in this research.

Finally, the stopping criteria are checked. If any of the stopping criteria are met, the algorithm will be terminated. If not, the new population is selected from all solutions available in the current generation, both parents and their offspring; then go back to step 2.

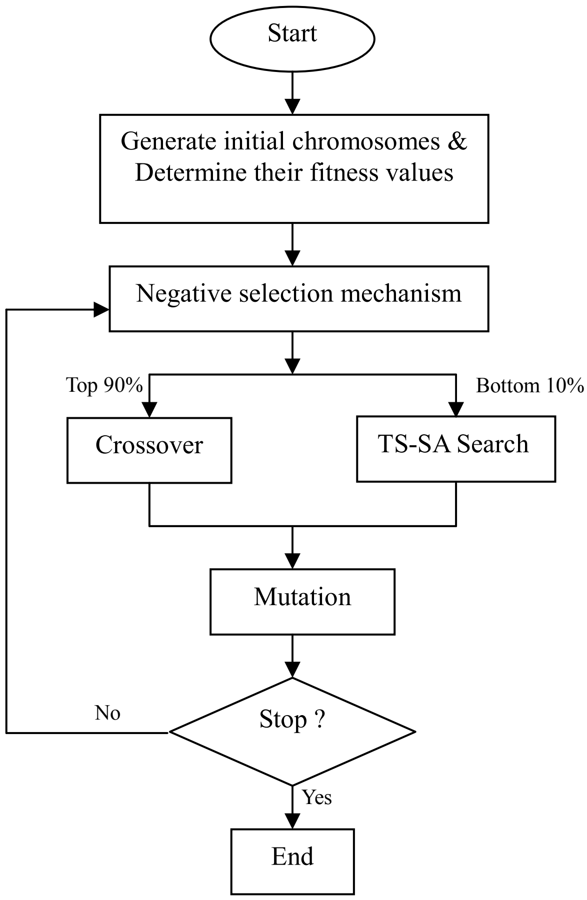

Fig. 2. Proposed algorithm

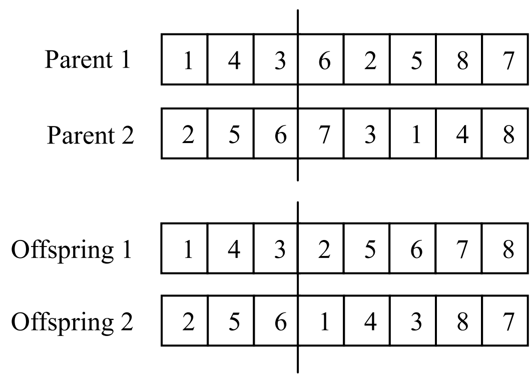

Fig. 3. Example of the permutation encoding crossover

3.1 Negative Selection Mechanism

Negative selection mechanism is inspired by the self/non-self discrimination behavior of the biological immune system. The purpose of the biological immune system is to recognize all cells within the body and categorizes those cells as either self (body cells) or non-self (antigens). When the antigens are found, the T-cells will bind themselves to the antigens and inject poisonous chemicals into them causing their destruction [8]. However, the immune system sometimes becomes dysfunctional by mistaking a body cell for a similar antigen. As a result, the body initiates the destructive operation against its own cells. In order to prevent the above undesirable phenomenon from happening, the negative selection mechanism is employed to remove the T-cells that bind too strongly to the body cells.

This paper employs the negative selection mechanism to remove the worst 10 percent of the whole population.

3.2 TS-SA Search Algorithm

The TS-SA search algorithm is a hybrid between the tabu search algorithm and the simulated annealing algorithm. For each filtered-out chromosome, M neighbor chromosomes are created by randomly mutating two genes in the chromosome. Next, the fittest neighbor is selected according to the tabu restrictions and aspiration criteria. If the best neighbor chromosome is fitter than the current chromosome, the current chromosome is replaced by the best neighbor chromosome. Otherwise, the simulated annealing concept is employed to determine whether the best neighbor chromosome should be accepted for further processing. If the criterion in (1) is met, the best neighbor chromosome will be used for further processing.

$$P(\text{accept}) > \varepsilon \tag{1}$$

$$P(\text{accept}) = \text{Exp}\ [-(E_n - E_c)/T] \tag{2}$$

where E_n is the fitness value of the best neighbor chromosome. E_c is the fitness value of the current chromosome. T is the temperature of the simulated annealing process. In this paper, the initial temperature is set at 90 degree; then the temperature gradually drops until it hits the pre-specified limit, which is 70 degree in this paper.

This TS-SA search is repeated until (1) the temperature of the simulated annealing process falls below a predefined value or (2) the best neighbor chromosome is fitter than the current chromosome.

4 EXPERIMENTAL RESULTS

The performance of the proposed algorithm is evaluated and compared to the current state of the art metaheuristic algorithms. In this study, the benchmark data sets used in testing the performance of the proposed algorithm are obtained from Project Scheduling Problem Library (PSPLIB) [9]. The whole set of projects with 60, 90, and 120 activities (data sets J60, J90, and J120) are considered. The test sets J60 and J90 contain 480 instances with 4 renewable resource types, while the J120 contains 600 instances.

The performance of the proposed model in solving the above mentioned test sets is shown in Table 1. The row labeled with "Sum" contains the sum of the makespans of all problem instances in each test set. The row labeled with "Avg. Dev. CPM (%)" displays the average percentage deviation from the critical path lower bound. The row labeled with "Avg. Dev. LB (%)" reports the average percentage deviation from the currently best known solution. The row labeled with "LB Found" displays the number of problem instances in which the proposed algorithm reports a makespan equal to the currently best known solution.

Table 2 illustrates the comparative results of the proposed algorithm and four of the current state of the art metaheuristic algorithms. In Table 2, the performance is compared in terms of the average percentage deviation from critical path lower bound. The experimental results show that the proposed algorithm outperforms the state of the art metaheuristic algorithms on all benchmark data sets.

Table 1. Experimental Results

	Data Set		
	J60	J90	J120
Sum	38397	45605	74179
Avg. Dev. CPM (%)	10.55%	9.57%	30.54%
Avg. Dev. LB (%)	0.99%	1.34%	4.42%
LB Found	410/480	390/480	291/600

Table 2. Comparative Results

	Average Percentage Deviation from Critical Path Lower Bound		
	J60	J90	J120
Proposed Algorithm	10.55%	9.57%	30.54%
Debels and Vanhoucke (2007) [10]	10.68%	10.35%	30.82%
Ranjbar (2008) [4]	10.56%	10.11%	31.42%
Ranjbar and Kianfar (2009) [5]	10.64%	10.04%	31.49%
Agarwal el al. (2011) [11]	11.29%	11.29%	34.15%

5 CONCLUSION

In this paper, a new metaheuristic algorithm for solving the resource constrained project scheduling problem is proposed. This proposed algorithm is based on the concepts of the biological immune system, the simulated annealing algorithm (SA), the tabu search algorithm (TS) and the genetic algorithm (GA). The experimental results show that the proposed model is capable of providing optimal or near-optimum solutions for all test sets.

Abstract: In this paper a flight evolutionary simulation of an artificial flying creature (AFC) is described. The three-dimensional motion of the AFC is calculated by the physical engine PhysX and a numerical expression of the simple drag force. The AFC is controlled by an artificial neural network (ANN). The three-layered ANN which has nine input neurons and four output neurons is used for a simulation of the AFC. To evolve ANNs and to have the AFC flight suitably for given target points, a particle swarm optimization (PSO) optimizes parameters of ANNs. The results of evolutionary simulation show that the ability of generalization does not always increase as evolution progresses, and it depends on given tasks of the AFC. It is also shown that the number of situations which the AFC goes through has positive correlation with the ability of generalization.

Keywords: Artificial life, Artificial neural network, Particle swarm optimization, Neuro-evolution, Physical engine

1 INTRODUCTION

Flight is a complex behavior. A sleeping dog can stay on the ground, while a bird not moving its wings can not stay in the sky. Ants can only move on surfaces, which are commonly regarded as the two-dimensional coordinates. On the other hand butterflies can fly freely in the air, the three-dimensional space. So it is interesting to understand the mechanism of flight, however, there are few researches on them.

Compared with flight, walking, jumping and swimming have been studied by many researchers. Sims [1] simulates evolution of the artificial virtual creatures and shows that creatures can acquire morphology and controllers by evolution with the physical interactions. Lipson et al [2]. and Rieffel et al [3]. also show similar results, however, it is a new point that Rieffel uses PhysX, one of physical engines, for calculating motions. In the field of bipedal walking, Allen et al [4]. and Reil et al [5]. show that bipedal robots can jump or walk through evolution. Wu et al [6]. proposes a bird model for computer graphics. This is one of a few studies on flight behaviors, although the evolutionary acquisition of flight is not done in it.

The objective of this study is to show a process in the evolution of flight behavior. In this paper, we describe a numerical simulation of flight evolution by the use of PhysX and drag force calculation. Although this method can calculate the motion faster, it is approximation and not completely accurate. However, we are focusing on the evolutionary process, and we do not deal with verification of the accuracy by experiments in the real world.

The method used for simulation is described in Section Two. Section Three explains a model of the artificial flying creature and how to evolve its controller by neuro-evolution. Section Four shows the evolutionary simulation and its result. Finally, the conclusion is described in Section Five.

2 COMPUTATIONAL METHOD

In order to calculate motion of the artificial flying creatures, we basically use a physical engine. Because it does not support the force which acts objects in a fluid, we use the simple drag force additionally.

2.1 Physical engine

The physical engine is software used for calculation of the multi body dynamics. The most common purpose of the physical engine is to improve reality in three-dimensional computer graphics. In addition, various types of physical simulations can be done easily by the physical engine, so it is used for researches on artificial-life in recent years.

The physical engine can calculate a motion of the complex object which consists of some objects connected by joints. It can also calculate effects of collision and friction and add force to objects. Since these calculations are automatically performed, the physical engine is regarded as a black box.

2.2 Drag force

Objects in a fluid are affected by the fluid via surfaces of the objects. The physical engine does not support this effect of the fluid yet. We use the simple drag force in order to implement the effect in the physical engine. The drag force D is given by

$$D = \frac{1}{2}\rho C_d A \boldsymbol{v}^2 \quad (1)$$

where ρ, C_d, A, and $\boldsymbol{v}$ are fluid density, a drag coefficient, an area of a minute surface, and velocity of the surface.

Although this drag force is a kind of the quasi-steady fluid force and a rough approximation, it is fast and easily combined with the physical engine.

3 MODEL OF THE CREATURE

The artificial flying creature (AFC) is controlled by an artificial neural network (ANN). To optimize parameters of ANNs, we use particle swarm optimization (PSO).

3.1 Artificial flying creature (AFC)

3.1.1 Structure

The AFC in Fig. 1. is similar to a bird. It is composed of four parts: a body, a tail, and two wings. The two wings are rotate on the axes $\boldsymbol{e}_{R1}$ and $\boldsymbol{e}_{L1}$, and on the axes $\boldsymbol{e}_{R2}$ and $\boldsymbol{e}_{L1}$. The tail rotates on the axis $\boldsymbol{e}_{T1}$, and on the axis $\boldsymbol{e}_{T2}$. Each rotation is controlled by an output signal of an ANN. To simplify control of the AFC, rotations of two wings are perfectly symmetrical.

3.1.2 Sensors

The AFC has some virtual sensors. They can measure states of the AFC, and perceive cognitive information. They are used as input signals of ANNs.

3.2 Artificial neural network (ANN)

The AFC has a three layered ANN as a controller. The ANN receives eight input signals from virtual sensors: the pitch and roll angles of the AFC, the forward velocity, the relative angles on the axes $\boldsymbol{e}_{R1}$ and $\boldsymbol{e}_{R2}$, the angular velocity on the axis $\boldsymbol{e}_{R1}$, and the angles relative to a target point. Then the ANN calculates four output signals: the angles on the axes $\boldsymbol{e}_{R1}$, $\boldsymbol{e}_{R2}$, $\boldsymbol{e}_{T1}$, and $\boldsymbol{e}_{T2}$.

3.3 Particle swarm optimization (PSO)

In order to optimize ANNs and control the AFC suitably, we use PSO. The PSO is one of the swarm intelligence and has strong convergence. Each position of a particle represents the parameters of an ANN. The position of the particle i at search step k+1, $\boldsymbol{p}^i_{k+1}$, is calculated by

$$\boldsymbol{v}^i{}_{k+1} = w\boldsymbol{v}^i{}_k + c_1 r_1\left(\boldsymbol{p_d}^i{}_k - \boldsymbol{p}^i{}_k\right) + c_2 r_2\left(\boldsymbol{p_g}{}_k - \boldsymbol{p}^i{}_k\right) \quad (2)$$

and

$$\boldsymbol{p}^i{}_{k+1} = \boldsymbol{p}^i{}_k + \boldsymbol{v}^i{}_{k+1} \quad (3)$$

where w, c_1, and c_2 are coefficients, r_1 and r_2 are uniform random numbers from 0 to 1. $\boldsymbol{p}_d$ is the best position of the particle i, and $\boldsymbol{p}_g$ is the best of all particles.

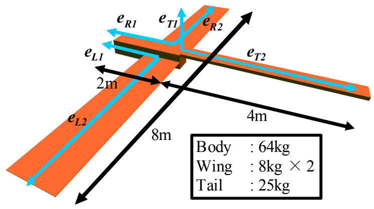

Fig. 1. The artificial flying creature (AFC)

4 EVOLUTION OF FLIGHT TO TARGETS

The AFC evolves to fly to a given target by PSO. We use two different conditions in evolution of the AFC, and then we analyze differences of the process in evolution and the evolved flight to given targets.

4.1 Evolutionary conditions

4.1.1 Common conditions

The AFC is initially placed on the point of (0,200,0) in a static state. Then the AFC starts flying to a target. If the AFC satisfies conditions of termination, the next flight to another target starts, or the next AFC starts flying. The time of numerical integration in PhysX is 1/100 seconds.

We use w = 0.4 and c_1 = c_2 = 2.0 as parameters of PSO. We also use 60 particles, and 2000 search steps of PSO.

4.1.2 Conditions in go-and-stay

In the evolution of "go-and-stay", the AFC evolves to go to only one target given by (200,300,200), and stay there. Each AFC flies for 30 seconds, and then it is evaluated by

$$\sum_{t=0}^{3000} \frac{1}{1 + d_t{}^2} \quad (4)$$

where t and d_t are a time step and a distance from the AFC to the target at time step t.

4.1.3 Conditions in 4-trials

In the evolution of "4-trials", the AFC evolves to go to the four targets given by (200,300,200), (-200,100,200), (-200,300,-200), and (200,100,-200). It does not have to stay around targets. Each AFC flies to a target for 30 seconds at most. If it is situated within 1m from the target, it is considered that the AFC arrives at the target and the flight is terminated. It repeats the flight for a different target four times, and then each is evaluated by

$$\sum_{s=1}^{4} \left\{ \sum_{t=0}^{T_s - 1} \left(\frac{1}{1 + d_{s,t}{}^2} \right) + \sum_{t=T_s}^{3000} 1 \right\} \quad (5)$$

where s, T_s, and $d_{s,t}$ are the number of trials, a time to arrive at a target in trial s, and a distance from the AFC to the target of trial s at time step t.

4.2 Results of evolution

4.2.1 Changing evaluation in evolution

We have done evolutionary simulations 10 times for go-and-stay and 4-trials. Fig. 2. shows changing evaluations at each search step. The result that differences between the maximum values and average values are larger than one between the minimum values and average values shows high variance of these evolutionary simulations.

4.2.2 Evolved flights

Fig. 3. shows the trajectory and snapshot at every second of the most successful flight given by go-and-stay evolution. In this flight, the AFC goes to the target quickly and flies around the target. This satisfies the aim of "go-and-stay". The number of satisfactory flights, however, is only three. The other flights satisfy only the aim of "go", do not satisfy the aim of "stay".

On the other hand, four different patterns of flight are given by 4-trials evolution. The worst flight is to go back and the AFC falls down. The next worse flight is to go to only one or two targets and the AFC falls down. Two better flights are interesting: one gets low evaluation but fully satisfies "go-and-stay", and the other obtains high evaluation but the AFC falls down after arrival. The arriving rate for (200,300,200), (-200,100,200), (-200,300,-200), and (200,100,-200) are 10%, 40%, 0%, and 70% in ten evolutionary simulations. In even the best flight, the AFC arrives at only two targets given by (-200,100,200) and (200,100,-200).

5 ANALYSYS OF EVOLUTIONARY PROCESS

ANNs have properties of generalization, which is the ability to learn many things by little learning. In the case of the AFC, we have defined the ability of generalization as the ability to reach the targets which are not related to the evaluation of the AFC, and then tested the change of the ability of generalization in evolution.

For tests of generalization, 64 target points are set: 32 points are located on circle-1, and the 32 other points are located on circle-2. The radiuses of circle-1 and circle-2 are $200\sqrt{2}$, and the centers of circle-1 and circle-2 are the points of (0,100,0) and (0,300,0). The length for judgment of arrival is 10m, which is larger than 1m in evolution.

Fig. 4. shows the average values of the successful rate of arrival for 64 targets in evolution. The rate of "4-trials" does not decrease as evolution progresses at least, while that of "go-and-stay" obviously decreases after 500 search steps. This result shows that the evolutionary conditions in go-and-stay are not suitable for increasing generalization.

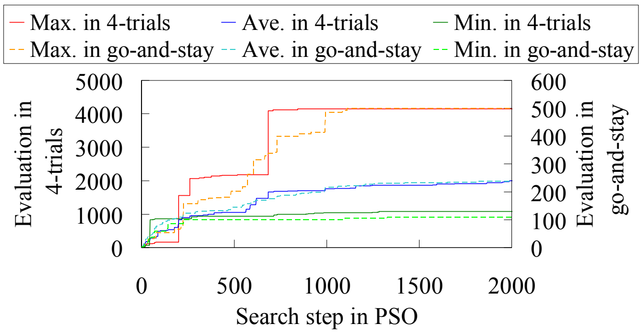

Fig. 2. The change of evaluations in evolution

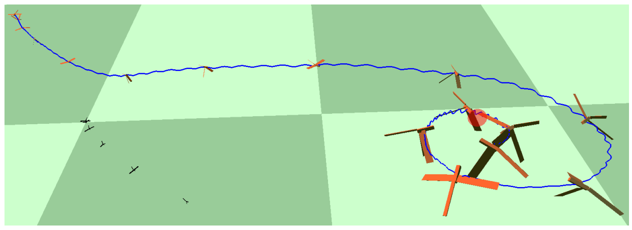

Fig. 3. The most successful flight of go-and-stay

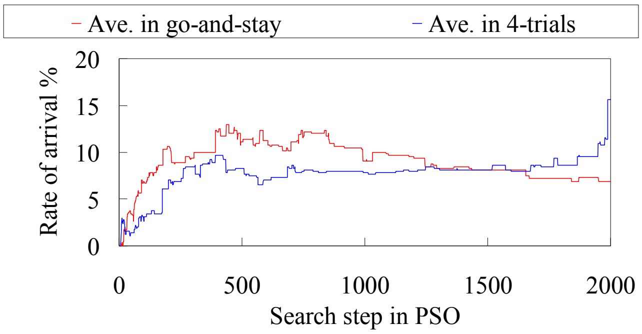

Fig. 4. The successful rate of arrival for 64 targets

We also have counted the "experienced target angles" in evolution of go-and-stay. It is the number of appearing sets of the angles relative to the target in flight. Angles are discretized into integers, and the total number of sets is $360° \times 360° = 129600$.

Fig. 5. shows the relations between the average values of the experienced target angles and the rate of arrival about go-and-stay, and Fig. 6. shows one between the average evaluation and the rate of arrival. Although Fig. 5. shows the relation of monotonic increase, so does not Fig. 6. This result leads us to the idea that increasing the experienced target angles may bring higher successful rate of arrival.

6 EVOLUTION USING TARGET ANGLES

To verify the given hypothesis, we additionally simulate the evolution of the AFC with "experienced target angles". The evolutionary conditions are all the same with that in the evolution of "go-and-stay" but evaluation. The evaluation

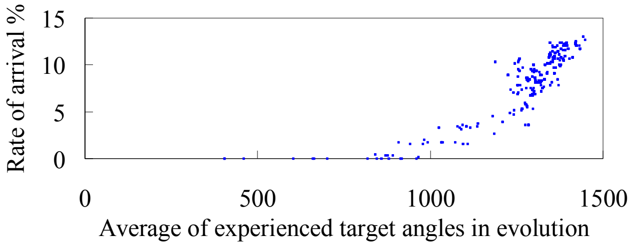

Fig. 5. The relation between the experienced target angles and the rate of arrival in evolution of go-and-stay

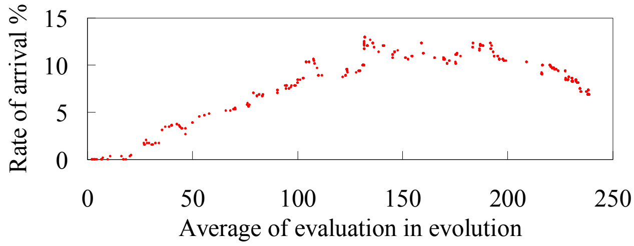

Fig. 6. The relation between the evaluation and the rate of arrival in evolution of go-and-stay

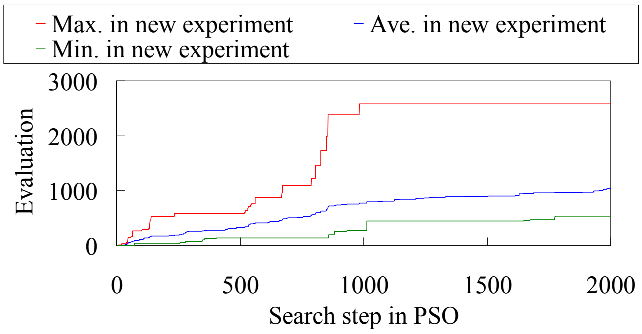

Fig. 7. The change of evaluations in new experiment

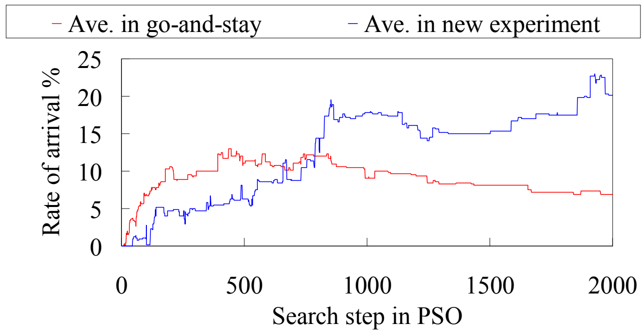

Fig. 8. The successful rate of arrival for 64 targets

of the AFC is given by

$$\left(\sum_{t=0}^{3000}\frac{1}{1+d_t^{\,2}}\right)\left(\frac{100a}{129600}\right)^3 \tag{6}$$

where a is the number of experienced target angles of the AFC. In short, the AFC which has both the ability of "go-and-stay" and more experiences survives by this evaluation.

Fig. 7. shows average evaluations at each search step given by 10 evolutionary simulations. A high variance between each evolution is similar to one of go-and-stay.

Fig. 8. shows the average values of the successful rate of arrival for 64 targets in evolution. The new experiment brings higher rates of arrival at later search steps, and they roughly show the relation of monotonic increase. This result gives support to our hypothesis.

7 CONCLUSION

We have simulated the evolution of the AFC by using PhysX and the drag force calculation. According to two evolutionary conditions, "go-and-stay" and "4-trials", there are some differences in both the evolved flights and the evolutionary processes. A difference in the successful rate of arrival for 64 targets is the most essential: it increases monotonically in the case of 4-trials, while it decreases as evolution progresses in the case of go-and-stay.

A positive correlation between the rate of arrival and the "experienced target angles" suggests that many experiences about angles for targets keep increasing the rate. The new evolution using experienced target angles verifies this hypothesis, and it also shows that indirect factors influence the ability of generalization in evolution. It is a future work to examine whether our theory applies to other cases or not.

Abstract: This paper proposes a novel optimization algorithm based on advanced Artificial Bee Colony (ABC) algorithm that has the good performance on large scale optimization problems named the differential ABC algorithm. In the proposed algorithm, the generation equation of the mutation vector of Differential Evolution (DE) is introduced in advanced ABC algorithm. We evaluate the proposed algorithm through numerical experiments on well-known benchmark functions, such as Rastrigin function, Schwefel function, Ackley function and Griewank function, and discuss its development potential. In numerical experiments performed, the performances of the proposed algorithm are compared with those of the existing optimization ones, such as Particle Swarm Optimization (PSO) algorithm, DE algorithm, ABC algorithm and advanced ABC algorithm.

Keywords: large scale optimization problems, multimodal functions, global optimization, differential evolution, ABC algorithm.

1 INTRODUCTION

The minimization of multimodal functions with many local and global minima is a problem that frequently arises in diverse scientific fields and numerous engineering design problems. This problem is NP-hard in the sense of its computational complexity even in simple cases. As techniques of computing a global minimum of the objective function, many meta-heuristics, which are search algorithms for optimization based on heuristic knowledge, have been proposed. Some well-known representative meta-heuristics are simulated annealing and tabu search which are the traditional optimization algorithms, genetic algorithms and immune algorithms which are classified as evolutionary computation techniques, and ant colony optimization algorithms and particle swarm optimization algorithms [1] which belong to the category of swarm intelligence algorithms.

In meta-heuristics, genetic algorithms and immune algorithms, classified as evolutionary computation techniques, are generally techniques for combination optimization problems. In genetic algorithms and immune algorithms, the variables of continuous type are frequently translated into those of discrete (genetic) type. If there is a dependency between variables, therefore, a promising solution may be destroyed during the solution search process (genetic operation) and the solution search performance may deteriorate. To the contrary, particle swarm optimization algorithm [1] can directly handle the variables of continuous type. Even when there is a dependency between variables, therefore, an efficient and effective solution search can be realized. Recently, particle swarm optimization algorithm is intensively researched because it is superior to the other algorithms on many difficult optimization problems. The ideas that underlie particle swarm optimization algorithm are inspired not by the evolutionary mechanisms encountered in natural selection, but rather by the social behavior of flocking organisms, such as swarms of birds and fish schools. Particle swarm optimization algorithm is a population-based algorithm that exploits a population of individuals to probe promising regions of the search space. The algorithm is simple and allows unconditional application to various optimization problems. However, it has been confirmed that the performance of particle swarm optimization algorithm on large scale optimization problems is not always satisfactory. Therefore, we have proposed a new optimization algorithm based on Artificial Bee Colony (ABC) algorithm [2] that has the good performance on large scale optimization problems [3]. However, for hundreds of dimensional engineering design problems, the improvement of the search performance is moreover required.

This paper proposes a novel optimization algorithm based on advanced ABC algorithm [3] that has the good performance on large scale optimization problems named the differential ABC algorithm. In the proposed algorithm, the generation equation of the mutation vector of Differential Evolution (DE) [4] is introduced in advanced ABC algorithm. We evaluate the proposed algorithm through numerical experiments on well-known benchmark functions, such as Rastrigin function, Schwefel function, Ackley function and Griewank function, and discuss its development potential. In numerical experiments performed, the performances of the proposed algorithm are compared with those of the existing optimization ones. The rest of this paper is organized as follows. In Section 2, the proposed algorithm named the differential ABC algorithm is outlined. In Section 3, the results of numerical experiments are reported. Finally, the paper closes with conclusions in Section 4.

2 PROPOSED ALGORITHM

In the original ABC algorithm, the colony of artificial bees contains three groups of bees: employed bees, onlookers, and scouts. Half of the bees that construct artificial bee colony consist of the employed bees and the rest constitute the onlookers. At the initial state of ABC algorithm, multiple solution search points are randomly set in multidimensional solution search space. For every solution search point, there is only one employed bee, i.e., the number of employed bees is equal to the number of solution search points.

Each employed bee updates its own allocated solution search point in the solution search process. Each onlooker selects one solution search point from the probability based on the fitness value of each solution search point and updates the solution search point chosen. The employed bee of the solution search point that is not undated during the set search iterations becomes a scout and starts to search a new solution search point randomly.

The original ABC algorithm is summarized as follows:

Step 1 (Initialization)

Generate and evaluate the population of solution search points ($\boldsymbol{x}_i$, i=1, ... , SN), where i indicates the solution search point's index. SN is the number of solution search points.

Step 2 (Update of search points by employed bees)

1. Produce and evaluate the new solution search point ($\boldsymbol{v}_i$) on each solution search point ($\boldsymbol{x}_i$) according to the following formula

$$v_{ij} = x_{ij} + \phi_{ij}(x_{ij} - x_{mj}), \quad i = 1,\ldots,SN \tag{1}$$

where $m \in \{1, 2, \ldots, SN\}$ represents randomly chosen solution search point's index and $j \in \{1, 2, \ldots, D\}$ represents randomly chosen variable's index. D is the number of optimization variables. Although m is determined randomly, it has to be different from i. ϕ_{ij} is a random number, uniformly distributed within the interval [-1,1].

2. Apply the greedy selection process between $\boldsymbol{x}_i$ and $\boldsymbol{v}_i$.

Step 3 (Update of search points chosen by onlookers)

1. Compute the probability (P_i) of each solution search point ($\boldsymbol{x}_i$) according to the following formulas

$$fit_i = \begin{cases} \dfrac{1}{1+f(\boldsymbol{x}_i)}, & f(\boldsymbol{x}_i) \geq 0 \\ 1 + abs(f(\boldsymbol{x}_i)), & f(\boldsymbol{x}_i) < 0 \end{cases} \quad (i = 1,\ldots,SN) \tag{2}$$

$$P_i = fit_i \bigg/ \sum_{n=1}^{SN} fit_n \tag{3}$$

where $f(\boldsymbol{x})$ is the objective function. Each onlooker selects one solution search point ($\boldsymbol{x}_i$) depending on the probability (P_i).

2. Produce and evaluate the new solution search point ($\boldsymbol{v}_i$) on the solution search point ($\boldsymbol{x}_i$) chosen by each onlooker, as in Step2.
3. Apply the greedy selection process between $\boldsymbol{x}_i$ and $\boldsymbol{v}_i$.

Step 4 (Update of solution search points by scouts)

If the solution search point that is not undated during the set search iterations exists, replace it with randomly produced solution search point within solution search space.

Step 5 (Update of best solution)

Memorize the best solution search point.

Step 6 (Judgment of end)

Finish the search when the end condition is satisfied. Otherwise, return to Step 2.

The algorithm of [3] is an advanced ABC algorithm. To detect a global optimum solution effectively, ABC algorithm is improved as follows:

1. Improvement of Eq.(2) to compute fitness value (fit_i)
   To improve the adaptability to various engineering design problems, in the proposed algorithm, the fitness value (fit_i) of each solution search point is computed as follows:

$$fit_i = \begin{cases} \dfrac{1}{f(\boldsymbol{x}_i) - f_{bound}}, & f(\boldsymbol{x}_i) - f_{bound} \geq f_{accuracy} \\ \dfrac{1}{f_{accuracy}}, & f(\boldsymbol{x}_i) - f_{bound} < f_{accuracy} \end{cases} \quad (i = 1,\ldots,SN) \tag{4}$$

   where f_{bound} represents the boundary value of $f(\boldsymbol{x}^+)$ on $\boldsymbol{x}^+$ acceptable as a solution for every problem and $f_{accuracy}$ indicates the exactness of convergence to f_{bound}.
2. Improvement of search point selection by onlookers
   To improve the performance of global solution search, in the proposed algorithm, the solution search is divided into two stages. Each onlooker selects one solution search point out of the high-order α solution search points of fitness value (fit_i) randomly during the first stage of the search.
3. Improvement of reference point (m) in Eq.(1)

To improve the update frequency of each solution search point, the reference point (m) in Eq.(1) is randomly chosen out of the high-order α solution search points of the fitness value (fit_i) during the first stage of the search and is chosen by the roulette selection based on the probability (P_i) of each solution search point ($\boldsymbol{x}_i$) during the second stage of the search.

In addition, Step 4 (Update of search points by scouts) in the original ABC algorithm is not executed in the algorithm of [3] because the performance of global solution search is improved by the above 2 (Improvement of search point selection by onlookers).

In the proposed algorithm, the following mutation vector generation equation of Differential Evolution (DE) [4] is introduced for the update of search points by employed bees.

$$\boldsymbol{v}_i = \boldsymbol{x}_{r1} + F(\boldsymbol{x}_{r2} - \boldsymbol{x}_{r3}), \quad i = 1, \dots, SN \tag{5}$$

where $\boldsymbol{x}_{r1}$, $\boldsymbol{x}_{r2}$ and $\boldsymbol{x}_{r3}$ represent the search point's index randomly selected, and F indicates a control parameter determined within the interval [0,1]. The above mutation vector generation equation has the good performance on the global search of multimodal functions. By introducing Eq.(5), it can be expected that the performance of the proposed algorithm is improved.

3 EXPERIMENTAL RESULTS

Through numerical experiments on D dimensional benchmark functions, which are Rastrigin function, Schwefel function, Ackley function and Griewank function, the performances of the proposed algorithm are investigated in detail to verify its effectiveness on large scale optimization problems. In numerical experiments performed, the performances of the proposed algorithm are compared with those of the existing optimization ones.

- Rastrigin function

$$\text{min.}\ f_1(\boldsymbol{x}) = \sum_{j=1}^{D}\left\{x_j^2 - 10\,cos(2\pi x_j) + 10\right\}$$

$$\text{subj. to}\ -5.12 \le x_j \le 5.12, \quad j = 1,\dots,D$$

$$\boldsymbol{x}^* = (0,\dots,0), \quad f_1(\boldsymbol{x}^*) = 0$$

- Schwefel function

$$\text{min.}\ f_2(\boldsymbol{x}) = 418.98288727\,D + \sum_{j=1}^{D} -x_j sin(\sqrt{|x_j|})$$

$$\text{subj. to}\ -512 \le x_j \le 512, \quad j = 1,\dots,D$$

$$\boldsymbol{x}^* = (420.968750,\dots,420.968750), \quad f_2(\boldsymbol{x}^*) = 0$$

- Ackley function

$$\text{min.}\ f_3(\boldsymbol{x}) = 20 + e - 20\,exp\left(-0.2\sqrt{\frac{1}{D}\sum_{j=1}^{D} x_j^2}\right) - exp\left(\frac{1}{D}\sum_{j=1}^{D} cos(2\pi x_j)\right)$$

$$\text{subj. to}\ -30 \le x_j \le 30, \quad j = 1,\dots,D$$

$$\boldsymbol{x}^* = (0,\dots,0), \quad f_3(\boldsymbol{x}^*) = 0$$

- Griewank function

$$\text{min.}\ f_4(\boldsymbol{x}) = \frac{1}{4000}\sum_{j=1}^{D} x_j^2 - \prod_{j=1}^{D} cos\left(\frac{x_j}{\sqrt{j}}\right) + 1$$

$$\text{subj.to}\ -600 \le x_j \le 600, \quad j = 1,\dots,D$$

$$\boldsymbol{x}^* = (0,\dots,0\,), \quad f_4(\boldsymbol{x}^*) = 0$$

where $\boldsymbol{x}^*$ of each benchmark function represents a global optimum solution. In **Fig.1**, the landscapes of multimodal functions are illustrated. The settings which were used in numerical experiments performed are shown in **Table1**. In the experimental results, the proposed algorithm is evaluated through a comparison with existing optimization ones.

Table1 Settings used in the experiments performed.

colony size(N)	*60*
employed bees(SN)	*50% of colony size*
onlookers(N - SN)	*50% of colony size*
Number of iterations	*1000*

The experimental results obtained by applying PSO algorithm, DE algorithm, ABC algorithm, Advanced ABC (AABC) algorithm and the proposed algorithm are arranged in **Tables 2, 3, 4** and **5**. In **Fig.2**, the convergence curves on Rastrigin function (D=100) are shown. From these experimental results, it can be confirmed that the proposed algorithm is substantially advantageous for large scale optimization problems.

4 CONCLUSION

In this paper, a novel optimization algorithm named the differential ABC algorithm has been proposed. In numerical experiments performed on some well-known representative benchmark functions, such as Rastrigin function and Schwefel function, the performances of the proposed algorithm were compared with those of the existing optimization ones. The experimental results indicate that the proposed algorithm is superior to the existing optimization ones for large scale optimization problems.

Abstract: User-System Cooperative Evolution (CEUS) is an Evolutionary Computation (EC) method to optimize quantitative and qualitative criteria. In previous work of CEUS, the whole population update is performed at every generation, and the user hardly observes all individuals. This paper proposes a generation alternation model designed for CEUS. The proposed model allows a user to find widely varied individuals in addition to the best individuals by replacing just one individual in a population for each generation, and consequently contributes user's idea generation by enhancing divergent thinking.

Keywords:
user-system cooperative evolution, generation alternation model, interactive evolutionary computation, genetic algorithm

1 INTRODUCTION

Interactive Evolutionary Computation (IEC)[1] faces a dilemma that general Evolutionary Computation (EC) algorithms require much trial and error but IEC can not use a large population and can not iterate so many generations due to user fatigue. To resolve this dilemma, the authors have proposed a method that is a fusion model of IEC and Non-Interactive EC (nIEC)[2]. In this paper we call the above method Cooperative Evolution by User and System (CEUS).

CEUS aims to incorporate user heuristics and/or preference into EC search dynamically. To achieve this, CEUS comprises following two essential functions.

1. CEUS optimizes both qualitative and quantitative objective functions simultaneously:
   CEUS can be regarded as IEC with domain knowledge that can be used to evaluate solutions, or as EC with a qualitative objective function. Designing a fitness function is crucial to find good solutions in real-world problems. But ideal function may not be sufficient to solve such real world problems, and ambiguous complementary subfunctions may be necessary to obtain practical quasi-optimal solutions. Incorporating ambiguous criteria such as user preference particularly makes it difficult to design the fitness function. Various real world problems can therefore be modeled as the problem involving explicit and ambiguous criteria.

2. CEUS has a mechanism to adopt user heuristics and preferences and to estimate user preferences from past user operation:
   To promote the effective use of EC, it is crucial to use large population size and to conduct a search long enough. But excessive user operations must be avoided. CEUS therefore allows a user to dynamically switch the role of EC at any time during the search. For instance, the user lets the system search for a solution like nIEC, and observes the search progress. Whenever the user finds an interesting individual, the user can stop the search, evaluate it, and add a genetic operation to it.

In previous work of CEUS, the whole population update is performed at every generation, and the user hardly observes all individuals. Only the best individuals can be seen by the user because it cannot be updated so frequently except the earlier stage of the search. Varied individuals with a moderate fitness value can be hardly found by the user because such individuals change and are replaced by new ones immediately. Consequently, although CEUS shows good performance to find a solution which can be expected by the user, CEUS was not effective to help the user find unpredictable, varied solutions.

This paper proposes a generation alternation model designed for CEUS. The proposed generation alternation model allows a user to find widely varied individuals in addition to the best individuals by replacing just one individual in a population for each generation. Consequently, the proposed model contributes user's idea generation by enhancing divergent thinking.

Experimental study showed that the proposed generation alternation model helped a user find various solutions not only the best individuals in the population.

2 USER-SYSTEM COOPERATIVE EC

Fig. 1 shows the process flow of CEUS. A typical CEUS search style is that the system searches for solutions by itself at the early stage of the search, and after the system produces some promising individuals the user chooses adequate one

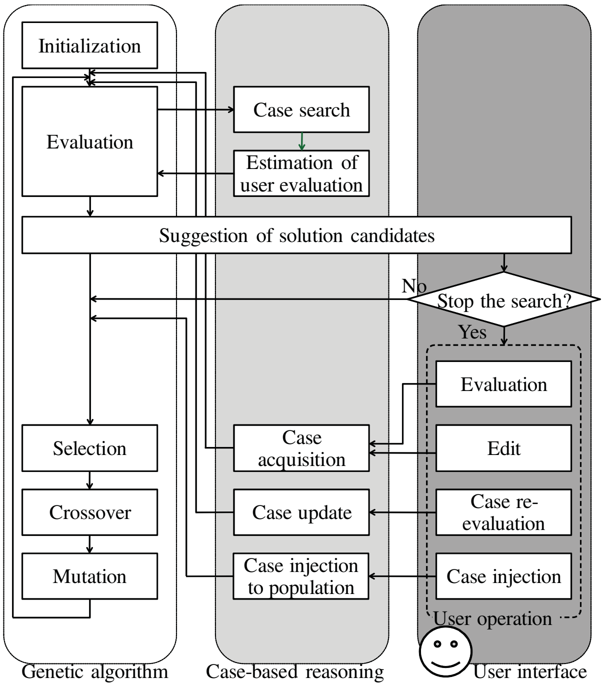

Fig. 1. Process flow of CEUS.

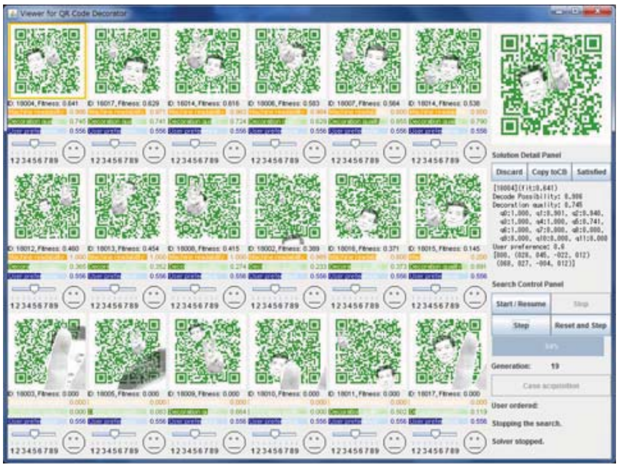

Fig. 2. User interface.

or directly revise them in order to enhance search intensification. nIEC search improves the population based on the chosen or revised individuals.

In CEUS, the user does not have to evaluate individuals at every generation. Unless the user stops the search, the system keeps searching for a solution. Although the user is allowed to concentrate on observing individuals reproduced by the system, it is hard to watch all individuals because the system grinds out individuals. CEUS proposed in [2] adopt simple GA (SGA), and most of individuals are replaced by new offsprings except top elites at every generation.

Therefore, to observe changes on the top elites and a few good individuals is the lowest the user can do. The user can not afford to watch other various individuals, and the user often passes over unpredictable and moderately good individuals. It is important to observe such individuals so that CEUS enhances the user's divergent thinking.

3 PROPOSED GENRATION ALTERNATION MODEL

The generation alternation model for CEUS proposed in this paper aims to increase the chance to discover unpredictable, good solutions. The proposed model is based on the following ideas:

1. **Minimize the gap between generations.**
   Just like Minimal Generation Gap (MGG)[3], one of the generation alternation models to prevent premature convergence, the proposed generation alternation model minimizes the gap between generations. The proposed model replaces only one individual at every generation, whereas MGG replaces two.

2. **Design some rules to choose a parent to be removed and an offspring to be added.** The proposed model generates as many offsprings as population size, and replaces one of the parents by one of the offspring. The parent and the offspring are chosen by rules in order to adjust the balance between search exploitation and exploration based on user preference.

Table 1 shows the generation alternation rules. Rules which have the smaller rule id have the higher priority. R_6 and R_7 are applied by random if none of R_1 to R_5 can be applied.

To esteem user operation and reflect it to the search, R_2 and R_3 removes individuals that are ranked as the minimum priority. R_4 enhances the local search based on user preference.

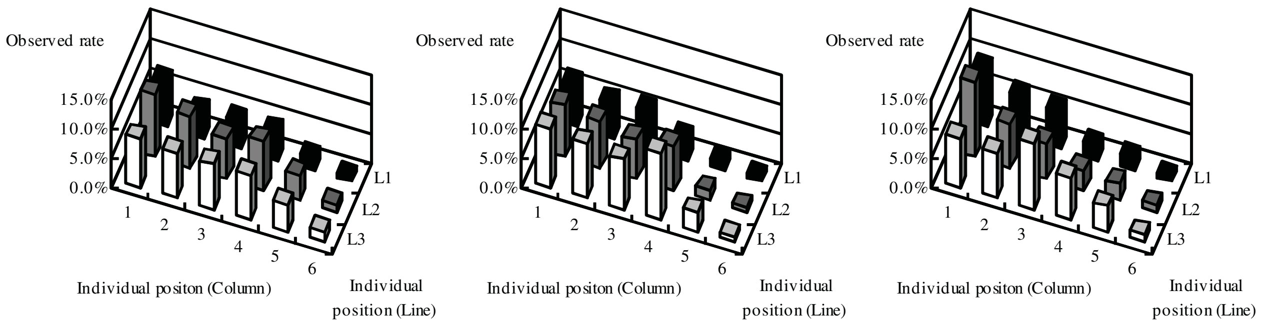
Although the proposed model can keep diversity by changing only one individual at every generation, bad individuals are hardly removed from the population. R_5, R_6 and R_7 are designed to shake out those individuals.

4 EVALUATION

To verify the effectiveness of the proposed generation alternation model in CEUS, the proposed method is compared with the previous work for CEUS[2] and MGG based method. A two-dimensional barcode decoration problem is used [2]. The problem has three objective functions: machine readability R, decoration quality Q, and user preference P. The readability R and decoration quality Q are quantitative criteria, and fitness F can be calculated by the following

Table 1. Generation alternation rules.

ID	Antecedent	Consequent	
		Deleted	Added
R_1	The parent P_ρ having higher density than T_ρ exists.	P_ρ	Farthest offspring from P_ρ
R_2	Both parent P_0 whose preference was set to 0 and parent P_1 whose preference was set to 1 exist.	P_0	Nearest offspring to P_1
R_3	P_0 exits.	P_0	Farthest offspring from P_0
R_4	Parent P_1, which are evaluated in the current generation, exists.	Parent with the worst preference	Nearest offsping to P_1.
R_5	Fitness of the best offspring O_{best} is greater than the fitness of the best parent P_{best}.	By roulette selection based on inverse fitness value	O_{best}
R_6	—	The worst parent P_{worst}	Offspring O_δ with the maximum improvement from the previous generation
R_7	—	P_{worst}	The nearest offspring to P_{worst}



(a) Previous method (Update all) (b) MGG (c) Proposed method (Update one)

Fig. 3. Eye-tracking results.

equation involving weights $w^{(p)}$, $w^{(q)}$, and $w^{(r)}$.

$$F = R^{w^{(r)}} \times (1 - w^{(p)}) \cdot Q^{w^{(q)}} \times w^{(p)} \cdot P \qquad (1)$$

A system used in this experiment that can show 18 individuals with three lines and six columns as shown in Fig. 2. In this system individuals are sorted by the fitness and placed from top-left to bottom-right.

In this experiment, we tracked user eyes to clarify how the user can see widely varied individuals. Ten examinees tested the above three methods in random order, and answered a questionnaire.

Fig. 3 shows the eye tracking results, and Fig. 4 shows the averaged number of evaluated individuals by the examinees for each individual position. Fig. 3 reveals that individuals in right side columns were hardly watched, and that there was not so much difference between lines in all methods.

According to the questionnaire result, some examinees felt that the proposed model helped to find unpredictable good solutions. Fig. 4 shows that MGG based method and the proposed method urged the examinees to evaluate individuals placed at the second and third lines in addition to elite individuals placed at top-left. Also in the previous method, individuals in the third position seemed evaluated frequently. But this is because the examinees tried to remove bad individuals with much evaluation cost.

There was no significant difference on satisfaction with derived solutions according to the questionnaire result. The fitness of the previous method indicated by "Update all" in Fig. 5 showed the best, and MGG and the proposed method indicated by "Update one" showed worse fitness values. In particular, there seems differences in preference shown in Fig. 5(b), but these results show just transitions of the best solutions and do not imply the satisfaction of the final solutions. Because readability and quality score values of the previous and proposed methods were almost the same, the difference on preference implies that the proposed method tried to reproduce diversified individuals.

5 CONCLUSION

This paper proposes a generation alternation model for CEUS aiming to discover moderately good and unpredictable individuals. Experimental results have shown that MGG and the proposed model helped uses to find such individuals, and that simple eye-tracking was not sufficient to clarify the effectiveness of generation alternation models.

In future we plan to design a simpler rule set, and to analyze the effectiveness of generation alternation models in CEUS.

A neutral evolutionary path-planner

Abstract: This paper explores methods for path-planning using evolutionary algorithms. Inspired by research on neutral mutations in evolutionary algorithms, we propose an algorithm based on the idea of introducing redundancy in the solutions, adding explicit neutrality to the evolutionary system. The algorithm introduce explicit neutrality by evolving roadmaps rather than single paths. Since some of the mutation and crossover operators used in conventional evolutionary path-planners are not well suited for this representation, appropriate evolutionary operators will also be explored. The performance of this algorithm on shortest distance path planning problems is compared to a known good genetic algorithm in three different static environments.

Keywords: genetic algorithm, neutrality, path-planning, roadmap

1 INTRODUCTION

Path planning is the problem of finding an optimal obstacle-free path through an environment. In a shortest distance problem, the optimal path is the one going from a start point to a goal point in the shortest possible distance travelled. Many methods have been proposed for solving this optimization problem. They all have certain trade-offs between planning time, robustness, requirements on environment representation and so on. An overview of the most common no-evolutionary methods can be found in [1].

Probabilistic roadmaps (PRMs) are one of the more common methods in path planning. A PRM samples random points in order to simplify the problem and scale well with environment dimensionality. However, it will seldom find optimal solutions unless the amount of samples taken is made impractically large. They also have problems with finding solutions at all in narrow passages and maze-like environments, a problem that to some extent can be remedied by sampling adaptively [2].

Several path-planning methods using evolutionary algorithms (EAs) have also been proposed. A straightforward approach to the shortest distance problem is presented in [3]. Once a good set of solutions has been found by an EA path-planner, it can easily adapt to changes in the environment simply by running the a few more iterations of the algorithm on the updated environment data. However, finding a good set of initial solutions from a set of random solutions can take some time. A remedy for this is to initialize the population with results from a PRM planner has been proposed in [4].

There has recently been some interest in EAs using neutrality and neutral mutations. Neutrality is having redundancy or extra information in the chromosomes so that they can change in ways that do not affect fitness. It is claimed that this can be greatly beneficial to EAs, making them both converge faster to the optimum and also escape local optima more easily. This is inspired by similar theories in biological evolution and some experimental findings, though many of these findings are considered inconclusive by others. A summary of this research can be found in [5].

Although the effects of neutrality in EAs in general are still inconclusive, it is an interesting avenue to explore in solving path-planning problems. One such method is proposed in this paper. Instead of trying to evolve good paths directly, this method tries to evolve good roadmaps for finding paths. We will rank the roadmaps only by the best path found in them by a graph traversal algorithm. Since this ranking does not consider the points in the roadmap that are not part of the resulting path it has explicit neutrality.

2 PROPOSED METHOD

Starting out with a set of PRMs as initial population, our algorithm evolves these roadmaps over many generations. We call this method a roadmap evolver. Roadmaps well suited to find a good path are more likely to survive to the next generation. The nodes that are not on a roadmap's best path can mutate without affecting the roadmap's fitness. This can enable the population to escape local optima more easily.

2.1 Representation and evaluation function

Each chromosome is a set of floating-point vectors that together with the start point and the goal constitute the nodes, or milestones, of a roadmap. If one can draw a straight line between two nodes without intersecting any obstacle, they are connected. A graph traversal algorithm is run to evaluate the chromosomes, finding the best path through it from the start to the goal node.

When an optimal path through the roadmap has been found, the fitness of that path is taken as the fitness of the roadmap. In the experiments done in this paper the path's are optimized for the shortest path. So the fitness of the path is the path's curve length, and the graph traversal is done by A*.

Since not all nodes are necessarily visited during the traversal, the connectivity of the roadmap graph is done dynamically during the graph traversal in order to reduce the number of connectivity checks needed. Still, in general, $O(n^2)$ connectivity checks will be needed in the traversal, where n is the number of nodes in the roadmap.

2.2 Evolutionary operators

The algorithm proposed has a single crossover operator and three mutation operators: nudge, insert and reduce size.

In order to emphasize average-sized children we use a crossover operator similar to uniform crossover: First each point in parent A is given to either child A or child B with equal probability. Then the points in parent B are distributed in the same way. The size of each child is the sum of n coin flips, so it has a binominal distribution. The chromosomes are sets of points and thus inherently unordered. Therefore, there is no need to try to maintain any ordering.

The nudge mutation goes through all the points in a chromosome. Each point has a probability P_{nudge} of being displaced a small distance in some random direction, but only if that displacement does not move the point into or over an obstacle: A normal-distributed vector is added to the point if the straight line between the original point and the point plus the random vector is obstacle-free. If this fails, it is reattempted up to 6 times with a new random vector with increasingly narrow normal distribution. If all attempts fail that point is left unchanged.

The insert mutation tries to add a single point to an individual. A candidate point is generated randomly with uniform probability within the bounds of the environment. If the candidate is obstructed, a short random walk is performed until an unobstructed point is found, or a maximum of three steps are taken. If the candidate is still obstructed, we try it up to 5 more times with different random start points. If no feasible candidate has been found, the operator leaves the individual unchanged.

The reduce size mutation goes through all the points in a chromosome and removes that point with a probability P_{remove} . Thus, on average $n \times P_{\text{remove}}$ points are removed from the set, where n is the original size of the set.

2.3 Initial population and evolutionary process

The population is initialized with N PRMs with an average of N_g non-obstructed nodes in uniform distribution over the environment. If none of the roadmaps give a feasible path from start to a goal then N_g is increased by a constant and N new PRMs are created. This is repeated until at least one initial feasible solution is found.

Each generation is generated as follows: N new individuals are created by crossover. The parents for each crossover operation are selected by simple tournament selection with a tournament size of 2. This is repeated until two different parents have been selected.

All the new individuals are then subjected to mutation. The nudge mutation is performed once, then the insert mutation is performed once with probability P_{insert} . Finally the reduce size mutation is performed. After that, new population is merged with the old. To reduce the population size back to normal, N one-round tournaments are held, and the losing individuals are removed.

Each new individual has P_{insert} points added on average, while $n \times P_{\text{remove}}$ points are removed. This helps the average chromosome size to stay relatively stable, while allowing for variations in order to adapt to different environments.

Table 1: Average run-time, including initialization

Environment	Reference path-planner (per iteration)	Roadmap evolver (per iteration)
"Rocks"	19.0s (10.6ms)	78.3s (174.0ms)
"House"	49.0s (27.2ms)	163.6s (363.6ms)
"Spirals"	25.7s (14.3ms)	131.0s (291.1ms)

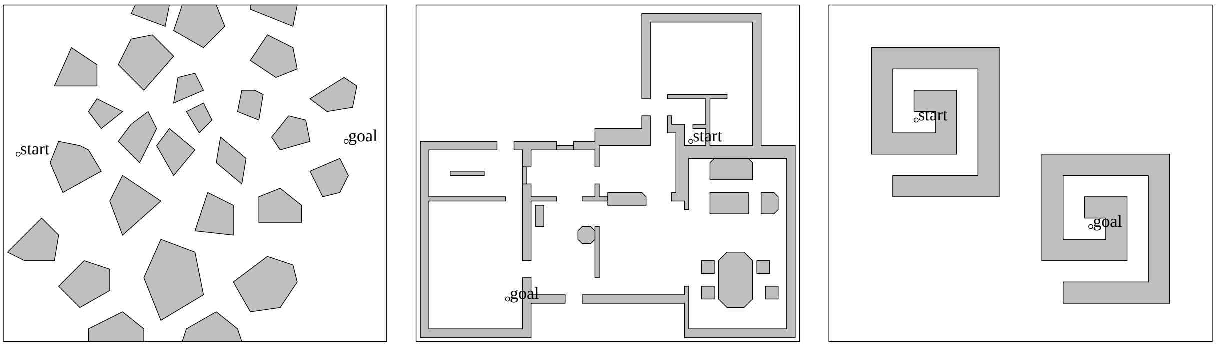
3 RESULTS AND DISCUSSION

The algorithm has been tested against a reference path-planner in different environments. The reference algorithm used is similar to the one described in [4], differing mainly in the parameters and selection operators used. It is run with a population size of 40 and a tournament-based selection. It should be noted that the parameters and implementation of the reference algorithm are not fine-tuned or optimized, and can therefore only serve as a general guideline to the performance of a reasonably robust evolutionary path-planner.

The roadmap evolver was run with a population size of 35 and an average initial number of nodes per chromosome of 35 or more. Mutation parameters were set to $P_{\text{nudge}} = 0.2$, $P_{\text{insert}} = 0.4$ and $P_{\text{remove}} = 0.05$.

Three different environments, shown in Fig.1 are tested. Each environment has different characteristics: The "rocky" environment consists of a number of scattered convex shapes, and has a large number of intersecting local optima. The second environment imitates the interior of a single-floor home, and has wall- and corridor-like obstacles, leading to a few, far-apart local optima. The third environment contains two spiral structures and has only one hard-to-find optimum.

The result of 100 runs of each algorithm in each environment is shown in Fig.2. The reference algorithm is run for 1800 iterations, while the roadmap evolver is run for 450 iterations. The large difference in number of iterations is due to differences in run-time per iteration and to differences in how



(a) The "rocks" environment (b) The "house" environment (c) The "spirals" environment

Figure 1: The different environments tested

quickly the algorithms converge. The average run-times are shown in Table 1. The average iteration time of the roadmap evolver is more than ten times that of the reference algorithm.

The reference algorithm shows very good performance in the "house" environment, with a good start and little variation. In "rocks" it converges quickly, but seems to get stuck in local optima, because the variation between runs stays high. In the last environment it closes in on the optimum with low variation, but at a very slow pace.

The roadmap evolver has good performance in the "rocks" environment, converging quickly towards a near-optimal solution quickly and with little variation between runs. In the other two environments it closes in on the optimal solution at a good average pace, but the pace is very uneven, with large variations in fitness between runs for many generations.

Compared to the reference algorithm in terms of generations only, the roadmap evolver performs as good or better in both "rocks" and "spirals" environments, but needs more generations to reliably produce near-optimal solutions in the "house" environment. In "rocks" it seems to avoid local optima better, while in "house" it shows signs of jumping out of local optima it have been temporarily stuck in. Note that both algorithms fail to ever find the globally optimal path in the "rocks" environment.

The good performance of the reference algorithm on "house" might be explained by the way the populations are initialized - the reference algorithm guarantees N different feasible solutions, while the roadmap evolver only guarantees at least one.

4 CONCLUSION

In this paper, we proposed a path-planning method using a genetic algorithm that has explicit neutrality. The algorithm was compared to an existing genetic path-planning algorithm that has no neutrality. The proposed algorithm closes in on the optimal solution in comparatively few generations, and shows signs of both avoidance and escape of local minima in a small selection of tested environments. However, run-time performance is poor, most likely because of comparatively high complexity in the fitness function.

The algorithm did display properties expected of a neutral evolutionary system. For future work it would be of interest to examine whether these properties are displayed in other situations too, such as dynamic or partially unknown environments, or path-planning problems with multiple objectives. Initializing the population in the same way as the reference algorithm might increase performance in early generations. Another possibility is developing other different and possibly more efficient neutral path-planning EAs and examine if the same properties appear in them.

Abstract: As more robots are expected to enter the families to provide assistance soon, many challenging problems shall emerge, when facing the uncertain and varying environments, rather than the organized environments in factories. To date, robots still demand human's assistance when working in home-like environments. To enhance their usefulness, one issue of much interest is how we can effectively operate them for task execution. If not for detailed analysis and program coding, one appealing alternate is to provide a kind of manipulative system for the user to manipulate the robot naturally and efficiently. That motivates us to develop a dextrous manipulation system for multi-DOF robot manipulators based on using the 6-DOF force-reflection joystick. To demonstrate its effectiveness, the developed manipulation system is utilized to govern the robot manipulator for the tasks of water pouring and screw fastening.

Keywords: Manipulation system, Haptic device, Virtual tool, Home-like environment.

1 INTRODUCTION

In the near future, more robots may enter the families to provide assistance. As expected, many challenging problems shall emerge in dealing with the uncertain and varying environments, rather than the organized environments in factories [4]. Up to now, robots still demand human's assistance when working in home-like environments. To enhance their usefulness, one issue of much interest is how we can effectively operate them for task execution. If we are not going to take the load of detailed task analysis and program coding, one alternate is to let the user manipulate the robot via a proper means directly. In other words, an effective manipulation system should be provided for the user to achieve natural and efficient robot governing. As traditional manipulative devices, like teach box, mouse, keyboard, and joystick, may not serve the purpose, we propose developing a dextrous manipulation system for multi-DOF robot manipulators based on using the haptic device.

As the manipulative device, we adopt the 6-DOF force-reflection joystick for the proposed manipulation system, which supports mutual interaction, involves both position and force information, and has the merit in its simplicity and generality. In this manipulation system, we design virtual motion constraints, which are based on the concept of virtual mechanisms and virtual fixtures previously proposed [1,3,7], to confine the movement of the manipulative device in the 3D working space, according to the status of the robot manipulator and task progress. In other words, the virtual motion constraints are designed (i) to help the user recognize the spatial deviation between her/his desired position and the end-effector via a haptic clue, and (ii) to guide her/his movement according to task requirements via some virtual tools. For instance, a virtual ruler can be used to help the user to move the robot along a straight line fast and precisely. The proposed manipulation system thus provides two kinds of virtual motion constraints to assist the user in an interactive and real-time manner. First, a virtual spring is installed between the user and robot manipulator to enhance a virtual linkage between them. In addition, a 3D graphical environment is also implemented to foster the virtual linkage in a visual way. Second, four basic types of virtual tools (point, line, plane, and fixed-rotating-axis) are furnished according to the user's demand on site, but not in a predefined environment or predicted way [2,5]. For demonstration, the manipulation system is utilized to govern the robot manipulator to conduct two kinds of tasks: pour the water between tubes and fasten the screw, both of which demand delicate maneuver. Satisfactory experimental results verify the effectiveness of the proposed manipulation system.

2 PROPOSED MANIPULATION SYSTEM

Fig. 1 illustrates the two major goals of the proposed manipulation system for a multi-DOF manipulator: (i) letting the user feel like she/he is manipulating the robot on site directly when teleoperating the task, and (ii) providing a set of virtual tools that guide the hand movement of the user. Its system block diagram is shown in Fig. 1b, which consists of mainly a 6-DOF haptic device, a virtual linkage, and virtual tools. Via the haptic device, the user sends in the commands, which may be refined by the virtual tools, to govern

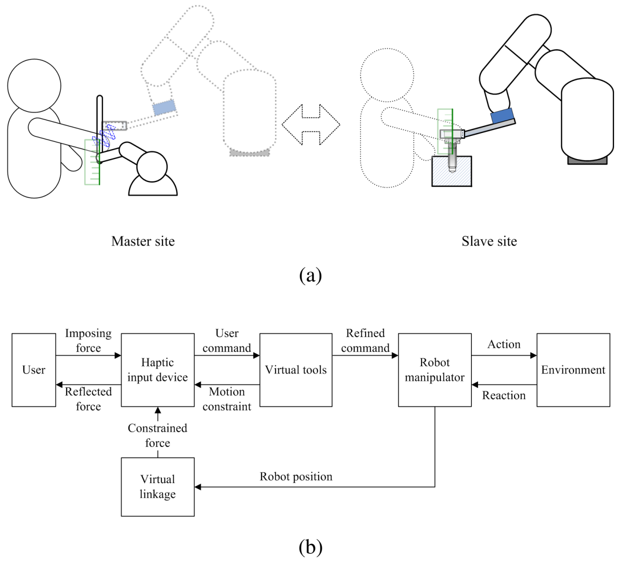

Fig. 1: Proposed manipulation system for a multi-DOF robot manipulator: (a) conceptual diagram and (b) system block diagram.

Fig. 2: The user applies the proposed system to manipulate the real robot manipulator via a haptic input device and 3D graphical environment.

the robot manipulator in the slave site to perform the task in a home-like environment. As the feedback, the robot position, via the virtual linkage and then the haptic device, becomes the reflected force, which is sent back to the user for following manipulation. Meanwhile, the system utilizes the virtual tools to furnish motion constraints for guidance. Based on the descriptions above, the success of the proposed manipulation system mainly depends on proper design of the virtual linkage and virtual tools. The former establishes the human-robot connection for natural and effective manipulation, and the latter provides proper assisting motion constraints along with the progress of task execution.

With the proposed virtual linkage, we intend to create better interaction between the user and robot manipulator, so that the user can perform the manipulation naturally and effectively. Fig. 2 shows a scene in which the user applies the proposed manipulation system to manipulate the real robot manipulator via a haptic input device and 3D graphical environment, which renders the user the linkage status between the master and slave devices in visual way. For the haptic counterpart, we intend to let the user feel like her/his hand holding on the end-effector of the robot manipulator directly. Although direct reflection of the environmental force to the master may yield the user a more realistic feeling, the induced master motion may make system unstable [6]. Therefore, the proposed linkage haptic cue is used to hint the position deviation between the robot manipulator and the desired command, reminding the user that the robot manipulator cannot catch up with the command, in an intuitive and efficient way compared with that provided by the visual information.

To achieve this, we use a simple spring model to generate the constrained force via the force-reflection joystick, serving as a virtual spring that bonds the joystick with the robot manipulator. This constrained force $\mathbf{f}_s(n)$ is formulated as

$$\mathbf{f}_s(n) = K_s(\mathbf{p}_s(n) - \mathbf{p}_u(n)), \tag{1}$$

where K_s stands for the stiffness of the virtual spring, and $\mathbf{p}_s(n)$ and $\mathbf{p}_u(n)$ the position of the end-effector and force-reflection joystick, respectively, both with respect to the coordinate system of the master.

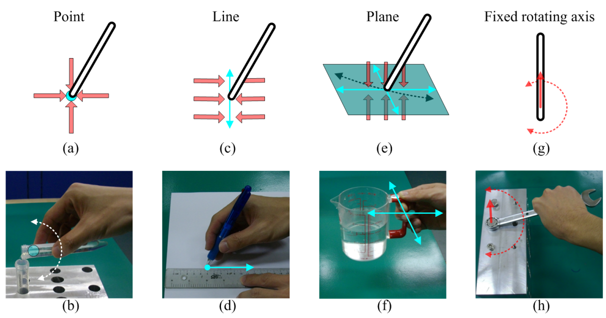

Fig. 3: Proposed virtual tools and their possible applications: (a)-(b) point, (c)-(d) line, (e)-(f) plane, and (g)-(h) fixed-rotating-axis.

To tackle common operations in home-like environments, we design three types of position tools: point, line, and plane, and one type of orientation tool: fixed-rotating-axis. Fig. 3 shows these four virtual tools and their possible applications. The position tools can let the haptic device only move on a point, a line, or a plane, for instance, a point tool for the water pouring task. The orientation tool can let the haptic device maintain a fixed rotating axis for rotation, such as for the screw fastening task. Details of their implementation will be in our following paper.

3 SYSTEM IMPLEMENTATION

As shown in Fig. 2, the proposed manipulation system consists of a 6-DOF Mitsubishi RV-2A robot manipulator, with a mounted end-effector, such as a box-end wrench or gripper, a SensAble Phantom Omni 6-DOF joystick with 3-DOF force feedback, and a personal computer (Intel Core Duo E8400 CPU and 2 GB RAM) for constructing the 3D graphical environment for rendering the virtual robot and virtual tools, in addition to the computation of the haptic feedbacks for both the virtual linkage and virtual tools. To satisfy the requirements from various devices, we use three threads to deal with the haptic data (about 1 kHz), visual data (about 60 Hz), and manipulator control data (about 141 Hz). To match up the workspaces between the haptic device and robot manipulator, the length ratio between these two coordinates is set to be 1:2.

4 EXPERIMENTS

To demonstrate its effectiveness, the proposed manipulation system was utilized to govern the robot manipulator to conduct two kinds of tasks: pour the water between tubes and fasten the screw, both of which demand delicate maneuver. For each experiment, there were two operation modes: with the help of both virtual tools and virtual linkage (mode V) and without those (mode NV). To alleviate the learning effect, eight subjects were first invited to conduct the first experiment, and then another seven subjects for the second one. Moreover, the order of these two operation modes was randomly arranged for the subject. Each subject was asked to achieve two successful trials for each mode. Most of them had no experience in manipulating the robot manipulator using the haptic input device before. Thus, before conducting the trial for each mode, the subject practiced several times to be familiar with the manipulation system.

Fig. 4 shows the setup of the first experiment, in which the robot manipulator was governed to grasp the tube vertically up, which was initially put in the hole on the right rack, and then horizontally moved it to pour the water inside into the tube on the left, and finally put it back to the original location in a reversal sequence. A successful trial should transfer at least 90% of the water. In responding to the operations, mode V provides two line tools for vertical up and down, two plane tools for horizontal leftward and rightward, and one point tool for water-pouring rotation. The experimental results show that, the medians of the execution time for the two modes (NV: 59.2 s and V: 50.0 s), indicating that the virtual tools helped to reduce about 9.2 s (15.5 %); the medians of the traveling path for the two modes (NV: 817 mm and V: 721 mm), indicating a reduction of about 96 mm (11.8 %). Fig. 5 shows the robot trajectories for a specific user as an example. In Fig. 5a, the virtual tools led to quite straight movements in up and down, more smooth movements in a horizontal plane during leftward and rightward, and steady rotation in water pouring. Most of subjects reported that the bonding forces from the virtual linkage and virtual tools did help to maintain stable movements.

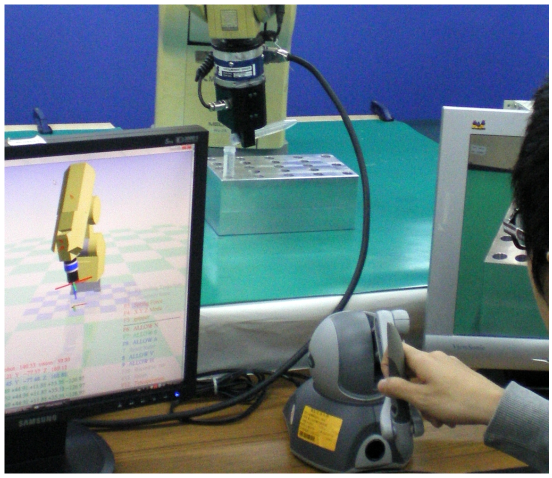

Fig. 4: Water pouring task.

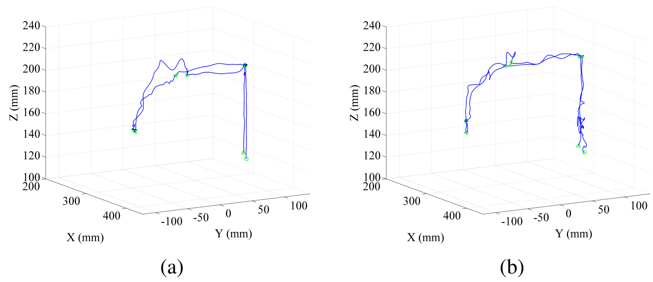

Fig. 5: Robot trajectories of water pouring for a user as an example: (a) with the help of virtual tools and (b) without the help.

The setup for the second experiment is shown in Fig. 2. The robot manipulator was governed to fasten a hexagonal screw via a box-end wrench. The procedure is as follows:

1. Place the box-end wrench over the screw head and pose a proper rotating axis for next step.

2. Rotate the wrench clockwise certain angle to fasten the screw and at the same time keep the rotating axis fixed.

3. Release the wrench from the screw and then rotate the wrench counter-clockwise certain angle.

4. Repeat the steps above until the screw is fastened.

In responding to these steps, the subject can utilize two kinds of virtual tools to assist in the manipulation, described as follows:

- The line tool is used to assist in the straight motion along with the rotating axis, which helps to place the wrench over the screw.

- The orientation tool is used to maintain a fixed rotating axis to prevent the user from inaccurate manipulation.

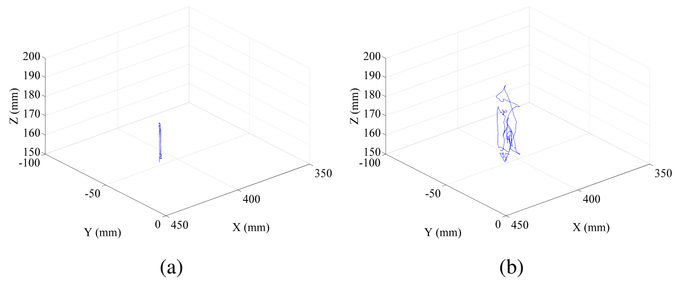

Fig. 6: Robot trajectories of screw fastening for a user as an example: (a) with the help of virtual tools and (b) without the help.

The experimental results show that, the medians of the execution time for the two modes (NV: 33.24 s and V: 25.06 s), indicating the virtual tools helped to reduce about 8.18 s (24.6 $\%$); the medians of the traveling path for the two modes (NV: 216.5 mm and V: 119.6 mm), indicating a reduction of about 96.9 mm (44.8 $\%$). Fig. 6 shows the robot trajectories for a specific user as an example. With the help of the proposed virtual tools, the trajectories in Fig. 6a were straight and more close together, compared with those in Fig. 6b. Furthermore, most of subjects reported that with the help of virtual tools they could place the wrench over the screw and stably fasten it more fast and precisely.

5 CONCLUSION

In this paper, we have proposed an effective manipulation system for multi-DOF robot manipulators based on virtual linkage and virtual tools. The virtual linkage enhances the connection between the user and robot manipulator, and virtual tools are helpful in dealing with the requirements from various tasks. We have applied the proposed manipulation system to conduct two different kinds of tasks, both of which demand delicate maneuver. Satisfactory experimental results have verified its effectiveness. In future works, we plan to enhance the proposed manipulation system, so that it can be applied for more versatile tasks in home-like environments.

Abstract: In most article retrieval systems using Kansei words, there exists a gap between user's Kansei and system's Kansei model. Therefore, it is not always easy to retrieve the desirable articles. The purpose of this paper is to bridge this gap by introducing a novel function to accept arbitrary Kansei words. The parameters related to newly added Kansei words are automatically estimated from articles selected by the user during search. Thereby, the system is customized for individual users, to bridge the gap. In the evaluation experiments, we took actual paintings as the articles, and evaluated the user-satisfaction, accuracy, *novelty* and *serendipity* of the system through actual user operations. Most of users were satisfied with the system and could find unknown desirable articles. Moreover they could often find unexpectedly interested articles.

Keywords: User profiling, Kansei information processing, Cooperative system, Web retrieval

1 INTRODUCTION

Web services are increasing day by day and the demands for e-commerce have also become higher. It is, however, not easy to retrieve a proper article from a lot of articles in web pages. One way of retrieving articles is to use keywords. Especially using adjective keywords called "Kansei words" is effective to represent human feelings and impressions. However, the accuracy of retrieval results is not sufficient due to the gap between user's Kansei and system's Kansei model. Therefore, it takes a long time to retrieve the desirable articles. To bridge this gap, we consider that it is necessary to introduce user profiles, and implementation of the following two functions: 1) to add arbitrary Kansei words freely, 2) to fit system Kansei words to the user's Kansei. Hijikata pointed out that user profiling methods can be classified as either explicit or implicit methods [1]. In the explicit method, users directly input the information about individual taste. In the implicit method, the system estimates the individual taste based on the past user behavior. As examples of explicit method, individual tastes are estimated by the questionnaire in advance [2][3], or by asking users to grade the browsed internet pages on their interest and relevance [4]. Such explicit methods put a strain on users. On the other hand, implicit methods infer individual taste by usage history [5][6]. However, they need enough usage history. Most of studies about Kansei retrieval system took an explicit method. However, we take an implicit method in order not to put a strain on users together with above two functions.

We already proposed the system to fit system Kansei words to the user's Kansei in prepared default Kansei words decided by a system architect [7]. In this paper, we append the function of adding arbitrary Kansei words to the previous system. The proposed system collects articles fitting or non-fitting to the added Kansei word while users search the desirable articles. Utilizing the collected articles, the system estimates the parameters related to the added Kansei words by using the support vector machine (SVM) method. Thereby, users can freely use arbitrary Kansei words, and customize to the own desirable system by editing retrieval criteria as they please. In the result, we expect to improve the satisfaction because users are not tired of the system and the flexibility of retrieval is improved. However, the parameters related to the added Kansei words are learned through user's most desirable article by neural networks because the added Kansei words are often low accuracy.

For the experiments, we developed an article retrieval support system implemented with the proposed method, and employed artistic painting images for article database. We evaluated the user-satisfaction and accuracy through actual operations. We also employed *novelty* and *serendipity* as the evaluation indices [8]. Users have potentially multiple preferences for diverseness of Kansei words [9]. Therefore, these two metrics are useful to measure how much ambiguous or unaware preferences are derived.

2 PROPOSED SYSTEM

Most users wish to search articles not only by given Kansei words but also by suitable their own Kansei words. However, the system cannot prepare all Kansei words in advance because all most of the words and expressions have the potential to be utilized as Kansei words. Therefore, it is important to add arbitrary Kansei words to the system freely. However, the system has to parameterize the arbitrary Kansei word in accordance with all articles, which

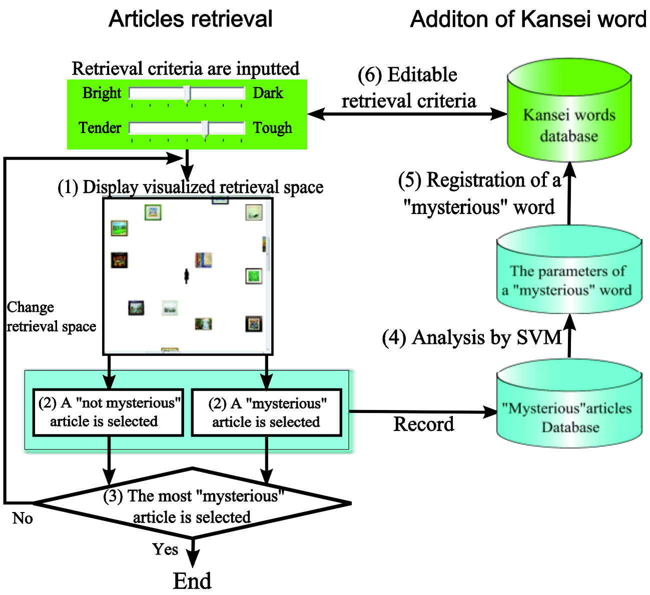

Fig.1. The schematic diagram of proposed system

is laborious. Meanwhile, Mukunoki el al reported that some typical and popular Kansei words can express other Kansei words [9], although it needs images selected by specialists in order to add arbitrary Kansei words. We suggest a new procedure to treat arbitrary Kansei words by utilizing the given default Kansei words.

2.1.1. Registration and usage of arbitrary Kansei words

Fig.1 shows the schematic diagram of the proposed system in case of adding an arbitrary word "mysterious". First, the proposed system needs to find out which articles fit the added Kansei word for users as teacher data for supervised learning. The Kansei retrieval system we proposed before is employed to collect such data efficiently. The previous system can visualize the two-dimensional retrieval space converted from Kansei parameter space by Self Organizing Maps ((1) in Fig.1). Moreover, the user can point not only desirable articles but also undesirable ones. In the case of selecting undesirable articles, the retrieval space is changed to follow the user's tendency. With the help of this system, users repeat the selection of articles fitting or non-fitting to the added Kansei word. This operation continues until users find the most fitting article for the added Kansei word, or select a sufficient number of articles. The user's strain to collect teacher data is minimized because the system concomitantly collects the data while users repeat the selection to find the most desirable article. At this stage, the articles fitting the added Kansei word are scored by +1. On the other hand, the articles not fitting it are scored by -1. After the teacher data are collected enough, the system estimates the parameters of the added Kansei word by SVM. The added Kansei word is registered as retrieval criteria in the same way as the default Kansei words after this procedure. Additionally, the system can also create the new retrieval space concerning the parameters of the added Kansei word. Therefore, the system can create an opportunity to discover unknown desirable articles as unexpectedly interested articles.

2.1.2. Editable retrieval criteria

Users can freely use arbitrary Kansei words added by themselves. Besides, Kansei words added by other users are also available as own retrieval criteria by accessing the database which stores the parameters of each added Kansei word. Users can also eliminate the added Kansei words from retrieval criteria ((6) in Fig.1). Therefore, users are not tired of the system because they can customize the system.

2.1.3. Learn parameters of added Kansei words

The previous system learns user's Kansei based on user's most desirable article with a three-layered perceptron. We extend the previous system to the range of added Kansei words. Learning method is the same as the previous system. The system learns the relationship between the initial input retrieval criteria's parameters including added Kansei words and the finally selected article ones. In other words, the perceptron's input data is the initial position on the visualized retrieval space, and the teacher data is the position of the article finally selected.

3 IMPREMENTATION

We made some experiments to evaluate the usage of the proposed retrieval system for painting images to assist the customers who wish to buy paintings. In the experiments, 135 painting images were stored in the database. They were rated by 20 people with 7-point scale of 8 adjective pairs shown in **Table 1**. The adjective pairs were chosen according to the Inoue's study on Kansei evaluation of paintings [10]. The average of human evaluation was set into the system database in advance as the initial system's Kansei model. The system also allowed users to add arbitrary Kansei words based on this 8 adjective pairs.

We utilized the software library LibSVM for SVMs modeling. We ran a preliminary experiment to avoid over fitting. In the result, we chose C-SVM with RBF kernel. If the teacher data existed only in one side, we chose one-class SVM. Cost parameter and ν parameter were set to 2 and 0.1. Other tool parameters were set to the default values of the LibSVM. The other system parameters and software's composition were conformed to the previous system.

Table 1. Pairs of Kansei word

Pair #	***Kansei Words***	
1	Bright	Dark
2	Tender	Tough
3	Cheerful	Melancholy
4	Fancy	Plain
5	Complicated	Simple
6	Sharp	Dull
7	Warm	Cold
8	Comfortable	Uneasy

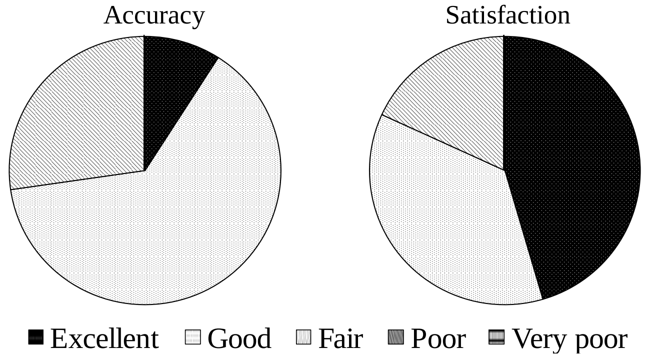
4 EVALUATION EXPERIMENTS AND RESULTS

In the evaluation experiments, we employed *novelty* and *serendipity* metrics as the evaluation indices other than the satisfaction or accuracy. They can measure the "non-obviousness" of the retrieval system as an important metrics for user-satisfaction. These metrics indicate whether the recommended item is both unknown and favorite. We evaluated that how many unknown desirable articles about a new Kansei word were recommended. A serendipitous recommendation helps users to find an unexpectedly interested item which might not be discovered in other way. For measuring serendipity, it is necessary to evaluate how the recommended items attract and surprise the user. However, no concrete calculation method has been proposed so far. Therefore, subjective assessment was adopted.

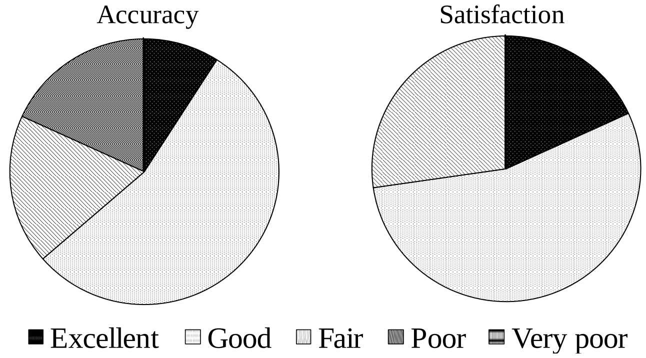
4.2.1. Satisfaction and accuracy

We asked 13 people the accuracy and satisfaction of an arbitrary Kansei word added by themselves. We also asked the accuracy and satisfaction when users utilized Kansei words added by other users. The result is shown in **Fig.2**. Here, we defined "Good" and "Excellent" evaluations mean "be satisfied". We concluded that added Kansei words are useful because over 70% of the users were satisfied with it. Though accuracy of Kansei words added by other users are occasionally inadequate, satisfaction level is high. Interestingly, some users commented "it is fun to feel other user's Kansei though the accuracy is low." Next, we asked the satisfaction of editable retrieval criteria. The result is shown in **Table 2**. Most of the users were satisfied with the function of editable retrieval criteria. We consider that users were satisfied with not only searching user's desirable articles but also customizing the system.

Moreover, we evaluated the function of neural networks. 8 users tried retrieving their preferred paintings five times. Afterward we compared the positions of Kansei learning with the initial positions. **Table 3** shows the average result for 8 users. The first and second columns represent the



(a) Arbitrary Kansei words added by themselves



(b) Kansei words added by other users

Fig.2. The accuracy and satisfaction for added Kansei words

distance values between the initial position and the finally selected position with Kansei learning. The values are the normalized distance of visualized retrieval space. The third column indicates the difference. The initial position gets about 0.36 closer to the selected article. It can be concluded that the system fits to individual user's preference in the course of using the system even if arbitrary Kansei words are included in retrieval criteria.

4.2.2. Novelty and serendipity

We evaluated the *novelty* and *serendipity*. We asked 10 people to show the articles in the database that fit to the added Kansei word. We then distilled teacher data used for creating a new Kansei word. We consider that these articles are regarded as novel articles because they are

Table 4. The novelty for adding Kansei words

Added Kansei words	*Novelty*		
	Precision	*Recall*	*F value*
mysterious	0.50	0.43	0.46
boisterous	0.33	0.50	0.40
realistic	0.38	0.26	0.31
unusual	0.43	0.20	0.27
disorganized	0.17	0.50	0.25
expansive	0.30	0.13	0.18
enjoyble	0.00	0.00	0.00
likeable	0.29	0.29	0.29
good	0.25	0.16	0.20
beautiful	0.17	0.06	0.09
average	**0.28**	**0.25**	**0.26**

Table 5. The serendipity for adding Kansei words

Evaluation	*Yes*	*Rather yes*	*Yes and no*	*Rather No*	*No*
Rate	38.5%	46.1%	0.0%	7.7%	7.7%

fit to the Kansei word. We evaluated the precision, recall and F value of novel articles. Here, if the values of the new Kansei word by SVM were above 0.85, they were regarded as fitting articles. The result is shown in **Table 4**. The F value of Hijikata's system specialized for novelty is about 0.3. However, the F value of typical system not specialized for novelty is under 0.1 [8]. Therefore, our proposed system showed better results than previous system in novelty. Moreover, the adjectives having high "evaluation factor" (e.g. *likeable*, *good* and *beautiful*) generally is difficult for utilizing as retrieval criteria because there are great differences between individuals. However, users can occasionally find unknown desirable articles.

We also evaluated serendipity by subjective assessment of the proposed system. 13 people tried and the result is shown in **Table 5**. Most of users answered "yes" or "rather yes" about adding arbitrary Kansei words. We consider that the system created a new retrieval space concerning the parameters of the added Kansei word, and an opportunity to find unexpectedly interested articles. In the result, we concluded that users could find unknown desirable articles, and could find unexpectedly interested articles by using the proposed system.

5 CONCLUSION

We have proposed an article retrieval support system that accepts arbitrary Kansei words not to put strain on users. Users can freely add arbitrary Kansei words, and edit retrieval criteria. Moreover, the parameters related to the added Kansei words are learned by neural networks. In the experiments, we confirmed that most of users were satisfied with adding arbitrary Kansei words, and customizing the system. Besides, the accuracy of the system was improved. We also confirmed that users could find unknown desirable articles, and could find unexpectedly interested articles by using the proposed system.

We are trying to apply the developed system for other different article retrievals to examine the universality of the proposed method. In the future, we would like to link physical parameters to Kansei factors, and to implement the automatic indexing of articles.

Abstract: In this paper, we design a user-support system for vision information using smart phones. When the user takes a picture of a target using the smart phone camera, our system can recognize the image of the target and recommend a suitable service to the user. The system with executes simple image analysis and determines a suitable service for the target image. The simple image analysis can extract 13 parameters (e.g., color information (RGB), number of intersections, depth of intersection, line width, and line depth). We use machine learning to classify the parameters into each service. In our research, we use a Support Vector Machine (SVM) as a learning machine tool. Our system design provides user support for several services such as translation, barcode readers, and diagnosis of skin images and demonstrates the effectiveness of our research.

Keywords: User Support System, Data Mining, Support Vector Machine, Smart Phone

1 INTRODUCTION

Recently, many multifunctional cellular phone terminals, such as smart phones (e.g., Androids and iPhones), have been developed as a result of the evolution of the computer, network infrastructure, and lightweight battery technology. Thus, the number of users is rapidly increasing [5]. The smart phone is equipped with various sensor systems (e.g., an acceleration sensor, an infrared sensor, and a luminosity sensor), besides the camera function. Furthermore, easily programmed applications acquire input from each function. Various research activities and services performed with a smart phone using such features. Examples are the study of service applications such as translation from English to Japanese, barcode readers, recognition of billboards, recognition of facial images, and diagnosis of skin images using visual information from the camera of a smart phone. Examples are the study of the diagnosis service of skin image that recommends cosmetics that are appropriate for the skin condition by transmitting the skin image from the camera function to an analysis server [1, 2] To use these services, a user should select a service application and point the smart phone camera (take a picture) toward the subject of the service, and then receive the information service from the application. However, when the subject size or focus do not match, the user cannot access the service. The user must then retake the picture. Such mistakes are frequently made when a user first accesses an application.

Considering this background, we have designed a user-support system for vision information using smart phones. In our study, when the user takes a picture of a target using the smart phone camera, our system can recognize the image of the target and recommend a suitable service to the user. In addition, our system provides advice by voice and a user interface using a touch panel. When the target image conditions are unsuitable for the service, our system can advise the user directly. The user can then adjust the size of the image target area by operating the touch panel. In our design, we use a design model of a server-client system; a smart phone is used as a client because the smart phone's CPU is not powerful enough to achieve these services, so the services are implemented by server machines. The system with the smart phone as a client executes simple image analysis and determines a suitable service for the target image. To improve its judgments, this system can advise and request input via voice and text to adjust the area of the target image using the touch panel. The simple image analysis can extract 13 parameters (e.g., color information (RGB), number of intersections, depth of intersection, line width, and line depth). We use machine learning to classify the parameters into each service. In our research, we use a Support Vector Machine (SVM) [3] as a learning machine tool.

Our system design provides user support for several services such as translation, barcode readers, and diagnosis of skin images and demonstrates the effectiveness of our research.

2 SUPPORT VECTOR MACHINE

The SVM that is used in our study to determine is a classification technique that uses supervised learning and that can be applied to pattern recognition and regression analysis. The learning algorithm of the SVM is derived from optimization theory, and the learning method introduced by Vapnik [3] calculates a super-plane that separates positive and negative examples as training data. High identification performance can

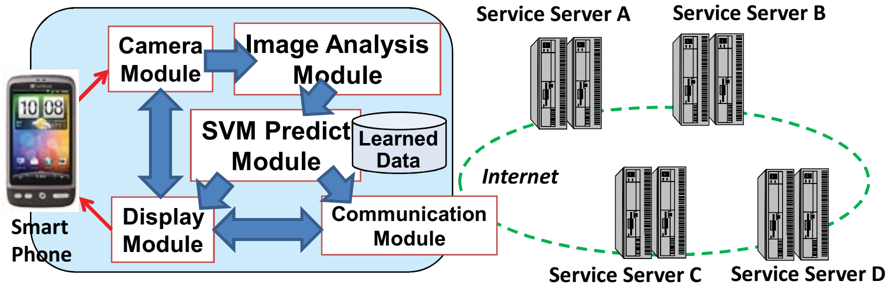

Fig. 1. Structure of the user-support system for vision information using smart phones

be demonstrated by adding the kernel function and margin maximization (e.g., mapping to a higher dimension space by using the nonlinear map, and introducing the kernel function to linear separate by the higher-dimension feature space). The pattern is mapped to the feature space of limited or infinite order, and it is possible to linear separate on the feature space. Thus, the SVM is used in various fields like categorizing text, image recognition, and bioinformatics, and was recently applied to Classification of Web services [4].

In our study, we use the Java version of libsvm [7] that can be implemented on an Android as the SVM and supports also multi-class classification.

3 SMART PHONE

A smart phone is similar to a small laptop computer. However, a smart phone has a telephone call function, and it is easy to carry because it is small and light. Its display is rather small, and it does not have a keyboard. Moreover, the development of an Android smart phone is comparatively easy, because the development language basically conforms to Java in the Android application (Android SDK[6]). In our study, the smart phone (Android) is an HTC Desire SoftBank X06HT (CPU: Qualcomm Snapdragon 1GHz, Internal memory: ROM 512MB/RAM 576MB, OS: Android 2.1 with HTC Sense).

The performance of the assumed smart phone (Android phone) in this study is as follows.

- Camera function

  A picture can be taken using the photography function of the Camera API (android.hardware.Camera) with which the Android phone is equipped. The camera focus when the picture is taken can also be checked using this API. The resolution of the picture changes with the performance of a smart phone; we use a size of 1216x2048 pixels in our research. (If the screen is too small, the accuracy will be affected; if it is too large, the processing speed of the smart phone will be affected.)

- Display function

  The picture and text can be displayed as output on the Android phone, which recognizes a finger touch and drag operation on a display as an input. These functions are provided to build the user interface of AndroidAPI (android.app.Activity).

Additionally, a smart phone is equipped with GPS and various sensor systems (e.g., acceleration sensor, brightness sensor, and temperature sensor) and can use voice annunciation through a speaker.

4 SYSTEM ARCHITECTURE

We have designed a user-support system for vision information using smart phones. When a user takes a picture of a target using the smart phone camera, this system executes simple image analysis and determines a suitable service for the target image. The system's simple image analysis can extract 13 parameters (e.g., color information (RGB), number of intersections, depth of intersection, line width, and line depth). We use machine learning to classify the parameters into each service. In our study, we use a Support Vector Machine (SVM) [3] as a learner, learn information collected with the smart phone beforehand, and judge the target image of newly collected information. The information is gathered and judged in a smart phone, and the learning process can be performed in a smart phone or a personal computer.

Figure 1 depicts the structure of the user-support system for vision information using smart phones. The modules in this system have the following roles.

- The camera module takes a picture using the camera function of the smart phone. This module judges the camera focus when photographing skin.

- The display module provides information to the user by displaying the input information and treats the operation on display as input from the user. This module displays the picture and text when the picture is taken, transmits

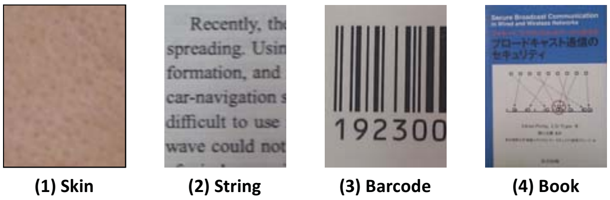

Fig. 2. Samples of parts of the image used by each service. (1) Skin image. (2) String image. (3) Barcode image. (4) Book image.

it to the service server, and provides the diagnostic result. The area of the picture to be transmitted to the service server can be selected using the touch-panel function of the smart phone.

- The image analysis module analyzes the image to extract the parameters from the image data. This image analysis extracts 13 parameters (e.g., color information (RGB), number of intersections, depth of intersection, line width, and line depth (image depth)). The image parameters are used by the SVM prediction module to determine a suitable service.

- The SVM prediction module judges the image parameters using learning data created by our learning tool (see the next section) and determines a suitable service for the target image.

- The communication module transmits information to and receives information from the suitable service server.

5 LEARNING BY SVM

In our study, the SVM creates the learning data of the image for which a suitable service is to be determined, and we implement the SVM prediction module in Fig. 1 by using the learning data. While learning, we collect image data that can be used by several services such as translation, barcode readers, and diagnosis of skin images; analyze each image and extract parameters; and execute parameter classification learning by SVM. We use the Java version of libsvm [7] that can be implemented on an Android as the SVM.

5.1 Extraction of Parameters by Image Analysis

To execute learning with an SVM, we implemented the function of image analysis to extract the parameters from the collected image data (such as Fig. 2) in the smart phone. This image analysis uses the same function implemented for the skin diagnosis service [1]. Processing was reduced to enable analyzing the image more quickly in the smart phone. The

13 parameters

The number of images

Fig. 4. Parameters used for SVM learning (before scaling)

image analysis process (Fig. 3) first extracts 240 to 320 pixels of the central portion of the acquired image (Fig. 3(A)). Next, the function converts the image into a gray-scale image (Fig. 3(B)), prepares a binary image (Fig. 3(C)), performs noise reduction (Fig. 3(D)), and creates a line image (Fig. 3(E)). This image analysis extracts 13 parameters (e.g., color information (RGB), number of intersections, depth of intersection, line width, and line depth (image depth)). (The skin diagnosis service extracts 45 parameters to recognize the state of the skin image in detail.) The learning data are created by learning these parameters using the SVM.

5.2 Creating Learning Data

To create learning data by applying SVM learning, we collected the images that became training data. There were 100 data images, 25 each for skin, string, barcode, and book images. Next, we extracted the parameters from the collected image data using the image analysis function.

Figure 4 presents data when collected parameters are learned by the SVM. The parameters of one line represent one image. The left-hand numbers (1 to 4) indicate whether the image is skin (1), string (2), barcode (3), or book (4). After scaling, these parameters can be learned by the SVM, and learning data is created. We used the Java version of libsvm [7] that can be implemented on an Android as the SVM and that also supports multiple classifications. We used the Gaussian kernel as a kernel function for SVM learning. Cross validation indicated a learning accuracy of 89.0%.

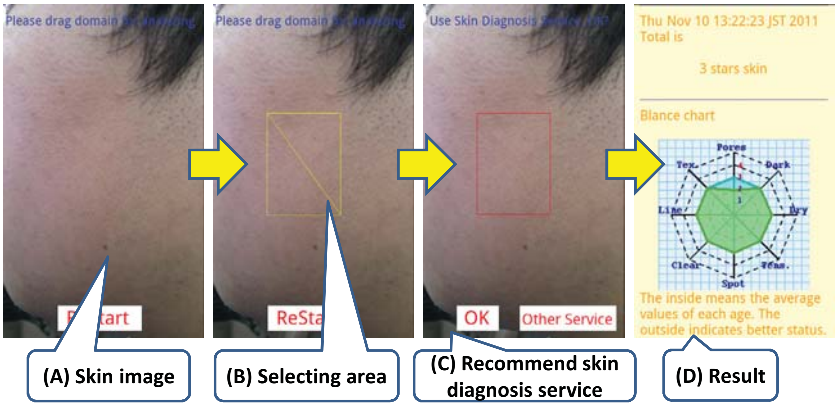

Fig. 5. Process of the user-support system for vision information using the smart phone

6 USER-SUPPORT SYSTEM

In our study, we implemented a user-support system that enabled service judgment based on the created learning data for vision information using smart phones (Fig. 1). We used HTC Desire X06HT (described in paragraph 3) as an Android smart phone. In our study, when the user takes a picture of a target using the smart phone camera, our system can recognize the target image and recommend a suitable service to the user. In addition, our system provides advice by voice and a user interface using a touch panel.

The process flow of the user-support system is presented in Fig. 5. In this figure, this user wants to use a skin diagnosis service. First, when the user photographs his/her own skin using the smart phone via the camera module, our system displays the skin image via the display module (Fig. 5(A)). Next, the user selects the area of the image (Fig. 5(B)) for which the service is to be used. The image analysis module then analyzes the image and extracts the parameters, and the SVM prediction module judges a suitable service. In Fig. 5(C), our system recommends the skin diagnosis service wanted by the user. When the user pushes the "OK" button (Fig. 5(C)), our system transmits the selected image data to the skin diagnosis service server via the communication module. Finally, the result is displayed (Fig. 5(D)). In these processes, our system can advise the user via text and voice while the user is taking a picture, for example, and provide operational advice based on the situation.

With our system, the user can take a picture of a target using the smart phone camera and receive a suitable service recommendation from our user-support system.

7 CONCLUSION

In this paper, we designed a user-support system for vision information using smart phones. When the user takes a picture of a target using the smart phone camera, our system can perform simple image analysis, recognize the target image, and recommend a suitable service to the user. To improve its judgments, this system can advise and request input via voice and text to adjust the area of the target image using the touch panel. We use machine learning with a Support Vector Machine (SVM) to classify the parameters extracted by the simple image analysis into each service. We implemented a user-support system that enabled the judgment based on the created learning data for vision information using smart phones and demonstrated the system's effectiveness.

Abstract: We proposed a method to detect distinctive mouth shapes from images that uttered Japanese. And a method to realize machine lip-reading from the order of detected mouth shapes was proposed. Therefore, we propose a communication system for hearing impaired persons using the machine lip-reading. This system supports the communication with the hearing impaired persons and remote persons using the Twitter. In addition, the input of the message is realized with machine lip-reading because hearing impaired persons have difficulty in utterance by the voice. We also devise the interface which can be operated only with a mouse. We carry out an experiment to send a message which is input with machine lip-reading to the Twitter, and evaluate this system.

Keywords: Hearing impaired persons, Twitter, Lip-reading, Communication

1 INTRODUCTION

For a hearing impaired person, both uttering and hearing a speech are difficult. Therefore, some special means are necessary to communicate with other people. As the one, there are lip-reading. The studies of so-called machine lip-reading using the image recognition technologies are performed. We are studying a method unlike the conventional machine lip-reading. We know that a person having the technology of lip-reading pays its attention to the distinctive mouth shapes and their transition, which appear intermittently during a speech. In our study, such knowledge from a human is used as the logical model for automatically recognizing the mouth shape movement. As the first stage, six kinds of basic mouth shape patterns are defined and expressed as the codes, which are easy to be handled by a computer. The pronunciation of Japanese words and sentences was proved to be expressed by series of such mouth shape codes. We called them MSSC (Mouth Shape Sequence Code) (Miyazaki et al [1]). In the second stage, we enabled the generation of MSSC from a video image, which is taken from the mouth movement of an uttering person (Miyazaki et al [2]). We consider that it is possible to generate a text string from utterance images using the machine lip-reading.

Acquired hearing impaired persons have ability to speak and to hear Japanese. This ability or experience is very useful for machine lipreading. In the hearing impaired persons, there are some persons that have physical disability, too. Therefore, we devise a system that sends a message to the Twitter from Japanese utterance images without using keyboard. We expect that this system is used as communication tools for hearing impaired persons.

In this paper, we describe the system that converts Japanese utterance images into a text message and sends the message to the Twitter. This system adopts the"mentions" to send messages to specific users. We propose the system that supports real-time communication with hearing impaired persons and remote place persons. The outline of this system is shown in Fig. 1.

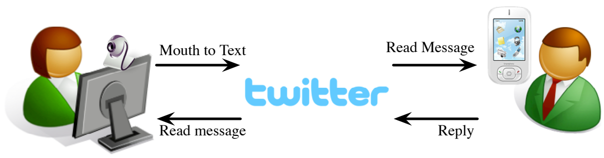

Fig. 1. Outline of this system

2 TWEET USING MACHINE LIP-READING

The block diagram of this system is shown in Fig. 2. This system consists of two subsystems (Part 1 and Part 2). The Part 1 generates MSSC mentioned above, from a video image (sound is not included), which photographed the movement of lips. It is sent to the Part 2 subsystem as text files. The Part 2 is controlled by a "Control window". By the operations on this Control window, Part 1 video picture is displayed, and the MSSC file is received. It is converted into the normal text. For this conversion, we have the pairs of MSSC code and the corresponding text in a phrases database. There is the case that different utterance contents are converted into a same MSSC code because of the principle of this conversion method. Therefore, it is necessary for the sender to choose an appropriate message among the candidates by some means. The chosen message is transmitted to the Twitter as a direct message. The reply text message from the addressee can be confirmed with this GUI screen, too.

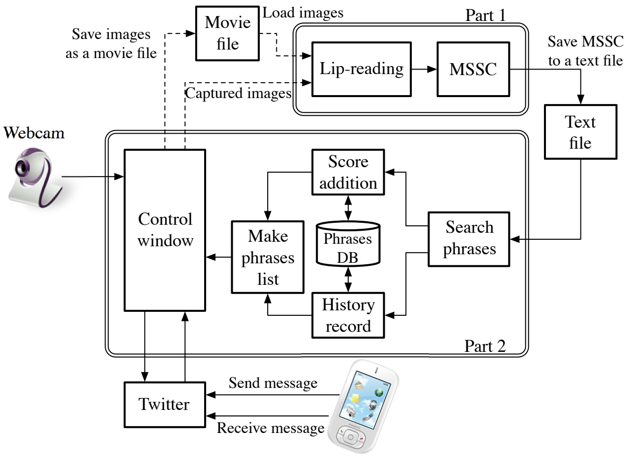

Fig. 2. Block diagram of this system

2.1 Generation of MSSC from utterance images (Part 1)

The lip-reading method which is used in this system is logically materialized knowledge of the lip-reading skill holders and detects distinctive mouth shapes. In the method, five mouth shapes of Japanese vowels and closed mouth shape were defined as "Basic Mouth Shape (BaMS)". We explain the relation between Japanese phones[1] and mouth shapes. A Japanese phone is uttered with only the "Beginning Mouth Shape (BeMS)" or the combination of the BeMS and "End Mouth Shape (EMS)". The BeMS are the mouth shapes which are formed at the beginning of utterance such as "ma", "sa" or "wa". The EMS are the mouth shapes which are formed at the end of utterance. When a Japanese words and phrases are uttered, the sequence of formed mouth shapes is expressed by "Mouth Shpaes Sequence Code (MSSC)". Each mouth shape is defined as $C = \{\mathtt{A}, \mathtt{I}, \mathtt{U}, \mathtt{E}, \mathtt{O}, \mathtt{X}, -\}$, which is called "Mouth Shape Code (MS Code)". Each MS Code corresponds to the mouth shape /a/, /i/, /u/, /e/, /o/ and closed mouth shape, respectively. The last MS Code "−" expresses that the BeMS is not formed. In an MSSC, the odd-numbered codes and the even-numbered codes correspond to MS Codes of BeMS and EMS respectively. For example, the MSSC of "EBINA" (name of a city in Japan) is expressed as "`-EXI-A`". This MSSC shows that a closed mouth shape "`X`" is formed on the second phone "BI".

In the Part 1, similarities between mouth shape image, which is captured by webcam or in movie file, and the BaMS images are calculated. After that, the BeMS terms and the EMS terms are detected from the utterance term using the similarities. Then, an MSSC is generated from the mouth shape of each term (Miyazaki et al [2]). Fig. 3 shows the generation process of MSSC.

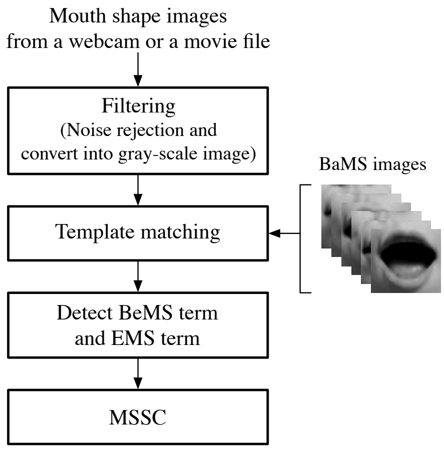

Fig. 3. The generation process of MSSC

2.2 Tweet from an MSSC (Part 2)

In this part, a Japanese phrase that is detected from the Phrases DB is sent to the Twitter (Makice [3]). To detect the phrase, two processes, "Score addition process" and "History record process", are executed. Table 1 shows the Japanese phrases and their MSSC stored in the DB.

After machine lip-reading, the phrase which the user required may not be detected. Therefore, in the Score addition process, points are added to each phrase stored in the DB.

In the History record process, a history count is added to the phrase which is sent to the Twitter. As the result of the two process, some phrases are listed by the score order and the history order. Then, the user selects a phrase from the list, and the phrase is sent to the Twitter.

2.2.1 Score addition process

To add a score to each phrase stored in the DB, each MS Code of MSSC generated in the Part1 is compared with the MS Code of the phrases stored in the DB. The score addition flow is shown in Fig. 4. In the Fig. 4, $c_n(s)$ means a s-th MS Code of MSSC of n-th phrase stored in the DB. $m(s)$ means a s-th MS Code of the MSSC generated in the Part 1 correspondingly.

An example is shown in Table 2. This result shows the case of utterance "Arigato". In the MSSC row, the MS Codes of "Arigato" stored in the DB are shown. In the Result row, the MS Codes that are generated in the Part 1 are shown. The row of *score*1 and *score*2 show the points that are calculated in the Score addition process. For example, the point of *score*1 in the case of $s = 2$ is 1 because of $c_n(2) = m(2)$. The point of *score*1 in the case of $s = 6$ is 0 because of $c_n(6) \neq m(6)$.

[1] The length of voice equivalent of one short syllable is called "mora", and the voice is called "phone".

Table 1. Phrases Database

#	MSSC	Japanese articulation	English meaning
1	-I-U-A-E-IXA-U-A	Itsu kaeri masuka	When do you come home?
2	-IXAUOIE-U-A	Ima doko desuka	Where are you now?
3	-I-X-U-I-A-I-E-U	Kinkyu jitai desu	State of emergency.
4	-A-I-AUO-U	Arigato	Thank you.
5	UA-IXA-I-A	Wakari masita	I've got it.

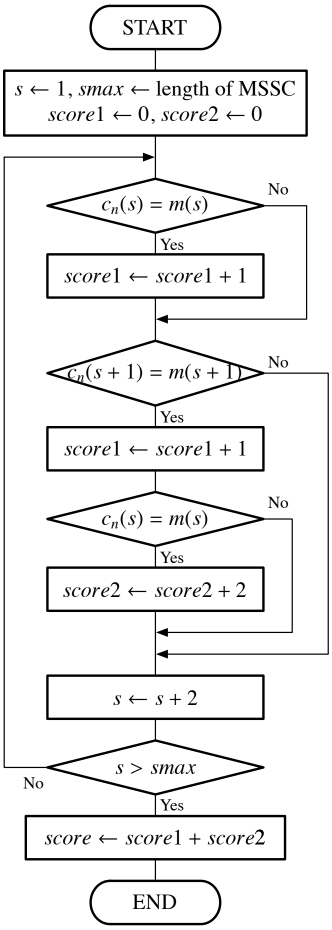

Fig. 4. The flow of Score addition process

About the *score*2, the first point is 2 because of $c_n(1) = m(1)$ and $c_n(2) = m(2)$. The third point is 0 because of $c_n(5) = m(5)$ and $c_n(6) \neq m(6)$.

Then, the total of *score*1 becomes 7 and the total of *score*2 becomes 4. As a result, the score of n-th phrase becomes $score1 + score2$.

2.2.2 History record process

In this process, the count that a phrase is sent to the Twitter is recorded. If some phrases get the same score, the phrase of which the count is greater is listed higher on the Control window. The phrases that are used frequently become easy to be selected.

Table 2. Example of point addition

s	1	2	3	4	5	6	7	8	9	10
MSSC	-	A	-	I	-	A	U	O	-	U
Result	-	A	-	I	-	E	-	O	-	O
*score*1	1	1	1	1	1	0	0	1	1	0
*score*2	2		2		0		0		0	

Firstly, The phrase list is sorted by the history order. Secondly, the list is sorted by the score order and some of top phrases of the list are displayed.

2.3 Control window

We describe the Control window of this system. The window is shown in Fig. 5. Four components are located in this window.

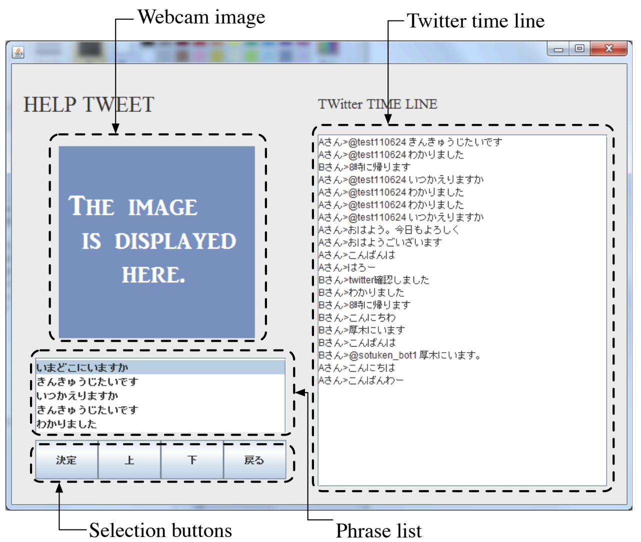

Fig. 5. Control window

The images captured by webcam are shown in the "Webcam image" pane. As the result of machine lip-reading, top five phrases are listed on the "Phrase list" pane. The user select a phrase from the list by using selection button and send a message to the Twitter. The four buttons are "Send", "Upward", "Downward" and "Cancel". After that, the posted message is listed on the top of the "Twitter time line".

Table 3. The detection rate and the ranking

Japanese articulation	English meaning	1st	2nd	3rd	4th	5th
Ashita	tomorrow	83% (1)	100% (1)	83% (1)	100% (1)	33% (2)
Ima	now	75% (1)	50% (1)	75% (1)	75% (1)	75% (1)
Istu	when	75% (1)	50% (2)	75% (1)	50% (2)	100% (1)

3 EXPERIMENTS

We carried out an experiment to convert into Japanese words and phrases from MSSC. The MSSC were generated from images that uttered Japanese. However, we used recorded utterance images.

Firstly, Japanese phrases and their MSSC were stored in the Phrases DB. The stored phrases were “Kyo” (today in English), “Ashita” (tomorrow), “Ima” (now), “Itsu” (when), “Dokoni” (where), “Dokohe” (where), “Imasuka” and “Kaerimasuka”.

During the experiments, the subject uttered phrases without moving head. Furthermore, the mouth shapes before utterance and after utterance assumed closed mouth shape.

3.1 Experimental results

A subject uttered Japanese phrases five times. The phrases were “Ashita”, “Ima” and “Itsu”.

The detection rate of each phrase and its ranking are shown in Table 3. The detection rate shows the ratio that is matching rate of each MSSC stored in the DB and generated in the Part 1. The number in parenthesis shows the ranking.

In most results, the detection rate was higher than 50%, and some of them got 100%. Besides, all phrases were ranked as the 1st or 2nd in the list. Through this experiment, we confirmed that the detection rates differed, though the same phrases were uttered.

4 CONCLUSION

In this paper, we proposed a system for supporting hearing impaired person by using machine lip-reading. An MSSC was generated from the utterance images and was able to be converted into Japanese. Furthermore, the converted Japanese was able to be sent to the Twitter as a message.

If the phrases in the Phrases Database are increased, incorrect phrases may be listed in high-ranking. As a remedy, we have to devise score addition method and examine comparison method of MSSC.

Although the system is only at a very early stage now, we can see that this approach has big possibilities to promote communication between hearing impaired persons and the general people. Additional facilities such as text-to-speech conversion and speech-to-text conversion are also being developed in order to provide more convenient usages. We also plan to improve the precision of the conversion from mouth shape images to readable text.

Abstract: The goal of Human-Computer Interface (or called Human-Robot interface) research is to provide humans with a new communication channel that allows translating people's intention states via a computer into performing specific actions. This paper presents a novel hands-free control system for controlling the electric wheelchair, which is based on Bio-signals as surface electromyogram signals. The Bioelectric signals are picked up from facial muscles then the Bio-signals are passed through an amplifier and a high pass filter. Motion control commands (Forward, Left, Right, Forward to the Right, Forward to the left and Stop) are classified by simple rule. These commands are used for controlling the electric wheelchair. However, it is difficult to safety control and fine control using the biological signal only. In addition, we introduce the semi-automatic control system using the laser range scanner. In this paper, we report the introduction of our proposal systems and our experimental results.

Keywords: Surface Electromyogram Signal, Electric Wheelchair, Motion Control Command Rule, Semi-Automatic Control

1 INTRODUCTION

Surface electromyogram signals (abbr. s-EMG) are detected over the skin surface and are generated by the electrical activity of the muscle fibers during contraction [1]. Moved muscle can be presumed by analyzing s-EMG. S-EMG is used to control artificial leg etc. s-EMG recognition of using the conventional neural network is a method which learns the relation between s-EMG patterns and is reproduced using a neural network. Our previous works [2] [3] [4] showed that technique of integrated EMG is much easier and superior than the fast Fourier transform analysis. Integrated EMG is a running average of the rectification s-EMG.

One of the major challenges for prosthesis or Human-Robot Device development is to produce devices to perfectly mimic their natural counterparts. A very popular approach for prosthesis or Robot control is based on the use of Bio-signals (s-EMG, electroencephalogram (abbr. EEG), electrooculogram .,etc). One of them is s-EMG collected from remnant or normal muscles and use them as control inputs for the artificial limb or Robot Device. As these devices, known as s-EMG-based Hands-Free Wheelchair [5][6][7] use a biological signal to control their movements, it is expected that they should be much easier to control [8]. Other techniques have the method of using gesture [9]. However, the system of gesture is not used by the severely handicapped human.

In this paper, we applied to the electric wheelchair hands-free semi-automatic control system for the severely handicapped human using facial muscles s-EMG pattern recognition system. The six motion control commands (Forward, Left, Right, Forward to the Right, Forward to the left and Stop) are classified by our proposal simple rule. In addition, it is difficult to safety control and fine control of the biological signal only, we introduce the semi-automatic control system using the laser range scanner.

We tried the experiment of driving in the course by using our proposal system. The experimental subjects were five healthy men in twenties whose physique looks like. One person was an expert of the system, and others were the inexperienced person. From their experiments, we showed that the control of our proposal system is easy. In addition, the obstacle evading function was added to our system for the speed control and the stop control. We also tested those control

2 ELECTRIC WHEELCHAIR HANDS-FREE CONTROL SYSTEM USING S-EMG SIGNALS[6][7]

Head movement is a natural form of gesture and can be used to indicate a certain direction [5]. Serious disabled people can't move neck and head, but can get face figures. S-EMG is a way of studying facial muscles activities by recording action potentials from contracting fibres. S-EMG can be detected with surface electrodes. Surface electrodes are easy to apply. This is a non-invasive way to record s-EMG while posing no health and safety risk to the users.

Figure 1 shows the formal scheme for the acquisition and analysis of the s-EMG signal for the control organization and flow of information through the system [6][7]. Our system is based on the five features, 1) surface electrodes, 2) Amplifier (INA114P), 3) High pass filter, 4) Personal Computer for s-EMG signal classification and motion control command output, and 5) Electric Wheelchair Control Box.

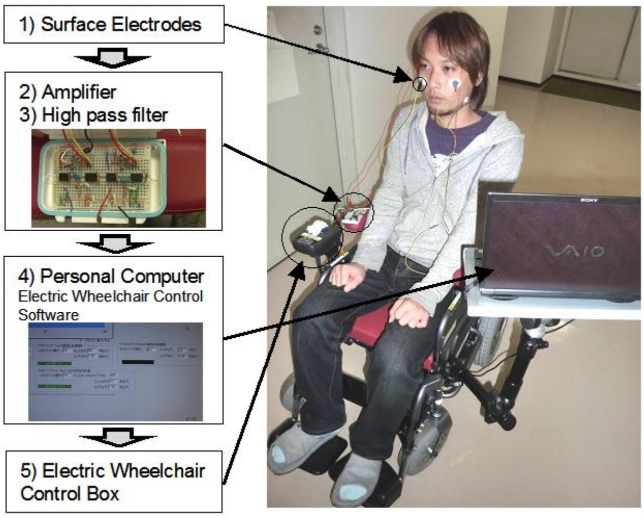

Figure 1. The Flow of Electric Wheelchair Control System using surface s-EMG.

The s-EMG signal detected by surface electrodes is amplified and filtered prior to data acquisition, in order to reduce noise artefacts and enhance spectral components that contain information for data analysis. Two channels of s-EMG signals can be used to recognize face figure movement. 5 Ag/AgCl electrodes are used (two for each channel and one is for ground). In order to remove the DC level and 60 Hz power line noise, the 4th order high pass filter is used. The cutoff frequency of high pass filter is 66.7Hz. In order to effectively filter functions, s-EMG measurement device is used two amplifiers. After filtering and the amplification (about 470 times) stages, the s-EMG signals are digitized (16 bit) and then transferred to the personal computer. The sampling frequency of the measurement data is 1 KHz. And the band is from 0 Hz to 500 Hz. The s-EMG signals are then processed by a classification technique which is based on the combination of 2 class classifier using the threshold. This proposal method is necessary to set the value of threshold of each user. At the finally, the electric wheelchair is controlled by the output command from personal computer using the D/A converter.

The utilized facial movements, motion control command classes and effective channels of bio-signals are defined in Table 1. The electric wheelchair is controlled according to the rule of Table 1. From Table 1, it is easy to select Stop Command in this rule. Because, it is the easiest to perform action to bite and the threshold of the STOP command is smaller than a front command. Therefore, our system is safety, because Stop Command is selected in the false identification case. The inputs for the rules of table 1 classification are given the moving average method process. Moreover, this system doesn't react to the usual blink.

Table 1. The Input Pattern and Classes of Our Rules.

Command	Motion	Active Channel
Turn Right	Wink with right eye	1
Turn Left	Wink with left eye	2
Forward	Bite	1 and 2
Stop	Bite in the state of the Forward, Turn Right and Turn Left Commands	1 and 2 * *These thresholds are smaller than Forward command.
Forward to the Right	Wink with right eye in the state of the Forward Command	1
Forward to the Left	Wink with left eye in the state of the Forward Command	2

3 FUNCTIONAL SAFETY AND SEMI-AUTOMATIC CONTROL

3.1 The Speed Control

The obstacle evading function is important for the safety control of the electric wheelchair. In this paper, we develop the obstacle evasion function using the laser range scanner (HOKUYOU Automatic Co.,Ltd : Classic-URG) for the electric wheelchair safety control. The URG laser range scanner is the most compact obstacle detection sensor with distance measurement principle using laser. Scanning angle of our system is 180° (max 240°). Our system measures the distance by 15° intervals. Figure 2 is image figure.

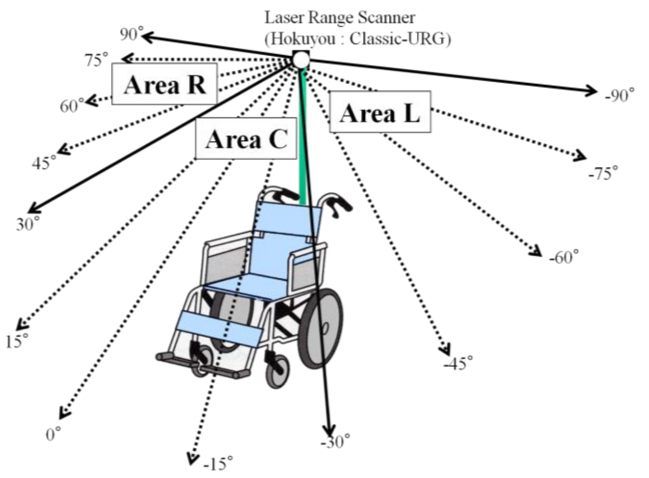

Figure 2. Functional Safety using Laser Range Scanner.

When the obstacle evading function detects the obstacle, our system sounds the alarm and speed control. Speed control is controlled according to the rules of the table 2. Our proposal system could detect about 3.0 meter before obstacle. Our proposal system slows down the speed for evading the obstacle, and wards off a collision. It became easy to evade the obstacle with this function.

Table 2. The Speed Control Rules.

Area R / C / L (0 : no obstacle, 1: obstacle)	Power of Turn Right / Forward / Turn Left (100%:max speed , 0%:stop)
0 /0/ 0	100% / 100% / 100%
0 /0/ 1	100% / 100% / 75%
0 /1/ 0	100% / 75% / 100%
0 /1/ 1	100% / 75% / 75%
1 /0/ 0	75% / 100% / 100%
1 /0/ 1	75% / 100% / 75%
1 /1/ 0	75% / 75% / 100%
1 /1/ 1	75% / 75% / 75%

3.2. The Stop Control

In this subsection, we introduce the safe stop control using the laser range scanner. The electric wheelchair which we developed turns at a radius of 1.5 meter. Therefore, the electric wheelchair cannot work when an obstacle is in the 1.5 meter range. As simple solution, the electric wheelchair stops when a radius of less than 2.0 meters includes an obstacle (Figure 3). Thereby, the electric wheelchair turns safely and can evade an obstacle.

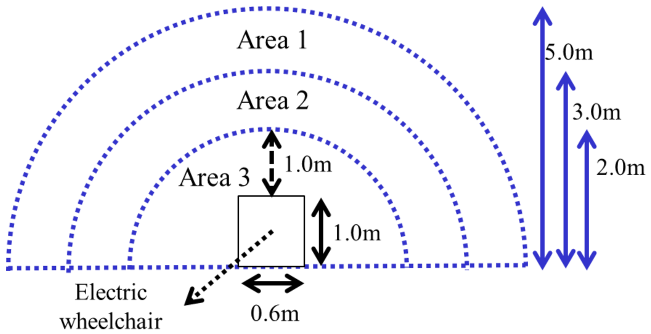

Figure 3. Sensor Measurement Area (Area 1: No control, Area 2: Speed control, Area 3: Stop).

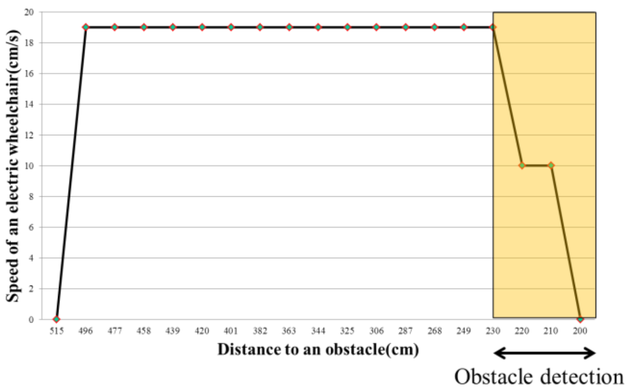

Figure 4. Result of Speed Control Test.

We tried the driving test in the hallway for evaluation of our proposed stop control system. The experiment operated the electric wheelchair toward to wall. The result is shown in Figure 4. From the result, our proposed system was able to detect the obstacle and was able to perform speed control and safe stop.

The electric wheelchair can be controlled in semi-automation by functional safety using laser range scanner. Our proposed system reduces the stress of user. However, our system has still some problems about the discovery of the movement object. These are our future works.

4 EXPERIMENTAL RESULTS

We tried the experiment of driving in the course by using our proposed system. The experimental subjects were five healthy men in twenties whose physique looks similar. One subject was an expert of the system, and others were the inexperienced subject. The driving course is shown in Figure 5. This driving course is about 125 seconds by original electric wheelchair using joystick. The task is to drive the electric wheelchair from position Start to Goal by contraction of facial muscles. The speed of electric wheelchair used low speed (1.0[k meter/hour]). We performed five experimental to each of five subjects. We compare our proposed system by the average time [sec] and the average classification rate [%].

The experimental results are shown in Table 3. The average time of 201 seconds in all, the average classification rate is 98.2 percent. The classification ratio indicates how much the correct command is selected for the total number of commands made by the subjects. From the experiment results, the classification rate of our proposed system and the computer simulation results of paper [10] are similar. The results of inexperienced subjects were almost same as the results of experienced subject. In particular, inexperienced subject S.H has the best results even though the first experiments. The usability of our proposed system was a good result. However, the difference between our proposed system and original electric wheelchair using joystick was 76 seconds.

From these experiments, we think that the control of our proposed system is easy. From these experiment results, the electric wheelchair control system using facial muscles s-EMG is a good system for the severely handicapped human. In addition, we think that the merit of our proposed system does not need a lot of training for user. Moreover, when the obstacle (the road cones) became near, our proposed system was able to be evaded smoothly without Stop command because the speed slowed by the obstacle evasion function. However, this processing reduced the speed.

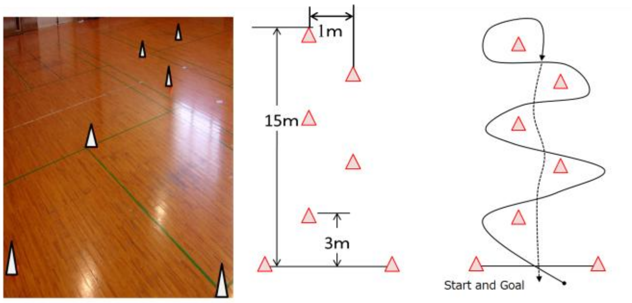

Figure 5. The Driving Course.

Table 3.Experiment Results.

Subject	Time		Classification	
	Average [sec]	Standard deviation	Average [%]	Standard deviation

5 CONCLUSION

In this paper, we applied to the electric wheelchair hands-free semi-automatic control system for the severely handicapped human using facial muscles s-EMG pattern recognition system. We tried the experiment of driving in the course by using our proposed system. The experimental subjects were five healthy men in twenties whose physique looks like. One person was an expert of the system, and others were the inexperienced person. From these experiments, we showed that the control of our proposed system is easy and our proposed system does not need a lot of training for user.

Our proposed system could also be used by handicapped person without training. Moreover, we think that our proposed system is useful than the system using the EEG signals. In the future works, we plan to develop of algorithm that can be turned more smoothly, improve the obstacle evading function and test the severely handicapped human.

Abstract: There is a drastic increment of the demand for prosthetic devices over the last few decades. This is caused by the increased amputees because of casualties due to civil wars, injuries due to accidents, *etc*. Therefore, the robotic prostheses are one of the highly interested research areas in recent robotic research. The target is to make sure the amputee gets a better chance to interact with the real world, in spite of the amputation he has. The paper presents the results of a comprehensive literature analysis towards a development of an upper-limb prosthetic arm. This study identifies the methods of prosthetic classification as the segment of application, number of degrees of freedom (DoF), types of applied actuators, types of power transmission methods and control methods. In this study, the upper extremity prosthetic devices are classified based on the segment of application. Thus, they can be mainly classified into shoulder prosthetics, transhumeral and elbow prosthetics, transradial and hand prosthetics. This study considers all the above categories of recent upper extremity prosthetics, and reviews their key technologies by taking state-of-the-art robots as examples.

Keywords: robotic prosthetics, transhumeral, transradial, upper-extremity.

1 INTRODUCTION

A prosthetic is a device that replaces an amputated body part of a person. It is expected to restore the physical appearance and the lost functions of the amputated body part. Limb replacements are taking place at a higher frequency, affected by casualties due to war, accidents, cardiovascular disease, tumors and congenital anomalies.

In 490 B.C., it was a Persian soldier who cut off his own feet in order to escape from a prison and later replaced it with a wooden foot which is the first prosthetic [1]. However, the development and the fabrication of the prosthetics dated back to about 500 years [2]. Recent development of the prosthetics was influenced by the World War I and II, which resulted in a remarkable loss of man power in USA and Europe. In 1948, the concept of Cybernetics, *i.e.*, the study of control and communication between human and machine [3], played a significant role later on for the improvement of the prostheses. Samuel Anderson created the first electrically powered prosthetic arm that uses external power, with the support of the US government and IBM in 1949 [4]. Russians in 1958 developed the first myoelectric arm and soon after, Otto Bock Company came up with a commercially available prosthetic arm for common application which was the first finished versions of the Russian design [4]. The researchers have been making effort to develop a perfect prosthetic system, which will mimic the exact human motion pattern, power requirement and anatomical/cosmetic features.

The advancement of the mechatronic technology over the recent years leads to a number of upper extremity prosthetics both commercially available and still in the research level [6]-[16]. Nevertheless, they are not that popular among the amputees due to their inability to meet the user expectations up to a desired level in real world. Most of them are with poor functional and controlling properties, which is the major, concern of the prosthetic user to loss their interest on the prosthetics [5].

During the last decade number of research work [6]-[11] had been carried out and some of research works are still ongoing. At present, Utah Arm [17], Boston Elbow and Otto Bock [12]-[16], which are commercially available can be considered as the pioneers in this filed. Dean Kamen's Luke Arm, Proto 2 and MANUS-HAND are still at the developing stage [18]. Most of these commercially available prosthetics [16] are capable of generating only few limited degrees of freedoms (DoF): elbow flexion/ extension, forearm pronation/supination, and prehension. Forearm pronation/supination is generated in a terminal device forfeiting the human upper limb anatomy. Therefore, the adaptation of the wearer to the real world might be an extra burden. Some prostheses are developed to generate the functions of the human hand. Touch Bionics's i-Limb [19] is the state-of-the-art upper limb prosthetic and before that it was Otto Bock's SensorHand Speed, which was a basic open and close mechanism only. The dexterity of hand prosthesis is still far from that of the state-of-the-art non-prosthetic mechanical hands, such as the DLR II [20].

Main target of this review paper is to cover brief history, challenges, current status and future developments of upper extremity prosthetic devices. Authors tried to review the state of the art prosthetics developed in the last six years.

Biomechanics of upper-limb toward the development of an upper-limb prosthetic device, challenges to the development of prosthetic limbs, a brief review on the state-of-art upper limb prosthetic limbs and a brief idea on future research directions are presented respectively.

2 BIOMECHANICS OF UPPER EXTREMITY

Before developing a robotic prosthetic device to mimic the upper extremity, a thorough understanding of its physics should be there. Three major components of the upper extremity are shoulder complex, elbow complex and wrist. Shoulder complex is built with three bones: clavicle, scapula and humerus and four articulations. Shoulder can be modeled into a ball-and-socket joint. The proximal part of the humerus, humeral head and the female part of the scapula, glenoid cavity respectively act as the ball. The main motions of the shoulder joint are shoulder flexion/extension, abduction/adduction and internal/ external rotation. During each motion, the position of the centre of rotation of the shoulder joint changes.

Three bones of the arm and the forearm, humerus, radius and ulna are connected to the elbow (radioulnar) joint at the distal part of thehumerus. The ulnohumeral and the radiohumeral articulations are contributing to the motions of the flexion/extension of the forearm. Further, the radioulnar articulation contributes the motions of supination/pronation of the radius and ulnar bones [21].

The wrist is a collection of eight carpal bones. It has two major articulations, radiocarpal and midcarpal based on their functionality. The radiocarpal joint allows motions in two planes: flexion/extension and radial/ulnar deviation of the wrist, which are generated around an instantaneous center. However, the centroide travels in a small path, therefore the displacement of the instantaneous center of rotation is ignored and the axes of rotation for the motions are considered to be fixed. These axes pass through the capitate. Even though the wrist joint motions are considered to be generated with respect to the two axes, some research work [14] has shown that they are generated with respect to four axes. The wrist flexion axis and the extension axis are different, but intersects at a point at capitate. Similarly the radial and ulnar deviation axes are also different and intersect at capitates [22]. The slight offset of the rotational axes of the flexion/extension and the radial/ulnar deviation is approximately 5 mm [22].

3 CHALLENGES

Even though the existing upper limb prosthetic devices are able to cater the amputees' requirements to a certain degree, still there are lot of improvements and design challenges that have to be addressed. They are briefly discussed here. Amputees expect a prosthetic not to be overweight, anthropomorphic in appearance and cosmetics [23] and the functionality of the prosthetic to provide expected motion intentions of the user as a normal human limb. Ultimate objective of a prosthetic limb is to make sure both user and the surroundings do not feel the difference of the amputation which the user is having. In addition, the prosthetic limb should demonstrate a significant decrease in the metabolic demands which will be equivalent to a human being without any amputation, for daily motions.

These expectations are still constrained by different technological barriers which needed to be overcome to develop a perfect prosthetic device. Most of the actuation methods that are being used are heavy and if not they are with limited torque and power. Furthermore, the actuator sizes and the operational behaviors such as smooth and simultaneous motion of joints, noises also should be rectified towards the anthropomorphism. Prehension, grasping or holding of an object is one of the main functions expected from the human hand. It is capable of holding anything and will not effect by the object to be hold. The surface finish, geometry, stiffness or strength of the object will not affect the grasping function of the human hand. All these requirements are not yet integrated at one place.

Further, tactile sensing is another important input from the human upper limb to the robot making a good interaction of the human being with the environment. It helps to make accurate motions which sensory inputs are required. Tactile sensing and force sensing are essential outcomes of a human upper extremity and yet to be developed such a system. Furthermore, the unavailability of proper accessory devices such as power sources with tolerable weight for long time use, material types for more anthropomorphic features, is also a challenge to develop a perfect upper extremity prosthetic. The motions of the robot should to be with required power and the joint movements have to be simultaneous. Since most of the amputees wear the prosthetic more than 8 hours per day [23] the user fatigue is a great concern in prosthetic design. When the actuators are large enough to provide the desired power they may be with a much weight and will be uncomfortable to use for longer time periods. In addition, the concern should be on the prosthetic sockets as well. It should be comfortable enough to wear for a longer period of time. Moreover, different control signals are available for the prosthetic devices. Electromyography (EMG) signals are mostly preferred by most of the researchers since EMG signals directly convey the human motion intention to the control system. However, the amputees have already lost their body part and muscles obviously. It limits the amount of control signals that can be gained through the EMG. This ultimately leads to a limitation of the number of communication channels available for the control of a multi-DoF upper limb prosthesis resulting them to underperform on showing the correct motion intention of the user.

4 REVIEW OF UPPER EXTREMITY PROSTHETICS

In recent years, a number of upper-limb prosthetic devices have been proposed [19], [24]-[33]. Available prosthetic devices can be classified considering different criterion. This study identifies the methods of prosthetic classification as the segment of application, DoF, types of applied actuators, types of power transmission methods and control methods. The methods of classification of prosthetic are shown in Fig. 1(a). Since this paper is mainly focused on application of the robotic upper limb prosthetics, the classification is carried out based on the location of application of the prosthetic. The classification is shown in Fig. 1(b).

Table 2 shows a comparison of existing prosthetic limbs. In the next sub sections recent upper-limb prosthetics are reviewed by explaining their basic designing concepts. They are selected based on their key technological features in their designs. Transhemral prosthetics and elbow prosthetics, Transradial and hand prosthetics are combined together in following subtitles for the ease of the presenting.

4.1 Shoulder Prosthetic Devices

Shoulder prostheses are worn by amputees with shoulder disarticulation. The following section presents the state-of-the art shoulder prosthetics.

4.1.1 DEKAs (DARPAs) Luke Arm [24]

The Luke Arm is the latest upper arm prosthesis developed by Defense Advanced Research Projects Agency (DARPA), designed by Dean Kamen [24]. Its advanced dexterity makes the Luke Arm better than the prosthesis currently in the market. The arm has 18DoF and it is more than the 03DoF other available in arm prosthesis today. In addition, high quality electronics and software allow for fine control of the arm which will allow amputees to perform many complex tasks such as to pluck chocolate-covered coffee beans one by one, pick up a power drill, unlock a door, and shake hands. The Luke arm is modular based, adjustable to use by anyone with any level of amputation since shoulder, elbow, forearm and the hand are independent from each other.

4.1.2 Proto 2 [25]

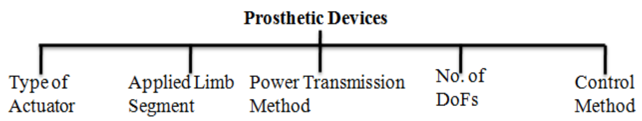
Proto 2 was launched as one of the phases of a four-year program to create prosthetic arms that can be better imitated natural limbs by Defense Advanced Research Projects Agency (DARPA) [25]. It is built with 100 sensors that connect the natural neural signals of body to the mechanical prosthetic arm making a sensory feedback loop. Thus the wearer interacts with an object and the arm feeds back in real time. The user could get a feeling of where the arm is in space, what object it is touching, whether that object is smooth or rough, how hard the hand is holding it, and what temperature the object is. Further, the motions of Proto 2 are smooth and not with jerks.

4.2 Transhemural & Elbow Prosthetic Devices

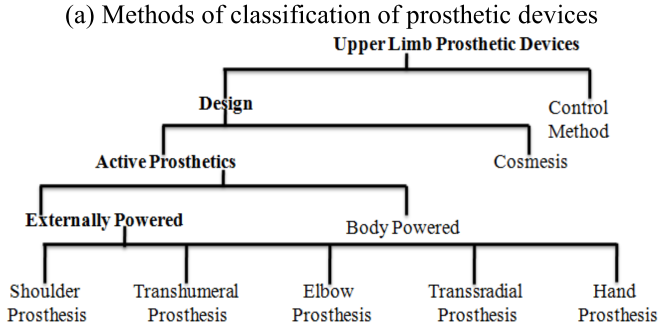
These are worn by amputees with elbow disarticulation or transhumeral amputation. State-of-the art transhumeral and elbow prosthetic devices are explained below.

4.2.1 A Gas-Actuated Transhumeral Prosthesis [26]

This is an anthropomorphic 21DoF, 9 degree-of-actuation prosthesis arm for transhumeral amputees. The arm utilizes a monopropellant, hydrogen peroxide as a gas generator to power nine pneumatic type actuators that drive elbow, wrist and a 17DoF compliant hand. The design makes the arm compact. Elbow and wrist joints are integrated with position and force sensing. The prosthesis is expected to approach the dexterity of an anatomical arm and is projected to deliver half of the force and power output of an average human arm. The usage of the gas-type actuators let the arm to achieve better volumetric and gravimetric power density.



(a) Methods of classification of prosthetic devices



(b) Classification based on applied limb segment

Fig. 1. Classification of Robotic Prosthetic devices

4.2.2 Saga University Prosthetic Arm [27]

The robotic prosthetic arm developed by Saga University is with 05DoF and targets to mimic the human anatomy as much as possible [27]. A T–mechanism is introduced here to mimic the human alike forearm motion and it contributes to the supination/pronation with the introduction of two shafts which act as the ulna and radial bones of the human arm. In order to achieve the objective of prehension, hand with a single DoF is attached to the distal end of the ulna and radial shafts with a ball joint.

4.2.3 MSUM elbow–2 [28]

The prosthetic is mainly capable of providing elbow flexion/extension. In the design the gears are substituted with linkages with ball bearing and by screw ball transmissions, when possible which has been lead to an increment of the mechanical efficiency of the hand [28]. In the initial design the axis of the ball screw is connected to a brushless motor via an epicyclical transmission and a belt-pulley system. The measured overall mechanical efficiency of this system was increased up to 64%. Later as an improvement, the screwball axis is oscillating and is directly connected to a "pancake" brushless motor. This architecture raises the efficiency to over 80%. The prosthetic could be integrated with other mechanisms to develop a transhumeral or shoulder prosthetic.

4.3 Transradial and Hand Prosthetic Devices

Transradial and hand prostheses are worn by amputees with wrist disarticulation or transradial amputation. Below mentioned devices are the state-of-the art transradial and hand prostheses.

4.3.1 Touch Bionics i-Limb [19]

Touch Bionics i-Limb is the first commercially available prosthetic device with five individually powered digits. Its inclusion of a thumb that works like the human thumb, let the hand to achieve different positions, enables important grip configurations [19], many of which have not been available to amputees before. The articulating fingers are able to close tightly around objects. Furthermore, the built-in stall detection for the each individual finger can detect the power cut-off position to the finger. Each individual finger will be locked in the position until the patient triggers an open signal through a muscle signal.

4.3.2 Under-actuated Hand Prosthesis [29]

Nasser *et al* proposed this hand to overcome the drawbacks of commercially available hand prostheses [29]. The hand design is based on an under-actuated 15DoF, 1DoF actuation configuration, fully capable of performing activities of daily living. Each finger is fully independent from each other and adaptable to grasp any object of any geometry. The system is capable of providing safe and reliable grasping without the need for feedback sensors, multiple servos, or any type of data processing. The design is focused towards providing upper limb amputees with the prosthetic hand that is cosmetically appealing, functionally comparable by means of DoFs, weight and cost.

4.3.3 FLUIDHAND III [30]

FLUIDHAND is hand prosthesis with enhanced functionality, cosmetic; enable security, and adaptive grasping as well as aesthetically appealing properties [30]. The combination of flexible fluidic actuators and soft passive elements reduces the required grasping force for a wide range of objects. Further, the enhanced actuator system allows high grasping forces if necessary. Two myoelectrodes in the socket together with the developed controller board and software enable quick selection of the most important grasping patterns. Vibrotactile force feedback and wireless programming and control options complete the characteristics of the FLUIDHAND III.

5 CONCLUSION AND FUTURE DIRECTIONS

This paper briefly reviewed available upper limb prosthesis developed over the recent years. It covers both commercially available upper limb prosthetics and the upper limb prosthetics still in the development stage. Nevertheless, following research goals could be followed for the future developments of a prosthetic device.

A biomechanical investigation should be carried for the upper-limb with and without the state-of-the-art prosthetics to identify the main problems of the state-of-the-art in the field. Using the results of the investigation the goals can be set for the future developments of the prosthetics limb. The goals can be standardized by means of weight, size, durability, actuation speeds, level of activity, and professional needs at a global level. In addition, a proper scheme can be proposed to evaluate the available prosthetic limbs by means of anthropometry, dexterity, user acceptance, etc. A measuring criterion should be defined for each different requirement of a prosthetic in order to achieve the objective of proper evaluation. The metabolic cost of transport (COT), which is the measuring of oxygen consumption and carbon dioxide production of human breathing during a task, can be used to benchmark the future developments of the prosthetic devices. Identification of the factors affecting the COT of a prosthetic user and the direct addressing of them in the designs will give better

Table 1. Comparison of Upper-Limb Prosthetic Devices

Reference	Location of Application	DoF	Actuator	Power Transmission	Special Feature	Control Method/ Input
DARPA's Luke Arm [24]	Shoulder, Elbow, Hand	18	DC Motors	Gear Drives	Adjustable to use for any level of amputation	EMG-TMR foot pad in shoe
Manus Hand [31]	Hand	3	DC Motors	Gear Drives, Geneva Mechanism,	Underactuateddesign principle	EMG
Proto 2 – John Hopkins University [25]	Shoulder and Elbow	25	DC Motors	Tendons	Real time feedback for grasping	EMG- TMR
i-Limb – Touch Bionics [19]	Hand and Fingers	11	DC Motors	Tendons	Five individually powered digits	EMG
Under-actuated Hand Prosthesis [29]	Hand and Fingers	15	Motors	Gears and steel rods	Independent fingers, Adapt to any geometry	Under development
The FLUIDHAND III [30]	Hand and Fingers	8	Fluidic Actuators	Pressurized Fluid	Vibrotactile force feedback	EMG
Prosthetic Arm – SAGA[27]	Elbow and Wrist	5	DC Motors	Cables and Gears	Anatomical Design Approach	EMG
Gas-Actuated Transhumeral Prosthesis[26]	Elbow	21	Pneumatic Actuators	Pressurized Fluid	Half of the force and power of a human arm	Under development
Prosthetic Hand Driven by Shape Memory Alloy Actuators [32]	Hand and Fingers	7	SMA Actuators	Shape Memory Alloys wires	lightweight, multifunctional, silent and cosmetically appealing	EMG
Bebionic Hand [33]	Hand and Fingers	11	DC Motors	Mechanical Links	position sensor to achieve the desired grip pattern	EMG

results. In addition, the existing actuation and power transmission methods have to be developed to meet the requirements towards a perfect prosthetic device. Improvements should be done on under-actuation topologies, artificial muscles and tendons.

To give a better prosthetic handling to the amputee, the number of control inputs has to be increased and more effective pattern recognition methods to extract detailed data from surface EMG signals from the residual muscles have to be invented. Furthermore, the usage of implantable EMG electrodes and the targeted muscle reinnervation also will lead the researchers to get more comfortable with the number of controller inputs available. In addition, mechanomyography (MMG) signals which is the detection of sound produced by contracting muscles and the pressure signals generated due to pressure exerted by the residual limb on the socket are also used as inputs to the control system. With properly developed pattern recognition methods, two or more hybridization of these control methods will ultimately produce a better control method for the prosthetics, which will operate according to the human motion intention.

Electroencephalogram (EEG) signals, which are the measurement of brains spontaneous electrical activity, will also become a control input when used with a proper signal classification mechanism. Furthermore, electrocorticogram (ECoG) signals and spike recordings from the primary motor cortex will also become future trends in prosthetics controlling.

Furthermore, biomechanical energy harvesting methods to harvest energy from body heat and from motions of various parts of the body during walking, such as heel strike; ankle, knee, hip, shoulder, and elbow joint motion; and center of mass vertical motion could be improved to power the prosthetic devices without making the power source and extra burden to the wearer.

Abstract: Previously, we developed a robotic system in collaboration with the Graduate School of Information, Production and Systems, Waseda University, and Shanghai Jiao Tong University. This system, named Ninomiya-kun, can read a book. It is a child-sized humanoid whose head that is equipped with two cameras, and it can communicate with humans via sounds voice and gestures. The image of a printed document, such as a picture book, textbook, or magazine, each of which has a large number of characters, is captured by the cameras, and the characters are extracted from the captured image. Using a built-in computer with character recognition software, the robot translates the extracted characters into spoken words, which are produced by a voice synthesizer. In this paper, we propose a wire-driven robotic hand system for the operation of tablet computers such as the Apple iPad and Sony Tablet, and electronic book readers such as the Amazon Kindle. It has two fingers, each of which has a wire-driven region and a touch pen at the fingertip for operating touch-sensitive panels. We describe the system configuration and wire-driven architecture herein.

Keywords: A wire-driven control, touch-sensitive panel operation, embedded software, robotic hand, two-finger hand

1 INTRODUCTION

Japan has a long and distinguished history of developing robot technologies, and robots reflect certain cultural aspects of Japan. Next-generation robot technologies are expected to be highly advanced; hence, the demand for robots for medical care and living assistance is expected to increase accordingly. Previously, we developed a robotic system in collaboration with the Graduate School of Information, Production and Systems, Waseda University, and Shanghai Jiao Tong University. This system, named Ninomiya-kun, can read a book (Fig.1) [1, 2]. It is a child-sized humanoid whose head is equipped with two cameras, and it can communicate with humans via sounds and gestures [3]. However, it has no legs; hence it cannot move around. The image of a printed document, such as a newspaper, magazine, or catalog, each of which has a large number of words, is captured by the cameras, and the words are extracted from the captured image [5, 6]. Then, the robot reads these words out loud using a voice synthesizer. In addition, it is able to turn the pages of a book. An electronic book reader with a touch-sensitive panel is extremely thin, like a magazine. It is smaller than most paperback books, and it can store hundreds of titles. Moreover, it can potentially revolutionize the struggling newspaper and magazine publishing industry. The objective of the proposed robotic hand system is to operate tablet computers such as the Apple iPad and Sony Tablet, and electronic book readers such as the Amazon Kindle. In this paper, we propose a wire-driven robotic hand system for the operation of tablet computers. It has two fingers, each of which has a wire-driven region and a touch pen at the fingertip for operating touch-sensitive panels of tablet computers. The system consists of three wire-driven actuators (pulse motors), and it is controlled using a personal computer [4, 7]. Some motions of the hand are achieved by embedded software. Each finger consists of three diarthrodial joints. A wire is fastened to each fingertip, and it is driven by each actuator. The fingertips are used for pinch-zoom, tap, and flick operations on a tablet computer in order to read words in a printed document. In this paper, we present the system architecture for realizing flexible wire-driven control, and we describe how the system achieves flexible motions.

Fig. 1. Robotic system Ninomiya-kun

2 SYSTEM STRUCTURE OF NINOMIYA-KUN'S HAND

The robotic system Ninomiya-kun is equipped with a mechanical hand in order to turn the pages of a book. This hand system is driven by a gear, and it has a mechanism of a suction pump for extracting the contents of a page. Figure 2 shows the hand of Ninomiya-kun. Further, a page whose contents are extracted by one hand is turned over, and the page turned over is held with the other hand. However, the following problems are encountered.

1. Unexpected behavior due to transient response.
2. Book damage due to metallic hand operation.
3. In turning a page by the suction pump, we looked like an unique behavior.

Solving these problems will enable us to realize flexible behavior of the robotic hand system.

(a) (b)

Fig. 2. Ninomiya-kun's mechanical hand

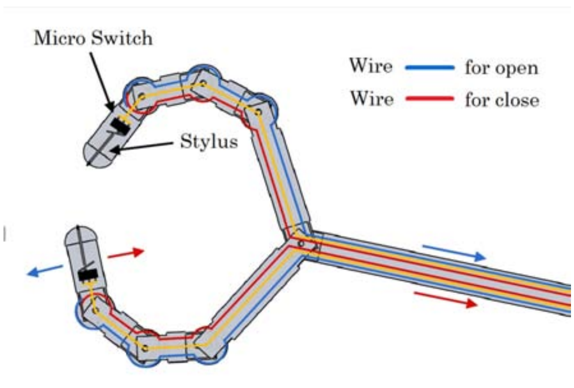

Fig. 3. Wire-driven system used to actuate the hand

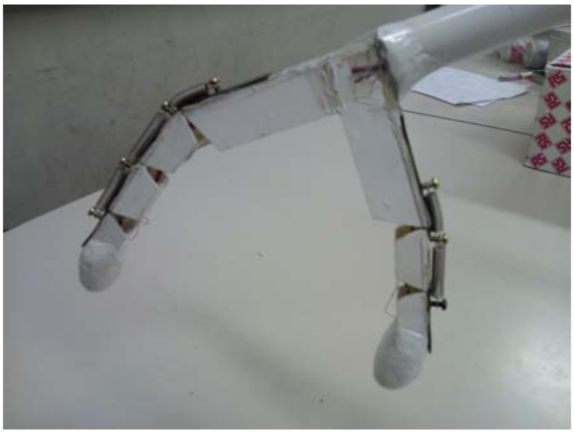

Fig. 4. Test model of wire-driven two-fingered robotic system

3 PROPOSED SYSTEM CONFIGURATION

The two fingers of the robotic hand are operated by two wires through actuators, as shown in Fig. 3. We have focused on designing a wire-driven robotic system [8, 9]. Because its performance is highly dependent on the geometry of the structure, we can easily modify it in order to adapt it to various tasks [10, 11]. The ability to vary the minimal and maximal wire length is crucial because these parameters play an important role in the robot workspace, accuracy, and maximal velocities [12, 13]. This has motivated us to design a coiling system based on an actuator and pulleys. We attempt to realize a system that is made from a plastic material and equipped with a wire-driven two-fingered robotic hand. In the future, this system can be used for operating tablet computers with touch-sensitive panels, such as the Apple iPad. We used a readily available plastic material in order to minimize the weight of the system. Wires were used for operating the fingertips to realize flexible behavior of the robotic hand system. Moreover, such a setup can prevent the positioning error due to gear's backlash . Springs were used for opening and closing the fingers. The test model of the robotic system is shown in Fig. 4.

The developed wire-driven two-fingered robotic system consists of a two-fingered hand, a built-in microcomputer, and a personal computer. Figure 5 shows the system configuration, and Fig. 6 shows its hardware components.

The two-fingered hand has three diarthrodial joints driven by a pulse motor whose rotational speed is defined by the number of the pulses fed by the controlling microcomputer. One extremity of the wire is attached to a fixed point of a fingertip, and from this point, the wire goes alternately to pulleys that are attached to the diarthrodial joints and the finger links. The wire goes from the final pulley of the finger to the actuator. The system is controlled by a personal computer with Linux OS, including electronic circuits that are

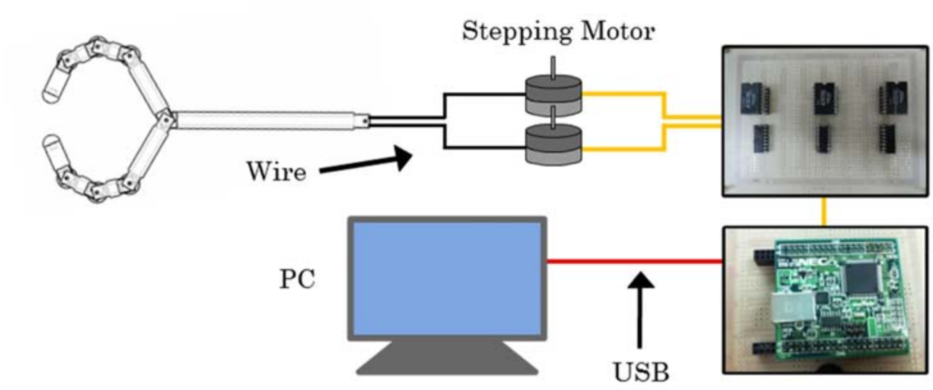

Fig. 5. System configuration

connected to a USB interface.

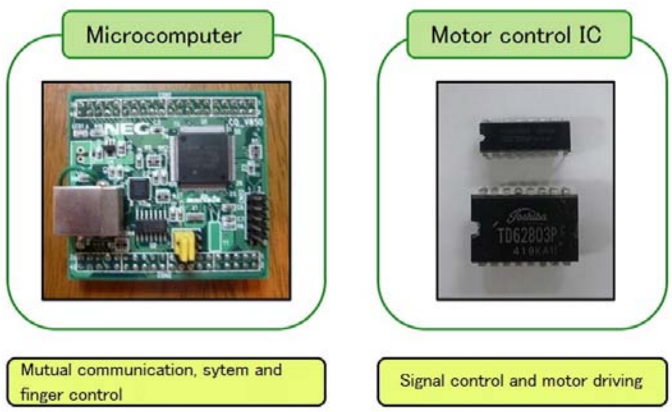

Fig. 6. Hardware components of robotic system

4 EXPERIMENTS

An experiment was conducted using the test model of the robotic system. An iPad and a smartphone placed on a special book stand were operated by the robotic hand. We evaluated the behavior of the driven parts and the system usability for tablet computers. Figure 7 shows a snapshot of the operation. We checked whether the tablet computer could be operated by the motion of the fingers. The following problems were encountered.

1. The finger size is large for operating a tablet computer and a smartphone.
2. The wire-driven mechanism becomes inoperative when the wires break.
3. The restoring force of the springs is insufficient.

5 CONCLUSION

We proposed a wire-driven robotic hand system for the operation of a tablet computer, and we realized a test model made from a plastic material. To evaluate the behavior of the driven parts and the system usability for tablet computers, we devised a strategy based on the light-weight body. This strategy was implemented experimentally using the test model of the two-fingered robotic hand system, and satisfactory results were obtained. Further development of the system is required in order to ensure flexible motion of the fingers. In addition, enhanced behavior of system can be realized by solving the identified problems.

Abstract: In this paper, we propose a novel robotic entertainment system that can read a musical score and sing a song in real time. The objective of this system is to provide on-demand entertainment to onlookers. Previously, we developed a robotic system in collaboration with the Graduate School of Information, Production and Systems, Waseda University, and Shanghai Jiao Tong University. This system, named Ninomiya-kun, can read a book. It is equipped with a camera to read printed material placed on a book stand. In this study, we attempt to realize a robotic system that can sing a song by producing human-like sounds on the basis of notes and words extracted from a music score. Experimental results show that the proposed technique consistently outperforms well-established procedures.

Keywords: Robot vision, entertainment robots, music score recognition, singing robotic system

1 INTRODUCTION

Recently, robotic systems have been enhanced considerably, and they have become an integral part of the manufacturing industry. In addition, robots play an active role in medical care, living assistance, and security. The demand for robots for living assistance is expected to increase with the ongoing development of robotic systems.

Fig. 1. Robotic system Ninomiya-kun

Previously, we developed a robotic system in collaboration with the Graduate School of Information, Production and Systems, Waseda University and Shanghai Jiao Tong University [1, 2]. This system, named Ninomiya-kun (Fig. 1), can read a book. It is a child-sized humanoid that does not have legs; hence, it cannot move around. Further, it is equipped with two cameras for processing visual information and it can communicate with humans via sounds and gestures. It reads text by focusing its camera on printed material, such as a newspaper, magazine, or catalog, which is placed on a special book stand. Using a built-in computer with character recognition software, the robot translates the text into spoken words, which are produced by a voice synthesizer.

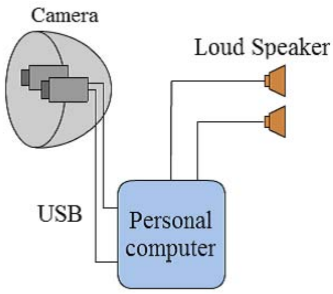

Fig. 2. System configuration of Ninomiya-kun

We have started enhancing Ninomiya-kun with new capabilities, and it must be trained to provide entertainment. It is important for an entertainment system to provide on-demand entertainment to onlookers. Our objective is to develop a robotic system that can read a musical score and sing a song in real time. We attempt to realize a system that can capture a printed music score using the camera installed in its the head, and sing a song by producing human-like sounds on the basis of the notes and words extracted from the captured music score[3, 4]. The input image should be properly processed for the successful recognition of the music score. In the first part of this paper, we discuss an image preprocessing technique for detecting musical notes, and we evaluate its performance. In the second part of this paper, we propose an adaptive technique for recognizing musical notes in order to deal with notes that belong to the same pitch class. Ex-

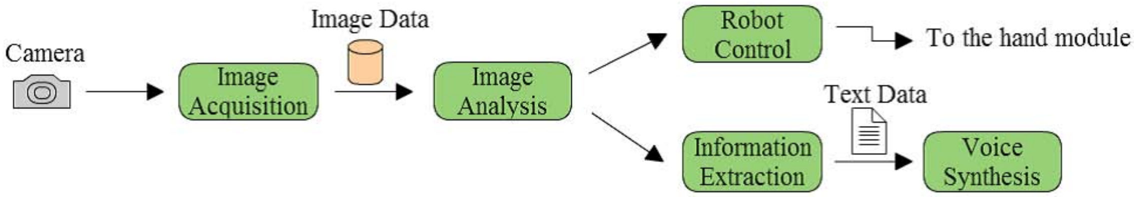

Fig. 3. Structure of the software system

perimental results indicate excellent music score recognition performance.

2 SYSTEM CONFIGURATION

The proposed robotic system has a backpack that consists of three units: a personal computer unit, an image acquisition unit, and a loudspeaker unit, i.e., an electro-acoustic transducer that produces sounds on the basis of the text that is translated into spoken words[11]. It has two hands that are driven by servomotors, enabling it to open a book and turn its pages; the rotational speed and angles of the hands are determined by the personal computer unit. Its head is equipped with two cameras as visual sensors. The video signals recorded by the cameras are transferred to the personal computer unit through the image acquisition unit, which provides high-resolution digitized images. The system configuration is shown in Fig. 2 [12, 13].

3 SOFTWARE CONFIGURATION

In this section, we describe an image processing technique for extracting notes and lyrics from printed music scores. A staff, or stave, is a set of five horizontal lines and four spaces, each of which represents a different musical pitch; it provides important information for musicians. As shown in Fig. 3, the software for the proposed robotic system consists of five modules: the image acquisition module, the image analysis module, the information extraction module, the voice synthesis module, and the robot control module. The image acquisition module captures a score using the camera and the image acquisition unit connected to the personal computer; then, this module performs image strain compensation and image binarization. Next, the image analysis module receives the binarized image and extracts the position of the staff. In the information extraction module, the pitch class of each note (C, C# , D etc.) is determined by the staff position information; in addition, it is determined whether the relative duration of each note is based on the ordering of sounds on a frequency-related scale. Simultaneously, the lyrics that are printed below the staff are extracted in this module. Accordingly, the voice synthesizer in the voice synthesis module produces human-like sounds; when required, requests for a rest period, i.e., is an interval of silence, are sent to the voice synthesis module by the information extraction module [5, 6].

4 EXTRACTION OF HEAD AND STEM

In an automatic music score recognition system, it is very important to extract the heads and stems of notes because these are the most ubiquitous and musically relevant symbols in a score [7, 8]. The objective of the system is to extract note heads quickly and accurately. It acquires the music score continuously in order to extract the heads and stems. In this study, we emphasize on the developmental aspect of the robotic system; hence, we employ a simple score with no chords. Initially, the camera is focused on the beginning of a score, and the score is continuously captured until a rest period is requested. Figure 4 shows the score that is used as a target. The image area that includes the candidates for heads and stems is extracted [9].

Fig. 4. Simple music score with no chords

The image area that includes the candidates for heads and stems is extracted. In order to extract the heads and stems, the stave is extracted by calculating the horizontal histogram of the music score, and the candidates for the areas with the lyrics are detected (Fig. 5). The black elliptical parts of the notes are the note heads; they indicate the note value (i.e., rhythmic duration), and they are extracted according to the relative position in the staff. The height of the head is equal to the interval between the lines in the staff, and the width of the head is 1.2 times its height. A template image is generated for heads whose height is less than the interval between the lines [10]. This template is compared with the overlapped image areas, while the detected stave is erased from the image (Fig. 6). The pitches of the notes are determined according to the position of the extracted heads. In the next step, stems, flags, and accidental notations are detected by template matching.

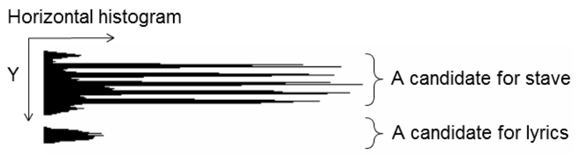

Fig. 5. Histogram of the music score

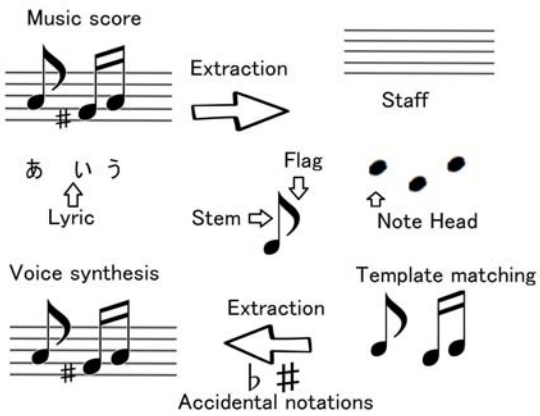

Fig. 6. Procedure for detecting notes

5 EXPERIMENTS

An experiment was conducted using the robotic system Ninomiya-kun. A captured music score is shown in Fig. 7. The robot extracted lyrics and music notes by focusing its camera on a printed music score placed on a special music stand. Fig. 8 (a) shows the recognition process; its side view is shown in Fig. 8 (b). The experiment was conducted as follows. Two music scores were used. One was "Kimigayo,"the national anthem of Japan; it is a short composition. The other was a 30-s extract from "Happiness," a song by the Japanese group Arashi. We used two scores in order to check whether the system is able to sing all the lyrics of different music scores. Figure 9 shows the staff extracted by calculating the histogram of "Kimigayo"; it was extracted with high accuracy. The accuracy of staff extraction from other music scores is more or less the same. The notes in the music scores "Kimigayo" and "Happiness" were detected by the template matching procedure, as shown in Fig. 10. The detected note heads are denoted by red boxes. However, the half notes were not detected, as shown in Fig. 10. A half note is a note having a white elliptical head. The template matching procedure fails to recognize a white note head that should be recognized because the pixel size of the elliptical part is different from that of the template image. We plan to devise ways to improve the accuracy off half notes detection.

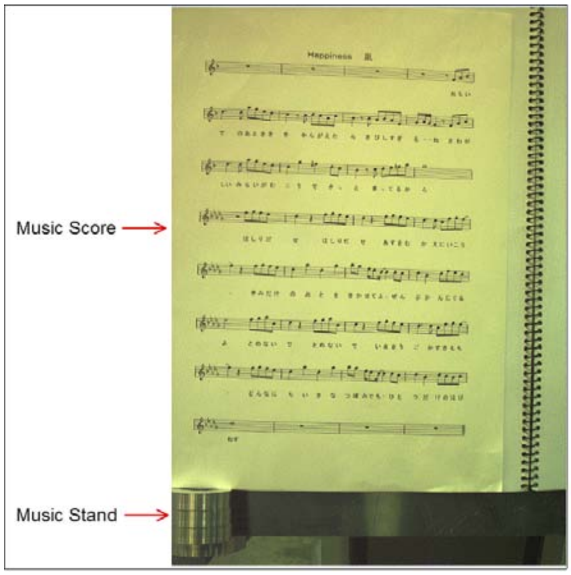

Fig. 7. Music score captured by Ninomiya-kun

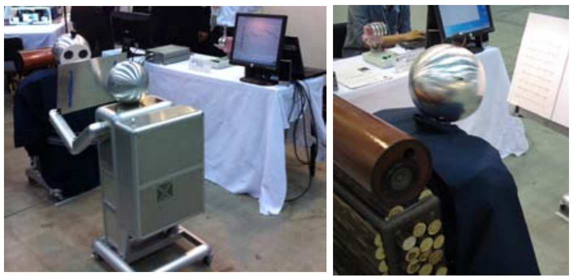

(a) (b)

Fig. 8. Ninomiya-kun extracting lyrics and music notes

6 CONCLUSION

We proposed a novel robotic entertainment system that can extract notes from printed music scores using solely visual information. To realize the recognition of simple music scores, we devised a strategy based on image processing. This strategy was evaluated experimentally using the robotic system Ninomiya-kun, and satisfactory results were obtained. Further development of the software is required in order to realize the recognition of more complex music

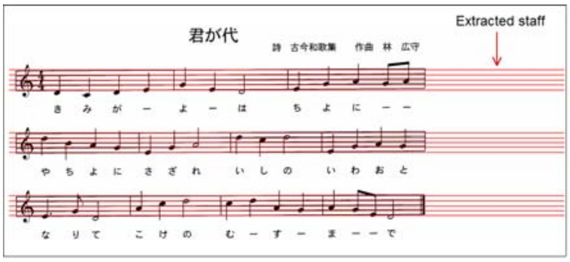

Fig. 9. Extracted staff in "Kimigayo"

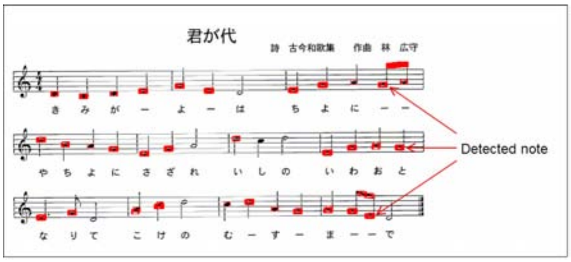

Fig. 10. Detected notes in "Kimigayo"

scores; investigation to this end is currently underway. In addition, a comprehensive evaluation of the recognition procedure remains to be established [14].

Abstract: This paper presents a robotic system in which a robot reads a printed document in Japanese. Currently, Apple's iPad, Amazon's Kindle, Sony Table, and other electronic book readers, are stimulating the electronic book market. These are, essentially smaller versions of personal computers and can be used to send emails, watch movies, or play games. In cooperation with Waseda University Graduate School and Shanghai Jiao Tong University, we have developed a robotic system called Ninomiya-kun that has the ability to read a book. This robotic system is the size of a child and has an appearance resembling a human being. The robot is equipped with two cameras as part of a visual information processing mechanism and can communicate with humans via voice and gestures. It automatically extracts character areas that contain Japanese characters, which are recognized using character recognition procedures. The system configuration is described, as well as the Japanese character recognition procedures performed by the robot. The experimental results are also discussed.

Keywords: Robot vision, entertainment robots, music score recognition, singing robotic system

1 INTRODUCTION

In fictional stories such as movies and cartoons, domestic robots are commonly used to assist humans; for example, Doraemon, a cat-like robot from the future, helps children fulfill their dreams using various secret devices. In a typical episode of this cartoon, whenever the central character becomes a target of bullying or fails in something, Doraemon uses unique technological devices from his belly pouch to help him. In the same way, robots will be working in offices, factories, and homes in the near future.

In 2004, a group of doctors suggested that parents limit their children's contact with TV and computer games. They claimed that TV and computer games reduced children's time for playing outside with their friends and having conversations with their families. They also recommended that parents read picture books to their children. Working in conjunction with Waseda University Graduate School and Shanghai Jiao Tong University, we have jointly developed a robotic system called Ninomiya-kun that can read a book (Fig. 1) [1, 2]. This robotic system is equipped with two cameras on the head and is able to communicate with humans via voice and gestures. It has an appearance that resembles a human being. The image of a printed document such as a picture book, textbook, or magazine, each of which has a large number of characters, is captured with the camera placed on the head, and the characters are extracted from the captured image.

Character recognition software in the robot translates

Fig. 1. Robotic system Ninomiya-kun

these characters into spoken words, which are produced using a voice synthesizer. We have already proposed a book reading robotic system, Ninomiya-kun, by training its TV camera. This system could be applied to reads a book out loud for children or a visually impaired person. In the parents' stead, the proposed system can be used to read picture books to their children. This robotic system automatically extracts areas with Japanese characters, which are recognized by the character recognition application software. It has a character dictionary with a layered structure that has the ability to recognize over 2,000 kanji, hiragana, and katakana characters and can currently read elementary texts. This paper describes the method for segmenting a sentence into Japanese kanji, hiragana, and katakana characters from the image data and retrieving them from the dictionary [3]. The proposed technique can be applied to read printed documents out loud using tablet computers such as Apple's iPad, Amazon's Kindle, Sony Table, or other electronic book readers. In the following, the system configuration is introduced, followed by the procedures for the Japanese character recognition. The experimental results are also discussed.

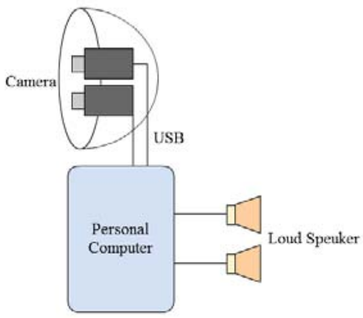

Fig. 2. System configuration of Ninomiya-kun

2 SYSTEM CONFIGURATION

The system configuration of Ninomiya-kun is shown in Fig. 2. This robotic system has three units in the robot's backpack: a personal computer unit, an image capture unit, and a loudspeaker unit, which is an electro-acoustic transducer that produces sound in response to the texts that are translated into spoken words. It has two hands that are driven by servomotors that are used to open a book and turn a page; the rotational speed and angles of the servomotors are given by the controlling personal computer unit [4]. Two cameras on the robots's head are used as visual sensors. The video signals from the cameras are transferred to the personal computer unit through an image acquisition interface unit, which provides digitized images at high resolution [6].

Processing a document to extract its content in an automated fashion is the essential task of this system. The following software modules are used to process a document, as depicted in Fig. 3.

1. The image acquisition module captures a document's image using the camera and the image acquisition unit attached to the personal computer and performs a binarization process on the image.

2. The image analysis module then extracts distinctive characteristics from the document being processed.

3. The information extraction module is a classification stage that identifies the characters and groups them according to certain classes.

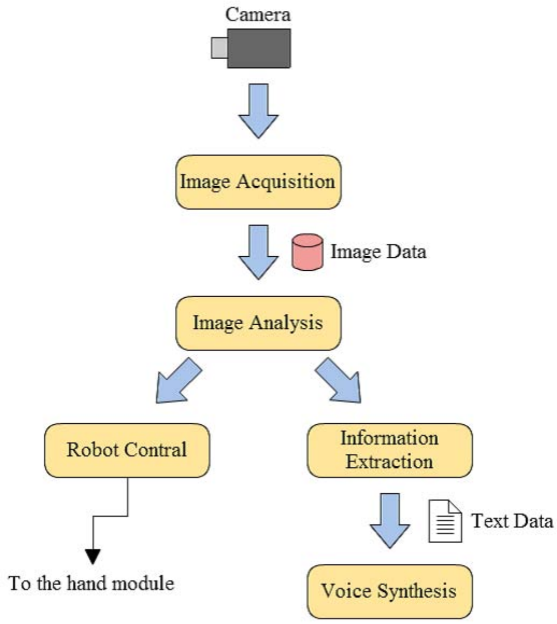

Fig. 3. Structure of software system

4. The voice synthesis module reproduces human voices using a voice synthesizer.

5. The robot control module controls the posture of two cameras and drives the servomotors for the two hands.

3 CHARACTER SEGMENTATION FROM A PRINTED DOCUMENT

This section provides an outline of the image processing and analysis for the character segmentation from the image captured by the camera [7, 8]. Real-time recognition is realized by recognizing the document when the robot opens it and turns a page. However, the recognition depends on an algorithm and the speed of the computer. No delay is caused in the task of reading the document out loud because the character segmentation is carried out in the background. The system needs be fast enough to keep up with this reading task.

3.1 Distortion correction and image processing

Off-line character recognition uses a scanned image. The proposed system uses an image captured by the robot equipped with the camera. When the captured image is used as an input image, there are two differences from the image scanned with a scanner.

1. Image distortion: The image scanned with a scanner has no distorted characters, whereas the image captured by the camera has numerous distorted characters in many cases.

2. Image resolution: The number of pixels that is assigned to a character in the image captured from the camera is considerably smaller than that assigned to a character in the considerably as image from the scanner.

The character recognition algorithm needs to recognize an input image with low resolution. The character distortion must be detected and corrected. Before the correction of a distorted character, an input image is digitized. The digitized image is divided into eight domains, and the histogram for these domains are calculated (Fig. 4).

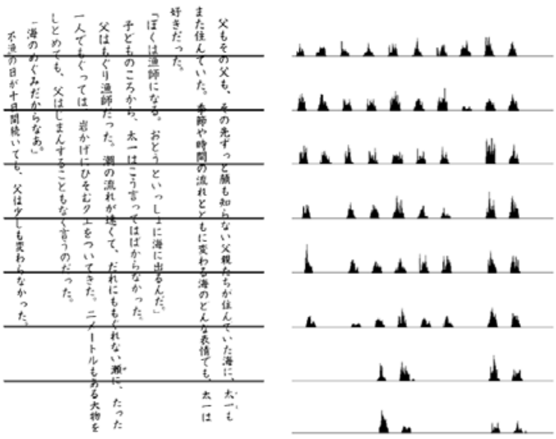

Fig. 4. Divided image and histogram

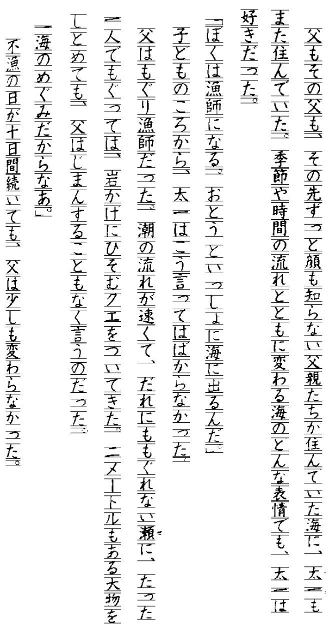

Fig. 5. Results for correction of distorted image

The inclination is calculated by using the histogram of a neighboring domain. In an image without inclination, we focus on the matching in the peak and trough positions in the histogram of the domain. With this matching, one side of the histogram of two neighboring domains is moved from side to side. The position that best matches the peak and trough in the histogram is calculated. The results of this correction are shown in Fig. 5.

3.2 Character segmentation

Next, the procedure for segmenting a character from an input image is described. The segmentation of a character is performed for every other line or column. One line is segmented out, and the segmenting candidate position of the character is calculated from the histogram of the line (Fig. 6 (a)). In the next procedure, the segmented characters merge sequentially from the top character. As an example, we take a case where two segmenting candidate characters are merged. If the length to width ratio is 1:1.2 or less, two candidate characters are merged. The merged case is shown in Fig. 6 (b) and (c). Another case is shown in Fig. 6 (d) and (e).

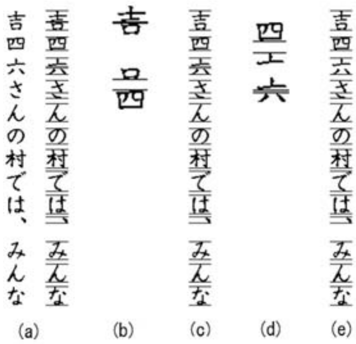

Fig. 6. Merging of two candidate characters

3.3 Feature vector detection

The features for every segmented character are calculated and compared with the system dictionary. The segmented characters differ in size. The outline box of a character is calculated and the size is normalized to 64 × 64 pixels. The directional element feature, which determines the amount of directional change in the outline, is used as a recognition feature. The outline pixels that match four directional changes are detected (Fig. 7).

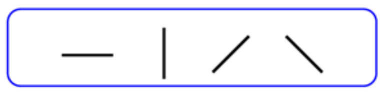

Fig. 7. Four directional changes

An outline from the normalized image is calculated, and 12 kinds of 3 × 3 pixel masked images are used to extract the directional change in the outline (Fig. 8). The mask and outline pixels are measured, and the directional change is given to the outline pixel that matches the mask. The directional change is then compared with the feature vectors stored in the dictionary.

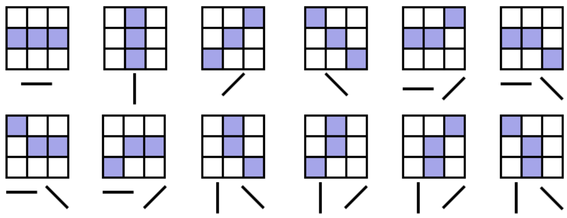

Fig. 8. 12 kinds of masked images

4 EXPERIMENTAL RESULT

An experiment was conducted using the robotic system Ninomiya-kun. A captured document and the character segmentation results are shown in Fig. 9. A portion of the recognition results is shown in Fig. 10. In the experimental results, for a document with 262 characters, 244 characters were correctly recognized.

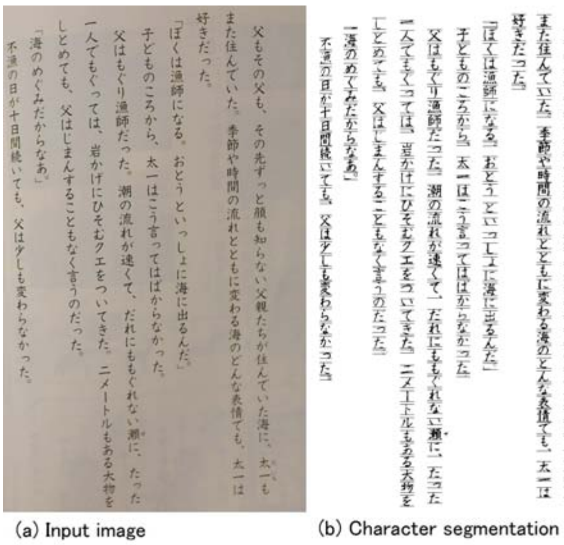

Fig. 9. Input image and character segmentation

5 CONCLUSION

We described a novel robotic entertainment system that can recognize Japanese characters from the a printed document. This system can recognize a printed document with nearly ninety percent accuracy. However, the recognition of a document printed with multiple letter types is difficult. The recognition accuracy is also greatly influenced by the lighting. The system needs to be further developed to improve the recognition accuracy for multiple letter types and the influence of lighting, which are now under investigation [9].

Abstract: This paper describes the design and implementation of an eye-gesture controlled electric wheelchair using the technique of Electro-Oculography. This is designed to be used as an intelligent mobility aid for the paralyzed which has features such as tilt detection, obstacle sensing, avoidance and path re-routing. The design employs an embedded control module that processes the bio-electric signals generated by the eye movements to actuate real world events. A microcontroller is used in place of a laptop computer, as the decision making entity, thereby making this an affordable solution. Various safety features are integrated using the control module to make a robust and optimized model.

Keywords: Electro-oculography, eye-gaze tracking, obstacle detection, paralysis, path re-routing, wheelchair

1 INTRODUCTION

Victims of severe paralysis, amputees and other physically challenged are unfairly deprived of an acceptable standard of life. Spinal cord injuries (SCI) and Progressive Motor Neuron Diseases (PMND) could cause a condition known as Quadriplegia which leads to loss of muscle functionality below the neck due to which the subjects are constantly dependant on others for their mobility. In such cases, ocular control is either not affected or affected last. Keeping in mind these constraints in muscle control and disease progression, a cost effective solution is developed in order to assure victims of paralysis a greater degree of independence and better quality of life. The idea involves the design and implementation of an eye-gesture controlled electric wheelchair using the bio-medical technique of Electro-Oculography (EOG).

Of the several methods exist to detect eye-gestures, the physiologies of EOG are better understood. It is simpler to complete the acquisition, feature extraction and analysis of EOG signals [2]. Therefore, EOG based approach is more suited for this application in terms of dependability, accuracy and cost.

Several designs of an EOG based wheelchair have been proposed [3,4]. These designs make use of a laptop computer as the processing and control centre. Other systems that do not employ a laptop have also been proposed but such methods lack intelligence in terms of the systems' awareness of the environment. This paper proposes a modular design of an EOG based Human-Wheelchair interface which incorporates an obstacle detection, avoidance and path re-routing algorithm for reliable navigation using simple and effective ultrasonic range sensors to acquire sensorial information from the ambiance for reliable navigation. Integration of tilt detection into the algorithm is also imperative in order to address the problem of the assembly toppling over at a critical tilt point considering the fact that the user may need to manoeuvre through uneven terrain.

Since the target group comprises of those who require constant medical supervision, Patient Health Monitoring Systems become an indispensable part of the mobility aid. This makes for a well-rounded, complete system that not only assists the user in safe, collision-free mobility but also keeps track of his/her vital statistics, generates alerts and notifications which effect arrival of timely medical attention when required. The intelligence algorithm along with Patient health Monitoring Systems seek to achieve increased reliability and safety.

2 DESIGN AND IMPLEMENTATION

This paper presents an EOG based wheelchair with active collision avoidance and tilt detection. The system architecture has four major parts:

(2.1) EOG signal acquisition
(2.2) Signal conditioning module
(2.3) Wheelchair mechatronics and sensor system
(2.4) Control module and Intelligence Algorithm

Fig. 1 shows the proposed system architecture, and these major parts are illustrated as follows.

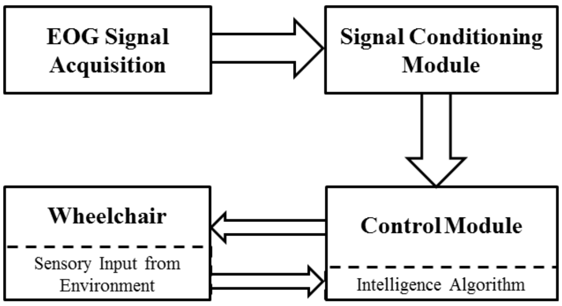

Fig. 1: System Architecture

2.1 EOG Signal Acquisition

Electrooculography (EOG/E.O.G.) is a technique for measuring the resting potential of the retina. The resulting signal is called the electro-oculogram. The main applications are in ophthalmological diagnosis and in recording eye movements. The eye, a seat of resting potential, acts as a dipole in which the anterior pole (cornea of the eye) is positive and the posterior pole (retina of the eye) is negative. This difference in potential can be explained by the metabolic activities in the eye which can be measured by means of EOG. The EOG signal has a magnitude in the range of 100µV to 1000µV with a frequency range of 0 to 30Hz [4].

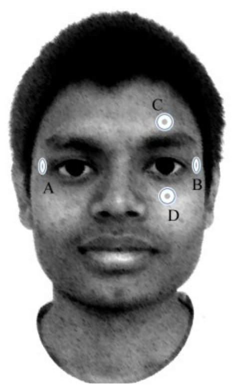

Fig. 2: Electrode Placement

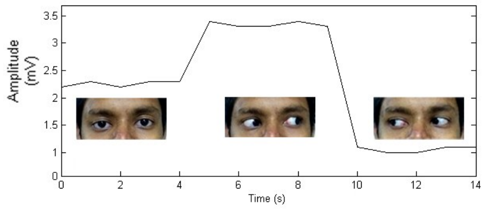

Fig. 3: EOG Horizontal Differential Signal

Silver-Silver Chloride (Ag-AgCl) electrodes are placed on the corners (lateral canthi) of both the eyes to capture the change in EOG signal for lateral eye motion. When the subject’s gaze is to the left, the positive end of the dipole the eye comes closer to the electrode on the left canthus and the negative end to the right canthus.

The vice-versa is observed for the eyes looking towards the right. This is portrayed in Figure 3. In a similar manner, electrodes placed above and below the eyes of the subject can be used to record change in EOG signal for eye-ball motion in the vertical direction (Figure 4). Ideally the difference in potential should be proportional to the sine of the angle the eye produces with respect to the central axis.

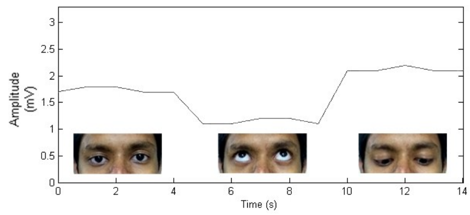

Fig. 4: EOG Vertical Differential Signal

2.2 Signal Conditioning Module

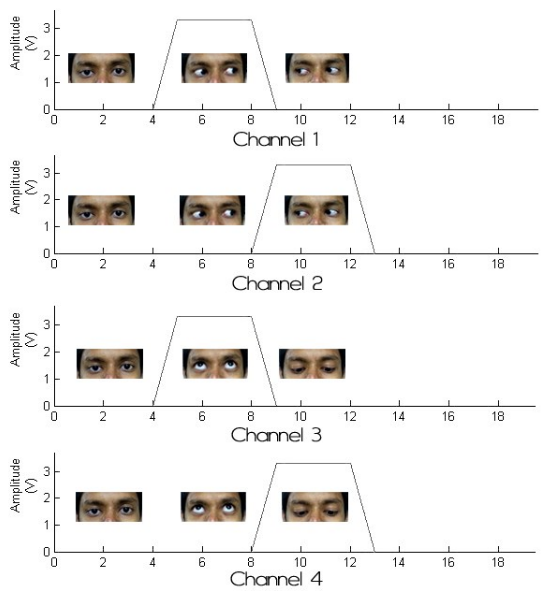

Fig. 5: Digital Input to Microcontroller

The EOG signal is a low voltage range bio-potential signal which can be easily corrupted by noise in the ambiance. It therefore is passed through a signal conditioning module to extract the horizontal and vertical gaze direction.

The signal processing module consists of amplification in two stages using instrumentation amplifiers (AD620) with a gain of 100 and 10 respectively. Noise is cancelled out using a low pass filter of cut off frequency 30Hz. The DC drift is removed using a high pass filter of cut-off frequency 0.16 Hz. A divider circuit is used using high-speed switching diodes and op-amps in inverting and non-inverting stages to achieve four separate channels of signal, one each for up, down, left and right [4].

Therefore eye gaze direction will be detected as a pulse which can be effectively considered a digital HIGH. The absence of such a pulse can be considered a digital LOW. This in effect renders the use of an Analog to Digital converter unnecessary. The output of the signal conditioning module is shown in figure 5.

2.3 Wheelchair and Sensory Input from Environment

The eye-gaze direction and speed control directives form the wheelchair motion commands that are generated by the EOG and signal processing modules are supplied to the microcontroller.

In most cases, an inconsistency exists between the goal direction and the direction of the wheelchair. This is caused due to the presence of obstacles in the motion path and the inability of the driver to navigate past them. Therefore, ultrasonic obstacle detection sensors are strategically placed on the wheelchair body, as shown in figure 6, to sense obstacles and thus aid in manoeuvring around them.

The sensory information is then sent to a microcontroller in the wheelchair which has an obstacle avoidance algorithm programmed. The final decision made by the microcontroller by a combination of eye- commands and sensory input is then sent to the DC motor drives.

As mentioned earlier, the speed of the wheelchair is set based on vertical eye-gaze. Pulse width modulation (PWM) technique is used to change and control the speed of the motors. The PWM signal is generated by the microcontroller placed on the wheelchair.

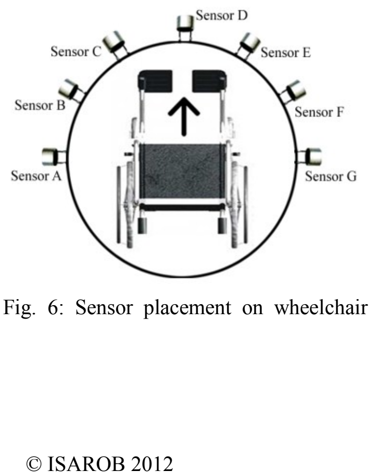

Fig. 6: Sensor placement on wheelchair

PID controllers are used to achieve linear and hence smoother turns.

2.4 Control Module and Intelligence Algorithm

The control module is split into two parts, the User Instruction Processor (UIP) and the Drive Control Module (DCM), each with its own microcontroller. Full duplex wireless communication exists between the two processors.

The microcontroller on the UIP accepts four-channel digital input from the divider module. It can be inferred from figure 5 that a digital HIGH pulse cannot be detected simultaneously in channels 1 and 2 (horizontal) or channels 3 and 4 (vertical). But a combination of horizontal and vertical motion can be detected along with pure horizontal or vertical gestures. This directly implies the UIPs capability of detecting 8 different positions of the eye ball. These various gestures can be used individually or as a combination of two or more, to generate simple or complex patterns.

Let up, down, right and left gaze directions correspond to North (N), South (S), East (E) and West (W) respectively and no pulse correspond to C (for centre). Simple eye gestures such N, S, E and W can be used to perform functions that need immediate execution such as stopping/braking and turning. For example, if the UIP receives a W signal, it makes the drive control decision that will cause a left turn. Similarly, a right turn is executed for E. Most importantly the wheelchair can be stopped/braked immediately for an S pulse. This allows immediate addressing of a user generated braking command.

A sequence of gestures that use combinations such as NW, NE, SW and SE along with N, S, E and W can be used to perform other functions that do not require quick response from the system. For instance, an N pulse followed by NE can be used to increase wheelchair speed and an N pulse followed by NW can be used to reduce wheelchair speed. This method of speed control can be pictured as sliding along a horizontal speed control bar. Also, powering on the system can be done using the following sequence: N-NE-E-SE-S-SW-W-NW-N-C. This pattern resembles a power button on any common household device. Drive control using such patterns are very intuitive and therefore make wheelchair control easy to learn and execute.

A Patient Health Monitoring system is interfaced to the UIP microcontroller which handles patient health stats data as a secondary function. Health monitoring systems are an integral part of the system since members of the target group sometimes require continuous medical supervision.

The drive control decisions made by the UIP are first encoded and then communicated to the DCM wirelessly. Wireless transmission is used to reduce wire clutter and increase modularity of the design. The DCM uses these decisions and sensory input data from the ultrasonic sensors placed on the wheelchair to make the final drive control decision using the intelligence algorithm that resides in the DCM microcontroller.

The intelligence algorithm works on the principle that the drive control decisions made by the UIP are always followed by the wheelchair until an obstacle is detected. Until such a time, the intelligence algorithm works in a transparent mode. The moment an obstacle is sensed by the ultrasonic sensors, the wheelchair is stopped immediately. Let us consider two cases: stationary obstacle and a moving obstacle.

In the case of a stationary obstacle, the wheelchair is firstly stopped. The outputs of all the sensors remain the same as the instant when the wheelchair was stopped even after some time has elapsed. The intelligence algorithm takes the constancy of the sensor outputs to classify the obstacle as stationary. The system now switches to the wall follower mode and generates an auditory alert, a beep for instance that notifies the user of the need for a "wall-follower direction" and remains in a wait state. In the wall follower mode, wheelchair speed control is not necessary and therefore the corresponding control gestures can be used to input wall-follower direction i.e., N followed by NW for left and N followed NE for right. Once the user inputs the desired direction of motion, the wheelchair turns toward the specified direction and navigates around the obstacle in the wall follower mode. To keep the wheelchair in this mode the user looks straight forward (C signal). In case the user needs to break away from the obstacle at any chosen time, he looks away from the obstacle, to the right or left, thus producing a W or E signal respectively which causes the wheelchair to turn away in that direction. This effectively aids the user in navigating around any stationary obstacle and also gives him/her maximum possible control.

A special case of a stationary obstacle is a dead-end. For the system to recognize a dead-end, the minimum requirement is that sensors B, C, D, E and F (figure 6) all output digital high at the same time. In such a situation, the only option of navigation is motion in reverse. Since wheelchair motion in reverse is not advisable for safety reasons, this obstacle is handled by making the wheelchair execute a 180° turn on the spot. Now the control is handed back to the user for further commandeering.

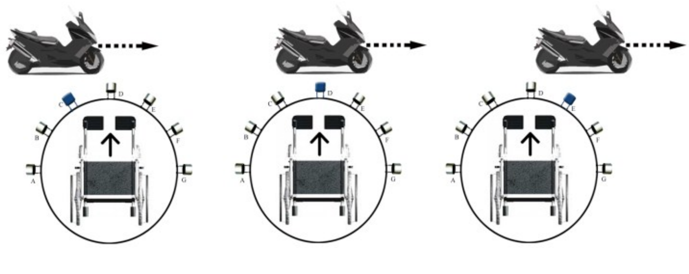

Fig. 7: Moving Obstacle

Now, let us consider a moving obstacle. When an obstacle is detected the wheelchair is immediately halted. The DCM waits to check if the sensor outputs remain the same even after some predefined time period. In this case the sensor outputs do not remain constant but change as the obstacle moves by. In figure 7, when the moving obstacle is first detected sensor C generates a digital HIGH signal as the obstacle is within its pre-set minimum distance. Then the obstacle moves to the right eliciting an active high from sensors D and E sequentially. The intelligence algorithm classifies such an obstacle that causes changing sensor output to be a moving obstacle. In such a case, the wheelchair is halted until the obstacle is beyond the minimum distance setting of all the sensors and is then allowed to move.

A gyroscope is interfaced with the DCM for wheelchair tilt detection. When the user drives through uneven terrain or on a ramp, there is a possibility of the wheelchair toppling over at a critical tilt point. The gyroscope is used to detect tilt angle which is supplied to the DCM microcontroller for processing. When the wheelchair reaches a predefined safe tilt limit, an auditory alert is generated warning the user of the imminent danger of toppling over so as to enable him to take corrective measures and the UIP is informed of this safe tilt limit breach wirelessly.

A GSM modem is also interfaced to the UIP. When the user cannot manoeuver through a region without external help due to excessive tilt or in case the wheelchair has toppled over, an alert in sent via text message to a pre-selected individual who can come to the user's aid. The same can be done to alert the user's doctor/nurse when the Health Monitoring system indicates that the user is in need of medical attention.

The complete functional block diagram of this design is illustrated in Figure 8.

3 PROPOSED MODEL

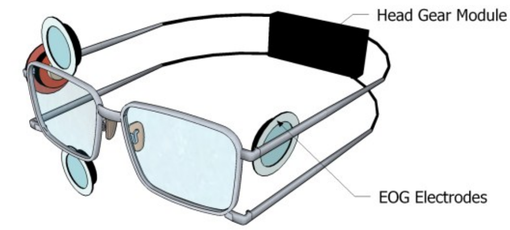

Figure 9: Proposed Head Gear

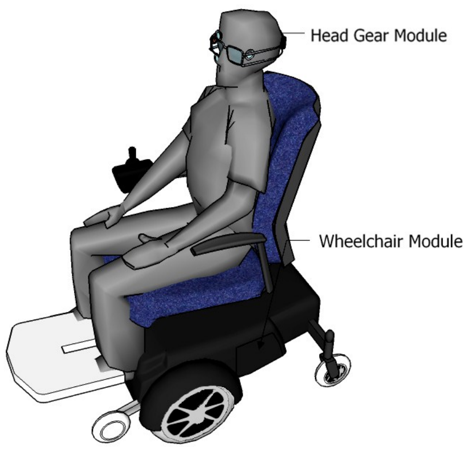

Figure 10: Proposed Wheelchair

4 CONCLUSION

This paper presents a method of eye gesture based wheelchair control using Electro-Oculography. User commands for wheelchair control are obtained from the EOG signal using the signal conditioning module. The extracted commands are processed through the intelligence algorithm that also takes into account ambient obstacle proximity detected by the wheelchair ultrasonic sensors to generate improved collision free drive control. This wheelchair is designed to be an intuitive and cost effective control method. A proof of concept has been successfully developed where the direction of motion of a wireless robot has been controlled using eye gestures (figure 11).

Abstract: This paper presents a novel pattern matching technique for motion estimation and visual tracking under varying illuminations, including a large amount of occlusions. To cope with the illumination problem, we previously proposed a matching technique using gradient orientation information, called gradient orientation pattern matching technique. Unlike conventional image features such as intensities and gradients, gradient orientations are known to be robust to illumination changes. In this paper, we introduce the Hamming distance to the gradient orientation pattern matching as a new similarity metric. Simulation results show that the new proposed method is robust to both illumination changes and a large amount of occlusions compared with existing matching techniques.

Keywords: gradient orientation pattern matching, hamming distance, object tracking, occlusion, template matching

1 INTRODUCTION

The purpose of this paper is to establish the novel pattern matching technique for motion estimation and visual tracking under varying illumination and partial occlusion scenarios. Various object tracking techniques have been proposed in the literature [1]. Most of them assume that illuminations are constant and occlusions are marginal, which does not always hold in real situations. To deal with the illumination variation problem, we previously proposed a matching technique using gradient orientation information, called gradient orientation pattern matching technique (GOPM) [2][3].

Unlike conventional image features such as intensities and gradients, gradient orientation information is far more independent of illumination changes over time. Generally, gradient orientation is extracted from image intensities using the trigonometric functions $\theta = arctan(I_y/I_x)$, where I_x and I_y are partial derivative of the intensity in x and y directions. This trigonometric function is slow and undesirable in the hardware implementation. GOPM technique has exhibited an alternative approach of utilizing unit gradient vectors (UGVs) to avoid the trigonometric function [3]. The efficiency of the matching method on decomposed unit gradient vectors is identical to the matching on the angular values but the calculation is reduced. We have examined it by implementing the technique on a real-time eye tracking [4][5].

For the GOPM, we can employ any traditional similarity metric, such as the sum-of-absolute differences (SAD), the sum-of-squared differences (SSD), zero-mean normalized cross-correlation (ZNCC) and so on. In this paper, we introduce the Hamming distance (HD) to the GOPM as a new similarity metric. The HD is considered robust to the occlusion problem because it is concerned with the number of pixels that match (or do not match) rather than paying attention to the differences between images. For quantitative evaluations, we have created three artificial image sequences using three still images and simulate illumination changes and occlusions in the similar fashion as in [2] and [3]. Furthermore, the new proposed technique has been examined on real video sequences and compares its efficiency over the other matching techniques. Simulation results show that the new proposed method is robust to both illumination changes and a large amount of occlusions compared with existing matching techniques.

2 MATCHING METHODS

2.1 Gradient Orientation Pattern Matching (GOPM)

The method decomposes orthogonal components of unit gradient vectors (UGVs) and performs similarity measurement on x and y gradient component separately. The UGVs could be obtained though the following normalized equations (Eq.(1))

$$\begin{aligned} n_x(x,y) &= I_x(x,y)/\sqrt{I_x^2(x,y)+I_y^2(x,y)+\epsilon} \\ n_y(x,y) &= I_y(x,y)/\sqrt{I_x^2(x,y)+I_y^2(x,y)+\epsilon} \end{aligned} \tag{1}$$

where I_x and I_y are gradient in x and y direction. The ϵ is a small constant added to prevent zero-division during normalization.

Using the unit gradient vectors obtained above, the best matching position is searched for with a full search strategy. In previous work, the similarity metric of GOPM are based on sum-of-absolute difference (SAD) [2] and sum-of-square difference (SSD) [5]. The SSDs for unit gradient vectors are expressed in Eqs. (2) and (3).

$$SSD\_n_x = \sum_{i=1}^{N}\sum_{j=1}^{N}(n_{x1}(x+i,y+j) - n_{x2}(i,j))^2 \quad (2)$$

$$SSD\_n_y = \sum_{j=1}^{N}\sum_{i=1}^{N}(n_{y1}(x+i,y+j) - n_{y2}(i,j))^2 \quad (3)$$

where SSD_n_x and SSD_n_y are results of similarity metric between UGVs of sample image and template at position (x,y). Note that *N* is the block size of matching, n_{x1} and n_{y1} are UGVs of sample image, and n_{x2} and n_{y2} are UGVs of template. The gradient orientation pattern matching (GOPM) is then given by Eq. (4).

$$GOPM(\vec{p},\vec{d}) = SSD\_n_x + SSD\_n_y \quad (4)$$

2.2 Hamming Distance based Gradient Orientation Pattern Matching

In this research, we introduce the Hamming distance (HD) as a new similarity metric of GOPM instead of SSD. General description of HD metric is defined by Eq. (5).

$$HD(x,y) = \sum_{i=1}^{N}\sum_{j=1}^{N} I_1(x+i,y+j) \oplus I_2(i,j) \quad (5)$$

where I_1 is intensity of sample image at position (x,y) and I_2 is intensity of template. Generally HD compares 2 corresponding binary pixels by exclusive OR operator. The technique is widely used in VHDL and Iris recognition [6]. HD concerns the number of pixels that match rather than overall differences and yields better results in occlusion scenarios. To apply HD with non-binary information such as intensities or gradient orientations, the exclusive OR operation would be represented by threshold absolute difference [7].

$$sim(I_1, I_2, (x,y)) = \delta(|I_1(x,y) - I_2(x,y)| > p) \quad (6)$$

Thus, we could derive the Hamming distance of gradient orientations by Eqs. (7) and (8).

$$HD\_n_x(x,y) = \sum_{i=1}^{N}\sum_{j=1}^{N}\delta(|n_{x1} - n_{x2}| > \tau_1) \quad (7)$$

$$HD\_n_y(x,y) = \sum_{i=1}^{N}\sum_{j=1}^{N}\delta(|n_{y1} - n_{y2}| > \tau_2) \quad (8)$$

where τ_1 and τ_2 are certain thresholds. The differences those are higher than thresholds yields distance 1 and 0 in the vice versa. The distances are accumulated over the block area and demonstrate the similarity of that block pattern to the template. After calculating Hamming distance of UGVs, the Hamming distance based gradient orientation pattern matching is then calculated by OR operator as shown in Eq. (9).

$$HDGOPM = HD\_n_x \vee HD\_n_y \quad (9)$$

3 EXPERIMENTAL RESULTS

In the experiment, we established 3 kinds of simulation: i) Illumination change test, ii) Occlusion problem in illumination change situation, and iii) Testing all of problems out in the video sequences.

In the first three simulations, we create an artificial motion sequence on still image. The standard test images; Lena, Cameraman, and House with size 512 by 512 pixels are used as first frames. The second frames of sequence are then generated by translating the first frames by 5 pixels in both vertical and horizontal direction. To compute the motion vector over the entire scene, we defined 961 blocks in the first frame as reference blocks, and each block have size 16 by 16 pixels. The 961 motion vectors are estimated by measuring the similarity of reference pattern and the pattern in the second frame. The search range in the second frame is set around reference block areas by +/- 8 pixels (32 by 32 pixels search range).

Fig. 2. (a) The standard test image House, (b) the image translated by 55 pixels, and (c) the translated image under non-uniform illumination

3.1 Illumination change test

To simulate the illumination change situation in the artificial motion sequence, we re-simulate the worst case condition of illumination change test in previous research [2][3]. The second frame is translated (5,5) pixels under Gaussian noise with SNR 40dB and non-uniform illumination change of intensities, which the image intensities within vertical and horizontal stripes are rapidly reduced to half and the intensity in the areas where two stripes overlap are reduce to one forth.

Table 1. Successful motion estimation rate (%) under non-uniform illumination change

Image	Standard SSD	GOPM with SSD	GOPM with HD
Lena	21.23	99.89	100
Cameraman	26.74	99.89	100
House	23.10	99.37	100

Successful motion estimation rate (%) of 961 motion vector estimated by standard SSD, GOPM with SSD metric, and HD based GOPM are shown in Table 1. GOPM is obviously overcome lighting change problem (successful rate approximately 99% by SSD similarity metric and 100% successful rate by HD metric). Meanwhile SSD on intensity features is incapable to estimate the motion (successful rates are approximately 20%).

3.2 Occlusion test under illumination change situation

In the second experiment, the second frame of sequences are also translated by (5,5) pixels and 40dB Gaussian noise added. The non-uniform illumination is varied in the same way as in the first experiment. To simulate the occlusion situations in the sequences, the pattern of reference block are then occluded by *mxm* zeros square (Fig. 3), where *m* iterate from 0 to 13, which is approximately 81% covered. The successful motion estimation rates of SSD, GOPM with SSD metric and GOPM with HD metric on each standard test images are plotted against occlusion size over the pattern (Fig. 6). According to the graphs, GOPM with HD metric yields the highest successful motion estimation rates, while the successful rates of GOPM with SSD metric are slightly lower than HD metric. For standard SSD, it is severely fail to estimate the motion vector under the circumstances. This shows the advantage of HD based GOPM under occlusion and non-uniform illumination change.

3.3 Test in video sequences

Finally the last simulation shows the performance of proposed matching technique on the video sequences. In this experiment, the face template is initialized manually in the first frame. The video sequences consisted of 4 different scenarios; *normal* situation, *illumination change* by shot the flashlight in various angle and distance, *occlusion* which an unknown object cover some part of the face and the last scenario is *occlusion problem under illumination change* situation (Fig. 4). As a result, all matching techniques; SSD on intensities, GOPM with SSD metric and GOPM with HD metric could perform a tracking very well under normal situation. However in the case of illumination change, SSD fails

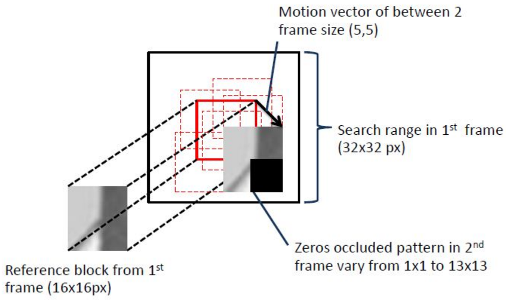

Fig. 3. Motion estimation on artificial motion sequence with (5,5) pixel translation, illumination change, 40dB Gaussian noise and zeros occlusion.

to archive the tracking, while both GOPM with SSD metric and GOPM with HD metric are fine. For occlusion problem (and occlusion under illumination change), only GOPM with HD metric could keep track the object almost of the entire video sequence. The similarity measurement results in Fig. 5 demonstrate the advantage of GOPM with HD metric over other techniques which matching results are disturbed due to the occlusion existence.

Fig. 4. Four real image sequences; constant light without occlusion, irregular lighting without occlusion, constant lighting with occlusion, and irregular lighting with occlusion.

4 CONCLUSION

In this paper, we have proposed a novel pattern matching technique for motion estimation and visual tracking, which combines the advantages of gradient orientation features and Hamming distance metric. Unit gradient vectors are computed from template and input images before measuring the similarity between them using the Hamming distance. The Hamming distance is equivalent to the number of pixels whose unit gradient vectors are similar to each other between the template and images. The proposed method can perform robustly in time-varying lighting conditions with partial occlusions. Our simulation results have shown those advantages over existing matching techniques on both synthetic and real image sequences.

Abstract: In microscopic image processing for analyzing biological objects, structural characters of objects such as symmetry and direction can be used as a prior knowledge to improve the result. In this study, we incorporated filamentous character of local structures of neurons into a statistical model of image patches so as to obtain an image processing method based on tensor factorization with image patch rotation. Tensor factorization enabled us to incorporate correlation structure between neighboring pixels, and patch rotation helped us obtain image bases that well reproduce filamentous structures of neurons. We applied the proposed model to a microscopic image and found significant improvement in image restoration performance over existing methods even with smaller number of bases.

Keywords: Image processing, Microscopic image, Tensor factorization, Local feature extraction

1 INTRODUCTION

Statistical modeling of image patches is a standard method to extract local structural features in image processing [1]. Rectangular image patches are cut out from a target image and regarded as random vector-valued samples. Statistical modeling of vector-valued variables provides a general tool for statistical feature extraction, unsupervised learning, and noise reduction by regression, to various application fields, such as natural image recognition, text recognition, and face recognition [2]. On the other hand, such statistical methods may suffer from information loss due to conventional transformation from rectangular image patches into vectors, which would lead to deterioration of image restoration performance. In this study, we try to reduce loss of structural information in microscopic image processing, by introducing the following two strategies: to obtain direction of foreground objects by fitting rotational image patches; and, to handle each fitted image patch as a matrix *(patch height patch width)* rather than a vector.

2 NOTATIONS FOR TENSOR ANALYSIS

In this section, we introduce notations necessary to describe the idea of tensor factorization.

2.1 Tensor & its matricization

Let $\underline{\mathbf{Y}} \in \mathbb{R}^{I_1 \times I_2 \times \cdots \times I_N}$ be an an N-way tensor whose real-valued element $y_{i_1 i_2 \cdots i_N} \in \mathbb{R}$ is indexed by $i_n \in 1, 2, \quad, I_n$ for $1 \quad n \quad N$. Each of $I_1, I_2, \quad, I_N \in \mathbb{N}$ denotes the largest index number for the corresponding mode. A zero-way tensor is represented by a scalar y, a one-way tensor by a vector $\mathbf{y}$, a two-way tensor by a matrix $\mathbf{Y}$, and a three or higher-way tensor by a general tensor $\underline{\mathbf{Y}}$. $||\underline{\mathbf{Y}}||_{\mathrm{F}}^2$ denotes squared Frobenius norm, which is a sum of squared elements of the tensor $\underline{\mathbf{Y}}$.

To operate and illustrate a multi-way tensor, we may rearrange tensor elements to a matrix form, which is called matricization. The mode-n matricization of a tensor $\underline{\mathbf{Y}}$ rearranges the tensor elements as $\mathbf{Y}_{(n)} \in \mathbb{R}^{I_n \times (M_n)}$, where $M_n = I_1 I_2 \quad I_{n\ 1} I_{n+1} \quad I_N$.

2.2 Tensor-matrix product

The mode-n product $(n = 1, 2, \quad, N)$ of a tensor $\underline{\mathbf{G}} \in \mathbb{R}^{J_1 \times J_2 \times \cdots \times J_N}$ and a matrix $\mathbf{A} \in \mathbb{R}^{I_n \times J_n}$, $\underline{\mathbf{Y}} = \underline{\mathbf{G}} \quad_n \mathbf{A}$, is a tensor $\underline{\mathbf{Y}} \in \mathbb{R}^{J_1 \times \cdots \times J_{n-1} \times I_n \times J_{n+1} \times \cdots \times J_N}$ whose elements are given by $y_{j_1 j_2 \cdots j_{n-1} i_n j_{n+1} \cdots j_N} = \sum_{j_n=1}^{J_n} g_{j_1 j_2 \cdots J_N} a_{i_n j_n}$.

Multiplication of a tensor over all modes other than one mode is denoted as $\underline{\mathbf{G}} \quad_{-n} \{\mathbf{A}\} = \underline{\mathbf{G}} \quad_1 \mathbf{A}^{(1)} \quad_{n-1} \mathbf{A}^{(n-1)} \quad_{n+1} \mathbf{A}^{(n+1)} \quad_N \mathbf{A}^{(N)}$ and the resulting tensor has dimensionality $I_1 \quad I_{n\ 1} \quad J_n \quad I_{n+1} \quad I_N$.

3 METHODS

In this section, we present our new image restoration method based on tensor factorization and rotational patches.

3.1 Image restoration incorporating patch rotation

Our image restoration method is a modification of the tensor factorization method proposed by Kim et al. [3]. Their method consisted of two steps; a basis learning step and a basis application step. We added a patch rotation process to both of these steps in order to incorporate symmetric structural features of image patch bases.

In the basis learning step, first, an image patch tensor is generated from an objective image; we obtain p samples of $m \quad m$ rectangular image patches from the full-size image; here, a rectangular image patch is said a foreground one if

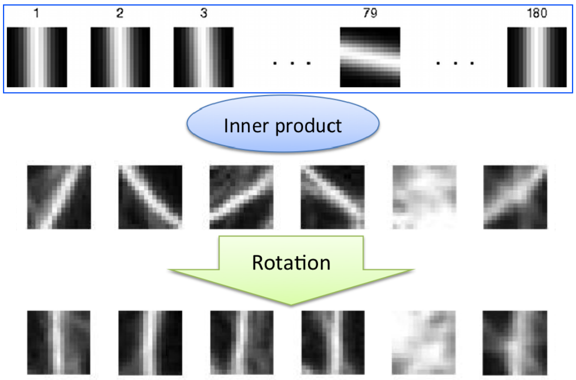

Fig. 1: Template image patch set by hand (leftmost panel) and its rotations (2...180). Foreground image patches before (middle) and after (lower) the rotation process.

its central pixel is brighter than the pre-determined level, or a background one otherwise. p samples of foreground patches are arranged into an $m \times m \times p$ three-way tensor, which is called a *train patch tensor*. Background patches were omitted in the following analysis. We calculate a *basis tensor* $\underline{\mathbf{U}} \in \mathbb{R}^{m \times m \times K}$ as a solution of the minimization problem:

$$\underline{\mathbf{U}} = \underset{(\underline{\mathbf{U}}, \mathbf{V})}{\arg\min} ||\underline{\mathbf{Y}} - \underline{\mathbf{U}} \times_3 \mathbf{V}||_F^2, \qquad (1)$$

where $\mathbf{V}$ is a $p \times K$ mixing matrix such to allow the linear sum of K *basis patches* $\underline{\mathbf{U}}(:,:,k)(k = 1, \cdots, K)$ to well approximate the *train patch tensor* $\underline{\mathbf{Y}}$; that is, the ith patch $\underline{\mathbf{Y}}(:,:,i)$ is well approximated by a linear sum of the basis patches $\sum_k \underline{\mathbf{U}}(:,:,k)\mathbf{V}(i,k)$ for all i. The number K ($< p$) of basis patches should be set appropriately by hand. This minimization problem is solved by three-way tensor factorization and we applied higer order orthogonal iteration (HOOI) algorithm for it, which is explained in detail in section 3.2.

In the basis application process, we restore a noisy image patch $\mathcal{Y}$ and achieve a restored image patch $\hat{\mathcal{Y}}$ by applying the basis tensor $\underline{\mathbf{U}}$ that was obtained in the basis learning step. We assume that an image patch $\mathcal{Y}$ is expressed by linear combination of K basis patches as follows.

$$\begin{aligned}\mathcal{Y} &= \underline{\mathbf{U}} \times_3 \mathbf{v} + \mathbf{E} \\ &= \sum_{k=1}^{K} \underline{\mathbf{U}}(:,:,k) v_k + \mathbf{E},\end{aligned} \qquad (2)$$

where $\underline{\mathbf{U}}(:,:,k)$ is an $m \times m$ matrix that represents the kth basis patch image, $\mathbf{v}$ is K-dimensional weight vector, and $\mathbf{E}$ is an $m \times m$ residual matrix. We calculate the weight vector $\hat{\mathbf{v}}^T = (\hat{v}_1, \cdots, \hat{v}_K)$ that minimizes the residual norm $||\mathbf{E}||_F^2$. Finally, we obtain the restored image patch $\hat{\mathcal{Y}} = \underline{\mathbf{U}} \times_3 \hat{\mathbf{v}}$. The entire image is restored by applying the above restoration process for all patches in the image.

Algorithm HOOI for three-way tensor factorization

Input: $\underline{\mathbf{Y}} \in \mathbb{R}^{I_1 \times I_2 \times I_3}$
Output: n th matrix $\mathbf{A}^{(n)} \in \mathbb{R}^{I_n \times J_n} (n = 1, 2, 3)$ and
a core tensor $\underline{\mathbf{G}} \in \mathbb{R}^{J_1 \times J_2 \times J_3}$
such that $\left|\left|\underline{\mathbf{Y}} - \hat{\underline{\mathbf{Y}}}\right|\right|_F^2$ is minimized.

begin
random initialization for all matrices $\mathbf{A}^{(n)}$
repeat
  for $n = 1$ *to* 3 **do**
    $\underline{\mathbf{W}}^{(n)} = \underline{\mathbf{Y}} \otimes_{-n} \{\mathbf{A}^{(n)T}\}$
    $[\mathbf{A}^{(n)}, \mathbf{\Sigma}^{(n)}, \mathbf{B}^{(n)}] = \mathtt{svds}(\mathbf{W}^{(n)}_{(n)}, J_n)$
  end for
until a stopping criterion is realized
$\underline{\mathbf{G}} = \underline{\mathbf{Y}} \times_1 \mathbf{A}^{(1)^T} \times_2 \mathbf{A}^{(2)^T} \times_3 \mathbf{A}^{(3)^T}$
end

In this study, we introduce a patch rotation process in order to incorporate symmetry in the objective cell structures. First, we prepared a template image (the leftmost panel in Fig. 1), which was set manually to represent a local neural filamentous structure in the vertical direction. Next, we prepared a set of its rotated image templates with rotation angles, 1, 2, ..., 180 degree (Fig. 1). In the patch rotation process, we fit each sampled patch to the vertical template in the following manner; calculate correlation coefficients between the sampled patch and the rotated templates of 180 rotation angles, determine the best rotation angle that maximizes the correlation, and rotate the sampled patch into the inverse direction with the determined rotation angle. In the above procedure, we rotated the template patch 180 times, rather than the sampled patch, in order to reduce the number of total number of rotation operation. Fig. 1 shows some examples of image patches before (middle) and after (lower) the patch rotation.

We applied the patch rotation process to the both of basis learning and basis application steps. Before the basis learning step, we align all image patches to fit the template image, and gather the rotated patches to construct a three-way patch tensor for the basis learning. Before the basis application step, we align each image patch to fit the template image, and restore the central pixel of the result of an application of the base.

Owing to the patch rotation, we can omit trivial variations of foreground patch images that can be generated by the rotation of rectangular spatial cutting windows, and, consequently, we expect that the set of bases reflect variations among neuronal local structures.

3.2 HOOI algorithm for basis learning step

The HOOI algorithm for the three-way tensor factorization in the basis learning step is based on an iterative Al-

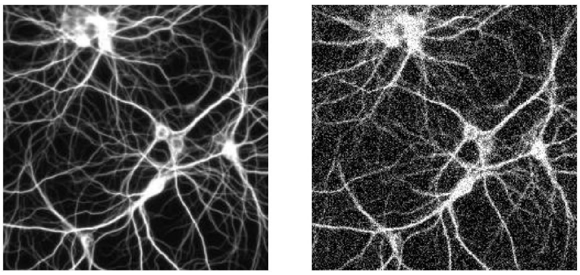

Fig. 2: An original microscopic image (size: 300 300 pixels) taken from `www.greenspine.ca` (Paul De Koninck, Laval University) (left) and a noisy image (right).

ternative Least Squares (ALS) algorithm. In each iteration of ALS, one basis is updated to minimize the residual error while keeping the others fixed, and finally we seek a (locally) optimal solution [4]. An extension of ALS for tensor factorization, HOOI was first introduced by De Lathauwer, De Moor and Vandewalle [4] and recently extended and implemented by Kolda and Bader in their MATLAB Tensor Toolbox[5]. We used this toolbox for tensor factorization in this study.

The HOOI factorizes the $m \quad m \quad p$ patch tensor $\underline{\mathbf{Y}}$ into an $m \quad m \quad K$ core tensor $\underline{\mathbf{G}}$ and three matrices $\mathbf{A}^{(1)}$, $\mathbf{A}^{(2)}$, and $\mathbf{A}^{(3)}$,

$$\underline{\mathbf{Y}} = \underline{\mathbf{G}} \quad {}_1\,\mathbf{A}^{(1)} \quad {}_2\,\mathbf{A}^{(2)} \quad {}_3\,\mathbf{A}^{(3)}. \tag{3}$$

We calculate the basis tensor that is defined in Eq. (1), $\underline{\mathbf{U}} \in \mathbb{R}^{m\times m\times K}$, by using the result of HOOI as follows, $\underline{\mathbf{U}} = \underline{\mathbf{G}} \quad {}_1\,\mathbf{A}^{(1)} \quad {}_2\,\mathbf{A}^{(2)}$.

In the HOOI algorithm, $\texttt{svds}(\mathbf{W}_{(n)}^{(n)})$ denotes a singular value decomposition procedure that decomposes a matrix like $\mathbf{W}_{(n)}^{(n)} = \mathbf{A}^{(n)}\mathbf{\Sigma}^{(n)}\mathbf{B}^{(n)T}$. The cost function $\left|\left|\underline{\mathbf{Y}} \quad \hat{\underline{\mathbf{Y}}}\right|\right|_{\mathrm{F}}^2$ is monitored so that the algorithm is terminated when its difference from that in the last step is smaller than a constant (' a stopping criterion ' on line 8 in the algorithm).

3.3 Image restoration by matrix factorization

We compared the proposed method with simple matrix factorization and two-way tensor factorization. In the case of two-way tensor factorization, the train patch tensor is arranged to an $M \quad p$ matrix, where the column size $M = m^2$ corresponds to the number of pixels in an $m \quad m$ image patch. The M-dimensional patch vector $\mathbf{y}$ is represented by a linear combination of $K(\ll p)$ bases. $\mathbf{y} = \sum_{k=1}^{K} v_k \mathbf{u}_k + \boldsymbol{\varepsilon}$, where $\mathbf{u}_k$ is the kth M-dimensional basis vector, v_k is a scalar weight of the kth basis, and $\boldsymbol{\varepsilon}$ is an M-dimensional residual vector. Let $\mathbf{U} = (\mathbf{u}_1, \quad , \mathbf{u}_K)$ be an $M \quad K$ matrix that gathers all basis vectors $\mathbf{u}_k$. In the basis learning step, we obtain a basis matrix $\mathbf{U}$ that minimizes $||\boldsymbol{\varepsilon}||_{\mathrm{F}}^2$, and, in the basis application step, we calculate $\hat{\mathbf{v}}$ and $\hat{\mathbf{y}} = \mathbf{U}\hat{\mathbf{v}}$.

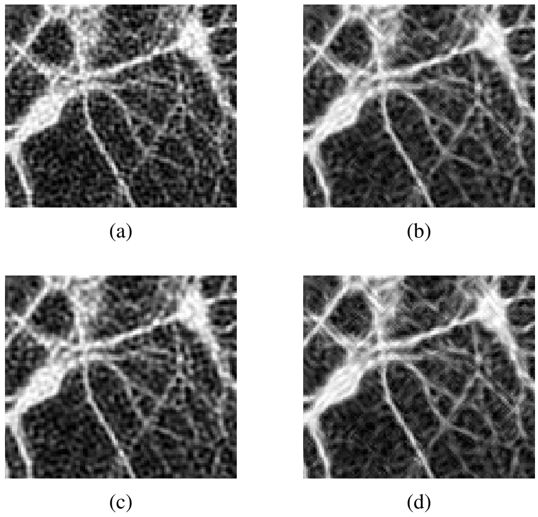

Fig. 3: Restoration by matrix factorization (a) without patch rotation ($K = 64$) and with patch rotation ($K = 52$). Restoration by tensor factorization (c) without patch rotation ($K = 52$) and(d) with patch rotation ($K = 46$).

4 RESULTS

Image restoration performance was compared between tensor factorization and matrix factorization, and between with and without the patch rotation process. A microscopic image of size 300 300 pixels was clipped from the original image (size: 634 800 pixels) of a neuronal network, registered on `www.greenspine.ca` (Paul De Koninck, Laval University) (Fig. 2, left). To examine the restoration performance, we artificially added white Gaussian noise (variance = 0.03) to the neuronal image (Fig. 2, right). Since we know the original image, we can evaluate the image restoration performance by calculating the root mean squared error (RMSE) of pixel brightness between the original and restored images. Since the performance depends on the number of bases, K, the RMSE was calculated with various K values for each method. For the basis learning, we extracted about 17,000 image patches of size 13 13 pixels from the original image before noise addition. Although the original image is not available in the actual image restoration application, we here assumed the basis learning has been accomplished by using clear images prior to the application of our image restoration method. Other possible procedure would be to iterate the basis learning step and image restoration by using the same (possibly noisy) images.

The image restoration results are shown in Fig. 3. The image restored by the tensor factorization with patch rotation obviously exhibited finer fiber structures than those by other methods. Such good restoration performance of the proposed method can be further seen in the numerical results summarized in Fig. 4. Since the performance was largely depen-

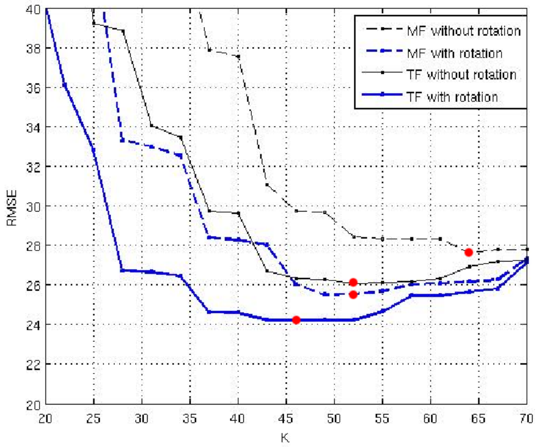

Fig. 4: Comparison of image restoration performance. Horizontal and vertical axes denote the number of bases (K) and the root mean squared restoration error (RMSE), respectively. Solid and chained lines denote the image restoration with and without image patch rotation process, respectively. Thick and thin lines denote the image restoration by means of three-way tensor factorization and matrix factorization, respectively. Red point denotes the best setting of K for each case.

dent on the number of bases, K, we here examined various K values. Although the RMSE of each method became the smallest with an appropriate setting of K, with the best setting being dependent on the method, the proposed method, the tensor factorization with patch rotation, showed the least RMSE value in every setting. In addition, tensor factorization (TF) showed better results that matrix factorization (MF), even though the former employed a smaller K value than the latter.

The advantage of the patch rotation was obvious especially when the number of bases was small. Table 1 shows the RMSE with the best setting of K for various noise levels added to the original image; our proposed method showed the best restoration performance with a smaller number of bases in all cases.

5 CONCLUDING REMARKS

In this study, we proposed an image restoration method based on the three-way tensor factorization of rotated image patches, which is suitable for restoration of microscopic images of biological targets such as neuronal networks. In the simulation experiment using a real image of neuronal network, we found significant performance gain in image restoration due to the two important ingredients of our method, tensor factorization and image patch rotation.

Fluorescence microscopy has a dilemma that increase in the frame rate suffers from larger shot noise, while decrease leads to the lack of information. Thus, a good image restoration technique is important for improving the data acquisition efficacy. For example, if we can restore low resolution images by utilizing basis images created from other high resolution images, the original low resolution images are restored cheaply in a software manner. Applications to 3D images and movies would be important future extensions, and capturing various finer structures of neuronal networks by further modifying our statistical model will also be promising.

Table 1: RMSE comparison for various noise levels added to the original image.

(a) variance $= 0.01$

RMSE	MF	TF
without rotation	18.27 ($K = 70$)	17.48 ($K = 64$)
with rotation	17.28 ($K = 64$)	**16.42** ($K = 55$)

(b) variance $= 0.03$

RMSE	MF	TF
without rotation	27.64 ($K = 64$)	26.09 ($K = 52$)
with rotation	25.51 ($K = 52$)	**24.21** ($K = 46$)

Abstract: Many robotics applications that rely on computer vision for long-term route planning can benefit from increasing the resolution of the imagery used for that planning. Increased resolution increases the effective planning timeframe and allows the AI planner to consider obstacles that are more distant. As a best-case scenario, a route that might otherwise be taken just to encounter a distant obstacle that requires significant backtracking could be avoided. Super-resolution image enhancement, however, introduces its own problems as it can create false positive and false negative inclusions. Thus, for many applications, basic super resolution is unsuitable for robotic planning applications as the level of accuracy of the enhanced data is unknown. A framework for reporting confidence in super-resolution enhancement is presented in this paper. This approach includes a numeric confidence map along with the super-resolved data. The AI consumer of the enhanced data can, thus, consider both the data as well as the confidence meta-data. This framework is demonstrated and evaluated via an implementation of a database-based super-resolution technique that also supplies confidence map data. Robotic applications are discussed.

Keywords: Image enhancement, super resolution, decision confidence.

1 INTRODUCTION

Robotic control decision-making can have disastrous effects when it is based on inaccurate data. When a failure happens, it is important to be able to ascertain what caused that failure. Many artificial intelligence (AI) techniques, however, make this difficult. Some techniques train on-the-fly resulting in a decision being made with a framework that existed for a single moment-in-time and may never reoccur. While, theoretically, the data, node weightings, and other factors relevant to a decision could be preserved via storage, this is practically problematic – particularly when one considers that a craft that makes a poor decision may be destroyed (as a result of the decision, or otherwise), making the data unavailable for analysis. While this problem is wide-ranging and affects all areas of AI decision making, this paper deals with error that can be introduced via super resolution (the enlargement of images via computer processing) and how this error can be quantified and its potential factored in to the decision making process.

2 BACKGROUND

Numerous approaches to super resolution have been suggested. These approaches can be divided in to two main categories: those which infer data and those which simply piece together existing data. Piecing solutions [e.g., 2, 3, 4, 7] use several images of a scene or subject and take advantage of camera shifts or movement to allow a higher resolution image to be constructed from two or more low-resolution images.

Inference-based super resolution [e.g., 6], alternately, draws on patterns in the image format, prior knowledge or other sources to create an output image that attempts to replicate what would produced by capturing the original scene or subject at the output resolution. Inference-based approaches can be further divided into approaches which attempt to apply an algorithm to a single image to enhance it without additional information and approaches which base the output on both the input image and prior knowledge. All present forms of super resolution only produce approximations of the actual high-resolution image; these approximations can (and usually do, to various extents) include false positive inclusion and false negative exclusion.

Robotic AI control systems use imagery for immediate decision-making and long range planning. Immediate decision-making can include obstacle avoidance, target location and identification, and such. Long range planning uses image analysis for target identification, prediction of traverse-ability and, terrain type.

A short-range perception failure could result in damage to or loss of the robot (due to misjudging the terrain and falling or flipping). This, however, is unlikely as at close range the obstacles are quite large and would be difficult to miss (to the extent where super resolution would generally be unnecessary). Also, other techniques can be used to avoid these perils (such as a scanning laser or whisker, etc.).

At a longer range, however, super resolution is very relevant and the cost of bad information can be significant. Two scenarios deserve consideration. In the first longrage imagery scenario, enhanced imagery is used for route planning. In this instance, detail removal (via super resolution smoothing) can result in obstacles going unrecognized – conversely, it can also result in a preferable path being smoothed over to look no different than near-by obstacles). This may cause the robot to commit to a path which it will later be forced to backtrack from when higher-resolution imagery correctly detects the true nature of the path.

In the second scenario, super-resolved imagery is used for target location and identification. Particularly if the object size is close to the working-block size of the super resolution (for prior knowledge SR systems), it is possible that one complete image is incorrectly replaced with another. A friendly craft may thus be targeted as a foe or a foe incorrectly ignored as a friend.

3 SUPER RESOLUTION TECHNIQUE

The proposed approach makes three important additions to previous super resolution research. It starts with a trained database-based approach with corner matching loosely based on [5]. It adds to this the integration of a commercial database product for storage and searching, weighting of the search based on pattern occurrence training, and the inclusion of a confidence level map with the produced image.

3.1 Training

Training populates the database. Source images are trained to identify patterns starting at each pixel (excluding those on the far right and bottom where the training box size would be cut off by the image edge) in the image, starting from the top left. Figure 1 demonstrates how a given area of the image actually is used to crate numerous training patterns. The number of patterns produced by a given image is N=(H-A)(W-a), where a is the height and width of the pattern size.

Patterns collected in training are stored in the database at three resolutions. They are stored at the full resolution, a medium resolution (which will equate to the resolution of the images to be presented later) and a low resolution which is stored to aid in pattern matching when processing a presented image. The database contains a column for each pixel-location in each pattern size. An index is applied only to the database columns for the low-resolution image, to speed searching later. A temporary index may be incorporated for the high-resolution patterns to speed the training process; however, this should be removed before presenting images for SR.

For each pattern that is sliced from each training image, the database is searched for a match. If a match is found an 'occurrence' counter is incremented and no further work is done. If no match is found, the medium and low versions of the pattern are created via averaging the corresponding pixels of the high-resolution pattern and stored; the occurrence counter for the pattern is set to 1.

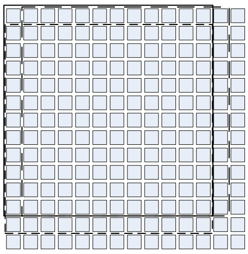

Fig. 1. Source Image Slicing

3.2 Image Enhancement

The image is processed through one medium-size pattern at a time, with a slight overlap. For each location, the medium resolution pattern from the source image is used to make a low-resolution pattern which is used to search the database and identify candidate patterns. Some previous work has attempted to fulfill a particular quota when selecting candidate patterns. In this instance, patterns are searched for based on a maximum difference from the low-resolution pattern (applied on a per-pixel basis). Any patterns which match the criteria are selected for consideration. If a match is not found, the tolerances are increased incrementally until a match is found or a maximum level of tolerance increase is reached. In the case where the search stops without finding a match, the medium resolution pattern is enlarged and placed in to the final image.

If candidates are identified, the medium resolution patterns (associated with the particular small size patterns selected in the search) are then used to select the pattern that will be placed in the final image. The medium patterns are compared to the medium pattern from the presented image and a difference value is computed. They are also compared to the overlap area and a difference value is computed. Finally, the 'occurrence' value stored with each pattern is retrieved. A final merged difference evaluation value is computed:

$$DEV = (a * DM) + (b * DO) - (c * O) \quad (1)$$

where a, b and c are the weighting constants (respectively) for the medium-pattern-difference (D_M), overlap-difference(D_O) and occurrence level (O). The prevailing pattern is placed in to the final image and the confidence map is updated.

3.3 Confidence

For each pattern of pixels placed in to the final image, a corresponding entry is placed in to the confidence map. The map, which is created as an ASCII text file, is depicted visually in figure 4. The confidence value is similar to the DEV used during the enhancement process; however, it is presented as a confidence value (as opposed to a weighted difference). The confidence value is calculated:

$$C=[(w*DM)+((1-w)*DO)]/K * (O/OMax) \qquad (2)$$

where K is the maximum difference possible and O_{Max} is the maximum number of occurrences recorded for a single pattern in the current database (O_{Max} could also be set to an arbitrary value). It is expected that this confidence map can be fed into the AI planning routine and incorporated in its internal route confidence assessment process.

4 TECHNIQUE EVALUATION

A frequently used approach to evaluating super resolution is to compare the SR output image to the original image on a pixel-by-pixel basis. While this approach has the benefit of simplicity, it does not provide a particularly useful metric for evaluating the real-world performance of super resolution. In the case of images that will be viewed by humans, the question (generally) isn't one of whether the image is pixel-perfect, but instead relates to whether the image looks to be of high enough resolution. For example, in super resolving video for recreational viewing (such as in [3]), the objective is not to make the image perfect – but to make sure that the image is believably high-res. In other applications (such as the discussed application of AI decision making or barcode enhancement [e.g., 1]), the smoothness and high-resolution-look of the image are unimportant. What is important, however, is the accurate representation of critical features. To this end, a suitable performance evaluation metric is the correlation of low confidence with error areas. We can't expect the SR algorithm to perfectly enlarge every part of every image, every time but we must be able to ascertain how good each super-resolved image area is in order to include it in decision-making.

4.1 Subjective Visual Evaluation

The visual effect of the super resolution process is, obviously, quite subjective. Further, in an application in robotic guidance, the appearance of the super-resolved image to human observers is secondary to its utility for decision-making. However, as this is a commonly used metric for evaluating super resolution, it is appropriate to discuss it briefly. As figures 2 and 3 demonstrate, the algorithm seems (visually) to perform quite well on pattern-filled areas. Edges, however, can prove difficult. Experimentation using a database trained with the high-resolution version of an image that is presented performs exceptionally well. This, thus, demonstrates that the edge problem is not an issue with the approach (that is, the approach can produce a visually pleasing edge-area) but with the data that is stored during training. Increasing the training set size (using images that have minimal correlation with the image to be presented) also demonstrates improvements, confirming this.

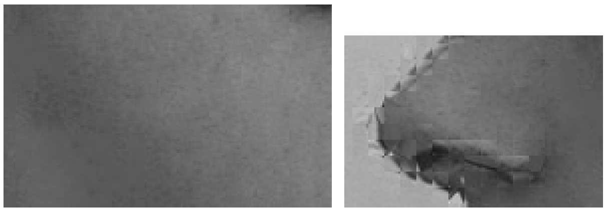

Fig. 2 & 3. Left: Enhanced Face Texture. Right: Pixilation Around

4.2 Pixel Comparison Evaluation

One of the most commonly used methods for evaluating super resolution is to compare the super-resolved image on a pixel-by-pixel basis to the original large-size image. This comparison averaged a 0.9% perfect match. However, given that the images are not black and white, but instead gray scale, it is not prudent to compare only perfect matches (as it is unlikely that a source pattern would have exactly the same shades of grey in pattern – the goal here is to get close). When we apply an error margin of 10% of the color range, the match average jumps to 89.3%. The visual difference of this 10% error margin is barely perceptible. It may, for example, manifest itself as a slightly different shading of an individual's face based on pattern matching of a lighter or darker skinned individual. However, similar effects could easily be caused by lighting in the location of photography or minor skin color change due to tanning, etc.

4.3 Confidence Correlation Evaluation

The evaluation technique that is of greatest interest to AI decision making, however, is confidence correlation. Confidence correlation compares each area of the image to the natural high-resolution image like in pixel comparison evaluation. The error value resulting from this is then compared with the confidence value for the pixel produced for the confidence map (as previously described). The confidence correlation, thus, indicates whether the confidence values should be trusted (while the confidence value indicates the accuracy of the super resolution process).

Confidence correlation is calculated as:

$$L = \frac{\left[\sum \left(\frac{C}{E} \times S\right)\right]}{n} \quad (3)$$

where C is the confidence value from Eq. 2, E is the error discussed in section IV-B, S is a scaling constant and n is the number of observations that are being used to compute the confidence correlation value. We, thus, end up with a scaled average correlation between the confidence and error value.

Confidence correlation was calculated for three cases: high error, medium error and low error. The confidence correlation values obtained through testing appear to be fairly consistent between the different error levels: 0.78, 0.82 and 0.79 for high, medium and low error, respectively.

5 SOURCES OF ERROR

Several sources of possible error were considered. Like most super resolution research, the experimental setup for this research is somewhat contrived. Images from prior facial recognition work were used to train and test the system. The images were headshots against a quasi-consistent background (though the actual color of the background in the images varied, likely due to the impact of lighting and using different cameras for different images). In each image, at least 25% of the image consisted of a lightly patterned background. The presence of this background could potentially increase or decrease accuracy calculations (depending on whether the database contained an exact or very close match) significantly, because of its prevalence. An additional test of two closely cropped face images was performed to assess the potential impact of this. One had a background color that was in the database and the other had a background color that the database was not trained with. While the accuracy metric values differed from the values for presenting the image with the larger background area, they did not fall outside of the range of values generated for testing with backgrounds.

6 CONCLUSION

It appears that a training-driven approach to super-resolution can produce acceptable results when the training and presented images are of similar objects. This would tend to suggest that a general-purpose database could be made that would be able to provide suitable enhancement for a variety of object and background types and which could be supplemented (to provide greater accuracy) with domain-specific databases.

When using a super-resolved image for AI decision-making, the potential error that is inevitably introduced by the super resolution process must be considered. The confidence map has been shown to provide a reasonable estimation of this error that can be considered by the AI as an estimation of the true error (based on comparing the actual high-resolution image to the super resolved one) which is, of course, not available in real world application.

Several topics of future research are suggested from this study. First, it would likely be possible to increase accuracy while reducing database size by storing difference patterns instead of gray scale values in the database. Future research could look at the feasibility of storing a pattern of delta-values from the mean-color-value of the image; [8] has looked at how patterns recur at different levels and thus it is reasonable to assume that they may recur in different shades as well. Second, this same concept could be applied to color images (including the aforementioned change). Finally, it would be prudent to compare the accuracy of decision-making using a higher-resolution super-resolved image with decision-making using a lower resolution image to determine the actual benefit of increasing image resolution.

ACKNOLEDGEMENT

Credit is hereby given to the Massachusetts Institute of Technology and to the Center for Biological and Computational Learning for providing the database of facial images.

Abstract: Recently, social security and natural disasters are worrying. In order to solve these problems and to reduce the damage, wide-area monitoring by computer vision is needed. Traditional monitoring systems have many problems that are caused by limited visual field in conventional technique. In this research, the air vehicle system which is to track a particular person indoors and outdoors where there are multiple people exist is proposed. Besides that, the four blades helicopter as a flying robot named AR.Drone is used. On experimental method, Hough transform method, Histogram method, Snakes method and Particle filter method are used in the research. Experimental results indoors and outdoors have shown the effectiveness of the proposed methods. The purpose of the study is to perform a wide area situation recognition and autonomous control of flying robot indoors and outdoors.

Keywords: Hough Transform, Histogram, Snakes, Particle Filter, Computer Vision, Wide Area Monitoring.

1 BACKGROUND

Recently, the number of crime incident at university, bank, convenience stores and so on occurs frequently because of the increase of invasion by intruders. In addition, natural disasters such as volcanic activities and earthquakes occur frequently, which makes damage become worse. For example, 400,000 people were affected by earthquake in Sichuan, China on May 12, 2008 while more than 200,000 people were affected by earthquake in Japan on March 11, 2011 because rescue was not done promptly after disasters (Fig.1.).

Fig.1. Northeast earthquake in Japan

In agricultural sector, it is a subject about how to understand the production status in vast farmland and how to prevent vermin damage. Therefore, the pesticide usage and residue status monitoring is also important.

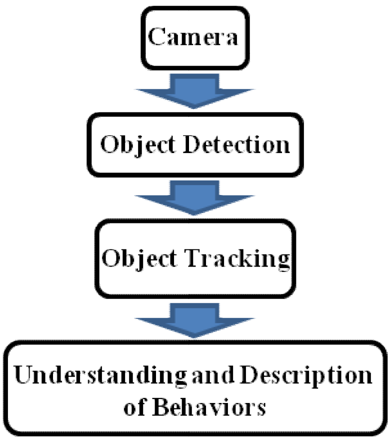
In order to solve these problems and to reduce the damages, it is important to carry out the wide area monitoring.

2 RELATED RESEARCHES

2.1 The Traditional Monitoring System

As for traditional monitoring system, firstly, it is to detect dynamic objects from image, and to track it. Secondly, it is to understand what is the object classified, and then to understand the structure of the object. The problem of background fluctuation and illumination change the effect of the recognition results. Flowchart of traditional monitoring system is as follows (Table 1.).

Table 1. Flowchart of traditional monitoring system [1]



2.2 The problem of conventional method

Typical approaches of automatic monitoring are the background difference method and model method. The background difference method is explained as follows. Beforehand, the background image is taken where dynamic objects do not exist. After that, dynamic object is detected depending on differential results of input image and background image. The robust of technique is influenced by complex environment. Detection accuracy of model method is reduced when part of the body is shielded (Fig.2.).

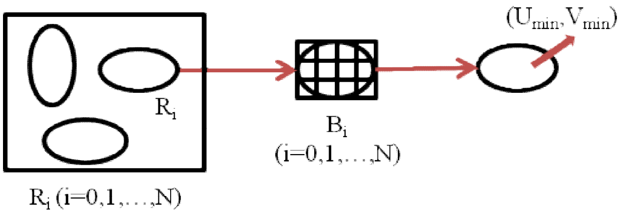


Fig.2. Conventional method [1]

There are many problems that are caused by limited visual field in the traditional monitoring system, such as difficulties to decide the border situation, shielding due to buildings and trees and difficulties to track target object.

On the other hand, in aerial images there are scarcely vision problems and obstacles problems that make it possible to track single or multiple target objects. Besides, it is easy to carry out wide area monitoring. The matter of aerial image is that it has less characteristics of target object and flying robot is likely to be susceptible to wind and weather.

3 AERIAL IMAGE

There are two ways to take aerial image. The first way is to use the retention type robot (balloon robot) and the second way is to use the flying type robot (flying robot). The merits and demerits of both are as follows (Table 2.).

Table 2. merits and demerits of Balloon Robot and Flying Robot

	Merits	Demerits
Balloon Robot	battery is not required	can not track target object
	safety is high	Low degrees of freedom
		susceptible to wind and weather
Flying Robot	can track target object	battery is required
	autonomous co-ntrol is possible	vibration effects image quality

Because the purpose of study is to track target object and the flying robot can be controlled automatically, the flying robot is chosen for this study.

4 PROPOSALS OF STUDY

The air vehicle system which is to track a particular person indoors and outdoors where there are multiple people exist is proposed. The purpose of the study is to perform a wide area situation recognition and autonomous control of flying robot indoors and outdoors. It is to detect a particular person by head of the person as a feature, because the characteristics is few from aerial image, and to track the person detected by head, clothing color and so on as features. As for autonomous control of flying robot, flying robot is controlled by landmark recognition.

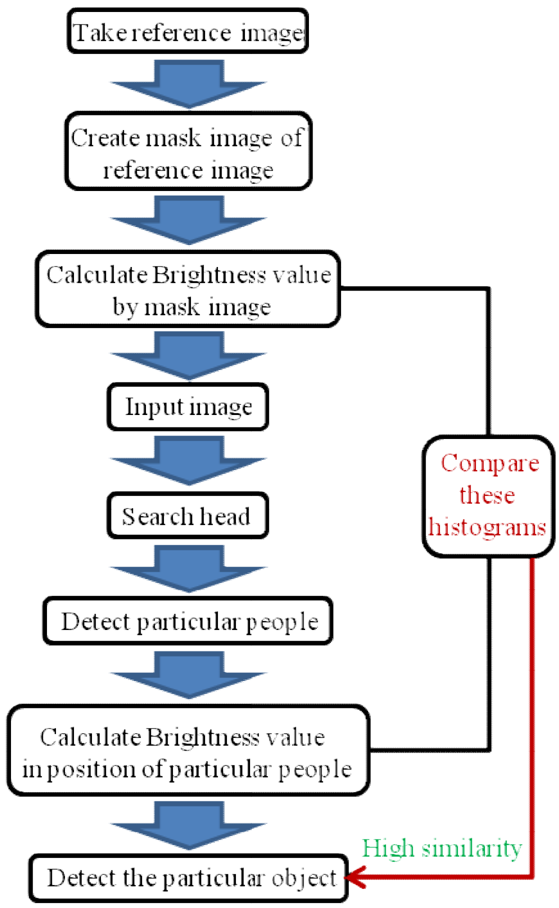
There are many types of flying robots such as helicopter type , flying robot with wings and flying robot with blades. In this research, four blades helicopter as a flying robot named AR.Drone shown in left of Figure 3 is used. AR.Drone can be controlled by ipod touch and iphone, because of the Wireless communication function (Fig.3).

Fig.3. Types of the Flying Robot

5 EXPERIMENTAL METHODS

5.1 Experiment for detecting a particular person

Table 3. Flowchart of detecting target object



Firstly, the reference image is taken in the same scene and the mask image is created from reference image by the

Photoshop. The size of mask image is the same as the reference image. Secondly, it is to perform the edge extraction on AVI video taken by AR.Drone in the scene. Thirdly, the video processed is done by expansion and smoothing processing. Then, it is to detect the head of person exist by the Hough Transform method (Equation (1)) [2].

$$r^2 = (x_i - centreX)^2 + (Y_i - centreY)^2 \qquad (1)$$

After that, the brightness histogram of the circles detected and mask image above-mentioned are calculated. Additionally, to compare two histograms to decide who is the particular person (Table 3.).

5.2 Experiment for tracking a particular person

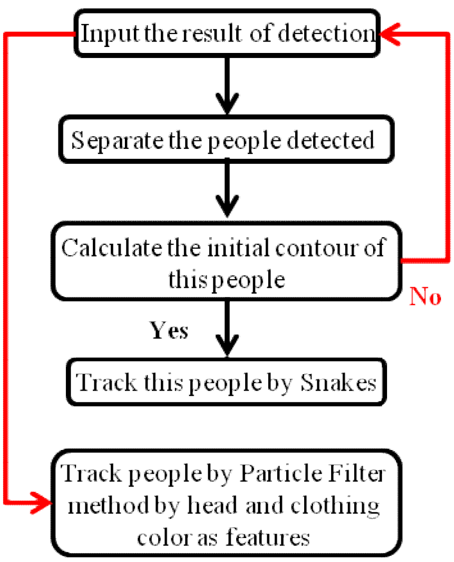
Firstly, input the image processed above. Secondly, it is to separate the people detected above and calculate the initial contour of this people. Thirdly, it is to track these people by Snakes method (Equation (2)).

$$E^*_{snake} = \int_0^1 E_{snake}(v(s))ds$$
$$= \int_0^1 E_{\text{int}}(v(s)) + E_{image}(v(s)) + E_{con}(v(s))ds \qquad (2)$$

Where E_{int} represent the internal energy of the spline due to bending, E_{image} gives rise to the image forces, and E_{con} gives rise to the external constraint forces [3].

When snakes failed, it returns to the beginning image, and tracks this people by Particle filter method (Table 4.).

Table 4. Track the particular target object

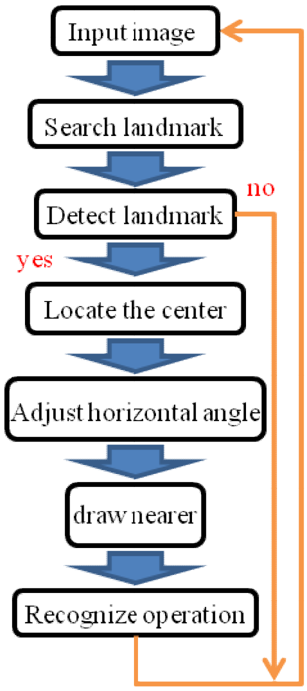


Particle Filters are usually used to estimate Bayesian models. The particle filter aims to estimate the sequence of hidden parameters, xk for k = 0,1,2,3,…, based only on the observed data yk for k = 0,1,2,3,…. All Bayesian estimates of xk follow from the posterior distribution p (xk | y0, y1… yk). In contrast, the MCMC or importance sampling approach would model the full posterior p(x0, x1… xk | y0, y1… yk) [4] [5].

5.3 Autonomous Control of Flying Robot

This part is to recognize landmark and be controlled by landmark. At first, the image is inputted. Secondly, it is to search the landmark, and then to detect the landmark. If landmark is detected successfully, the center is located, and horizontal angle is adjusted. Finally, flying robot draw nearer to object and to recognize it (Table 5.).

Table 5. The method of autonomous control



6 EXPERIMENTAL RESULTS

At first, the problem of height restriction is solved. There is a three meters height restriction on AR.Drone. In order to ensure the range of vision and be able to track the objects, this problem has to be noted. In addition, there are two cameras with AR.Drone. They are located at the bottom of AR.Drone and the front of AR.drone. In order to take the front image and bottom image, the problem with switching the camera has been solved (Fig.6.).

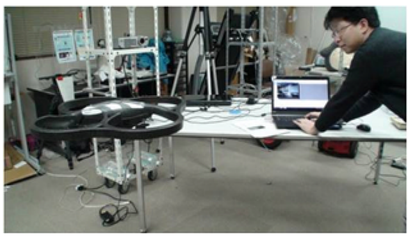


Fig.6. AR.Drone is controlled

6.1 Detect People by Flying Robot

Figure.7 shows the four blades helicopter as flying robot named AR.Drone is controlled by PC. In addition, automatic setting of the thresholds used in Hough Transform method has been achieved (Fig.7).

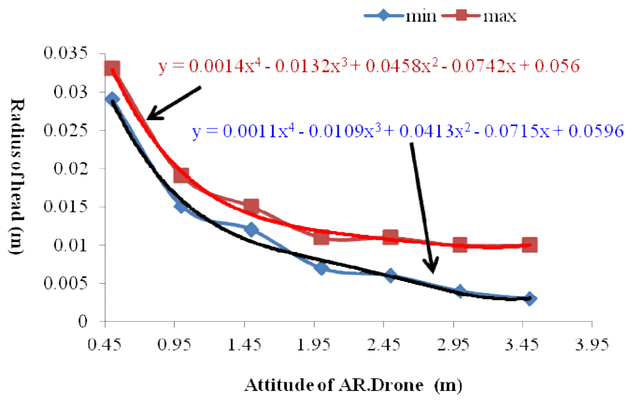

Fig.7. The Relation Between Attitude of AR.Drone and Radius of Head

It shows that particular person is detected by AR.Drone by Hough Transform method and Brightness Histogram method in Figure.8.

Fig.8. Detect person by Hough Transform and Brightness Histogram

The images on the top are without obstacle and the images on the bottom are with obstacle in the scene. Images on the left show people were detected and results are drawn by green rectangles. Images on the middle show results of edge extraction by the Sobel Operator. Images on the right show results of brightness histograms of head.

6.2 Track a Particular Person

The process of tracking person by Snakes method is shown in Figure.9. At first, the initial contour is decided and then parameters of Snakes are fixed by Equation (2) above-mentioned.

6.3 Results of Autonomous Control

Fig.10 is the result of autonomous control. Left image shows AR.Drone is controlled by red object, and right image shows it has detected red object successfully.

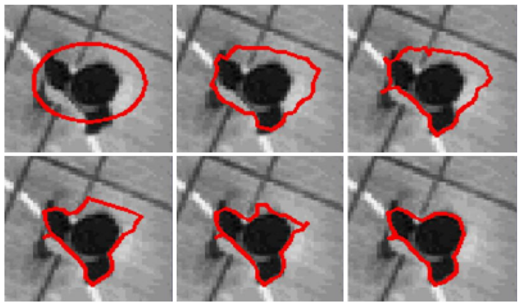

Fig.9. Tracking Process by Snakes Method

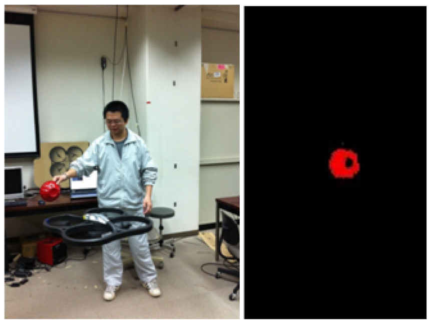

Fig.10. Red Object Recognition

7 CONCLUSION

The study is to detect and track the specific people. We hope that the flying robot is able to track the person by itself. Therefore, it is important to carry out autonomous control on flying robot. We also hope to achieve the aim that flying robot is able to detect and track target object automatically and help the people who wants to be helped.

Abstract: In this paper we presented a novel robust method for a visual IMU in manhattan-like environments i.e. the frequently observed dominance of three mutually orthogonal vanishing directions in man-made environments. Our approach is based on the idea of the separate estimation of the rotational and translational motion based on dense 3D and 2D features. We estimate the Manhattan-like structure by using an MSAC variant that estimates the Manhattan system directly from the 3D data. In contrast to other methods we use only the normal vectors of each voxel rather than estimating it indirectly using plane estimation. In a next step we estimate the translative motion of the robot relative to the Manhattan system using constrained visual odometry. Both rotational and translational motions are fused in a UKF. We show the robustness of our Manhattan-estimation using real world data. In this paper we demonstrate our approach using a Microsoft Kinect, while the approach will work with all kind of 2.5D sensors.

Keywords: Visual IMU, Manhattan-System, Computer Vision

1 INTRODUCTION

The domain of service robotics has become an important and fast growing market in the last decade. While service robotics has become more and more common in the industry domain they are still rare in the home robotics domain. Recent demographic developments in Europe and Japan have shown that there is a need for service robotics in everybody's home due to the elderly society phenomenon. With the home robotics domain we have usually a relative small area (e.g. 100m2), clutter and visually weakly structured environments. To cope with these environments, the use of 2.5D sensors has become quite popular in the last decade. With the recent release of Microsoft's Kinect sensor, the popularity of 2.5D sensors gained a boost. The Kinect sensor is suitable for the task for two reasons: The sensors are cheaper than laser scanners and its offers a depth image at frame rate. The challenge with data from 2.5D data is to cope with noise and uncertainty due to the nature of the sensors. For instance, the quality of 2.5D data from the Kinect depends on the reflection properties of the observed surface and the angle of incidence (assuming Lambert surfaces).

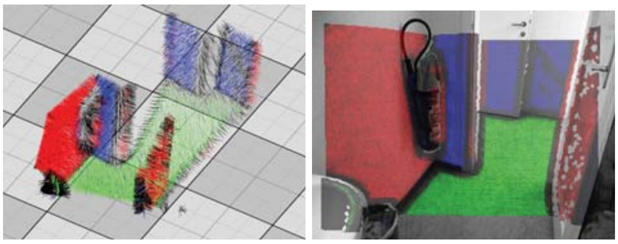
In this paper we propose a novel method to estimate the absolute rotation (namely roll, pitch and yaw) and relative translative motion from 2.5D data by exploiting partial Manhattan-like Geometry of an indoor environment. Manhattan-like structures are the frequently observed dominance of three mutually orthogonal vanishing directions in man-made environments. Many indoor environments can be considered as Manhattan-like since most walls of a room are aligned orthogonally to the ground or quasi Manhattan-like if the walls are not aligned orthogonally to each other. In many cases, furniture is also aligned Manhattan-like to its environment, e.g. a couch or cupboard can be aligned with a wall. Here we emphasize that it is not necessary that the furniture is aligned to all three major axes i.e. even if a table is not aligned to a wall its table surface is usually parallel to the ground.

The novelty of the paper is twofold: First an MSAC variant that directly estimates an Manhattan-system based on normal vectors. In this paper we use it to detect the dominant Manhattan system in the image. The second contribution is a geometric constrained visual odometry in combination with a UKF that exploits kinematic constrains of robot motion. The approach is efficient and robust to noise.

The paper is organized as follows: After a brief discussing on the state of the art, we describe in section 3.1 the proposed approach in two major parts: The first part describes the estimation of the Manhattan system within the 2.5D data. The second part (3.2) presents the constrained visual Odometry. Finally, we give the conclusion and results in section 4.

2 RELATED WORK

Visual odometry is a relative young area in the field of robotics. A poplar approach is the estimation using motion models (top-down). Davison et al. [1] proposed a method where a underlying motion model predicts the position of features to the next frame and updates it with a EKF. This idea was also used by Clipp et al.[2] by using multiple EKF filters or by [3] using more sophist aced features for tracking. Another idea is to use structure from motion techniques



(a) Normal Vectors (b) Image

Figure 1: Estimated Manhattan System of a sample scene. The colors indicate the membership to one of the three major axis.

instead of EKF filter as proposed by Klein et al. [4] or only using spares bundle adjustment Konolige et al. [5] for pose refiement.

The use of the *Manhattan-World* assumption is quite popular in the computer vision literature, for instance, in the use of multi view-reconstruction [6, 7, 8]. Gallup et al. [6] use *Manhattan-World* assumption as prior for plane sweeping i.e. using only orthogonal planes. Furukawa et al. [8] use a similar approach for reconstructing piecewise planar patches and Markov random field formulation for exact planes. Sinha et al. [7] use a similar method, but with a less strict model. Gupta et al. [9] extend the idea by including not a-priory known kinematics on image structure.

3 OUR APPROACH

Our approach consist of three steps: First, we estimate the Manhattan-like structure by using an MSAC variant that estimates the Manhattan system directly from the 3D data. In contrast to other methods we use only the normal vectors of each voxel rather than estimating it indirectly using plane estimation. In a next step we estimate the translative motion of the robot relative to the Manhattan system using constrained visual odometry. Finally we combine both estimates with a unscented Kalman filter to reject implausible motions.

3.1 Manhattan System Estimation

We propose an approach using a variant of the well known Random Sample Consensus (RANSAC) techniques. RANSAC based methods obtain their estimate by randomly selecting coefficients from a given dataset to a known model. The estimation is iterative, in each iteration the number of inlier is counted. After a fixed number of iterations, the model with the most inlier is used as estimate.
The idea is to describe the Manhattan-world as three normal vectors $\vec{N}_1, \vec{N}_2, \vec{N}_3$ one for each axis. We use the normal vectors to express the *orientation* to an axis i.e. the vector is virtually aimed in both directions of the axis. We use a normal vector estimation based on integral images and is a good

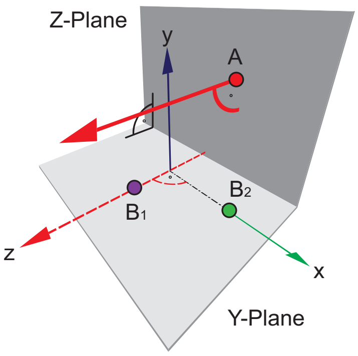


Figure 2: Estimating the Manhattan configuration using three normal vectors and RANSAC methods: A is used as seed for the Manhattan system for the first axis. B_1, B_2 are used to calculate the "roll" of the second axis and the third axis is redundant. Here we assume that A and B_1, B_2 do not share the same orientation plane of the Manhattan system, but that B_1, B_2 does.

trade off of runtime and quality. The normal vector of a voxel counts as an inlier, if the angle to one of the three axis normal vectors is within a certain threshold e.g. 5 degrees. The resulting angle is always between 0-90 degrees, since an axis does not have an orientation like a normal vector. The model is given as follows: Let $\vec{A}, \vec{B}_1, \vec{B}_2 \in V$ randomly selected voxels of the 2.5D grid and $\vec{a}, \vec{b}_1, \vec{b}_2$ its associated normal vectors. The three vectors are calculated with:

$$
\begin{aligned}
\vec{N}_1 &= \vec{a} \\
\vec{N}_2 &= \vec{B}_2 + \vec{a}((\vec{B}_1 - \vec{B}_2) \cdot \vec{a}) - \vec{B}_1 \\
\vec{N}_3 &= \vec{N}_1 \times \vec{N}_2
\end{aligned}
$$

The entire concept is depicted in figure 2: The overall assumption is that A is a point on a Manhattan-like structure for instance on the "Z-Plane". B_1 and B_2 are both on corresponding different Manhattan-like structure for instance the "Y-Plane" or "X-Plane". Since the Manhattan system is redundant to one axis, we only need to calculate two axes e.g. in figure 2 the x axis is redundant. The first vector is given by the normal vector of A itself. The second vector is obtained by shifting the first vector to B_1 and using B_2 as "roll" component. The third vector is the cross product of both previous vectors. This approach generates always a valid Manhattan system using three vectors. Note that we do not check in advance if e.g. B_1 and B_2 are on the same plane, since we have no prior information about planes in the 2.5D data at this step. Such "inplausible configurations" usually generate a Manhattan system with a significant less inliers than a "proper configuration" like in figure 2.

In practice we use MSAC [10] for estimation, an M-

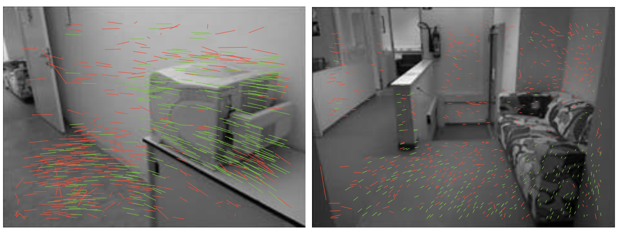
Estimator RANSAC variant: Instead of counting inlier within a specific threshold, we accumulate the error of the model from the original data. The MSAC uses a threshold to specify a maximum error that a voxel belong to the model. Since we assume that we have one dominant Manhattan system we adapt this approach. The idea is to use an additional fixed error if an error exceeds the maximum error. In practice the additional fixed error is significant greater than the measured maximum error according to the threshold. This will raise the probability that the MASC will favor the dominant system rather than a valid random one as long the dominant one is also the largest one in the data. In our setup we use 5 degrees as threshold and 10 times as max constant error. Figure 1 shows an correct estimated Manhattan system.

3.2 Geometric Constratined Visual Odometry

The visual odometry is used to estimate the relative translative motion of the robot to the estimated Manhattan system since the rotation was already obtained on the previous step. We use standard KLT [11] features to track to estimate the motion in the 2.5d data. The tracking is done on the 2D grayscale image using the GPU within $> 1ms$ with Zach et al. [11] implementation. The depth estimation for each point is straight forward, we use the xyz coordinates from the depth data. The motion estimation is done with a one point RANSAC matching with known depth and known correspondence per point. One tracked point is chosen as model i.e. the relative motion of the point in 3D and the previous point while the roation is removed before. As with the standard RANSAC the solution with the most inliers in chosen and used for motion estimation, see figure 3. Only tracked KLT points with valid (non interpolated) depth are used. We use a maximum distance of 10cm for inliers and 50 iterations. The entire runtime for our visual odometry is $> 1ms$.

3.3 Data filtering with UKF

In a first step we track the rational movement and convert it to a angular motion speed for all three angles. The translational part is converted similar to translation speed. In order to cope with either homonymic and non-holonomic robot, we use a motion inertia model, in the fashion of Rao-Blackwellized particle filters [12]. We a central point of mass (like the center of the wheels) as center for all rotations and translational motions. We also assume that the robot is heavy and that a mass lays on top of the center point of mass to prevent that the robot jumpsy up and down in the estimation process. We decompose the six speeds into forces that push the center of mass, plus the gravity (or mass on top) on the center of mass point. Using this sevens force leads to that the UKF filters out implausible motions without expoliting the kinematics to much in detail. We use a straight forward uncended Kalman filter UKF for data fusion, as proposed in various literature e.g. [13]. We don't use an EKF due to it can easly get stuck in local minima, while UKF allows multiple hypothis in the uncended transformation.



(a) Rotative Motion (b) Translative Motion

Figure 3: Visual Odometry using KLT features and RANSAC motion estimation. Outliers are shown in Red, Inliers in Green

4 CONCLUSION AND RESULTS

In this paper we presented a novel robust method for a visual IMU in manhattan-like environments. Our approach is based on the idea of the separate estimation of the rotational and translational motion based on dense 3D and spares 2D features. The proper estimation depends on the amount of visible structure of the Manhattan system within the 2.5D data. As long structure of two axis is visible a robust estimation is possible. As long as Manhattan structure of one axis is clearly visible in the image, its enough that the second axis is partially visible within the data i.e. at least 1 percent of the data. The use of normal vectors is efficient for Manhattan system estimation, but can be computational expensive. The use of integral image style normal vector estimation is a good trade off of runtime and quality and allows to use the entire data set rather than a sub sampled set. Our implementation of the constrained visual odometry is efficient and simple due to only the translative motion part remains.

The overall rotational error is less than 0.2degree, the relative translative error is less than 2mm within a travelling distance of 10m using a Microsoft Kinect. In contrast to other methods we obtain the absolute rotation to the environment instead of the relative rotation like with Visual SLAM. While our work uses the Kinects as sensor, it is also applyable to all kind of 2.5D sensors. We successful used our approach for mapping with a tilting laser scanner using only our visual IMU.

Experiments have shown that many home and office environments contains Manhattan like structure with all three axis. We want to emphasize that the minimal Manhattan system for our approach are two axis, which is very likely in the most indoor environments. That is usually the ground and a random wall which will be aligned orthogonal in most indoor cases. We figured out that this kind of condition does not hold true in some museums, for instance the Solomon R. Guggenheim Museum in New York.

We also find our Manhattan system estimation every useful in the combination with SLAM in indoor environments. Since our system eliminates to 99.8% the rotation from the data, SLAM has only to deal with the translational mapping error. First experiments with the gmapping package in willow garages Robot Operation System "ROS" have shown improved results with fewer misalignment scans. Due to that gmapping assumes an non-holonomic robot, we had to hack the code to support a psydo-holonomic one.
Our next steps is to relax the Manhattan constrains and to combine our method with SLAM with visual finger prints for place recognition.

Abstract: Image texture analysis is very crucial research topic for various vision-based applications. In this paper, robust gray-level co-occurrence matrix (GLCM)-based statistical model is explored and exploited for various image texture analysis. After demonstrating the model, experimental analyses are accomplished with datasets to demonstrate the performances of the statistical model. It illustrates that these statistical modules can be very much functional for image texture understanding.**.** Initially, we run our model in some ground-truth images covering few basic patterns, so that we can vividly compare the results on various images on datasets. The experimental dataset is the standard 'building surface dataset', where the experimental results relate the ground-truth data significantly.

Keywords: Co-occurrence matrix, GLCM, Texture analysis.

1 INTRODUCTION

Texture analysis is an attractive area of research because of its wide applicability in many fields. We can define texture as the surface of the objects. Several researchers define texture as a number of combined structurizing elements. Haralick et al. [7] assume texture as a spatial statistical distribution of gray pixels. We know that we can differentiate various image surfaces, objects, etc. A machine usually fails to identify an object based on its surface of similar patterns [10]. In these circumstances, identify complex surface using texture cue from a single image is an intricate problem [10]. In this paper, we explore statistical models for various image texture surfaces in order to develop a robust recognition and classification system. It is known that identification of similar objects under various real-world lightings is very challenging task for a machine/robot vision system. From the experimental results based on our analyzed statistical models, we achieve promising hypothesis by employing a benchmark dataset along with our ground truth dataset for in-depth analysis. To the best of our knowledge, these models in the building dataset along with ground truth analysis have not been undertaken by others.

Section 2 demonstrates some related works of this topic. Section 3 describes the statistical methodology exploiting the Gray Level Co-occurrence Matrix for texture analysis. Then, in Section 4, we illustrate some experimental results using a benchmark dataset. Finally, conclusion is presented in Section 5.

2 RELATED WORK

Texture analysis is very important research area in Machine vision system. Many researchers did their research based on different patterns of texture image. This research is very important for industry, medical experiment, and garments sector for automatic inspection of product. Texture analysis describes a variety of image-analysis techniques that quantify the variation in surface intensity or patterns, including some that are imperceptible to the human visual system. Quality control is important in textile industry. Texture analysis plays an important role in the automated visual inspection of texture images to detect their defects. For this purpose, Ozdemir *et al.* [1] did comparative experiment based on deferent textile sample. Model-based and feature-based methods are implemented and tested for textile images in a laboratory environment. Texture features, such as energy, entropy, contrast, homogeneity, and correlation, are then derived from the co-occurrence matrix. Several works have reported using co-occurrence matrices to detect defects, such as [2-7]. For example in [6], Iivarinen *et al.* applied co-occurrence texture features to detecting defects in paper web where the normal textures have characteristic frequency. Texture analysis is a valuable and adaptable implement in neuro-MR imaging. Texture analysis plays a encouraging role in the medical image interpretation. In some cases, however, statistical or spectral textural features have outperformed visual assessment in discriminating between or among intracranial tumors, as well as in discerning subtle anatomic changes associated with a high risk of seizures in patients with epilepsy.

3 METHOD

We explored the 2nd order statistics, called Gray Level Co-occurrence Matrix (GLCM). It is a way of extracting 2nd order statistical texture features. A GLCM is a matrix where the number of rows and columns is equal to the number of distinct gray levels or pixel values in the image of that surface. GLCM is a matrix that describes the frequency of one gray level appearing in a specified spatial linear relationship with another gray level within the area of investigation [11-12]. Fig. 1 shows the system flow diagram of this work.

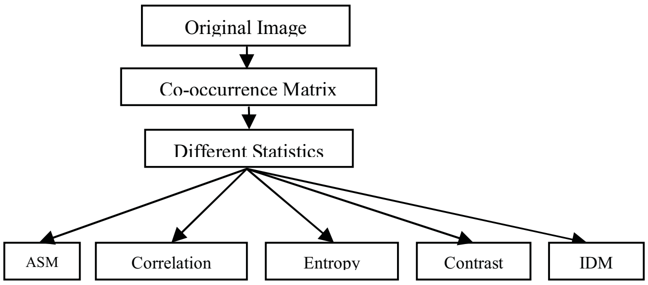

Fig. 1. System flow for this method.

In this paper, we exploit the Gray Level Co-occurrence Matrix (GLCM) for texture analysis. Given an image, each with an intensity, the GLCM is a tabulation of how often different combinations of gray levels co-occur in an image or image section. Texture feature calculations use the contents of the GLCM to give a measure of the variation in intensity (i.e., image texture) at the pixel of interest. Typically, the co-occurrence matrix is computed based on two parameters, which are the relative distance between the pixel pair *d* measured in pixel number and their relative orientation θ. Normally, θ is quantized in four directions (e.g., 0º, 45 º, 90 º and 135 º) [11-12], even though various other combinations could be possible. As our dataset is based on buildings – it is not necessary to explore all different angles. The other parameter *d* is also important. Based on our experiment, we consider *d* as 1. If we have an image that contains *N* gray levels from 0 to *N*–1, and if we consider *f*(*m*,*n*) is the intensity at sample *m*, line *n* of the neighborhood, then we can have the gray level co-occurrence matrix as,

$$p(i,j \mid \Delta x,\Delta y) = WQ(i,j \mid \Delta x,\Delta y) \tag{1}$$

where, $$W = \frac{1}{(M-\Delta x)(N-\Delta y)}$$

$$Q(i,j \mid \Delta x,\Delta y) = \sum_{n=1}^{N-\Delta y}\sum_{m=1}^{M-\Delta x} A$$

where,

$$A = \begin{cases} 1 & \text{if } f(m,n)=i \text{ and } f(m+\Delta x, n+\Delta y)=j \\ 0 & \text{otherwise} \end{cases}$$

The resultant texture images show the pixel-based spatial distribution of magnetic anomalies, associated with elements of subsurface structure, with much higher lateral resolution than the original magnetic images. In this paper, we consider seven different cues based on GLCM texture features. These features are – angular second moment (ASM), contrast, correlation, variance, inverse difference moment, sum entropy and information measures of correlation. The features are thoroughly promising [7].

Angular Second Moment (ASM):

$$ASM = \sum_{i=0}^{N-1}\sum_{j=0}^{N-1} p_{ij}^2 \tag{2}$$

It is also known as energy, uniformity, and uniformity of energy, returns the sum of squared elements in the GLCM. ASM ranges from 0.0 for an image with many classes and little clumping to 1.0 for an image with a single class.

Contrast:

$$Contrast = \sum_{i=0}^{N-1}\sum_{j=0}^{N-1} (i-j)^2 p_{ij} \tag{3}$$

It provides a measure of the intensity contrast between a pixel and its neighbor over the whole image. Contrast is also known as variance and inertia.

Correlation:

$$Corr = \sum_{i=0}^{N-1}\sum_{j=0}^{N-1} \frac{(i-\mu_i)(j-\mu_j)}{\sqrt{(\sigma_i^2)(\sigma_j^2)}} p_{ij} \tag{4}$$

It returns a measure of how correlated a pixel is to its neighbor over the whole image. We also explored *entropy*.

Entropy:

$$Entropy = -\sum_{i=0}^{N-1}\sum_{j=0}^{N-1} p_{ij} \times \log(p_{ij}) \tag{5}$$

It is a statistical measure of randomness that can be used to characterize the texture of the input image. We use he normalized GLCM as it is the joint probability occurrence of pixel pairs with a defined spatial relationship having gray level values of an image.

Inverse difference moment (IDM):

$$IDM = \sum_{i=0}^{N-1}\sum_{j=0}^{N-1} \frac{1}{1+(i-j)^2} p_{ij} \tag{6}$$

The inverse difference moment is another textural measure that attains a maximum value when all the image pixels that are compared have the same value, then yields a strong response at the central locations of the features of interest. IDM ranges from 0.0 for an image that is highly textured to 1.0 for an image that is untextured (such as an image with a single class).

4 EXPERIMENT AND RESULT

In this paper, we present a ground truth analysis for the GLCM-based image features. In Fig. 2, the ground-truth data contains 5 images – full white, strips in black and white – vertical direction and horizontal direction, gray, etc. This dataset shows comparative robust intuition of this concept. We cover different building images to analyze the statistical model features and some frames are shown in Fig. 3.

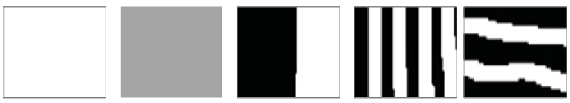

Fig.2 Ground-truth images.

Fig.3 Sample frames for the Building surface dataset.

In Fig. 4, we demonstrate the ASM. We can see that for bld-14, the ASM value is higher than others. We think that bld-14 has less texture elements and the pixels are very similar. The GT data for gt1 and gt2 has similar pattern with higher ASM value. Similarly, Fig. 5 shows contrast for ground-truth (GT) and building dataset. Similar to Fig. 4, it is evident that bld-14 has very less contrast. Contrast is zero when the neighboring pixels have constant values. The bld-6 has higher contrast values.

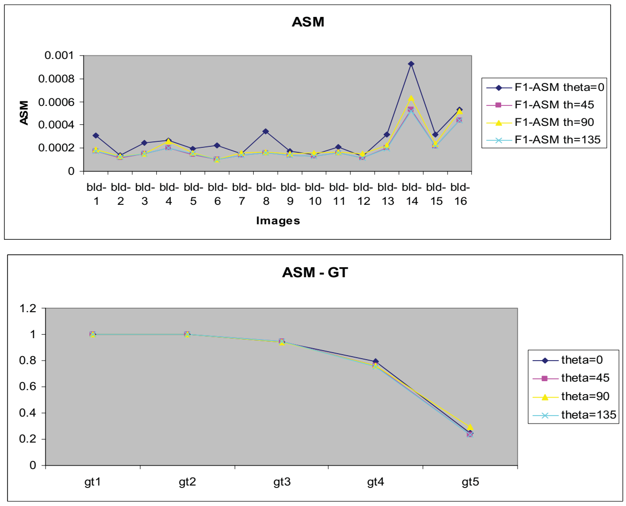

Fig.4 ASM for four angles with ground-truth (GT) and building dataset.

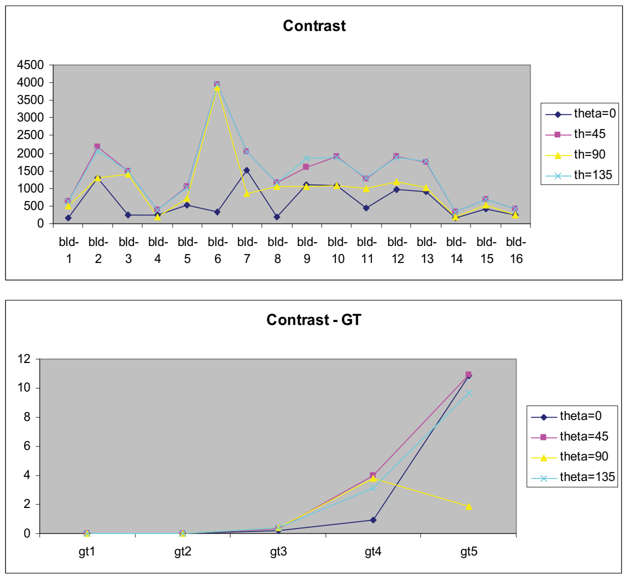

Fig.5 Contrasts evaluation for four angles.

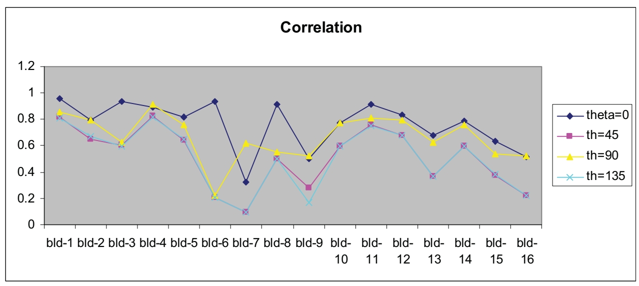

Fig.6 Correlation measures for four angles.

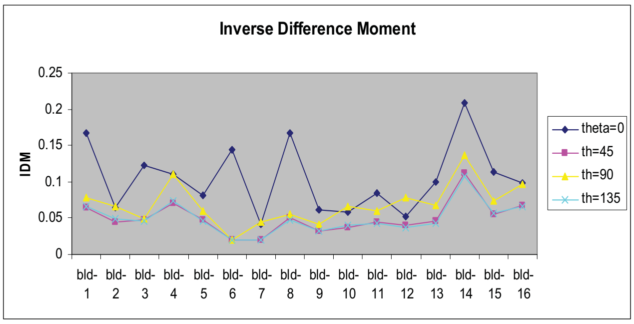
In Fig. 6, correlation measures are analyzed for the building surface dataset. Finally, the inverse difference moment (IDM) is computed as well for four angles for the ground-truth (GT) and building surface images. From the

GT graph in Fig. 7, it is visible that the IDM has higher value when all elements of the image are same. The bld-14 image has higher values for IDM and ASM.



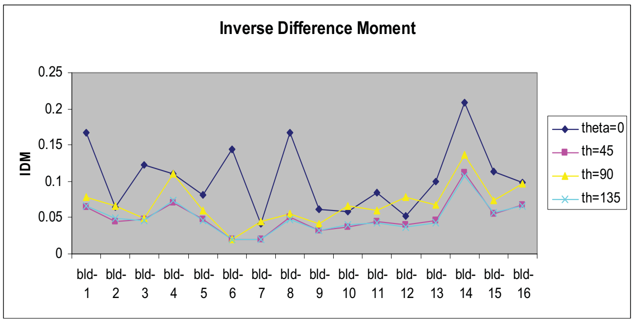


Fig.7 Graph for inverse difference moment.

5 CONCLUSIONS

In this paper, we explored image texture analysis, which is an important area for different real-life applications. Here, we exploited some of the robust gray-level co-occurrence matrix (GLCM)-based statistical measured for various image texture analyses. The gray-level co-occurrence matrix is a way of extracting 2nd order statistical texture features. In this paper, we computed and analyzed the angular second moment (ASM), correlation, contrast and inverse difference moment (IDM) based on the gray-level co-occurrence matrix. After demonstrating the model, we accomplished some experimental analyses by using a dataset to demonstrate the performances of the statistical model. It illustrates that these statistical modules can be very much functional for image texture understanding.. Initially, we ran our model in some ground-truth images covering few basic patterns, so that we can compare the results on various images on datasets. The experimental dataset is the standard 'building surface dataset', where the experimental results relate the ground-truth data significantly. In future, we will extract more features based on GLCM for texture analysis and evaluation, and we will classify various textures by employing classifiers. We will also analyze by using other datasets.

Abstract: The conventional log scaling, which is measured with a ruler by manual operation in order to get higher precision, is carried on by more workers working hard for a longer time. With the new developed technique, it is possible to use the machine vision for the log scaling. In order to get satisfactory results for that scaling process, the distance between the log and camera should be measured accurately. At the same time, the environment conditions for image capture will be considered carefully. In this paper, the laser rangefinder is developed to determine the distance between the log and camera automatically. The log scaling based on the machine vision was developed, and its properties were tested with various experiments.

Keywords: Machine vision, Log scaling, Image processing

1 INTRODUCTION

Log scaling is the measurement of the gross and net volume of logs. The primary purpose of scaling is to determine the volume of logs that will be charged at a different price. For the conventional scaling, it is necessary to measure log diameters and lengths first, and some defects will be considered based on an approved set of rules. Generally, a given number of logs will be determined for the gross and net volume in that scaling process. Although there are many methods to scale the volume of a log, such as weight scaling that is frequently used on low value materials or when the weight difference is very small for the similar logs, most of the scaling still performed manually by measuring the diameter and length of the log with a tape measure. The working conditions and physical labor intensity can be improved, but most operations sometimes have to be done in the high places, hot or cold environments. If we can change the manual log scaling operation with some machine operation, the efficiency and accuracy will be improved.

In the railway freight, the logs before scaling are loaded in the carriage as shown in figure 1. Two or three bundles of logs are laid on each carriage with height about 4 meters. Their diameters are different in different carriages. For the big diameter log, there are about ten pieces of logs in each bundle. There will be more than twenty or thirty piece of logs in each bundle if the log diameter is smaller. No matter what type of the log diameter, the height of each bundle is nearly the same (about 4 meters high). Compared with the small diameter log scaling, the scaling is easier for the big diameter log. When a log will be scaling, both sides need be done and the smaller one will be chosen as the scaling result. If it is a small diameter log, it is difficult even to find both sides for that log in that bundle. Moreover, many workers have to climb to higher place to measure. Generally, more than 200 operators work at the same time more than 12 hours for a freight train. The scaling results will also be influenced by human factors etc.

1) Bigger diameter

2) Both bigger and smaller diameter

Figure 1 Illustration of logs with different diameters

Aimed at the various problems of manual log scaling, many researchers try to use machine visions to substitute manual scaling. Although some researchers have applied the image processing technique to the log scaling, the best operation will be the scaling process of machine vision that is the same as manual operation. Because many logs' interface can be taken in an image, we can scale more logs at the same time from one captured picture. If necessary, we can also scale the log one by one based on the machine vision technique. The scaling efficiency can be improved remarkably. Moreover, the captured images can be saved in a database for the systematic management. Certainly they can also be used as the certification for later application. There are many advantages for the machine vision scaling, but the scaling accuracy is determined by such as lighting conditions, video image quality, etc.

When we use machine vision for log scaling, the distance between camera and the log interface should be determined first. Then the log diameter of its interface can be calculated based on the camera focus and previous distance. Now the distance generally is determined with infrared sensors or ultrasonic sensors, etc. Because the distance is longer than the effective range of such sensors and there is a gap among the log interfaces, those sensors can not work robustly. The laser rangefinder sensor can satisfy our requirements, but it is generally expensive. In the machine vision scaling, the image processing technique is used to determine the geometric dimensions of measured objects. Therefore, we can also determine that distance based on the image processing with point laser.

For the manual scaling, workers can find the shortest interface diameter fast based on their experience. If we develop some algorithms of image processing, the process will be complicated and its result will not always be reliable. Because the computer is good at calculation, many diameters in different angles of each interface will be measured and the smallest will be selected as the final result. The experiments showed, it is possible to replace the manual scaling with the computer vision scaling.

1. 2

2 DISTANCE CALCULATION BASED ON IMAGE PROCESSING

For the machine vision scaling, the first step is to decide the distance between the camera and the measured log. Although there are many sensors can be used to get the distance, considering the working conditions, we will use the image processing technique to get that distance. The conventional distance calculation based on image processing should use two cameras. That technique is not appropriate to our applications. In order to get the distance, here a point laser is used.

The relationship between the camera and pint laser is shown in Figure 2. Here, we assume the camera view angle in width direction is λ_x , λ_y is in the height direction, the length between the lens center and laser center is L, the coordinates of the laser center in image plane is P(x,y), θ is the angle between the lens center line and the vertical line from camera center to the laser center line, the image dimension is 2w×2h. Thus we can get the angle β, which is the angle between the connection line from camera center to P(x,y) and the optical axis of the camera.

$\beta = \arctan(\tan(\lambda_y) * (y-h)/h$

Then the distance between the camera and the object point will be:

HY $= L * \tan(\theta - \beta)$

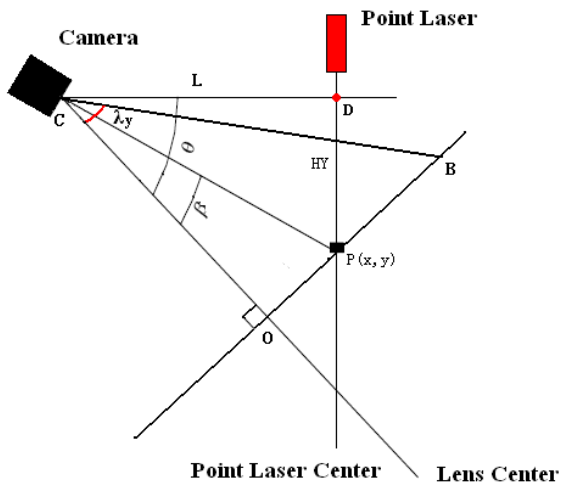

Figure 2 The illustration of distance calculation for image processing

Each paper size should be A4 size (210mm by 297mm). Write the paper in English.

3 EXPERIMENTS

In order to test the system whether it is appropriate for the application of the log scaling, the flowing experiments were carried out.

3.1 Experiments on the distance calculation based on image processing with point laser

If we want to proceed the log scaling based on the image processing, the first step is to get the distance between the camera and some target cross section. According to practical applications' requirements, the distance from 30cm to 300cm is tested.

In the experiment, seven groups of data were verified. We fixed the camera first, then marked seven points which are the distance of 30cm，45cm，85cm，100cm，150cm，300cm to the camera respectively. The test sample and point laser is shown in figure 3. The sample size is w0×h0=15mm×7.6mm. At each marked point, we will calculate the distance from camera to the sample. At the same time, we will also calculate the width and height respectively based on the distance gotten from image processing. Moreover, the relative error will be calculated. All results are listed in the table 1.

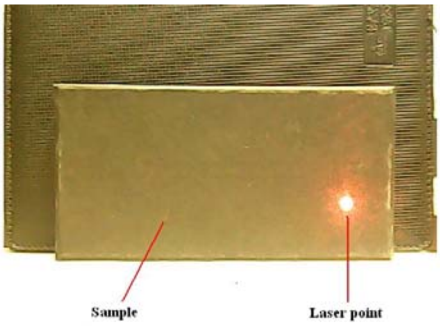

Figure 3 The illustration of the test sample and laser point

Table 1 The comparison between image processing and manual measurement (Unit: cm)

Manual d0	30	45	85	100	150	200	300
Camera d	29.93	44.34	84.16	98.60	146.49	193.54	285.29
(d-d0) /d0	-0.2%	-1.5%	-1%	-1.4%	-2.3%	-3.2%	-4.9%
Width w	14.81	14.75	14.64	14.53	14.91	15.06	14.68
(w-w0) /w0	-1.2%	-1.7%	-2.4%	-3.1%	-0.6%	0.4%	-2.1%
Height h	7.56	7.54	7.51	7.49	7.53	7.67	7.37
(h-h0) /h0	-0.5%	-0.8%	-1.2%	-1.4%	-0.9%	0.9%	-3%

Because the captured image size is 640×480pixels, the resolution is not high enough for objects far from the camera. When the object is put on the 300cm mark, the calculation accuracy of the distance, sample width and height is lower than the near marks to the camera. For our experiment camera, if the distance between camera and sample is controlled less than 100cm, we can get better calculation results based on the image processing. Although the results are also good for the distance from 100cm to 200cm, the edge points of the sample can not be extracted accurately.

3.2. Experiments on the log scaling based on image processing

In order to simulate the practical log scaling, the log cross sections are laid as shown in figure 4. First the distance between the camera and the log cross section is calculated based on the image processing, and its result is 84.76cm.The manual measurement is 85cm, and the relative error is 0.28%.

Figure 4 The illustration of log scaling experiment for distance calculation

The log scaling of the cross section is shown in figure 5. In order to get a more accurate calculation result, the whole cross section is divided equally by six angles, so six diameters can be calculated at the same time. In our experiment, the defect on the cross section will not be considered. Our experiment purpose is to verify the accuracy of the machine vision scaling. Each diameter is calculated based on two intersection points of each line. The initial length of each diameter is shown in the bottom of the figure 5, which are calculated only based on the coordinates on the image plane. When we consider the distance between the camera and log section, the real length will be calculated. The real length is shown in the right upper part of figure 6, which is transformed from the shortest one after the comparison among the above six calculation results. The manual result is 22cm. The image calculation result is 22.096cm, so the relative error is 0.4%. The manual result is also an approximate dimension.

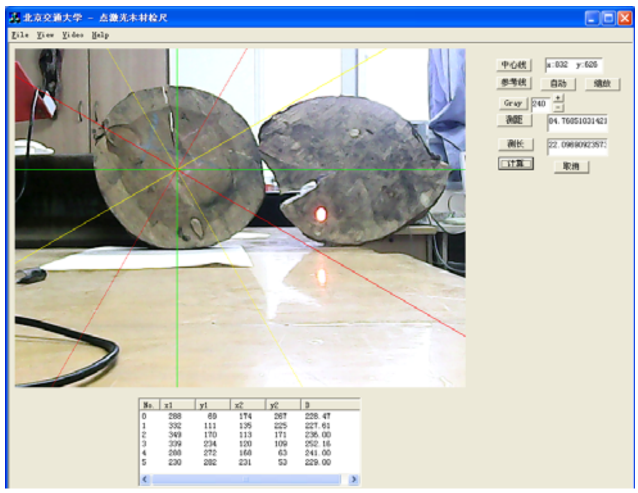

Figure 5 The illustration of the cross section scaling for left sample

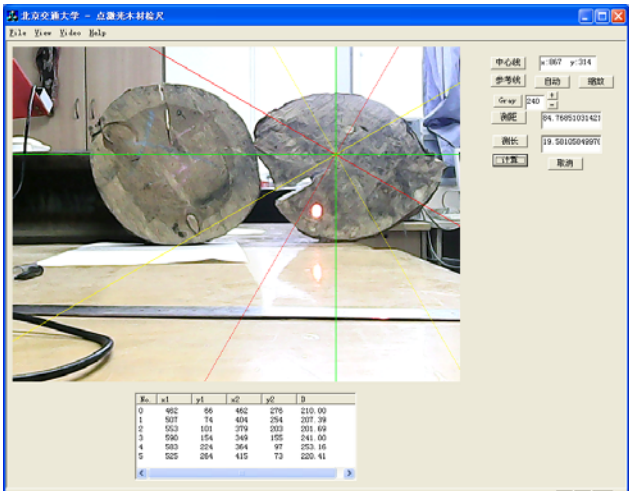

Figure 6 The illustration of the cross section scaling for right sample

In order to verify the machine vision scaling, another similar operation is done with another sample. The manual result is 20cm, and the image processing result is 19.58cm. The relative error is 2.1%. The big error is caused by the irregular cross section. It is difficult to get the shortest diameter by manual scaling.

4 CONCLUSIONS

According to the experiments on the distance calculation and log scaling based on the image processing, we can get following conclusions:

With our designed device, the distance between camera and target object can be calculated. If we want to get more accurate result, the distance can not be too far and the camera should have high resolution.

We can carry out the log scaling with machine vision. With this technique, the single log can be measured automatically, and multiple logs also can be measured in a same image. When we scale multiple logs in one image, their accuracy will be higher if their cross sections are in the same vertical plane. On the other hand, it is better to use camera with higher resolution.

Abstract: Peripheral arterial disease (PAD) is caused to the lower extremity atherosclerotic disease. Its diagnosis is needed to obtain much kind of the information of vascular morphology as well as the blood flow information based on hemodynamics. The diagnosis of the PAD using magnetic resonance imaging (MRI) equipment without contrast medium is available as a useful visual screening in clinical practice. In this paper, we propose a novel method for visualizing hemodynamics to arterial images obtained by a non-contrast enhanced magnetic resonance angiography (MRA) based on the Lucas-Kanade optical flow with the image pyramid processing, and satisfied experimental results are obtained.

Keywords: PAD, non-enhanced MRA, Lucas-Kanade optical flow, image pyramid processing

I. INTRODUCTION

Peripheral arterial disease (PAD), also called peripheral vascular disease, is atherosclerosis of the lower extremities causing ischemia. Severe PAD usually requires angioplasty or surgical bypass and may require amputation. Prognosis of this disease is generally good for treatment, although mortality rate is relatively high because coronary artery or cerebrovascular disease often coexists. In order to perform endovascular treatment or surgery, it is necessary to understand the vascular morphology and hemodynamic. In other words, by tracking the amount of blood flowing into the tissue, the treatment strategy is determined for the symptom. In diagnostic imaging for the PAD, computed tomography angiography (CTA) and magnetic resonance angiography (MRA) has seen widespread acceptance as noninvasive vascular diagnosis. When CTA and MRA are performed, however, it is necessary to consider the side effects when using contrast agent and these images are mainly used to diagnosis vascular morphology. On the other hand, non-contrast enhanced MRA is a very useful imaging technique which is obtained by magnetic resonance imaging (MRI). It has various advantages, for example, the ability to provide vascular morphology and hemodynamic without contrast agents. Especially, fresh blood imaging (FBI) method is useful for a non-enhanced MRA to detect a variety of vascular diseases causes of the PAD [1, 2].

The FBI is an electrocardiogram gated non-contrast enhanced MRA technique, which employs arterial signal difference between systole and diastole during a cardiac cycle, i.e. subtraction of the diastolic bright-blood arteries from the systolic black-blood arteries allowed visualization of the arteries by cancelling the veins. According to this experiment, the FBI has some density information corresponding to the cardiac cycle, which may be closely related to blood flow. In other word, the hemodynamic can be expressed by imaging the MRI signal information related to the pulse wave using the image density information during the cardiac cycle phase [3]. Nevertheless, it is difficult to express the direction and the velocity of blood flow on the FBI by using only image density information. In the medical image processing field and computer vision, it is important to develop hemodynamic analysis system. In particular, the vascular systems in human organs are distributed throughout the body, which generates a large number of image data in a single examination. In order to observe blood flow in a wide area may be also required some software for playing a supporting role in diagnosis such as the CAD systems [4]. Many CAD systems have been developed to analyze the internal organs based on CT, and MRI on the medical field [5]. Despite many researchers have developed various image processing techniques for blood flow, the related research papers concerning these techniques are very small, for which MRI imaging technique to acquire the original image are difficult. In addition, since the density information of the image rely on the subjects, determining between the normal region and the noise is also difficult.

A new development of CAD system to visualize hemodynamic using optical flow analysis is presented in this paper. The arterial images are obtained from non-enhanced MRA technique.

II. PROPOSED METHODS

In this section we will present our proposed image preprocessing method for detecting hemodynamic on MR images. Fig.1 shows the procedure of the subtraction for FBI images as an illustration. The FBI image is depicted as white blood in the early-systolic

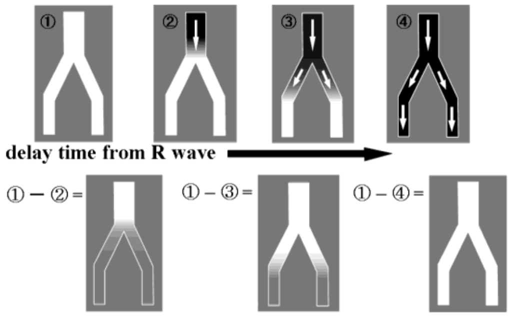

Fig. 1 A subtraction technique using successive MR images

Fig. 2 Examples of MIP images after subtraction

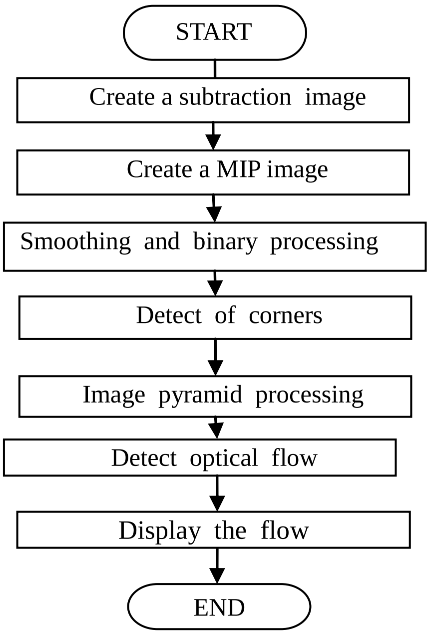

Fig. 3 Flow of procedure

phase, furthermore in the end-systolic phases; these images will become black blood as flows from the central to peripheral. From this result, these vessels are visualized such as angiogram by using subtraction technique as shown in Fig.1.

Fig. 2 gives examples of the maximum intensity projection (MIP) images obtained by the above method. A white area in Fig. 2 shows the blood vessel area. The outline of some image analyzing technique is shown below. Moreover, the overall scheme of the image processing techniques for tracking the region of blood vessels is illustrated in Fig. 3. The method consists of three main steps; detecting corners on the blood vessel region, feature tracking based on the Lucas-Kanade optical flow, and displaying the blood vessel. To acquire flow information on FBI images, some image processing techniques are introduced. In the first step, pre-processing technique such as smoothing and binarization are performed to reduce image noise, and then corners of features point are derived on these images. In the second step, using the Lucas-Kanade optical flow with an image pyramid processing to respond to rapid changes in the flow, velocity fields of the image are performed. In the third step, the estimated velocity vectors in the second step are depicted some arrows on the FBI images.

2.1 Detecting corners using Harris operator

Harris operator [6] is a method to derive feature points based on the correlation of image signal and the operator increase each correlation output value at the feature points of edges and corners. According to Schmid [7], this operator can be high repeatability to detect the points with the similar features. Even if the original image encounter these image transformations such as rotation and enlargement.

Given a point (x, y) and its shift (Δx, Δy), the weighted auto-correlation function is defined as,

$$E(x,y)=\sum_{W}\left[I(x_i,y_i)-I(x_i+\Delta x,y_i+\Delta y)\right]^2. \tag{2.1}$$

Where W is the weighting function. Here we applied the Gaussian function. $I(\Delta x_i,\ \Delta y_i)$ denotes the image function and (x_i, y_i) are the points in the window W centered on (x, y).The shifted image is approximated by a Taylor expansion truncated to the first order terms,

$$I(x_i+\Delta x,y_i+\Delta y)\approx I(x_i,y_i)+\left[I_x(x_i,y_i)I_y(x_i,y_i)\right]\begin{bmatrix}\Delta x\\ \Delta y\end{bmatrix} \tag{2.2}$$

In this study, auto-correlation matrix; $\boldsymbol{M}$, can be expressed as follows:

$$M=\begin{pmatrix}\sum w\left(I_x(x_i,y_i)\right)^2 & \sum wI_x(x_i,y_i)I_y(x_i,y_i)\\ \sum wI_x(x_i,y_i)I_y(x_i,y_i) & \sum w\left(I_y(x_i,y_i)\right)^2\end{pmatrix} \tag{2.3}$$

This can be expressed as the following

$$E(x,y)=(\Delta x,\Delta y)M(\Delta x,\Delta y)^T. \tag{2.4}$$

Two eigenvalues of this matrix $\boldsymbol{M}$ ($\lambda 1$, $\lambda 2$) said that while the highest corner. We use the following formula R rating in order to reduce the computational cost.

$$R=\lambda 1\lambda 2-k(\lambda 1+\lambda 2)=Det(M)-k(TraceM)^2 \tag{2.5}$$

However, when the curvature is k=0.06, there is a feature point (R>0). Feature points of corners with these procedures are utilized for the following optical flow analysis.

2.2 Lucas-Kanade optical flow method for detecting the feature points

The optical flow is a method to detect the motion of the object by determining a flow vector which calculated the velocity of the image from a continuous image sequence in time. The gradient method, optical flow estimation, is calculated motion vectors based on the equation relating the temporal gradient of local characters on the image and a spatial gradient. A basic constraint equation in the gradient method is based on th e condition that the pixel value of any point is no changed when the subject has moved. The equation is calculated as follows. The initial hypothesis in measuring image motion is that the intensity structures of local time-varying image regions are approximately constant under motion for at least a short duration [8]. Formally, if $I(x,y,t)$ is the image intensity function,

$$I(x,y,t) = I(x+\Delta x, y+\Delta y, t+\Delta t) \tag{2.6}$$

where (Δx, Δy) is the displacement of the local image region at $I(x,y,t)$ after time(Δt). Expanding the left-hand side of this equation in Taylor series yields

$$I(x+\Delta x, y+\Delta y, t+\Delta t) = I(x,y,t) + \Delta x\frac{\partial I}{\partial x} + \Delta y\frac{\partial I}{\partial y} + \Delta t\frac{\partial I}{\partial t} + \varepsilon \tag{2.7}$$

where $I_x = \frac{\partial I}{\partial x}, I_y = \frac{\partial I}{\partial y}$ and $I_t = \frac{\partial I}{\partial t}$ are the 1st order partial derivatives of $I(x,y,t)$ and ε. The 2nd and higher order terms are assumed negligible. Subtracting I = (x, y,t) on both sides, ignoring ε and dividing by Δt yields

$$I_x u + I_y v + I_t = 0 \tag{2.8}$$

Where I_x, I_y and I_t are spatio-temporal intensity derivatives and (u, v) is the image velocity. Equation (2.8) is known as the optical flow constraint equation and defines a single local constraint on image motion. However this constraint is not sufficient to compute both components of (u, v) as the optical flow constraint equation is ill-posed because of the reason such as the aperture problem. For this reason, the second constraint condition is added.

In Lucas and Kanade method the second constraint condition is that assume the neighborhood pixels in a small region have the same flow vectors. Under this assumption, the following equation for the k-th pixel is given by

$$I_{xk} u + I_{yk} u = -I_t k \cdot \tag{2.9}$$

The simultaneous equation is solved at a ($n \times n$) pixel of this neighborhood region. A solution of this simultaneous equation is obtained by using weighted least-squares. In order to estimate the optical flow, the window function (5×5) is performed.

2.3 Optical flow analysis using image pyramid

The blood flow in the human body often appears a small motion as well as a large motion in some vessel regions. The Lucas-Kanade optical flow is assumed to be as small and coherent motions; therefore, a large window will be required to detect large motions such as the blood flow. In the case of large and noncoherent motions, however, the large window would break the coherent motion assumption easily. We employed image pyramid to mitigate the problems caused by breaking the assumptions. When a pyramid-shaped a hierarchical structure is created by reducing the original image successively, the image moves accordingly decreases based on these image sizes. The feature points between images in a larger spatial scale with the optical flow are estimated initially, these feature points are then used as initial values between images at the following layer. Since these processes are iterated until the size of the original image, the reliability of the rapid changes in estimated flow is improved.

III. EXPERIMENTAL RESULTS

To acquire blood flow information, we applied automatically proposed method to MRA images obtained by FBI method. Image size is 256 x 256 [pixels] and the image set consists of 60 to 80 slices images per case. Visualizing hemodynamics for the blood flow is performed by utilizing L-K optical flow with the image pyramid processing in order to respond to rapid changes of blood flow. 8 cases experimental results on flow processing, displaying the flow vectors, are shown that the proposed method performed well. The results of the optical flow vectors processing in cardiac cycle are shown in Fig. 4(a), 4(b), and 4(c), respectively.

The flow vectors are generated from the abdominal artery near the heart, and these vectors are viewed as a movement from the external artery to the femoral artery over time. It was possible to display the flow vectors comparable to some antegrade arterial blood flow from the abdominal aorta to the femoral vessels in all cases.

Overall the performance for these flow detection results are evaluated by tested a statistically significant differences between each cardiac cycle times that are detected first moment at the femoral artery and are most often detected flow vectors. An example of a graph measured the velocity of the cardiac cycle in the femoral artery with a velocity measurement method by using MRA technique called the phase shift (PS) is shown in Fig. 5. The results of the cardiac cycle time obtained from the respective first moment obtained by the results of Fig. 5 are shown in Table 1. The result counted the number of vectors at the first moment in the ROI set in the femoral artery. The analysis results of cardiac cycle time obtained from the respective first moment and the cardiac cycle time of the maximum count number are shown in Table 2, respectively.

(a) (b) (c)

Fig. 4 Results of optical flow

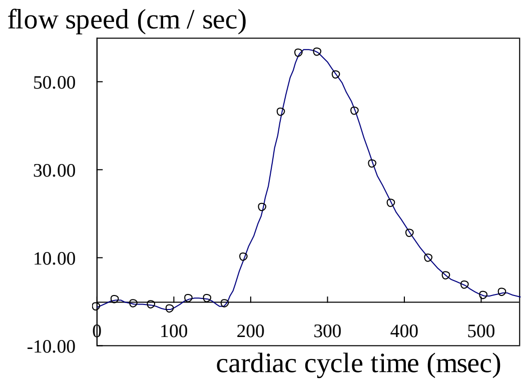

Fig. 5 An example of flow speed measurement using PS

Table 1 Result of calculated times at the first moment to each subject of 8 cases

Subject	First moment (msec)
A	170
B	170
C	155
D	165
E	165
F	160
G	155
H	155

Table 2 Results of cardiac cycle time of 8cases

Subject	maximum count (msec)	first moment (msec)
A	150	170
B	180	170
C	180	155
D	150	165
E	180	165
F	150	160
G	150	155
H	180	155

Based on these results, a significant difference test was performed by Mann-Whitney U test. The results of the analysis of the eight samples are $p = 0.39$ ($p> 0.05$), and there were no statistically significant differences between two groups.

IV. DISCUSSION AND CONCLUSIONS

In this paper, we developed a CAD system to visualize the hemodynamic using arterial images which are obtained from a non-enhanced MRA technique. Due to employ the ideas of subtraction technique between images, after pre-processing such as smoothing and Binarization, a good performance was obtained by using corner detection and analysis of optical flow. From the Table 2, since there were no statistically significant differences between the times of cardiac cycle detected the maximum number of the flow vectors and the time at each first moment of the blood flow, it may be considered that the flow vectors are able to show blood flow in the human body. Therefore, this correlation is considered that the flow vectors indicate a first motion of blood flow in the cardiac cycle. Although, the flow vectors do not necessarily indicate reflection for the speed of blood flow and blood volume. The first motion of blood flow reflects a pulse wave of the blood ejected from the heart. It is predictable from these discussions that the flow vectors obtained by optical flow analysis on the non-enhanced MR angiography images are able to estimate blood flow indirectly.

In order to set the threshold value based on the experience for binarization processing to process image noise, however, it should always be considered a risk that the detection rate of flow depend on the quality of original image. For these reasons, it is necessary to develop a flow detection algorithm without depending on the quality of the original image.

Abstract: In this paper we consider the reduction of the computational cost of reinforcement learning. When we apply the reinforcement learning to a robot with a large number of DOF, it needs a tremendous amount of time for learning because of the large state space. This problem is called "the curse of dimensionality". To solve the problem, we propose a phased approach on reinforcement learning. In the proposed method, we apply reinforcement learning to a robot with limited DOF at first, then release the restriction and resume the learning from the previous learning result. The computer simulation using arm robots having four and five joints proved the effectiveness of the proposed method. We also conducted an experiment in the case that an obstacle exists around the arm.

Keywords: Arm Robot, Reinforcement Learning, Phased Learning, Q-Learning.

1 INTRODUCTION

In recent years, robots have been expected to work not only in structured environments like factories, but also in different unstructured environments. The reinforcement learning [1], which is able to make robots acquire objective behaviors by themselves, attracts attention as a method to avoid the difficulty of programing of robot behavior in such environments. However, the reinforcement learning has a big problem called "the curse of dimensionality". This means that learning cost gets huge with increased DOF of the robot because the robot's state space exponentially expands.

Previously, some researchers have used the reinforcement learning for a robot with a number of DOF. They have manually given the environmental information to the robot to make the state space as small as possible [2][3]. However, it is workable only under the special conditions, and it is inevitable that learning time must be lengthened when large amount of information to solve a problem is not given in advance.

In this research, we attempt to reduce the learning cost by introducing a phased procedure in applying to a robot with a number of DOF. In this approach, the reinforcement learning is applied to the robot with the limited DOF beforehand, which can reduce the learning cost because the scope of state space gets narrower. Then we release the limitation of the robot's motion and restart the reinforcement learning with the state value of the previous learning result. In this way we expect that the robot learns objective task faster than the standard reinforcement learning starts with the full DOF from the beginning. In this paper, we call the first phase learning "previous learning" and final phase learning "eventual learning". To confirm the feasibility of the proposed method, we applied it to arm robots having four and five joints in the computer simulation. We also experimented in the environment with an obstacle.

2 PROPOSED METHOD

2.1 Reinforcement Learning

In this research, we use the Q-learning, the typical algorithm of reinforcement learning. Here, we briefly introduce the method.

When the agent at step t takes the action a_t based on its current state s_t, the state-action value function $Q(s_t, a_t)$ is updated as follows:

$$Q(s_t, a_t) \leftarrow Q(s_t, a_t) + \alpha[r_{t+1} + \gamma \max_a Q(s_{t+1}, a) - Q(s_t, a_t)] \quad (1)$$

where r_t is the reward the agent receives at step t, α is a learning rate and γ is a discount rate.

We employ the Radial Basis Function (RBF) network [4] for the approximation of the state-action value function. Thereby, Q-values are treated as a continuous function and neighboring state-action values are related in the value space. We use the Gaussian distribution as the RBF and place them in the value space divided into segments uniformly. Therefore, the approximated state-action value function is given by:

$$Q_a(\boldsymbol{s}) = \sum_j w(\boldsymbol{\mu}_j) \exp\left[-\frac{|\boldsymbol{s} - \boldsymbol{\mu}_j|^2}{\sigma^2}\right] \quad (2)$$

where w, $\boldsymbol{\mu}$ and σ^2 are the weight, the average and the variance of the RBF network. The weight w is updated as Q_a gets close to right-side value of (1).

2.2 Phased Approach

Here, we assume that an agent takes two-dimensional state $\boldsymbol{s}=(s_1, s_2)$ for explanation, and introduce an outline of the phased approach, the proposed method in this study. At first, the agent learns with a restricted dimension of state $\boldsymbol{s}$ in the previous learning phase. In this case, s_1 is fixed at constant value s_1', and the agent learns only with variable s_2 as shown in **Fig. 1.** (a). Thereby, the learning cost is reduced because it allows the agent to explore narrow area of the entire state space. However, the learning result exists in the only limited region of the space. Next, we spread out the resultant state value into the whole state space by using the Gaussian distribution function as follows:

$$w(s_1, s_2) = c \cdot w(s_1', s_2) \exp\left[-\frac{(s_1 - s_1')^2}{{\sigma_s}^2}\right] \qquad (3)$$

where ${\sigma_s}^2$ is the variance of the Gaussian and c is the constant for adjusting an effect of the previous learning. The weight of the RBF network w spreads in a direction toward s_1-axis as shown in **Fig. 1.** (b). Finally, after releasing the limitation of state $\boldsymbol{s}$, the agent restarts learning from the expanded result and acquires an optimal behavior in the eventual learning phase.

In this way, we expect that the agent learns objective task faster than simply learns the whole value space from the beginning. This approach can be expanded to the more dimensional cases.

3 ARM ROBOT

Here we introduce an arm robot with multiple joints for the experimentation. The robot is implemented with Open Dynamics Engine (ODE), the free library for simulating physical dynamics. **Fig. 2.** (a) shows the arm robot with four joints and environment created by the ODE. The joints rotate around the z-axis, therefore robot moves only in the xy-plane. Each link can overlap other links. The whole length of the robot is constant regardless of the number of joints and each link length is the same.

As shown in **Fig. 2.** (b), a movable range of the each joint is from -150 to 150 degrees, and each joint rotates 30 degrees clockwise or counter-clockwise in one step. The first joint from the root adopts absolute angle and the other joints adopt relative angle. The agent action a is defined to rotate any one of joints in 30 degrees. The state $\boldsymbol{s}$ is defined as a combination of respective joint angles, thus the number of all the states is 11^n, where the n is the number of joints.

4 EXPERIMENTS

4.1 Experimental setup

We examined both the proposed method and the standard reinforcement learning with the arm robot for comparison. In the experiments of the proposed method, the agent learned with some fixed joints in the previous learning phase as shown in **Fig. 3.** (a). Then, as shown in **Fig. 3.** (b), the agent learned again by using all the joints starting with the value space expanded from the previous learning result as the eventual learning. Meanwhile, the agent began learning with all the joints in the standard reinforcement learning. Both of the methods employed the Q-learning approximated by RBF network.

The robot's task was to reach a target with its tip. The agent received a reward only when the robot accomplished its task. On the other hand, the agent paid a penalty when the robot touched an obstacle. There were two experimental environments; with and without an obstacle. The robot having 2 joints cannot reach the target when the obstacle exists. The robot restarted from an initial position when it reached the task or touched the obstacle. If the obstacle existed, the initial position took the other side of the target across the obstacle. If it didn't exist, the initial position was took randomly.

In the Q-learning, the agent updated its state-action value $Q(s, a)$ at each step. One episode was defined as the robot reaching the target once. However, if the agent

(a) Fixing a part of the joints (b) Moving the all joints

Fig. 3. Applying the proposed method to the arm robot.

couldn't accomplish the task until $N_{\max}$ steps, the next episode started from another initial position. We employed the softmax function as a policy of the agent as follows:

$$\pi(s,a) = \frac{\exp(Q(s,a)/T_B)}{\sum_b \exp(Q(s,b)/T_B)} \tag{6}$$

where $\pi(s, a)$ is the probability distribution of taking the action a based on the state s and T_B is the Boltzmann temperature.

4.2 Configuration

We conducted three experiments to compare the proposed method with the standard reinforcement learning. In the first experiment, we applied our method to the arm robot with four joints in the environment without an obstacle. The agent learned under the condition with fixing the 2nd and 4th joints as the previous learning. Then, the agent restarted the learning as the eventual learning. In the same way, we conducted another two cases: fixing 1st and 3rd joints, and 2nd and 3rd joints. In the second experiment, we utilized the arm robot with five joints without an obstacle. As the previous learning, the agent learned with the robot fixed the 2nd, 4th and 5th joints. In the third experiment, we applied the proposed method to the arm robot with four joints in the environment with an obstacle. The previous learning was conducted with fixing 2nd and 4th joints without the obstacle. The agent then learned with the obstacle in the eventual learning phase. We compared the learning cost of our method with the cost of the standard reinforcement learning.

In each experiment, the agent learned during 50 episodes as the previous learning. The shapes and locations of the target and the obstacle are shown in **Table 1**. The values of these lengths were based on the condition that the whole length of the arm robot was 1 and the origin position was placed at the root of the arm robot. In the Q-learning, a values of the reward and penalty were 1 and -1, and $N_{\max}$ was set to 10,000. The RBFs variance σ^2 equaled 0.01 in the value space divided into 11^n segments. **Table 2.** shows the detail of the other experimental parameters. These parameters were determined empirically by exploratory experiments.

Table 1. The shapes and locations of the target

	Shape	x area	y area
Target	0.20×0.20 Square	[0.40, 0.60]	[0.40, 0.60]
Obstacle	0.10×0.55 Rectangle	[-0.05, 0.05]	[0.45, 1.00]

Table 2. The experimental parameters

	α	γ	T_B	σ_S	c
Previous learning	0.4	0.6	0.005	-	-
4 joints	0.5	0.6	0.005	0.2	0.5
5 joints	0.4	0.8	0.005	0.2	0.1
4 joints with obstacle	0.4	0.8	0.005	0.3	0.2

5 REUSLTS

Fig. 4. shows the step cost of reaching the target at each episode number of each experiments. **Fig. 5.** shows the total cost of steps until the 50th episode finished. The every resultant value is an average of the 100 times experiments.

As shown in **Fig. 4.**, the agent with the proposed method learned the tasks with less steps in all the experiments. Thus the feasibility of the proposed method is confirmed regardless of fixed joints or the number of joints. The eventual learning resultant of our method shows the slow convergence speed in **Fig. 4. (c)**. It is considered that the value around the obstacle which built in the previous learning interrupted the robot to reach the goal target.

As shown in **Fig. 5.**, the number of total steps with phased learning was less than the standard reinforcement learning in all the experiments. Especially, **Fig. 5. (c)** shows higher reduction ratio of total steps than when no obstacle exists. It represented that our proposed method is more efficient in complex environment.

6 CONCLUSION

We have developed an algorithm of reinforcement learning, phased learning. In this method, an agent learned with limited robot's DOF in the previous learning phase. The proposed method allows robots having a number of DOF to learn tasks efficiently. The conducted experiments with arm robots having four and five joints proved the feasibility of the proposed method. However, in the experiment with an obstacle, the proposed method converged slower than standard method. We need to research in detail how the resultant of previous learning affects the eventual learning for further improvement.

Abstract: This paper deals with a nonparametric identification of continuous-time Hammerstein systems using Gaussian process (GP) models. A Hammerstein system consists of a memoryless nonlinear static part followed by a linear dynamic part. The identification model is derived using the GP prior model which is described by the mean function vector and the covariance matrix. This prior model is trained by the separable least-squares approach combining particle swarm optimization with the linear least-squares method to minimize the negative log marginal likelihood of the identification data. Then the nonlinear static part is estimated by the predictive mean function of the GP, and the confidence measure of the estimated nonlinear static part is evaluated by the predictive covariance function of the GP. Simulation results are shown to illustrate the proposed method.

Keywords: continuous-time system, Gaussian process model, Hammerstein system, particle swarm optimization, system identification

1 INTRODUCTION

The Hammerstein system is expressed by a memoryless nonlinear static part followed by a linear dynamic part and has many advantages for control design or stability analysis due to its simple model structure. Numerous identification methods have been proposed for discrete-time Hammerstein systems [1, 2, 3]. Since these approaches are categorized into parametric identification, one needs to use a large number of weighting parameters to describe the nonlinearity and handle a complicated model structure determination. Moreover, no confidence measures for the estimated nonlinear static part are obtained in parametric identification. On the other hand, we have developed a nonparametric identification method based on the Gaussian process (GP) models, which can give the estimated nonlinear function with the confidence measure [4]. However, since most practical systems are usually continuous-time, it is very important to develop an accurate identification method for continuous-time Hammerstein systems.

Therefore, in this paper, we discuss the nonparametric identification of continuous-time Hammerstein systems using the GP model. The identification model is derived using the GP prior model which is described by the mean function vector and the covariance matrix. The prior mean function is represented in linear form of the input and the prior covariance function is expressed by the Gaussian kernel. This prior model is trained by the separable least-squares (LS) approach combining particle swarm optimization (PSO) [5] with the linear LS method to minimize the negative log marginal likelihood of the identification data. PSO is a swarm intelligence optimization technique, which was inspired by the social behavior of a flock of birds or a shoal of fish, and has been empirically shown to be very efficient for optimization. The use of PSO might increase the efficiency of identification due to its simple algorithm. The hyperparameters of the covariance functions and the numerator parameters of the linear dynamic part are represented with the particles and are searched by PSO, while the denominator parameters of the linear dynamic part are estimated by the linear LS method. Then the nonlinear static part is estimated by the predictive mean function of the GP, and the confidence measure of the estimated nonlinear static part is evaluated by the predictive covariance function of the GP. Simulation results show that the accuracy of the proposed method is superior to that of a conventional identification method.

2 STATEMENT OF THE PROBLEM

Consider a single-input, single-output continuous-time nonlinear system described by the Hammerstein model shown in Fig. 1. This system can be mathematically described as

$$\begin{cases} \sum_{i=0}^{n} a_i p^{n-i} y(t) = b_0 x(t) \quad (a_0 = 1) \\ x(t) = f(u(t)) + \epsilon(t) \end{cases} \tag{1}$$

where $u(t)$ and $y(t)$ are input and output signals, respectively. $x(t)$ is intermediate signal that is not accessible for measurement. $f(\cdot)$ is unknown nonlinear function, which is assumed to be stationary and smooth. $\epsilon(t)$ is assumed to be a zero-mean Gaussian noise with variance σ_n^2. $A(p) = \sum_{i=0}^{n} a_i p^{n-i}$ is the denominator polynomial of the linear dynamic part, where p denotes a differential operator. n is assumed to be known.

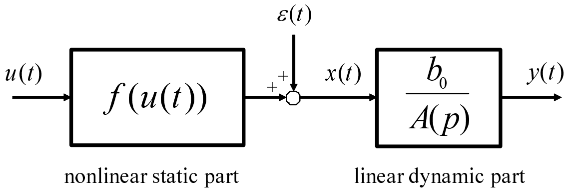

Fig. 1. Continuous-time Hammerstein system

The aim of this paper is to identify the system parameters $\{a_i\}$ and $\{b_j\}$ of the linear dynamic part, and the nonlinear static function $f(\cdot)$ with the confidence measure, from input and output data in the GP framework.

3 IDENTIFICATION MODEL BY THE GP

The following state variable filter $F(p)$ is introduced in order to evaluate higher order derivatives of signals:

$$F(p) = \frac{1}{p^q + \gamma_1 p^{q-1} + \cdots\cdots + \gamma_q} \quad (q > n) \tag{2}$$

Multiplying both sides of Eq. (1) by $F(p)$ yields

$$\begin{cases} \displaystyle\sum_{i=0}^{n} a_i p^{n-i} y^f(t) = b_0 x^f(t) \\ x^f(t) = F(p) f(u(t)) + \epsilon^f(t) \end{cases} \tag{3}$$

where $y^f(t) = F(p)y(t)$, $x^f(t) = F(p)x(t)$ and $\epsilon^f(t) = F(p)\epsilon(t)$. When $F(p)$ has a transport lag characteristic, the filter $F(p)$ and the nonlinear function $f(\cdot)$ are exchangeable and it follows that $F(p)f(u(t)) = f(F(p)u(t)) = f(u^f(t))$. Thus Eq. (3) becomes

$$\begin{cases} \displaystyle\sum_{i=0}^{n} a_i p^{n-i} y^f(t) = b_0 x^f(t) \\ x^f(t) = f(u^f(t)) + \epsilon^f(t) \end{cases} \tag{4}$$

In general the Butterworth filter has approximately a transport lag characteristic for frequencies $\omega \le \omega_c$, where ω_c is the cutoff frequency. Therefore, the Butterworth filter is utilized as the delayed state variable filter $F(p)$ in this paper.

Putting $t = t_1, t_2, \cdots, t_N$ into Eq. (4) yields

$$\boldsymbol{y} = \boldsymbol{A}\boldsymbol{\theta}_a + b_0 \boldsymbol{x} \tag{5}$$

where

$$\begin{aligned} \boldsymbol{y} &= [p^n y^f(t_1), p^n y^f(t_2), \cdots, p^n y^f(t_N)]^{\mathrm{T}} \\ \boldsymbol{x} &= [f(u^f(t_1)) + \epsilon^f(t_1), f(u^f(t_2)) + \epsilon^f(t_2), \\ &\qquad \cdots, f(u^f(t_N)) + \epsilon^f(t_N)]^{\mathrm{T}} \\ \boldsymbol{\theta}_a &= [a_1, a_2, \cdots, a_n]^{\mathrm{T}} \\ \boldsymbol{A} &= \begin{bmatrix} -p^{n-1} y^f(t_1) & \cdots & -y^f(t_1) \\ -p^{n-1} y^f(t_2) & \cdots & -y^f(t_2) \\ \vdots & & \vdots \\ -p^{n-1} y^f(t_N) & \cdots & -y^f(t_N) \end{bmatrix} \end{aligned} \tag{6}$$

A GP is a Gaussian random function and is completely described by its mean function and covariance function. We can regard it as a collection of random variables with a joint multivariable Gaussian distribution. Therefore, the function values $\boldsymbol{f}$ can be represented by the GP:

$$\boldsymbol{f} \sim \mathcal{N}(\boldsymbol{m}(\boldsymbol{u}), \boldsymbol{\Sigma}(\boldsymbol{u}, \boldsymbol{u})) \tag{7}$$

where

$$\begin{aligned} \boldsymbol{f} &= [f(u^f(t_1)), f(u^f(t_2)), \cdots, f(u^f(t_N))]^{\mathrm{T}} \\ \boldsymbol{u} &= [u^f(t_1), u^f(t_2), \cdots, u^f(t_N)]^{\mathrm{T}} \end{aligned} \tag{8}$$

$\boldsymbol{u}$ is the input (variable) of the function $\boldsymbol{f}$, $\boldsymbol{m}(\boldsymbol{u})$ is the mean function vector, and $\boldsymbol{\Sigma}(\boldsymbol{u}, \boldsymbol{u})$ is the covariance matrix. In this paper the mean function is expressed as $m(u^f(t)) = u^f(t)$, i.e., the mean function vector $\boldsymbol{m}(\boldsymbol{u})$ is described as follows:

$$\boldsymbol{m}(\boldsymbol{u}) = \boldsymbol{u} \tag{9}$$

The covariance $\Sigma_{pq} = s(u(t_p), u(t_q))$ is an element of the covariance matrix $\boldsymbol{\Sigma}$, which is a function of $u(t_p)$ and $u(t_q)$. Under the assumption that the nonlinear function $f(\cdot)$ is stationary and smooth, the following Gaussian kernel is utilized in this paper:

$$\begin{aligned} \Sigma_{pq} &= s(u(t_p), u(t_q)) \\ &= \sigma_y^2 \exp\left(-\frac{|u(t_p) - u(t_q)|^2}{2\ell^2}\right) \end{aligned} \tag{10}$$

From Eq. (7), the intermediate signal vector can be written as

$$\boldsymbol{x} \sim \mathcal{N}(\boldsymbol{m}(\boldsymbol{u}), \boldsymbol{K}(\boldsymbol{u}, \boldsymbol{u})) \tag{11}$$

where

$$\begin{aligned} \boldsymbol{K}(\boldsymbol{u}, \boldsymbol{u}) &= \boldsymbol{\Sigma}(\boldsymbol{u}, \boldsymbol{u}) + \sigma_n^2 \boldsymbol{I}_N \\ \boldsymbol{I}_N &: N \times N \ \text{identity matrix} \end{aligned} \tag{12}$$

and $\boldsymbol{\theta}_c = [\sigma_y, \ell, \sigma_n]^{\mathrm{T}}$ is called the *hyperparameter* vector.

Applying the property of the multivariable Gaussian distribution for the linear transformation to Eqs. (5) and (11), the identification model by the GP is derived as

$$\boldsymbol{y} \sim \mathcal{N}(b_0 \boldsymbol{m}(\boldsymbol{u}) + \boldsymbol{A}\boldsymbol{\theta}_a, b_0^2 \boldsymbol{K}(\boldsymbol{u}, \boldsymbol{u})) \tag{13}$$

4 IDENTIFICATION

4.1 Training by PSO

First, the GP prior model is trained by optimizing the unknown parameter vector $\boldsymbol{\theta} = [\boldsymbol{\theta}_a^{\mathrm{T}}, b_0, \boldsymbol{\theta}_c^{\mathrm{T}}]^{\mathrm{T}}$. Although this is a nonlinear optimization problem, we can separate the linear optimization part and the nonlinear optimization part. Therefore, in this paper, we propose a separable LS approach combining PSO with the linear LS method. Only $\boldsymbol{\Omega} = [b_0, \boldsymbol{\theta}_c^{\mathrm{T}}, \omega_c]^{\mathrm{T}}$ is represented with the particles and searched by PSO. The proposed training algorithm is as follows:

Step 1: Initialization

Generate an initial population of Q particles with random positions $\boldsymbol{\Omega}^0_{[i]} = [b_{0[i]}, \boldsymbol{\theta}^{\mathrm{T}}_{c[i]}, \omega_{c[i]}]^{\mathrm{T}}$ and velocities $\boldsymbol{V}^0_{[i]}$ $(i = 1, 2, \cdots, Q)$.

Set the iteration counter l to 0.

Step 2: Filtering of the identification data

Construct Q candidates of the state variable filter using $\omega_{c[i]}$. Calculate the filtered input $u^f_{[i]}(t)$, filtered output $y^f_{[i]}(t)$ and their higher-order derivatives, using each candidate of the state variable filter. Then construct Q candidates of $\boldsymbol{y}_{[i]}$, $\boldsymbol{A}_{[i]}$ and $\boldsymbol{u}_{[i]}$ $(i = 1, 2, \cdots, Q)$.

Step 3: Construction of covariance matrix

Construct Q candidates of covariance matrix $\boldsymbol{K}_{[i]}$ using $\boldsymbol{\theta}_{c[i]}$ $(i = 1, 2, \cdots, Q)$.

Step 4: Estimation of $\boldsymbol{\theta}_{a[i]}$

Estimate Q candidates for $\boldsymbol{\theta}_{a[i]}$ corresponding to $\boldsymbol{\Omega}_{[i]}$ $(i = 1, 2, \cdots, Q)$:

$$\boldsymbol{\theta}_{a[i]} = (\boldsymbol{A}^{\mathrm{T}}_{[i]}\boldsymbol{\mathcal{K}}^{-1}_{[i]}\boldsymbol{A}_{[i]})^{-1}\boldsymbol{A}^{\mathrm{T}}_{[i]}\boldsymbol{\mathcal{K}}^{-1}_{[i]}(\boldsymbol{y}_{[i]} - b_{0[i]}\boldsymbol{u}_{[i]}) \quad (14)$$

where $\boldsymbol{\mathcal{K}}_{[i]} = b^2_{0[i]}\boldsymbol{K}_{[i]}$.

Step 5: Evaluation value calculation

Calculate the negative log marginal likelihood of the identification data:

$$\begin{aligned} J(\boldsymbol{\Omega}^l_{[i]}) &= \frac{1}{2}\log|\boldsymbol{\mathcal{K}}_{[i]}| \\ &+\frac{1}{2}(\boldsymbol{y}_{[i]} - b_{0[i]}\boldsymbol{u}_{[i]} - \boldsymbol{A}_{[i]}\boldsymbol{\theta}_{a[i]})^{\mathrm{T}}\boldsymbol{\mathcal{K}}^{-1}_{[i]} \\ &\times(\boldsymbol{y}_{[i]} - b_{0[i]}\boldsymbol{u}_{[i]} - \boldsymbol{A}_{[i]}\boldsymbol{\theta}_{a[i]}) + \frac{N}{2}\log(2\pi) \end{aligned} \quad (15)$$

Step 6: Update of the best positions $\boldsymbol{pbest}$ and $\boldsymbol{gbest}$

Update $\boldsymbol{pbest}^l_{[i]}$, which is the personal best position, and $\boldsymbol{gbest}^l$, which is the global best position among all particles as follows:

If $l = 0$ then

$$\begin{aligned} &\boldsymbol{pbest}^l_{[i]} = \boldsymbol{\Omega}^l_{[i]} \\ &\boldsymbol{gbest}^l = \boldsymbol{\Omega}^l_{[i_{best}]} \quad i_{best} = arg\min_i J(\boldsymbol{\Omega}^l_{[i]}) \end{aligned} \quad (16)$$

otherwise

$$\boldsymbol{pbest}^l_{[i]} = \begin{cases} \boldsymbol{\Omega}^l_{[i]} & (J(\boldsymbol{\Omega}^l_{[i]}) < J(\boldsymbol{pbest}^{l-1}_{[i]})) \\ \boldsymbol{pbest}^{l-1}_{[i]} & (\text{otherwise}) \end{cases}$$

$$\boldsymbol{gbest}^l = \boldsymbol{pbest}^l_{[i_{best}]} \quad i_{best} = arg\min_i J(\boldsymbol{pbest}^l_{[i]}) \quad (17)$$

Step 7: Update of positions and velocities

Update the particle positions and velocities using Eq. (18):

$$\begin{cases} \boldsymbol{V}^{l+1}_{[i]} = w^l \cdot \boldsymbol{V}^l_{[i]} + c_1 \cdot rand_1() \cdot (\boldsymbol{pbest}^l_{[i]} - \boldsymbol{\Omega}^l_{[i]}) \\ \qquad\qquad + c_2 \cdot rand_2() \cdot (\boldsymbol{gbest}^l - \boldsymbol{\Omega}^l_{[i]}) \\ \boldsymbol{\Omega}^{l+1}_{[i]} = \boldsymbol{\Omega}^l_{[i]} + \boldsymbol{V}^{l+1}_{[i]} \end{cases} \quad (18)$$

where w^l is an inertia factor, c_1 and c_2 are constants representing acceleration coefficients, and $rand_1()$ and $rand_2()$ are uniformly distributed random numbers with amplitude in the range $[0, 1]$.

Step 8: Repetition

Set the iteration counter to $l = l + 1$ and go to Step 2 until the prespecified iteration number l_{max}.

Step 9: Determination of the GP prior model

Determine the vector $\hat{\boldsymbol{\Omega}} = [\hat{b}_0, \hat{\boldsymbol{\theta}}^{\mathrm{T}}_c, \hat{\omega}_c]^{\mathrm{T}}$ and the corresponding denominator parameters of the linear dynamic part $\hat{\boldsymbol{\theta}}_a = [\hat{a}_1, \hat{a}_2, \cdots, \hat{a}_n]^{\mathrm{T}}$ using the best particle position $\boldsymbol{gbest}^{l_{max}}$. Construct the suboptimal prior covariance function:

$$\begin{aligned} &s(u^f(t_p), u^f(t_q)) \\ &\quad = \hat{\sigma}^2_y \exp\left(-\frac{|u^f(t_p) - u^f(t_q)|^2}{2\hat{\ell}^2}\right) \end{aligned} \quad (19)$$

4.2 Estimation of the nonlinear static function

The estimates of the intermediate signal vector $\hat{\boldsymbol{x}}$ can be evaluated as follows:

$$\hat{\boldsymbol{x}} = \frac{1}{\hat{b}_0}(\boldsymbol{y} - \boldsymbol{A}\hat{\boldsymbol{\theta}}_a) \quad (20)$$

Let the test input vector and the corresponding function value vector and intermediate signal vector be $\boldsymbol{u}_*$, $\boldsymbol{f}_*$ and $\boldsymbol{x}_*$, respectively. Then the posterior distribution for $\boldsymbol{f}_*$ is obtained as

$$\boldsymbol{f}_*|\boldsymbol{u}, \hat{\boldsymbol{x}}, \boldsymbol{u}_* \sim \mathcal{N}(\bar{\boldsymbol{f}}_*, cov(\boldsymbol{f}_*)) \quad (21)$$

where $\bar{\boldsymbol{f}}_*$ is the predictive mean vector and $cov(\boldsymbol{f}_*)$ is the predictive covariance matrix, which are given as follows:

$$\begin{aligned} \bar{\boldsymbol{f}}_* &= \boldsymbol{m}(\boldsymbol{u}_*) + \boldsymbol{\Sigma}(\boldsymbol{u}_*, \boldsymbol{u})\boldsymbol{K}^{-1}(\hat{\boldsymbol{x}} - \boldsymbol{m}(\boldsymbol{u})) \\ cov(\boldsymbol{f}_*) &= \boldsymbol{\Sigma}(\boldsymbol{u}_*, \boldsymbol{u}_*) - \boldsymbol{\Sigma}(\boldsymbol{u}_*, \boldsymbol{u})\boldsymbol{K}^{-1}\boldsymbol{\Sigma}(\boldsymbol{u}, \boldsymbol{u}_*) \end{aligned} \quad (22)$$

Thus, the nonlinear static function of the objective system is estimated as

$$\begin{aligned} \hat{f}(u_*(t)) &= m(u_*(t)) \\ &\quad + \boldsymbol{\Sigma}(u_*(t), \boldsymbol{u})\boldsymbol{K}^{-1}(\hat{\boldsymbol{x}} - \boldsymbol{m}(\boldsymbol{u})) \end{aligned} \quad (23)$$

and its covariance function $\hat{s}$ is evaluated as

$$\begin{aligned} \hat{s}(u_*(t_p), u_*(t_q)) &= s(u_*(t_p), u_*(t_q)) \\ &\quad - \boldsymbol{\Sigma}(u_*(t_p), \boldsymbol{u})\boldsymbol{K}^{-1}\boldsymbol{\Sigma}(\boldsymbol{u}, u_*(t_q)) \end{aligned} \quad (24)$$

The predictive covariance function $\hat{k}$ of the intermediate signal is obtained as

$$\hat{k}(u_*(t_p), u_*(t_q)) = \hat{s}(u_*(t_p), u_*(t_q)) + \hat{\sigma}^2_n \delta_{pq} \quad (25)$$

where δ_{pq} is the Kronecker delta, which is 1 if $p = q$ and 0 otherwise. Equations (24) and (25) are used as confidence measures of the estimated nonlinear static function and the intermediate signal, respectively.

5 NUMERICAL SIMULATIONS

Consider a continuous-time Hammerstein system described by

$$\begin{cases} \ddot{y}(t) + a_1\dot{y}(t) + a_2 y(t) = b_0 x(t) \\ x(t) = f(u(t)) + \epsilon(t) \\ a_1 = 3.0, \quad a_2 = 1.5, \quad b_0 = 1.0 \\ f(u(t)) = u(t) + 0.5u^3(t) \end{cases} \tag{26}$$

The output signal is generated by a random signal of band-pass 3.0[rad/s]. The sampling period is taken to be $T = 0.05$[s]. $\epsilon(t)$ is zero-mean Gaussian noise with a standard deviation σ_n of 2.1, which means the noise-to-signal ratio (NSR) is 20%. The number of input and output data is $N = 300$. The design parameters for PSO are chosen as follows: particle size: $Q = 50$, inertia factor: $w^l = w_{max} - (w_{max} - w_{min})l/l_{max}$ $(w_{max} = 0.9, w_{min} = 0.4)$, acceleration coefficients $c_1 = 1.0$, $c_2 = 0.9$, maximum iteration number $l_{max} = 200$.

Estimates of of the parameters in the linear dynamic part are $\hat{a}_1 = 3.072$ and $\hat{a}_2 = 1.490$, respectively, where estimate of b_0 is omitted because the final estimated model is normalized by $\hat{b}_0$. Fig. 2 and Fig. 3 show the estimated nonlinear function and the estimated intermediate signal with the double standard deviation confidence intervals, respectively.

Monte-Carlo simulations of 20 experiments are implemented for the proposed method and conventional RBF-based method. Table 1 shows the mean squares errors between the true outputs and the outputs of the estimated models for various values of σ_n on the average of 20 experiments.

6 CONCLUSIONS

In this paper a novel nonparametric identification method for continuous-time Hammerstein systems has been proposed using the GP model. The GP prior model is trained by the separable LS approach combining the linear LS method with PSO so that the negative log marginal likelihood of the identification data is minimized. The nonlinear static part of the objective Hammerstein system is estimated by the predictive mean function of the GP, and the confidence region of the estimated nonlinear static part is given by the predictive covariance function. Simulation results show that the accuracy of the proposed method is superior to that of a conventional identification method.

Abstract: In this paper, we address the autonomous control of a 3-dimensional snake-like robot through the use of reinforcement learning, and we apply it in a dynamic environment. In general, snake-like robots have high mobility that is realized by many degrees of freedom, and they can move over dynamically shifting environments such as rubble. However, this freedom and flexibility leads to a state explosion problem, and the complexity of the dynamic environment leads to incomplete learning by the robot. To solve these problems, we focus on the properties of the actual operating environment and the dynamics of a mechanical body. We design the body of the robot so that it can abstract small, but necessary state-action space by utilizing these properties, and we make it possible to apply reinforcement learning. To demonstrate the effectiveness of the proposed snake-like robot, we conduct experiments; from the experimental results we conclude that learning is completed within a reasonable time, and that effective behaviors for the robot to adapt itself to an unknown 3-dimensional dynamic environment were realized.

Keywords: Dynamic Environment, Reinforcement Learning, Crawler Robot

1 INTRODUCTION

Recently, robots that have many degrees of freedom have drawn considerable attention. Snake-like robots or robots of serially connected crawlers are typical examples. In general, these robots have high mobility that is realized due to the many degrees of freedom while in motion. So, they can be operated in complex and quick-shifting environments like rubble, and they are expected to be used for practical applications such as rescue operations [1-8].

On the other hand, the application of reinforcement learning for controlling real robots also attracts considerable attention because robots can learn effective behavior by trial-and-error [9]. Therefore, by applying reinforcement learning to a robot with many degrees of freedom, an autonomous robot with high mobility can be realized; such a robot will be very useful for various tasks such as rescue operations. However, conventional reinforcement learning has a serious problem when applied to robots with many degrees of freedom that operate in complex environments. This is known as the state explosion problem. The size of the state-action space increases exponentially with an increase in the robot's degrees of freedom as well as the complexity of the environment. As a result of this increase, learning cannot be completed within a reasonable time limit. In addition, if some part of environment is changed, additional learning is required. So, it is highly difficult to apply reinforcement learning to robots operating in a dynamic environment.

In contrast, animals can learn by trial-and-error in spite of the many degrees of freedom afforded by their bodies and despite the fact that the daily environment that they live in, and contend with, is very complex and dynamic. How animals are able to cope with such a challenging environment is still an open question. But in embodied cognitive science [10], or ecological psychology [11], it is thought that the body plays an important role in realizing adaptive behaviors.

In this paper, we have designed the mechanical body of a robot such that it can abstract state-action space, on the basis of our previous work [12]; this design is expected to solve the problems outlined above. Using the proposed mechanism, the size of the state-action space can be reduced drastically, so that it is possible for the robot to learn in real time. Moreover, the robot's obtained policy is generalized and is applicable without additional learning even if the environment is changed dynamically.

To demonstrate the effectiveness of the proposed mechanism, we conduct experiments. The task of the robot is to learn the effective behavior for moving towards a light source in a dynamic environment. There are many unknown obstacles in the environment, and the obstacles move up and down constantly. The learning process is performed in both the static and dynamic environments, and the obtained policy is applied to other environments as well, where the obstacles are placed in different positions.

2 TASK AND ENVIRONMENT

Fig. 1 shows a dynamic environment. The environment is composed of 24 modules, and each module has two obstacles that move vertically. The range of movement of the obstacles ranges from a height of 5 cm to 12 cm. The dimensions of the environment are 240 cm (length) and 180 cm (width). We employ 5 different modules, as shown Fig. 2, all of which are placed randomly. There is one light source that the robot must move towards, and the aim of the task is to learn effective behavior for homing in on the light source within this 3-dimensional dynamic environment.

3 PROPOSED METHOD

3.1 General framework

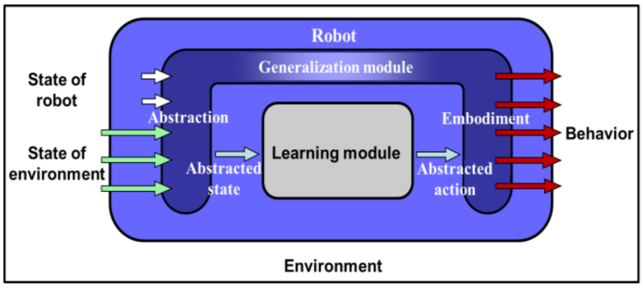

Fig. 3. General framework

Fig. 3 shows the general framework for the abstraction of the state-action space that we proposed in past studies [12, 13]. The robot consists of the generalization module and the learning module. A remarkable concept central to the proposed framework is that the generalization module is realized by the body of the robot itself instead of being implemented in a remote computer. The body is designed such that the necessary calculations for generalization are performed by utilizing the physical properties of the real world. The abstracted information is passed to the learning module in a computer, where the learning process is actually completed, with the selected action being fed back to the generalization module. The generalization module embodies the abstracted action that enables the complex movement of the robot. In the following subsection, we discuss the design the body of a snake-like robot on the basis of this framework.

3.2 Hardware design of body

In this study, we develop a 3-dimensional snake-like robot by improving our previous robot [12]. Fig. 4 shows the mechanism of the robot. The robot is composed of three links that have crawlers. The joints are realized by rubber poles and are moved passively. Two wires are installed on both the sides, and their length can be adjusted by an active pulley that is mounted on the rear end. Upon turning the active pulley, one wire is rolled up while the other wire is loosened. This causes the body of the robot to turn, as shown in Fig. 5.

Due to the passive nature of the joints and the constraining influence of the wires, the robot can adapt to a bumpy and unstable environment. The robot's direction of movement can be controlled by just actuating the active pulley.

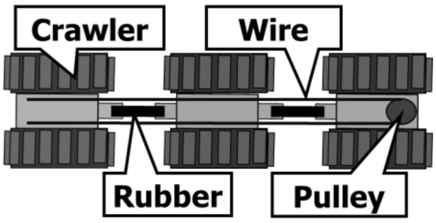

Fig. 4. Outline of robot

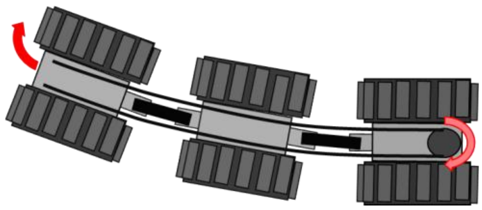

Fig. 5. Mechanism for pulling wires

3.3 Hardware design for sensing

We employ 18 CdS cells for detecting the direction that the light is coming from, as shown in Fig. 6. Each module is composed of 6 CdS cells (Fig. 6 a)), and 3 such modules are embedded on the robot as shown in Fig. 6 b). The CdS cells have directional characteristics and their layout is hemispherical. Therefore, the light direction can be obtained by equation (1):

$$x = \frac{3\sum_{i=1}^{3}(1/R_{i1}) + 2\{\sum_{i=1}^{3}(1/R_{i2}) + \sum_{i=1}^{3}(1/R_{i3})\} + \sum_{i=1}^{3}(1/R_{i4}) + \sum_{i=1}^{3}(1/R_{i5})}{\sum_{j=1}^{6}\sum_{i=1}^{3}(1/R_{ij})} \quad (1)$$

where R_{ij} denotes the electrical resistance of the j-th CdS cell in the i-th module. x represents the center of gravity of the light intensity and is equivalent to the light direction. For more details, please refer to [12].

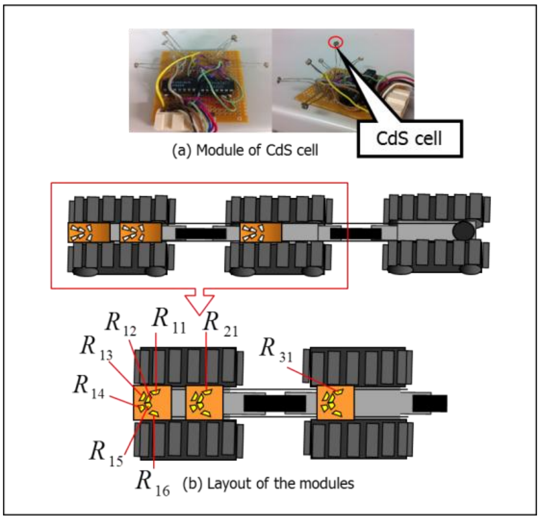

Fig. 6. Sensing system using CdS cells

3.4 Developed robot

Fig. 7 and Table 1 show the developed robot and its specification. The passive joints are realized by using rubber poles. To obtain adequate elasticity, the dimensions of the rubber poles are very important. However, it is very difficult to determine the dimensions theoretically. So, in this paper, these sizes were tuned by preliminary experiments.

Table 1.
Specification of the developed robot

Length	85 cm
Width	13 cm
Height	11 cm
Weight	2 kg

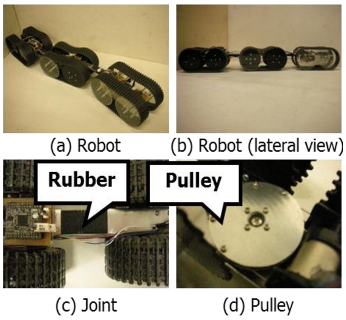

Fig. 7. Developed robot

Fig. 8 shows the result of the preliminary experiment performed for examining the capability of the sensor module. From the results, we find that the horizontal direction of the light can be obtained from the output voltage.

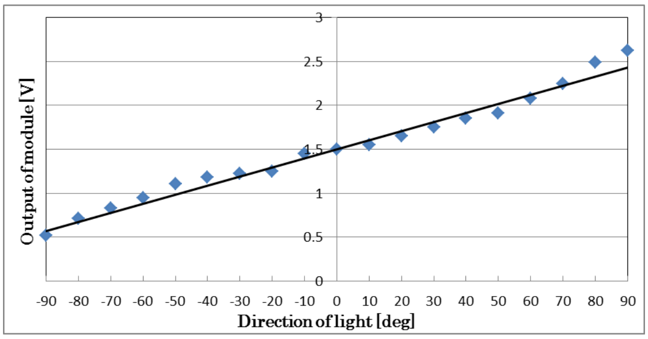

Fig. 8. Output of the sensor module

4 EXPERIMENT

4.1 Setting of reinforcement learning

We employ typical Q-learning [9] as reinforcement learning. Equation (2) represents Q-learning [9].

$$Q(s,a) \leftarrow (1-\alpha)Q(s,a) + \alpha\{r(s,a) + \gamma \max_{a'} Q(s',a')\} \quad (2)$$

where s is the state; a, the action; r, the reward; α, the learning rate; and γ, the discount rate.

We set α as 0.5 and γ as 0.9. The action is selected by using the ε–greedy method, and the probability of random selection of the action is 0.1.

One trial was conducted for a duration of 24 s, and calculations were performed every 0.5 s by using equation (2). Table 2 shows the state of the light direction. The values are the outputs of equation (1). Table 3 shows the state of the body. These values are the angle of the active pulley. Table 4 shows the actions. While the robot is moving towards the light source (the state of the light direction is 2 and the value of the angle of the active pulley is 2), a reward of 100 is assigned. When the robot loses the light source (light source goes out of the perceivable range), a negative reward −100 is assigned. The trial then ends, and the next trial starts.

Table 2.
States of the direction of light

State	Voltage[V]
0	(0.50,1.00]

Degree [deg]	-50	-25	0	25	50
State of robot	Left bend		Straight	Right bend	

Table 4. Action

Action	Motion
0	Turn tail motor by – 25° (Robot will turn left)
1	Hold the tail motor (Maintain state of the body)
2	Turn tail motor by + 25° (Robot will turn right)

4.2 Experiment

The obstacle is placed randomly as shown in Fig. 10, and we conduct the learning process by using a real robot. We consider two cases. One is a static environment where the obstacles do not move. The other is a dynamic environment in which objects move vertically. The learning process is conducted separately for each case.

After the learning process is completed, we apply the policy that is obtained in the static environment to the dynamic environment without additional learning, and we confirm the generalization capabilities of the proposed framework.

Fig. 10. Environment

Fig. 11 shows the learning curves, and Figs. 12 and 13 show the behavior after learning. In both cases, the value of the obtained reward has converged during the 40th trial. This implies that the learning can be completed in a reasonable time. From the result, we conclude that the problem of real-time learning is solved.

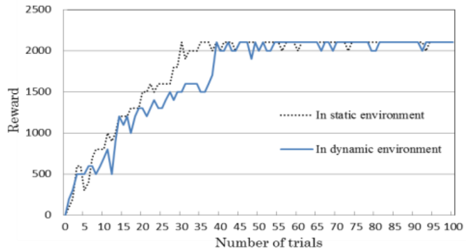

Fig. 11. Learning curve

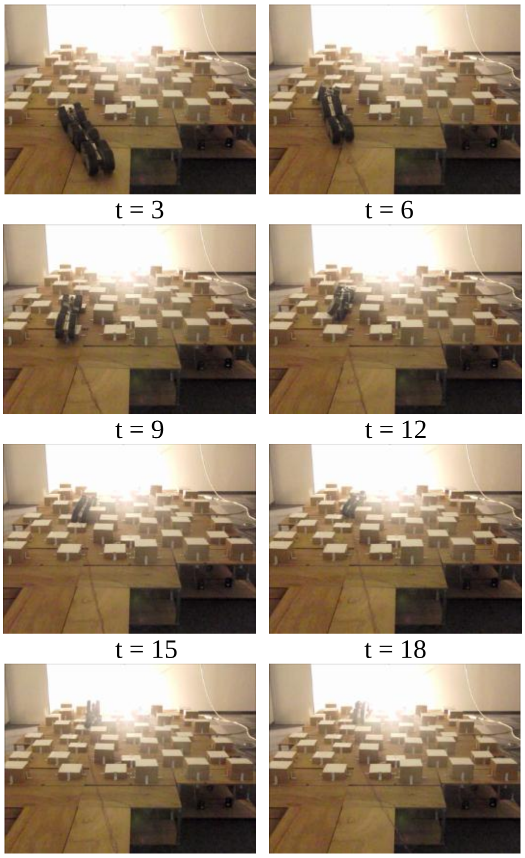

Fig. 12. Behavior after learning (static environment)

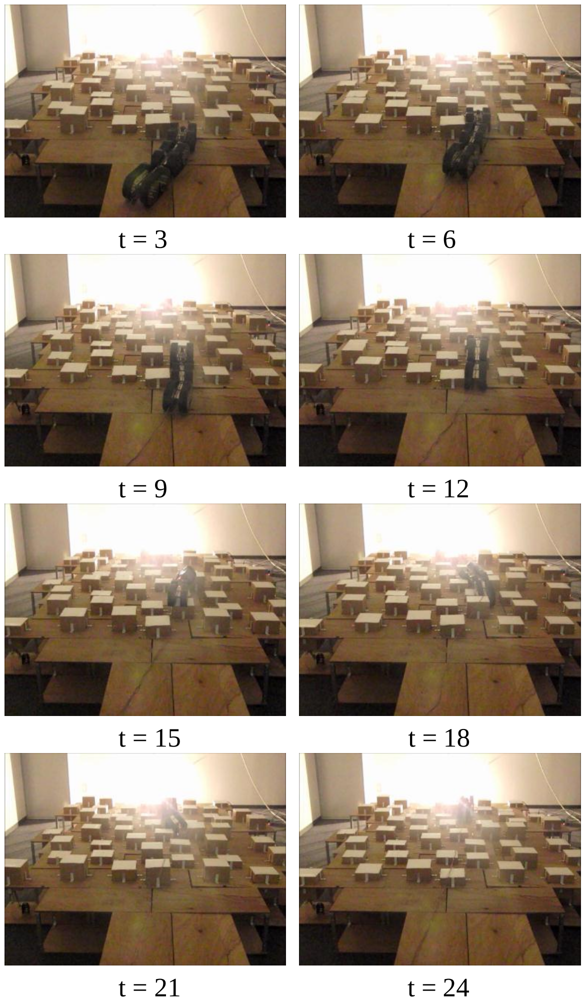

Fig. 13. Behavior after learning (dynamic environment)

Next we consider the generalization capability of the proposed framework. Fig. 14 shows an example of behavior realized by applying the policy obtained in the static environment to the dynamical environment. In this case, there was no additional learning. Nevertheless, the robot could move to the light source. This implies that the obtained policy can be generalized and is applicable to unknown but similar environments without requiring re-learning.

To confirm the generality, we compare state transitions. Fig. 14 shows an example of a state transition graph in the static environment, and Fig. 15 shows one for the dynamic environment.

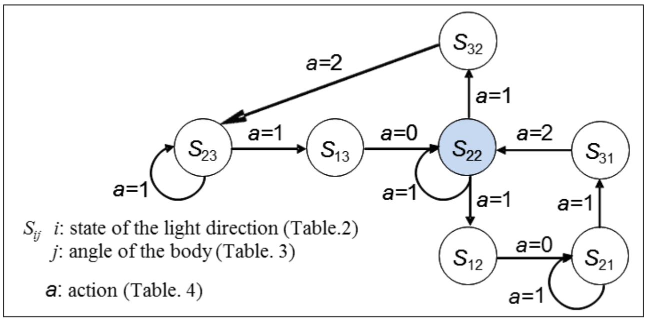

Fig. 14. State transitions in the static environment

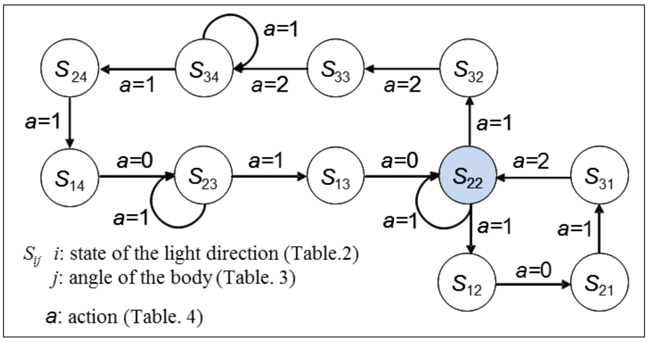

Fig. 15. State transitions in the dynamical environment

5 CONCLUSION

In this study, we examined autonomous control of a multi-crawler robot in a dynamic environment through the use of reinforcement learning. To solve the problems inherent to conventional approaches, which pertain to real-time learning and a lack of generality, we redesigned the mechanical body to abstract state-action space by utilizing the physical properties of the body. To demonstrate the effectiveness of our proposed approach, a prototype robot was developed and experiments were conducted. As a result, the behavior for moving towards a light source was learned within a reasonable time limit and the obtained policy could be generalized.

We conclude that the proposed framework is effective for developing autonomous robots that operate in dynamic environments.

Abstract: This paper proposes an Intelligent Control Method for Autonomous Vehicle which will roughly-appropriately and automatically recognize and judge the running environment and run along a given orbit without disarray by using Fuzzy-Neural Network (FNN). To realize autonomous running by using FNN, We extracted human's driving knowledge (teaching data for the FNN) from the running data. For acquiring the teaching data for the FNN, the running data are processed and normalized by rough set and defuzzy method. Moreover, we proposes an error correction method called "self-position-azimuth correction" to detect and correct the position and azimuth error between estimated position and actual measured position of the vehicle by using a pole at already-known position. The efficiency of the method has been verified by computer simulations and tests using a model vehicle.

Keywords: Autonomous vehicle, Fuzzy-neural network, Rough set, Self-position-azimuth correction

1 INTRODUCTION

Recently, labor saving in agricultural area is being needed increasingly because of decrease of agricultural workers due to the aging society. The autonomous running for the agricultural vehicle is one of the methods for the labor saving.

The purpose of this research is to construct an intelligent control system by using the fuzzy-neural network (FNN) for an autonomous vehicle which will roughly-appropriately and automatically recognize and judge the running environment and run along a given orbit without disarray.

Though various methods for orbit tracking of the vehicle have been proposed, there are many problems which have not been solved for learning human's driving knowledge and controlling the vehicle quickly as driven by a human driver. To solve these problems, this paper proposes an intelligent control method using fuzzy-neural network and Self-position-azimuth correction.

2 CONSTRUCTION METHOD

2.1 Model vehicle

The model vehicle used for the verification (called RoboCar^{TM}) is shown in fig. 2.1.

The dimensions of the model vehicle are W195.0 mm/D429.0 mm/H212.2 mm.

Speed control and steering angle control can be carried out by the rotary encoder and the servo motor respectively.

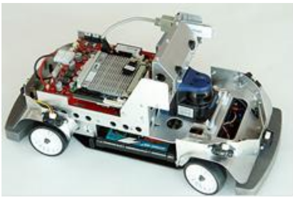

Fig. 2.1. RoboCar

2.2 Setting target orbit

The target orbit is sampled as points expressed by coordinate values which are set with the interval of about 20 cm. The straight line connecting points on the target orbit is regarded as approximate orbit of the target orbit. Also, these points are memorized in the computer of the model vehicle beforehand. The relative distance between the vehicle and point of target orbit are sequentially calculated while running. Then the point with the smallest relative distance is selected as the present target orbit point, the next point of that is regarded as sequential target orbit point. Finally, next point of now target orbit point is next target orbit point.

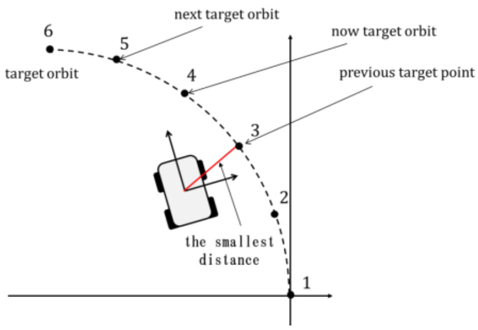

Fig. 2.2. Recognition of target orbit

2.3 Parameters between the vehicle and target orbit

*P*a is the relative distance between the center point of the vehicle and the target orbit. *P*b and *P*c are the relative angle between the direction of the vehicle and the line connected cross point 1 or cross point 2 to the center of the vehicle. Cross point 1 and cross point 2 are the points that the circle centered on the vehicle with the radius 30 cm, 60 cm intersects a target orbit. The vehicle recognizes a relative position by these parameters.

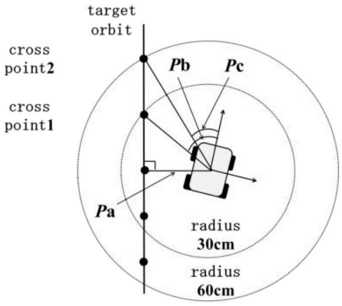

Fig. 2.3. Relative parameters

2.4 Method for extracting driving knowledge

Firstly, the running data is recorded while the vehicle is driven along target orbit by a human driver. *P*a, *P*b, *P*c and steering angle are acquired as the running data. Then, the running data is processed and normalized by rough set and defuzzy method. Human's driving knowledge (teaching data for the FNN) is extracted from the running data.

2.4.1 Normalization

Firstly, we need to normalize *P*a, *P*b, *P*c and steering angle for processing the teaching data by rough set. The range of the normalized relative distance and angle is narrow when the vehicle position is near to the target orbit, else it is wide when the vehicle position is distant from the target orbit. Steering angle is normalized with the interval of 3 degree.

Table 2.1. Range of normalization

Parameters	Pa [cm]	Pb [deg]	Pc [deg]
1	～-30	～-90	～-90
2	-30～-20	-90～-70	-90～-70
3	-20～-10	-70～-55	-70～-55
4	-10～-6	-55～-40	-55～-40
5	-6～-3	-40～-30	-40～-30
6	-3～-1	-30～-20	-30～-20
7	-1～1	-20～-15	-20～-15
8	1～3	-15～-10	-15～-10
9	3～6	-10～-6	-10～-6
10	6～10	-6～-3	-6～-3
11	10～20	-3～-1	-3～-1
12	20～30	-1～1	-1～1
13	30～	1～3	1～3
14		3～6	3～6
15		6～10	6～10
16		10～15	10～15
17		15～20	15～20
18		20～30	20～30
19		30～40	30～40
20		40～55	40～55
21		55～70	55～70
22		70～90	70～90

2.4.2 Rough set

In this section, we explain the rough set used this research. As a simple example, the data set is shown in Table. 2.2. *P* (the set of kinds of parameter) is shown by formula (2.1).

Table 2.2. Before rough set

Data No	Parameters P a	b	c	Sk
X1	3	2	1	0
X2	3	4	1	1
X3	1	7	3	0
X4	1	4	1	0
X5	3	4	1	1
X6	1	4	1	1
X7	4	6	2	0
X8	3	2	1	0
X9	4	6	2	1
X10	1	4	1	1

$$P = \{a, b, c\} \tag{2.1}$$

The i^th set of parameter value is shown by formula (2.2).

$$\begin{aligned} &{}^{1}P = \{3,2,1\} \\ &{}^{2}P = \{3,4,1\} \\ &\ldots \\ &{}^{10}P = \{1,4,1\} \end{aligned} \tag{2.2}$$

Approximation space set A is shown by formula (2.3).

$$A = \{r_1, r_2, r_3, r_4, r_5\} \tag{2.3}$$
$$= \{\{X_1, X_8,\}, \{X_2, X_5,\}, \{X_3\}, \{X_4, X_6, X_{10}\}, \{X_7, X_9\}\}$$

Then,

$$\begin{aligned} &r_1 = \{3,2,1\},\ {}^{r1}S = \{0,0\} \\ &r_2 = \{3,4,1\},\ {}^{r2}S = \{1,1\} \\ &r_3 = \{1,7,3\},\ {}^{r3}S = \{0\} \\ &r_4 = \{1,4,1\},\ {}^{r4}S = \{0,1,1\} \\ &r_5 = \{4,6,2\},\ {}^{r5}S = \{0,1\} \end{aligned} \tag{2.4}$$

By formula (2.4), ${}^{S}\beta_{ri}$, uncertainty of measurement to state *S* of equivalent class r_i, are

$$\begin{aligned} &{}^{0}\beta_{r1} = 2/2 = 1{:}100\% \\ &{}^{1}\beta_{r1} = 0/2 = 0{:}0\% \\ &{}^{0}\beta_{r2} = 0/2 = 0{:}0\% \\ &{}^{1}\beta_{r2} = 2/2 = 1{:}100\% \\ &{}^{0}\beta_{r3} = 1/1 = 1{:}100\% \\ &{}^{1}\beta_{r3} = 0/1 = 0\ {:}0\% \\ &{}^{0}\beta_{r4} = 1/3 = 0.33{:}33\% \\ &{}^{1}\beta_{r4} = 2/3 = 0.67{:}67\% \\ &{}^{0}\beta_{r5} = 1/2 = 0.5{:}50\% \\ &{}^{1}\beta_{r5} = 1/2 = 0.5{:}50\% \end{aligned} \tag{2.5}$$

Table 2.3. After rough set

rough sets r_i	Probability		Parameters P		
	${}^{0}\beta_{ri}$	${}^{1}\beta_{ri}$	a	b	c
$r_1=\{X_1^0,X_8^0\}$	100%	0%	3	2	1
$r_2=\{X_2^1,X_5^1\}$	0%	100%	3	4	1
$r_3=\{X_3^0\}$	100%	0%	1	7	3
$r_4=\{X_4^0,X_6^1,X_{10}^1\}$	33%	67%	1	4	1
$r_5=\{X_7^0,X_9^1\}$	50%	50%	4	6	2

2.5 Fuzzy-Neural Network

FNN can control the vehicle automatically and roughly-appropriately recognize and judge the running environment as human driver. Because FNN can output the appropriate results even if the input data have not been learnt beforehand, if we have appropriately made the leaning for the FNN. In this research, the inputs of the FNN are *P*a, *P*b and *P*c, the output of the FNN is steering angle. The construction of the FNN is shown in Fig. 2.4.

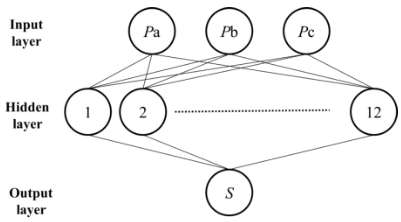

Fig. 2.4. Construction of the FNN

3 POSITION-AZIMUTH CORRECTION

We use the Dead Reckoning Method for the vehicle's positional presumption. But dead reckoning method has the disadvantage that the cumulative error of the vehicle position becomes a big gradually while running. The error is caused by slipping the wheel, etc. To solve this problem, we adopt self-position-azimuth correction using external information. In the verification, a pole (height is 200 mm; diameter is 65 mm) is set at already-known position on the world coordinate system Σ (*x*,*y*). Laser-Range-Finder (LRF) installed on the model vehicle measures a relative distance and angle between the vehicle and a pole. The range of detection of LRF is 5m and 240 degree like Fig. 3.1. Principle of Self-Position-azimuth Correction is shown in Fig. 3.2. $\overrightarrow{W}_{j'1}$ and $\overrightarrow{W}_{j'2}$ are the vector from the center of the vehicle to a pole. Also, the vector $\overrightarrow{W}_{j2-j1}$ can be calculated as follows.

$$\overrightarrow{W}_{j2-j1} = \overrightarrow{W}_{j2} - \overrightarrow{W}_{j1} \tag{2.6}$$

$$\theta_{\mathrm{L3}} = \theta_{\mathrm{L2}} - \theta_{\mathrm{L1}} \tag{2.7}$$

$$\theta_{\mathrm{L4}} = \sin^{-1}\left(\frac{l_2}{l_3} \times \sin\theta_{\mathrm{L3}}\right) \tag{2.8}$$

$$\theta_{\mathrm{G}} = \theta_{\mathrm{L4}} - \theta_{\mathrm{L1}} \tag{2.9}$$

$$R^{-1} = \begin{bmatrix} \cos\theta_{\mathrm{G}} & \sin\theta_{\mathrm{G}} \\ -\sin\theta_{\mathrm{G}} & \cos\theta_{\mathrm{G}} \end{bmatrix} \tag{3.0}$$

$$\vec{G} = \overrightarrow{W}_{j2} - R^{-1}\overrightarrow{W}_{j'2} \tag{3.1}$$

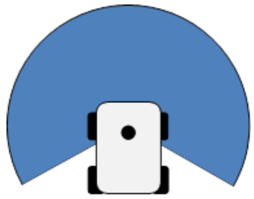

Fig. 3.1. The range of LRF

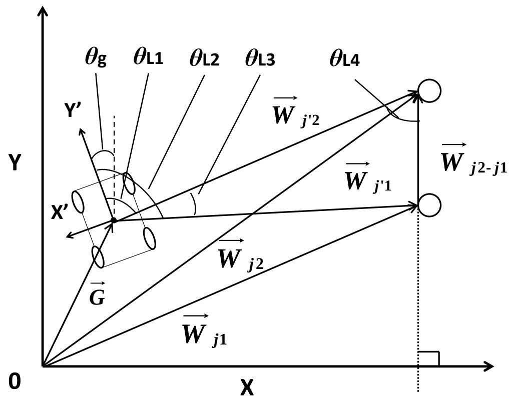

Fig. 3.2. Self-Position-azimuth correction

4. VERIFICATION

4.1 Vehicle communication environment

The model vehicle has Linux and is operated by other PC using access point.

Autonomous running will be operated by installed program.

Fig. 4.1. Communication system

4.2 Method for control of autonomous running

We need to construct the FNN in advance to control the vehicle. For the purpose, the teaching data is acquired by driving the model vehicle by human driver. And the learning for the FNN is done by Back Propagation Algorithm. When autonomous running is executed, the vehicle is controlled by output of the FNN. Output of the FNN is calculated by input *P*a, *P*b and *P*c to the FNN which has learnt the teaching data.

4.3 Acquisition the teaching data

Target orbit are the straight line and half circles with the radius 57.5 cm, 150 cm and 200 cm when we acquire the teaching data for the FNN. The initial positions are shown in Fig. 4.2, Fig. 4.3 when acquiring the teaching data.

The model vehicle's speed is at 10 cm/s. The initial directions are 0, 30 and -30 degrees when the vehicle run along a half circle with the radius 150 cm.

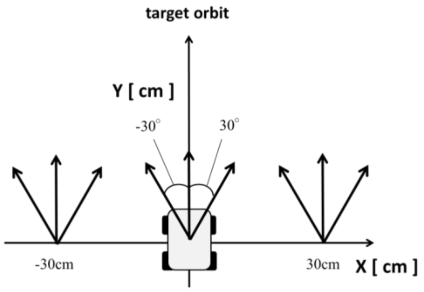

Fig. 4.2. The initial position of the vehicle when the target orbit is straight line

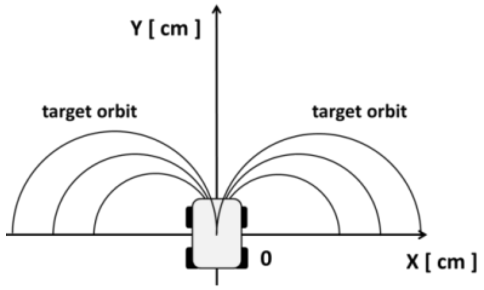

Fig. 4.3. The initial position of the vehicle when the target orbit is a circle

4.4 Running experiment

4.4.1 Verification by simulation

We did the autonomous running simulation using the FNN. The model vehicle's speed was 10 cm/s. The result of the autonomous running simulation is shown in Fig. 4.4, and by the result, the vehicle successfully returned to the straight orbit from the initial position which the FNN has not learnt.

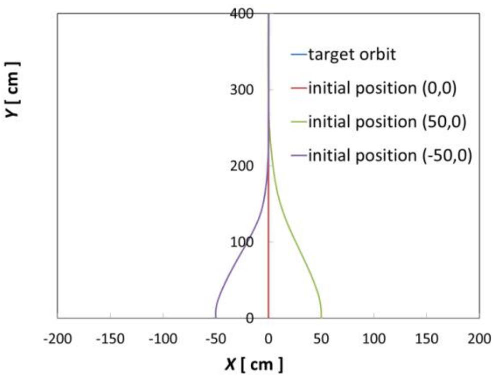

Fig. 4.4. The result of simulation

4.4.2 Verification by the model vehicle

The compound track orbit was set as the target orbit. The vertical straightway section of the target orbit is about 46.2 m, the crosswise straightway section is about 61.9 m, the curve section is a quarter of a circle with the radius 1 m. Also, two poles are set with about 4m intervals. We did the running experiment of the model vehicle. The vehicle's speed was 0.1 m/s, the initial position was (0,0) on the world coordinate system $\Sigma(x,y)$ and the initial direction was 0 degree. The result of running experiment is shown Fig.4.5. The vehicle tended to go to the left side. But the vehicle recognized the position and direction error between the estimated position and actual measured position by Self-position-azimuth correction and returned to the target orbit again. So, the model vehicle can run longer distance than previous experiment results.

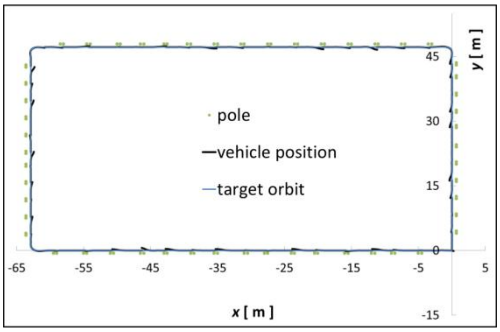

Fig. 4.5. The result of running experiment

5 CONCLUSION

It can be done efficiently to learn the teaching data for the FNN by acquiring the human's driving knowledge from the running data and by processing normalized rough set and defuzzy method even if there is only a small amount of teaching data. It is proved by the verifications that the FNN constructed by these methods can control the vehicle to run along the target orbit while roughly recognize and judge the running environment when the vehicle is in a condition which has not been learnt by the FNN in the vehicle. Also, it is proved that the Self-position-azimuth correction is useful for long distance running. The following problems are considered as the future subjects.

・To install a gyro sensor in the model vehicle and to run automatically in a condition with few poles
・To run automatically at a higher speed than ever
・To establish effective method for avoiding obstacles

Abstract: When the bottom-up learning approaches are implemented for mechanical systems, we must face a problem including huge number of trials. They take much time and give hard stress to the actual system. Simulator is often used only for evaluation of the learning method. However, it needs simulator modeling process, and never guarantees repeatability for the actual system. In this study, we are considering a construction of simulator directly from the actual robot with neural-networks. Afterward a constructed simulator is used for reinforcement learning to train a task, and the obtained optimal controller is applied to the actual robot. In this work, we picked up a five-linked manipulator robot, and made it track a ball as a training task. Both learning processes make load against the hardware sufficiently smaller, and the objective controller can be obtained faster than using only actual one.

Keywords: manipulator robot, neural-networks, reinforcement learning, simulator construction.

1 INTRODUCTION

The machine learning method is one of the typical techniques that may provide robots a capability to work in unpredictable and variable human life environment. Until now, many kinds of machine learning method have been proposed and they yield very effective results [1][2]. However, if they are directly applied to the actual machine, they face a problem including huge number of trials, which requires much time and gives stresses against the hardware and then makes a practical application difficult. To avoid such problems, a computational simulator is often employed and performed with a learning method since it permits many trials in short time without physical stresses [3]. However, the simulator utilization for the real system also includes some problems in its construction. Normally, the simulator is manually modeled by differential equation according to the physical law. Consequently, it never makes us completely free from exacting works. Moreover, there is no guarantee that the modeled simulator performance matches the actual machine when its construction is complicated. Hence, we propose a simulator construction directly from the actual hardware. In our method, a simulator learns the relationship between command signal and its resultant state of the hardware. Therefore, if the learning proceeds well, a simulator emulates the hardware behavior certainly, and we are relieved from arduous simulator modeling. After simulator construction, the optimal controller for an objective behavior is trained only with the constructed simulator. Therefore, this process never gives harsh load to the hardware and performs faster than directly using the hardware.

In this paper, we describe a novel method of machine learning using both a simulator and an actual hardware. A simulator of the hardware is directly built from the acquired input and output data of the real hardware and it performs with the neural-networks and the back-propagation learning method without any information of kinematics model. Afterward, the objective controller of the hardware is trained only with the built simulator by the reinforcement learning method. Finally, the optimum controller is applied to the actual hardware. In this manner, the optimal controller is generated via hybrid platform: simulator and hardware, without any knowledge in advance. Here we employed a five-linked manipulator robot as an actual hardware platform, and the only treated properties are state and command signals of actuators assembled into the robot. The task for the robot to train is to track a colored ball. Under these conditions, experiments were conducted and the prosed method was evaluated.

2 BASIC STRATEGY

Fig.1 illustrates a basic structure and process of our method. At first, data of the actual hardware behavior is sampled and collected into a buffer. In this case, data means a set of command and state of the actual hardware, and a resultant state corresponding to the command, which represents the relationship between input and output of the hardware. And then the buffer supplies reference data to

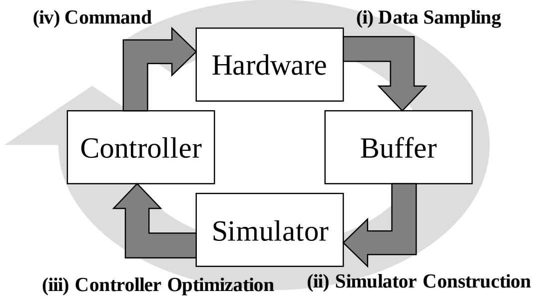

Fig.1. The over view of learning strategy

build a simulator in the appropriate manner. Afterward a controller is trained the optimal control for the objective task using the built simulator. At this time, because of a computational simulator, the hardware does not have to be actually operated and training process performs faster than using the actual hardware. Finally, the optimized controller operates the actual hardware to perform the objective behavior. In this way, the whole process starts from the hardware acting, and the information is returned to the hardware. Based on this structure, we apply to the five-linked manipulator robot to get the optimal task control. The implementation of each process for this problem is explained in the chapter 4.

3 MANIPULATOR ROBOT

In this paper, our method is applied to an actual robot. The robot we employed is a five-linked manipulator robot, composed of five servo motors as shown in Fig.2, and their link relations are illustrated in Fig.3. The motor is digital servo type and performable in serial communication to receive the action command and return the status information. The motor control mode is configured to "speed" mode. Finally the robot hardware consists of such motor, and state and action command of robot mean angle and speed command value for each motor. Specifically, we can just send a speed command value $a = (a_1, a_2, a_3, a_4, a_5)$ to each motor as action command for robot, and observe each motor angle $s = (s_1, s_2, s_3, s_4, s_5)$ as robot state. Some control limitations are given in software level. Every joint is configured to be able to move in range [-π/2, +π/2]. If it is out of the range, it stops until command to move for inside direction comes. Using this platform robot, our method is evaluated by training ball-tracking task.

4 IMPLIMENTATION

As shown in Fig.1, there are four processes in our strategy and their efficient implementation provides a self-

Fig.2. The manipulator robot

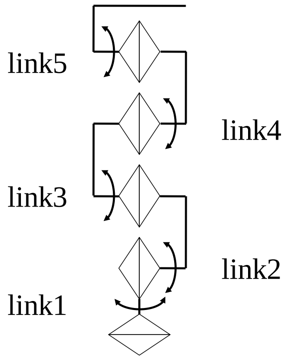

Fig.3. The link structure

learning ability to the system. In this chapter, detailed implementation for the manipulator robot is described.

4.1 Data Collection and Supply

The data sampled from the actual robot is collected into a buffer. In this work, data to collect is a pair information of (s_t, a_t) and $s_{t+\Delta t}$. These mean the robot state s and command a at time t, and its response state s at time $t+\Delta t$. And it is supplied to a simulator for construction. Therefore, the buffer has to keep and supply the suitable data to represent the actual robot.

In order to supply the suitable data to construct a simulator, the limited parameter space $\mathbf{S} \times \mathbf{A}$ is divided into some sub-spaces in a number of $N_S \times N_A$ in similar way. Each sub-space keeps corresponding data. At simulator construction by neural-networks, one sub-space is chosen at random and one sampled data is provided as learning data.

4.2 Simulator Construction

The Multi-Layered Perceptron (MLP) of the neural-networks which is effective for the approximation of a nonlinear function is employed to simulate the hardware. It directly represents the robot behavior. The MLP consists of three layers, i.e. input, hidden and output layer. The MLP is input 10 parameters, namely the manipulator state s_t and command a_t for each motor, while it outputs next robot state $s_{t+\Delta t}$. Each neuron in the output layer is a nonlinear unit expressed with the arctangent sigmoid function whose output is limited in [-1, 1]. Therefore, the output value s_i [-π/2, +π/2] is normalized into [-1, 1].

A simulator has the MLP network inside. In the simulation process, it follows the MLP. The simulator inputs the data set (s, a) at time t, and obtains the normalized difference values in [-1, 1] as an output signal from the MLP. The de-normalized values s is simply represented as the state at time $t+\Delta t$. Fig.4 illustrates the overview of running process of simulation with the MLP.

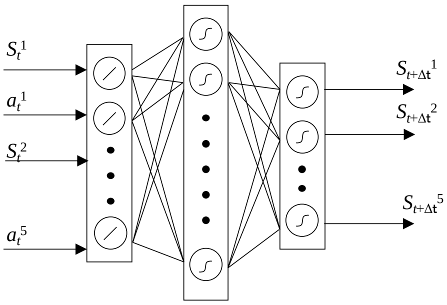

Fig.4. Neural-networks process for robot simulator

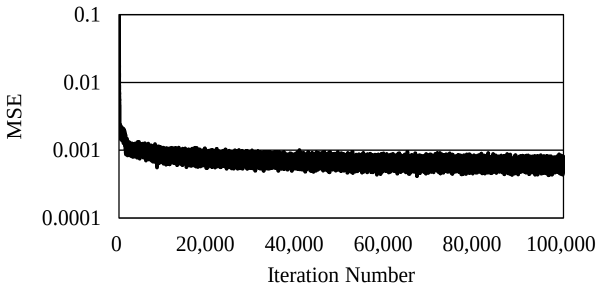

Fig.5. Result of simulator construction learning

And in the process of learning, the teacher data is supplied from the buffer, and the back-propagation method performs.

4.3 Controller Optimization

A controller learns the optimal control using a simulator. Here, we focus on the reinforcement learning [4] to make robot track a ball. In the reinforcement learning, the action is evaluated by the given rewards, and the system learns empirically the optimum action by trials and errors. In this work, we employ the Q-Learning method for the reinforcement learning. This is a typical method of reinforcement learning. When the agent at time t takes the action a_t based on the current state s_t, the state-action value function $Q(s_t, a_t)$ is updated as follows:

$$Q(s_t, a_t) \leftarrow Q(s_t, a_t) + \alpha[r_{t+1} + \gamma \max_a Q(s_{t+1}, a) - Q(s_t, a_t)] \quad (1)$$

where r_t is the reward the agent receives at time t, α is a learning ratio and γ is a discount ratio. In the phase of training, the agent chooses an action randomly. The other hand, it takes the action a where $Q(s_t,a)$ is the max value at state s_t in execution phase. In this way, a controller of the robot explores the optimum action command for each state and then performs tracking the ball.

5 EXPERIMENT AND RESULT

5.1 Data Collection

The target data to train a simulator was sampled from the actual manipulator robot described in the chapter 4. To collect data, an action command a selected in the previously mentioned manner was given with interval Δt = 50 msec. Consequently, the robot moved in the range of motion. The division numbers N_S and N_A for the five-dimensioned state space and action command space were set to 11^5 and 4^5, respectively. This collection process continued for one hour in real world. In other words, 72 thousands sample data were collected.

5.2 Simulator Construction

The learning of the neural-networks was performed by the backpropagation method. The number of neurons in the input, hidden and output layer were 10, 20 and 5, and a target sample data set (s_t, a_t) and $s_{t+\Delta t}$, were randomly took from a divided sub-space, which was selected at uniformly random from whole space. Learning ratio was set to 0.1, and nonlinearity ratio of nonlinear neurons in the MLP was set to 1.0. The number of learning iterations was 10 million times.

This operation was performed just in 10 minutes. Fig.5 shows the mean squared error (MSE) of MLP every one thousand learning. The MSE value decreased until around 1.0×10^{-3}. This means that the accuracy of learning was about 3% in normalized space, namely about 2.6 degree of actual angle.

5.3 Controller Optimization

Learning to track a ball was performed with the obtained simulator in the previous section. The state space **S** and command space **A** was divided into 9 sub-spaces at even intervals and treated as a discrete space for each joint. Hence, whole parameter space **S** × **A** was divided into $5^9\times5^9$ sub-spaces. The 250mm-diameter ball to track was put in the robot-reachable space, and then, task learning processed until the robot touched it or 2,000 steps was done without "touch". Here, "touch" means that the forward point 250 mm from the robot head is inside the ball area. This cycle is defined as "episode" in this experiment. y and z-coordinate value of ball position was fixed, and only x-coordinate value was selected at random for one episode. The controller to optimize was selected, depending on the ball x-coordinate value. Consequently, controllers as many as division number of x-coordinate were prepared. Finally, ball position x was selected at random from [-100, +100]

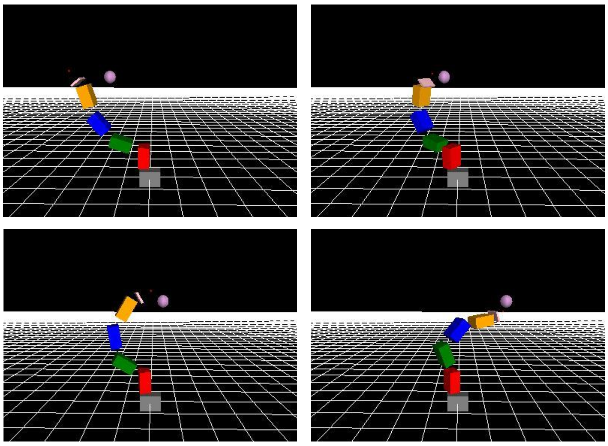

Fig.6. Ball tracking with simulator

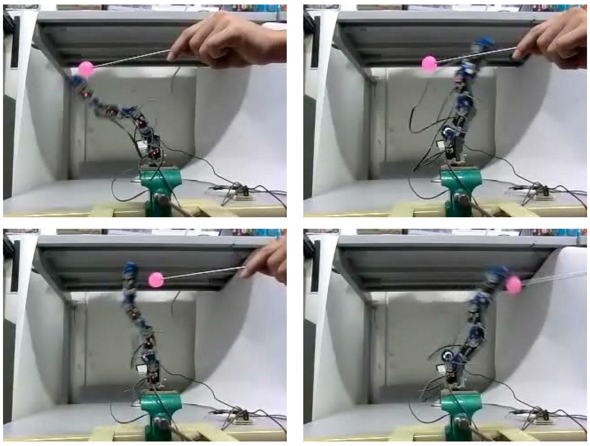

Fig.7. Ball tracking with actual robot

mm, which was divided into 10 areas, y and z were fixed into -32 mm and +192 mm, respectively.

The episodes to learn were repeated a million times in the simulation world. If this operation is executed in the real world, it would take about 28 thousand hours. The reinforcement learning performed according to the formula (1) with interval 50 ms. The parameters α and γ used for the update, were set to 0.1, and 0.9, respectively. The reward 1.0 was given only at the state "touching".

The learning process finished in twelve hours at most, though it would take about three years in the real world. Fig.6 shows the sequential images of ball tracking by simulator. Depending on the target ball position, the corresponding controller was selected and tried to make the robot touch the ball. The moving ball finally made continuous touching into tracking ball.

5.4 Application to actual robot

Finally, we applied the learning result of the previous section to the actual robot controller. In this experiment, the real ball position was detected by image processing in real time. Two web cameras were put around the robot and detect the red ball. The ball positions in camera image were converted into the real world coordinate by the Direct Linear Transformation method.

Fig.7 shows that the sequential images of the actual robot tracking ball. At the beginning of tracking, the robot tried to track the ball correctly. However, it shook more widely than the simulator robot to hold its state. As the ball moved, the robot tried following it. Nevertheless, the robot went down as if it lost the strength. On investigation, the command for the bottom-positioned motor was too weak to lift up self-body though it attempted. These results raise the possibility that accuracy of simulator by the neural-networks was not enough.

6 CONCLUSION

We proposed a novel method of machine learning associating with an actual hardware and its simulator. The simulator of the manipulator robot was constructed by the neural-networks trained with acquired data from the actual hardware without information of the physical law. Afterward, the ball tracking control for the manipulator robot was learned only through the built simulator by the reinforcement learning method. By using the simulator, the reinforcement learning could be finished much faster than using the real hardware without stress. However, when the controller applied to the actual robot, it could not represent the same way of the simulator completely.

Now we have a plan to construct a simulator after some executions of loop flow illustrated in Fig.1. Sampled data information is carried to the hardware controller and data is sampled from hardware cyclically. This is very adaptable process though physical information of target hardware is changed due to deterioration or component exchange. If this is actualized, our method comes more generalized for various machinery systems.

Abstract: Recently, the physical concept of quantum entanglement has been introduced into the two distant insects (butterflies) to cooperatively find each other by the previous study of J. Summhammer. According to his experimental results, we have confirmed that the two butterflies with quantum entanglement may need as little as half of the flight path of independent butterflies to find each other. However, the case where the learning factor, the length of a short straight flight and the threshold of the scent intensity are different between two butterflies has not been clarified in his previous study. Hence we have simulated the cooperation of two butterflies while changing the condition of these parameters. This paper describes the experimental results. We aim at the optimum modeling of cooperative relation of two individuals as the first stage, and the contents in this paper deserve the initial experiment in the case of two distant butterflies which must find each other.

Keywords: cooperative behavior, cooperative action, quantum cooperation, quantum entanglement

1 INTRODUCTION

Recently, the physical concept of quantum mechanical principle such as quantum superposition, quantum interference and quantum entanglement has inspired the information and computer science domain as well as the biology. For example, the physical concept of quantum interference has been brought to Genetic Algorithm by A. Narayanan et al. Quantum superposition has been brought to Evolutionary Algorithm by K.-H. Han et al., too. Regarding quantum entanglement, J. Summhammer has described the possibility of quantum entanglement in the biological domain [1]. He has introduced it into two insects (ants) to cooperatively push a pebble which may be too heavy for one ant, and has introduced it into two distant insects (butterflies) to cooperatively find each other. That is, each of ants/butterflies makes measurements on quantum particles to decide whether to execute certain actions. According to his experimental results, we have confirmed that the two ants with quantum entanglement, i.e., quantum-entangled ants, can push the pebble up to twice as far as independent (classical) ants, and the two butterflies with quantum entanglement, i.e., quantum-entangled butterflies, may need as little as half of the flight path of independent butterflies to find each other. However, the case where important parameters of two ants/butterflies are different each other has not been clarified in his previous study.

As for ants, we have clarified the relation between the force needed to push a pebble, the force of ant1 and the force of ant2 in our previous study. From the experimental results, we have proven that two ants with the bigger difference of force can push the pebble farther in competitive society in both classical ants and quantum-entangled ants [2].

As for butterflies, the relation between the learning factor, the length of a short straight flight and the fraction for threshold of the scent intensity is not yet clarified. In order to clarify the relation among these important parameters, we have simulated the cooperation of two butterflies while changing the condition of these parameters. This paper describes the experimental results. The optimum modeling of cooperative relation is expected by this study. We aim at the optimum modeling of cooperative relation of two individuals as the first stage, and the contents in this paper deserve the initial experiment in the case of two distant butterflies which must find each other.

2 OVERVIEW OF QUANTUM ENTANGLEMENT IN THE PHYSICAL DOMAIN USED IN QUANTUM-ENTANGLED BUTTERFLIES

In this paper we deal with the simplest kind of quantum entanglement. It is the correlation of the angular momentum between two particles of the same kind. The angular momenta of two such particles can easily be measured along different directions. The possible results are then "↑↑", "↓↓", "↑↓", and "↓↑", here "↑" and "↓" are *spin up* and *spin down*, respectively. Quantum theory can only predict the probabilities, $p_{\uparrow\uparrow}$, $p_{\downarrow\downarrow}$, $p_{\uparrow\downarrow}$, and $p_{\downarrow\uparrow}$, for these measurement results. An important state of quantum entanglement, which will be used in butterflies, is the so called *singlet state*. Here, the angular momenta of the two particles are always in the opposite direction each other. Symbolically, this state is written as

$$|\psi\rangle = \frac{|\uparrow\downarrow\rangle - |\downarrow\uparrow\rangle}{\sqrt{2}}. \tag{1}$$

The probabilities for the possible measurement results are

$$p_{\uparrow\uparrow} = p_{\downarrow\downarrow} = \frac{1}{2}\sin^2\left(\frac{\alpha}{2}\right), \tag{2}$$

$$p_{\uparrow\downarrow} = p_{\downarrow\uparrow} = \frac{1}{2}\cos^2\left(\frac{\alpha}{2}\right), \tag{3}$$

where α is the angle between the two chosen directions of measurement.

3 THE MODEL OF QUANTUM-ENTANGLED BUTTERFLIES FINDING EACH OTHER PROPOSED BY J. SUMMHAMMER

J. Summhammer showed the model that two distant butterflies find each other. Two butterflies, which are distant sufficiently each other, are located on the *x*-*y* plane as shown in **Fig. 1**. They can catch only information which is an intensity of scent emanated by other butterfly. Thereby for approaching each other, they must flight respectively to increase the intensity of the scent. The scent has the following character:

- The intensity of the scent emanated by each butterfly drops off as $1/r^2$ where r is the distance from the butterfly.
- The propagation of the scent is very much faster than the speed with which the butterfly, so that each butterfly can notice a change of intensity of the scent at once.
- The direction of the origin of the scent cannot be obtained from physical quantity involved in the scent.

3.1 Flight procedure of a modeled butterfly

As mentioned above, two butterflies can encounter by flying to the direction which increase the intensity of the scent. The algorithm for the flight toward the direction increasing the intensity of the scent is shown below:

[*Step 1*] Choose a direction for a short straight flight.

For the short straight flight, the butterfly chooses the direction randomly, but weighted with a probability distribution of directions. The probability distribution of directions is one which it considers appropriate in view of its experience of change of the scent intensity in the previous short flights. In the beginning, this probability distribution of directions is isotropic.

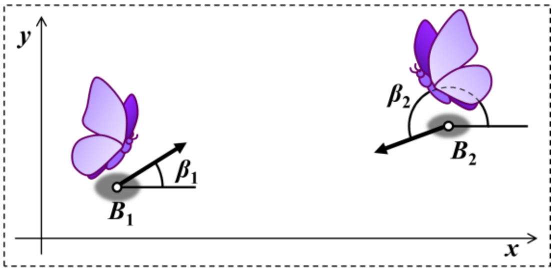

Fig. 1. The example of the flight directions β_1 and β_2 of the butterfly B_1 and the butterfly B_2 on the *x*-*y* plane.

[*Step 2*] Decide whether to really do the short straight flight, or whether to have a little rest.

Independent butterflies decide randomly either the short straight flight or the little rest, respectively. In this case, the probability of each behavior selected is constantly 1/2. On the other hand, the decisions of quantum-entangled butterflies come from quantum measurement which will be explained later. If the butterfly has decided the short flight, that performs a short straight flight of constant length l_f toward the chosen direction, go to *Step 3*. Otherwise, that is, if the butterfly has decided the little rest that does not perform any action, go to *Step 5*.

[*Step 3*] Judge whether the butterfly should fly back or not.

The butterfly measures the scent intensity and compares an increase from the last measurement with a certain threshold. The threshold is taken as a certain fraction f_t of the strongest increase $s_{d\max}$ of the scent intensity encountered in the short flights until then. If the increase s_d is below the threshold ($s_d < f_t \times s_{d\max}$), the butterfly judges this to have been a bad direction and flies back. The butterfly returns to the position before the short flight by flying back. On the other hand, if the increase is above the threshold, the butterfly judges this to have been a good direction and does not fly back.

[*Step 4*] Learn, i.e. update the probability distribution of directions.

Based on the above-mentioned judgment, the probability distribution of directions is updated using a learning factor l. When the butterfly had judged as a good direction, the butterfly enhances the corresponding probability weight by the factor $(1+l)$. This direction is then more likely to be chosen again in one of the next short flights. In contrast, when the butterfly had judged as a bad direction, the butterfly reduces the corresponding probability weight by the factor $(1+l)^{-1}$. This direction is then less likely to be chosen again.

[*Step 5*] Repeat until the butterflies meet each other.

When the distance between two butterflies is less than a certain small value, it is concluded that the two butterflies met each other and this trial is ended. If the distance is still large, return to *Step 1* because the butterfly performs to the next short flight.

3.2 Behavior of the quantum-entangled butterflies

The difference between quantum-entangled butterflies and independent butterflies is shown when the butterfly decides either to really do the short straight flight or to have a little rest (above-mentioned *Step 2*). The independent butterflies decide randomly, whereas the quantum-entangled butterflies decide on the basis of a quantum measurement. The quantum-entangled butterflies share a large number of maximally entangled pairs of spin-1/2 particles, of which each butterfly holds one particle. Here the entangle state is the singlet state. The quantum measurement determines the value of the angular momentum of the particle along the flight direction which is chosen by the butterfly at *Step 1*. If the measurement result is "↑", the butterfly performs the short straight flight. If the result is "↓", the butterfly rests.

Here if we assume a butterfly B_1 chooses β_1 as the flight direction and a butterfly B_2 chooses β_2 as shown in **Fig. 1**, there are the following three possibilities.

Case 1: Both butterflies fly in the direction selected based on self-judgment respectively. This case happens with probabilities

$$p_{\uparrow\uparrow} = \frac{1}{2}\sin^2\left(\frac{\beta_1 - \beta_2}{2}\right), \tag{4}$$

according to Eq. 2.

Case 2: Both butterflies have a little rest. This case happens with probabilities

$$p_{\downarrow\downarrow} = \frac{1}{2}\sin^2\left(\frac{\beta_1 - \beta_2}{2}\right), \tag{5}$$

which is equal to $p_{\uparrow\uparrow}$.

Case 3: One butterfly flies and another rests. This case happens with probabilities

$$p_{\uparrow\downarrow} = p_{\downarrow\uparrow} = \frac{1}{2}\cos^2\left(\frac{\beta_1 - \beta_2}{2}\right), \tag{6}$$

according to Eq. 3.

Note that, when the difference between β_1 and β_2 gets closer to 0, the probability of Case 3 increases. In other words, when the quantum-entangled butterflies choose same direction which does not decrease the distance although both flight, only one butterfly flies frequently.

4 EXPERIMENTAL ANALYSIS

4.1 Method of the experiment

There are the following three important parameters characterizing behavior of the butterfly: the learning factor (l), the length of a short straight flight (l_f) and the fraction for the threshold of the scent intensity (f_t). About each of these three parameters, we have experimented by setting different value between two butterflies. In each following experiment, we have verified the relationship between the total flight distance until two butterflies encounter and the change of the target parameters.

Experiment 1: Varying the learning factor l for two butterflies.

We changed the learning factor l_1 of the butterfly B_1 from 1.00 to 0.00 in -0.05 steps, and also changed l_2 of the butterfly B_2 from 1.00 to 2.00 in +0.05 steps, respectively, where $l_1 + l_2 = 2.00$.

Experiment 2: Varying the flight length l_f for two butterflies.
