The Eighteenth International Symposium on Artificial Life and Robotics will be held in Daejeon, Korea, January 30 – February 1, 2013. This symposium will bring together researchers to discuss development of new technologies concerning *artificial life and robotics* based on computer simulations and hardware designs of state-of-the-art technologies, and to share findings on how advancements in artificial life and robotics technologies that relate to artificial intelligence, virtual reality, and computer science are creating the basis for exciting new research and applications in various fields listed in the following topics.

Topics of interest include, but are not limited to

- Artificial brain research
- Artificial living
- Bipedal robot
- Cognitive science
- Control techniques
- Evolutionary computations
- Human-machine cooperative systems
- Intelligent control & modeling
- Medical surgical robot
- Molecular biology
- Nano-robotics
- Pattern recognition
- Renewable energy
- Soccer robot
- Artificial intelligence
- Artificial mind research
- Brain science
- Complexity
- Data mining
- Fuzzy control
- Human-welfare robotics
- Learning
- Micromachines
- Multi-agent systems
- Neurocomputing technologies and its application for hardware
- Resilient infrastructure systems
- Virtual reality
- Artificial life
- Bioinformatics
- Chaos
- Computer graphics
- DNA computing
- Genetic algorithms
- Image processing
- Management of technology
- Mobile vehicles
- Nano-biology
- Neural networks
- Quantum computing
- Robotics
- Visualization

Important Dates

- **September 1, 2012** Deadline for abstract submissions
- **September 15, 2012** Notification of acceptance
- **October 31, 2012** Final camera-ready papers due
- **November 1, 2012** Deadline for Early Registration

Publication

Accepted papers will be published in the Proceedings of the AROB. Extended versions of the selected papers will be published in the international journal : ARTIFICIAL LIFE AND ROBOTICS and in the special issue on special topics of Artificial Life and Robotics, Applied Mathematics and Computation.

Artificial Life and Robotics

We invite you to publish your paper
in this journal full of inventive scientific findings and state-of-the art technologies.

Two types of papers from the world are

I. Contributed papers
II. Recommended papers presented at **the International Symposium on Artificial Life and Robotics (ISAROB),**

Contribution fee:

4 pages or Under **¥19,950 / page** (¥19,000 + 5 % consumption tax: only in Japan)
Extra page charge **¥16,800 / page** (¥16,000 + 5% consumption tax: only in Japan)
(Pages are counted on double-columns basis as they appear in the journal.)

Shipping Cost:

domestic **¥735 / delivery** (¥700 + 5 % consumption tax)
overseas **¥3,000 / delivery**

We deliver every corresponding author (or sponsor) one copy of journal in which his/her paper is included. We would like to thank authors for their support in the form of contribution fee payable before publication, which funds the production of this journal contracted by Springer Japan.

Order:

I. Price for co-authors

¥ 5,250 (¥5,000 + 5 % consumption tax: only in Japan) **per copy (for every co-author)**

If necessary, please order extra copies for co-authors to the Journal Office.

II. Subscription fee

	domestic	**overseas**
Annual subscription rate	**¥21,000*/year**	**¥20,000/year**
Shipping Costs	**free**	**¥2,000/year**

*including consumption tax

III. Purchase price for single issue

¥ 8,400 (¥8,000 + 5 % consumption tax: only in Japan) **per issue**.

AROB Journal Office : joffice@alife-robotics.co.jp

Artificial Life and Robotics

Our Review System

For contributed papers,

1. Duration:

   Two months is our target time of the whole review process, however, we are trying our best to make it as short as possible.

2. Review results:

   Every contributed paper will be reviewed by three assigned reviewers with score ranging from 1 (highest mark) to 4 (lowest mark);

   1. publish with no revision,
   2. publish with minor revisions,
   3. possibly publish with revision and re-review,
   4. reject.

Review results, a total score of the three evaluation scores, would be read as;.

3 or 4	:	accepted and to be published as it is,
4, 5, or 6	:	accepted and to be published after minor revisions,
7, 8, or 9	:	acceptable but subject to rewriting and re-review,
10, 11, or 12	:	rejected

For recommended papers,

The recommended papers are ones that the chair of each session and reviewers read before the symposium that year and recommend to AROB Journal Office using the same evaluation score above. Therefore, the quality of recommended papers is apparent at the time of recommendation.

We express our heartfelt gratitude to chairs and reviewers of ISAROB for their support and sincere voluntary work without which this journal never exists.

INTERNATIONAL PROGRAM COMMITTEE

HISTORY

The AROB was founded in 1996 under the support of Science and International Affairs Bureau, Ministry of Education, Culture, Sports, Science and Technology, Japanese Government. Since then, the symposium organized by the AROB has been held every year at B-Con Plaza, Beppu, Japan except AROB 5th ’00 (Oita) and AROB 6th ’01 (Tokyo). The seventeenth symposium will be held on January 19–21, 2012, at B-Con Plaza, Beppu, Japan.

OBJECTIVE

This symposium will bring together researchers to discuss development of new technologies concerning *artificial life and robotics* based on computer simulations and hardware designs of state-of-the-art technologies, and to share findings on how advancements in artificial life and robotics technologies that relate to artificial intelligence, virtual reality, and computer science are creating the basis for exciting new research and applications in various fields.

GENERAL SESSION TOPICS

Artificial intelligence
Artificial brain research
Artificial intelligence
Artificial life
Artificial mind research
Bioinformatics
Brain science
Complexity
Control techniques
Data mining
Evolutionary computations
Genetic algorithms
Human-machine cooperative systems
Human-welfare robotics
Image processing
Intelligent control & modeling
Learning
Multi-agent systems
Neural networks
Pattern recognition
Robotics
Poster Session

ORGANIZED SESSION TOPICS

Advanced Vehicle Control
Aware Technologies for e-Services
Bioinformatics
Bio-inspired theory and applications
Biomimetic Machines and Robots
Computer Vision and Sound Analysis
Computer-Supported Learning Systems
Control Application
Control Theory and its Application
Embracing Complexity in Natural Intelligence
Embracing Complexity in System Sensing
Information Technology for Environmental Research
Intelligent control
Intelligent control & modeling
Intelligent System and Control
Intelligent Systems and Applications
Intuitive Human-System Interaction
Management of technology
Mechatronics and Intelligent Systems
Medical Science and Complex System
Network Dynamics in Biological Information System
System sensing and control
Systems for defense of disaster

COPYRIGHTS

Accepted papers will be published in the proceedings of AROB and some of high quality papers in the proceedings will be requested to re-submit their papers for the consideration of publication in an international journal ARTIFICIAL LIFE AND ROBOTICS. All correspondence related to the symposium should be addressed to AROB Secretariat.

ADDRESS

Takayuki Hirai

President, Nippon Bunri University

It is a great pleasure to have the Seventeenth International Symposium on Artificial Life and Robotics. It is highly evaluated that many researchers known internationally have attended this event and presented the results of advanced valuable research since the first symposium in 1996. The research made public in each symposium has been the great moving force to develop the technologies of Artificial Life and Robotics. The researchers all over the world pay attention to the presentations of research and make good use of them to promote their own academic research. We have a lot of the presentations of research this time as well, and their academic contribution is remarkable. I would like to show honor to all of you in the committee who have such a valuable international symposium.

MESSAGES

Fumio Harashima

Advisory Committee Chair of AROB

Professor, Tokyo Metropolitan University

The science and technology (S&T) on Artificial Life and Robotics was born in 1996, and it’s been providing human being with happiness. This S & T is not only important but also necessary for people living in the world to maintain high quality of life. Research is heart and desire of human being and the S&T is going toward clarifying tool to achieve our objective.

I would like to congratulate researchers who work in the fields on Artificial Life and Robotics.

Masanori Sugisaka

General Chair of AROB

Professor, Nippon Bunri University and President,

ALife Robotics Corporation, Ltd. , Japan

It is my great pleasure to invite you all to the Seventeenth International Symposium on Artificial Life and Robotics (AROB 17th '12).

The symposium from the first (1996) to the Thirteenth (2008) were organized by Oita University and Nippon Bunri University (NBU) and the Symposium from the Fourteenth (2009) to the Sixteenth (2011) were organized by Nippon Bunri University (NBU) and ALife Robotics Corporation Ltd. under the sponsorship of the Science and Technology Policy Bureau, the Ministry of Education, Science, Sports, and Culture (Monbusho), presently, the Ministry of Education, Culture, Sports, Science, and Technology (Monkasho), Japanese Government, Japan Society for the Promotion of Science (JSPS), The Commemorative Organization for the Japan World Exposition ('70), Air Force Office of Scientific Research, Asian Office of Aerospace Research and Development (AFOSR/AOARD), USA. I would like to express my sincere thanks to not only Monkasho, JSPS, the Commemorative Organization for the Japan World Exposition ('70), AFOSR/AOARD but also Japanese companies (Mitsubishi Electric Corporation, Advanced Technology R&D Center, Oita Gas Co., Ltd., ME System Co. LTD, and Sanwa Shurui Co., LTD.) for their repeated supports.

This symposium is organized by International Organizing Committee of AROB and is sponsored by ALife Robotics Co., Ltd., and technically co-sponsored by IEEE Robotics and Automation Society Japan Chapter, JARA, SICE, ISCIE, IEICE and CAAI (P.R. China).

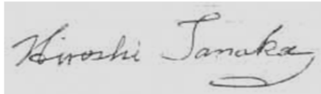
I hope that the new technologies presented in this symposium bring happiness to human society and will facilitate the establishment of an international research Institute of Artificial Life and Robotics.

Welcome and enjoy your stay in Beppu.

Hiroshi Tanaka

Program Chair and Vice-Chair of AROB

Professor, Tokyo Medical and Dental University



On behalf of the program committee, it is my great pleasure and honor to invite you all to the Seventeenth International Symposium on Artificial Life and Robotics (AROB 17th 2012). This symposium is made possible owing to the cooperation of Nippon Bunri University and Santa Fe Institute. We are also debt to Japanese academic associations such as SICE, RSJ, and several private companies. I would like to express my sincere thanks to all of those who make this symposium possible.

As is needless to say, the Alife or biologically-inspired Robotics approach now attracts wide interests as a new paradigm of science and engineering. Taking an example in the field of bioscience, the accomplishment of HGP (Human Genome Project) and subsequent post-genomic comprehensive “Omics data” such as transcriptome, proteome and metabolome, bring about vast amount of bio-information. However, as a plenty of omics data becomes available, it becomes sincerely recognized that the framework by which these omics data can be understood to make a whole picture of life is critically necessary. Thus, in the omics era, biologically-inspired systems approach like Alife is expected to give one of new alternative ideas to integrate this vast amount of bio-data.

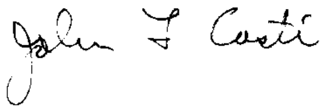
This example shows the Alife and biologically-inspired approach is very promising and may exert a wide influence on the effort to develop a new paradigm for next generation of life science. We hope this symposium becomes a forum for exchange of the ideas of the attendants from various fields, including the life science field, who are interested in the future possibility of biologically-inspired computation and systems approach. I am looking forward to meeting you in Beppu, Oita.

John L. Casti

Vice-Chair of AROB

Professor, International Institute for Applied Systems Analysis,

Vienna, Austria



As a member of the AROB committee since the first AROB in 1994, it's always a pleasure for me to begin the year with this event. So once again I'm very pleased to invite you all to the Seventeenth International Symposium on Artificial Life and Robotics (AROB 17th ‘12). The program for this year's meeting contains the customary wide variety of themes, ranging from robotics and human-machine interfaces to mathematical and computer modeling of human systems. I think I can fairly say that the AROB has now taken its place as the premier event in Asia each year for researchers in these areas.

Over the coming days, I anticipate many productive exchanges of idea and feel that the AROB symposium will give rise to many fruitful ways for international cooperation in the areas of simulation of human systems. In these very difficult times, the world must find new tools for solving the pressing problems of climate change, energy and food supply, economic growth and many other domains of modern life. Hopefully, the work presented at the AROB will contribute to finding effective solutions to these growing threats.

Yingmin Jia

Vice-Chair of AROB

Professor, Beihang University

The 17th International Symposium on Artificial Life and Robotics (AROB) will be held in Beppu, Oita, Japan from Jan. 19th to 21th, 2012. As a vice-chairman, I am honored and privileged to invite you all to this fruitful 3-day event, which provides an excellent opportunity for the formal exchange of information, ideas, and research results between leading scientists and engineers in the areas of artificial life and robotics.

In 1996, the first Symposium was created and organized by Prof. Masanori Sugisaka, the general chairman of AROB. Since then, the symposium has attracted an impressive range of researchers from all around the world, and distinguished achievements have been obtained that shows his foresight in merging two disciplines of artificial life and robotics. Moreover, it is gratifying to see that there are more and more young colleagues, researchers and engineers from the universities, research institutions and industries interested in the field. I believe there is a rapid and better development in the near future.

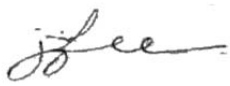
Finally, I would like to acknowledge the contributions of operating and programming committee members for their great efforts to make this symposium successful. Also, I would like to express my sincere appreciation to the plenary speakers and invited speakers for their willingness to give us their excellent lectures.

Looking forward to meeting you at the 17th AROB, and wishing you all have fruitful technical discussions and enjoy the symposium.

Ju-Jang Lee

Vice-Chair of AROB

Professor, KAIST



The Seventeenth International Symposium on Artificial Life and Robotics (AROB) will be held in Beppu, Oita, Japan from Jan. 19th to 21th, 2012. This year's Symposium will be held amidst the high expectation of the increasingly important role of the new interdisciplinary paradigm of science and engineering represented by the field of artificial life and robotics that continuously attracts wide interests among scientist, researchers, and engineers around the globe.

Since the time of the very first AROB meeting in 1996, each year, distinguished researchers and technologists from around the world are looking forward to attending and meeting at AROB. AROB is becoming the annual excellent forum that represents a unique opportunity for the academic and industrial communities to meet and assess the latest developments in this fast growing artificial life and robotics field. AROB enables them to address new challenges, share solutions, discuss research directions for the future, exchange views and ideas, view the results of applied research, present and discuss the latest development of new technologies and relevant applications.

In addition, AROB offers the opportunity of hearing the opinions of well-known leading experts in the field through the keynote sessions, provides the bases for regional and international collaborative research, and enables to foresee the future evolution of new scientific paradigms and theories contributed by the field of artificial life and robotics and associated research area. The twenty-first century will become the century of artificial life and intelligent machines in support of humankind and AROB is contributing through wide technical topics of interest that support this direction. It is a great for me as the Vice Chairman of the 17th AROB 2012 to welcome everyone to this important event. Also, I would like to extend my special thanks to all authors and speakers for contributing their research works, the participants, and the organizing team of the 17th AROB.

Looking forward to meet you at the 17th AROB in Beppu-Oita and wishing you all the best.

Henrik Hautop Lund

Vice-Chair of AROB

Professor, Center for Playware, Technical University of Denmark

I am much honored to invite you to the Seventeenth International Symposium on Artificial Life and Robotics (AROB 17th '12). The international symposium has been held each year since 1996, initially organized by Oita University and now being organized by Nippon Bunri University, and supported by Ministry of Education, Culture, Sports, Science and Technology, the Japanese Government.

The symposium attracts an impressive range of researchers from all continents, who all share the vision of merging research based upon artificial life and robotics. The symposium is visionary in merging these two, science and engineering disciplines, and has become the most important forum for research into merging artificial life and robotics.

The research in artificial life and robotics is very important since it both brings us insight into ourselves as human beings and natural systems, and brings us new engineering solutions that may influence our lives. It is my hope that you will use this insight and opportunity to develop systems that help humankind in socially responsible ways. Indeed, the symposium puts high emphasis on the social impact of interdisciplinary (based on artificial life and robotics combined with other fields, e.g. social science, art) developments, and has become an important forum for the discussion of global developments of socially responsible technology.

I would like to take this opportunity to thank the general chairman of AROB, Prof. Masanori Sugisaka, for being so visionary 17 years ago to engage in creating and organizing this important annual event for our research community. It takes a lot of courage to be the first to create a novel interdisciplinary research field such as the one that comes from the merge between artificial life and robotics. Prof. Sugisaka has shown how being courageous enough to engage in the adventurous activities of merging two fields may lead to very fruitful research and to the lively research community that you are now part of with your participation in this international symposium.

I would also take this opportunity to thank Springer-Verlag for supporting this research community, and remind all participants of the Springer-Verlag Artificial Life and Robotics Journal. Hopefully, we will see numerous, high quality contributions to the journal as the outcome of this symposium and the research collaboration that may entail the symposium. Indeed, it is my hope that you will all engage in open and fruitful scientific discussions with your colleague researchers during the symposium, and that these discussions may open up for future research collaborations in order to bring new insight into artificial life and robotics to the community.

Ken Naitoh

Vice-Chair of AROB

Professor, Waseda University, Faculty of Science and Engineering

What is the essential difference between living beings and machines? This may be the mystery which cannot be solved forever. However, deep thought experiments on the mystery will bring new technologies: quantum leaps of biological, medical, and mechanical technologies. The International Symposium on Artificial Life and Robotics related to the mystery and wonderful hot springs in Oita, Beppu, are wellsprings for inducing wonderful idea, concepts, scenario, and concrete systems. It is a great pleasure for us to discuss on the future with a lot of researchers in the world and also to encourage the next generations here.

Takao Ito

Assistant General Chair of AROB

Professor, Ube National College of Technology

Since our first symposium was held in Beppu Oita in 1996, we have met every year. We are now about to begin our 17th symposium. As one of the program committee, I am delighted to invite you all to the Seventh International Symposium on Artificial Life and Robotics which will be held in Beppu Oita next year.

Given the intense competition in the field of artificial life and robotics, the effective coordination and efficient maintenance of information exchange take on increased importance. The AROB international symposium provides us a unique opportunity to enjoy the discussion of all new issues, and to share experiences related to the advanced technologies and management skills. I am pleased to put together this excellent program that represents submissions from many countries around the world. I sincerely hope that those participating in this symposium as delegates from their various countries will have something to offer regarding our study of the present situation of the artificial intelligence and its management and will contribute to its future development.

I end these words of welcome with an earnest prayer for the great success of this symposium.

Plenary speakers:

PT1 : Modular Playware Technology

Prof. Henrik Hautop Lund

Professor, Center for Playware, Technical University of Denmark, Denmark

Abstract:

Playware is intelligent hardware and software that creates play and playful experiences for users of all ages. Such playware aim at providing play forces to bring the user into play dynamics, and in this way motivate the user to perform desired behaviors, e.g. for play, education, sports training, and health improvements. However, designing playware technology that results in specific behaviors of the user in not a trivial task, and it demands an array of background knowledge in a number of scientific fields. Indeed, definition of desired interactions and behaviors should arise from deep knowledge of the field of application (e.g. play of a specific user group, clinical knowledge of therapy of a specific patient group, professional music knowledge, and professional sport knowledge). In order to meet a practice, where several disciplines can join to develop such playware, we conceptualized the approach of modular playware in the form of building blocks. Building blocks should allow easy and fast expert-driven or user-driven development of playware applications for a given application field. The development of such modular playware technology takes its inspiration from modular robotics, human-robot interaction and embodied artificial intelligence. In this talk, I will present the design principles for creating such modular playware technology with focus on the play principles and educational principles that forms the foundation for the design principles of modular playware technology. I will exemplify the design principles with practical applications from the fields of play, education, sports, music, performance art, and health.

Biography:

Henrik Hautop Lund is head of the Center for Playware at Technical University of Denmark (DTU Elektro). Prof. Lund is known world-wide for his work in bringing robotics to use in novel ways. His approach is to combine modular robotics and modern artificial intelligence to create novel solutions to problems that occupy the citizens of the World, e.g. obesity, rehabilitation, and 3rd World development. He has recently founded the Center for Playware to focus even further on how playful aspects of robotics may provide motivation for any citizen to perform different kinds of interaction with the robots of our future daily life. He chaired the Robots at Play festivals in the open city areas where researchers, artists, entertainers, and citizens meet through playful hands-on experience with robotics in the daily life of the citizens. In all cases, Prof. Lund has shown how the combination of a modern artificial intelligence, modular robotics and entertainment may provide novel opportunities in play, rehabilitation, sport, music, teaching, third World development, etc., by trying to allow non-expert users easy access to the technology in a playful and motivating way.

Prof. Lund has published 150 scientific articles in the field of robotics, he has been a member of the Danish Research Council, and he has been invited to present his robotic work in numerous occasions, for instance for the Emperor of Japan at Akasaka Palace in Tokyo. He founded and headed the LEGO Lab in 1997-2000. He invented the RoboCup Junior robot football game for children, and his Adaptronics group won the RoboCup Humanoids Free Style World Championship 2002 in front of 120.000 spectators. Further, he developed the RoboMusic in collaboration with World Music Award winner, remix musician Funkstar De Luxe. Prof. Lund's work has received world-wide interest from news media, and he was nominated for the award for the best entertainment robots and systems research over the last 20 years at the IEEE International Conference on Intelligent Robots and Systems (IROS).

Prof. Lund is director of the spin-off company Entertainment Robotics.

PT2 : Fundamentals of Neurodynamics: Statistical neurodynamics and Neural Field Theory

Prof. Shun-ichi Amari

Senior Advisor, RIKEN Brain Science Institute, Japan

Abstract:

The brain consists of a vast number of neurons and processes information through their dynamical interactions. Peculiar characteristics neural networks would be useful for designing algorithms for artificial life and applying them to robot navigation. The present talk will focus on two types of neurodynamics, one is generalized majority decision dynamics and the other dynamics of excitation patterns in a neural field.

A neural network is a generalized majority decision system, in which each element calculates a weighted sum of the outputs of the other elements and decides its own output. Such a system is common in many biological systems such as a gene expression network, social communication network etc. We consider randomly connected binary elements and compare its dynamical behavior with that of a random Boolean logic network. We prove that a generalized majority decision system can make very quick decision (short transient time) compared with a random Boolean net. We also show that its state transition graph has a scale-free property so that a small number of states monopolize the incoming branches.

Neurons are arranged in a two-dimensional sheet in the cortex, where neighboring neurons are connected. Excitations in a neural field propagate and interact. We show an interesting phenomenon of traveling local excitations and their collision. Such phenomena will be applied to information processing having topology of the outer environment. This will be applied to the problem of robot navigation.

Biography:

Shun-ichi Amari was born in Tokyo, Japan, on January 3, 1936. He graduated from the Graduate School of the University of Tokyo in 1963 majoring in mathematical engineering and received Dr. Eng. Degree.

He worked as an Associate Professor at Kyushu University and the University of Tokyo, and then a Full professor at the University of Tokyo, and is now Professor-Emeritus. He served as Director of RIKEN Brain Science Institute for five years, and is now its senior advisor. He has been engaged in research in wide areas of mathematical engineering, in particular, mathematical foundations of neural networks, including statistical neurodynamics, dynamical theory of neural fields, associative memory, self-organization, and general learning theory. Another main subject of his research is information geometry initiated by himself, which provides a new powerful method to information sciences and neural networks.

Dr. Amari served as President of Institute of Electronics, Information and Communication Engineers, Japan and President of International Neural Networks Society. He received Emanuel A. Piore Award and Neural Networks Pioneer Award from IEEE, the Japan Academy Award, Gabor Award from INNS, Caianiello Award, and C&C award, among many others.

Invited speakers:

IT1 : Future Technology and Market Developments for Unmanned Maritime Vehicles

Mr. Bob Nugent

Vice President, Advisory Services, AMI International, USA

Abstract:

The paper forecasts technological and market developments that will shape the future role and demand for unmanned maritime vehicles (UMV), to include unmanned underwater vehicles (UUV) and unmanned surface vehicles (UMV) over the next decade. We will begin with a review of the current UMV market by application/mission segment, technology and vehicle type, covering UUVs, both autonomous (AUV) and remotely operated (ROV), as well as USVs. Will then examine improvements in power and communications technologies that will change the UMV market in the coming decade and blur some of the current capability and design differences between commercial and military UMV markets. The paper will consider the thesis that improvements in UMV power and communications technologies will, following a trajectory seen in the UAV market, lead to growth in demand for UMVs in the civil, military and security sectors. These UMVs would be capable of augmenting manned platforms in conventional Anti-Surface, Anti-Submarine, and Anti-Air naval operations. However, AMI market and technical research suggests that the next decade of changing patterns of world economic and commercial maritime activity, and continuing technological limitations will limit the growth potential for weaponized UMVs. Rather, the period will see more demand among a broader customer base of commercial, security, and military users for hybrid UMVs optimized for port/harbor/facility security and environmental survey and exploration rather than combat missions. We will conclude with future UMV market forecast scenarios in a "high-medium-low" framework for both commercial and defense applications. These market scenarios predict significant increases in UMV sales and use, but temper some overly optimistic forecasts currently being made for these vehicles in both commercial and military/security sectors. The prospects of integration of scientific research and theoretical results in the robotics field (regularly publicized at the AROB symposia) with practical development and use of unmanned systems, especially in maritime domain, will be discussed too.

Biography:

Bob Nugent joined AMI in Bremerton WA in 2007 as a Senior Consultant following a 22 year career as a US naval officer. In 2010 he relocated to Northern Virginia as Vice President of Advisory Services to head up AMI's Washington DC Operations Office. He advises on defense, naval, maritime, C4/ISR, aerospace, and unmanned systems markets. Bob has been quoted and published on naval, defense and economic issues in CNBC, Defense News, Naval Forces Magazine, Singapore Straits Times, BBC, Al-Jazeera and a wide range of national and regional media around the world. He has also presented papers at naval industry expos and conferences in the US, Europe and Asia. Bob's skill sets include strategic planning, competitive assessment, business development and capture, defense systems, tactics, and platform analysis; and market and risk research. Bob earned undergraduate degrees at New Mexico State University and attended the U.S. Naval Postgraduate School and Defense Language Institute, where he studied Russian. He graduated with distinction from the U.S. Naval War College in 2004 and received an M.B.A from Marymount University in Arlington, Virginia in 2007. His last Navy assignment was as Director of Command and Control overseeing major C4ISR programs on the U.S. Navy's acquisition staff in the Pentagon. Bob has also served as Assistant Naval Attache in Moscow, current intelligence department head on the U.S. Navy staff in London, and in analytic and watch officer assignments in Hawaii, South Korea, and Japan. His operational assignments included duty as an Intelligence Officer afloat with expeditionary and aviation units. Bob is married to Nancy Smedberg of McLean, Virginia where they live with their 7 children. Bob has been an adjunct university instructor in Economics and Accounting and a youth athletics coach.

IT2 : JAEA Robotics' Emergency Response to FUKUSHIMA-DAIICHI Accident

Mr. Shinji Kawatsuma

Japan Atomic Energy Agency, Japan

Abstract:

Japan Atomic Energy Agency (JAEA) developed Nuclear Emergency Response Robotics, two RESQ-A, a RESQ-B, a RESQ-C and a RaBOT, in 2001 after JCO criticality accidents occurred, and a Remote operated vehicle (ROV) for Glove Box dismantling cold test in 2008. It is very sorry that RESQ-A, RESQ-B and RESQ-C could not work because of lack of budget when the Fukushima-Daiichi accident occurred by a big earthquake and a huge Tsunami on March 11th 2011, that RaBOT was abandoned from the view point of Practicality, and that ROV could work but was in the facilities damaged by the earthquake.

According to status and condition of the accident at Fukushima-Daiichi, JAEA have modified ROV and two RESQ-A to JAEA-1, JAEA-2 and JAEA-3, and prepared Robotics Control vehicles.

JAEA has provided Robotics and Robotics Control vehicle to TEPCO and is continuously supporting TEPCO for plant restoration.

The summary and lesson learned of Robotics' emergency response to Fukushima-Daiichi accident, would be presented.

Biography:

Shinji Kawatsuma is a senior Principal Engineer and General Manager of Remote and Robotics Engineering Office, Department of Partnership Operation for Plant restoration, Headquarters of Fukushima partnership Operation, Japan Atomic Energy Agency (JAEA).

He is responsible for JAEA support in the field of Remote and Robotics to FUKUSHIMA-DAIICHI accident, Nuclear Emergency Response Robotics of JAEA and basic research and development in the field of Remote and Robotics in JAEA.

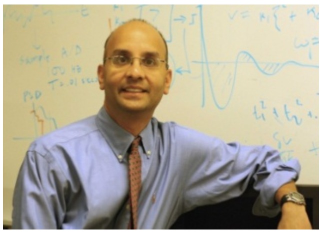
He served as General Manager of Backend cooperation office and was responsible for promoting of decommissioning and waste management in JAEA.

He began his career as engineer in Power reactor and Nuclear fuel development Corporation (PNC), to develop Bilateral-Servo-Manipulator, and research Radiation Resistance Technology, Man-Machine-Interface. He has been assigned to Oak Ridge National Laboratory as an exchange engineer for co-developing remote maintenance system including servo manipulator.

He received his bachelor of Mechanical Engineering from Waseda university.

IT3 : Using Robots to Understand Natural Behavior

Dr. Sanjay S. Joshi



Ph.D. Associate Professor,

College of Engineering University of California, Davis, USA

Abstract:

Since its beginnings, robotics has been inspired by animal and human behavior. However, more recently, roboticists and biologists have been using robots as new tools to better understand animal behavior itself. These new biorobots are not meant to look and move like real animals in all respects. Rather, they are designed to test specific biological hypotheses and lend insight into the complexity of natural behavior. In our lab, we are building artificial rat pups that have helped discover the factors responsible for the emergence of both individual and group rat pup behavior patterns. A central theme in this research is the emergence of behavior from the interaction of brain, body, and environment. In another project, we are building robotic squirrels to interact with live rattlesnakes, to study predator-prey interaction. These squirrel models have already helped discover the first-known infrared communication in the animal world. New versions of the robot are currently being used in natural environments to collect long-term information on squirrel and snake behavior. As robotics and biology researchers continue to work together, robotics tools will surely facilitate a deeper understanding of natural behavior.

Biography:

Sanjay Joshi is currently Associate Professor of Mechanical and Aerospace Engineering at the University of California, Davis where he directs the Robotics, Autonomous Systems, and Controls Laboratory. This interdisciplinary laboratory studies natural and artificial control systems and robotics, with applications in medicine, biology, and space exploration. Dr. Joshi received a BS from Cornell University in 1990, and MS/PhD from UCLA in 1992/1996, all in Electrical Engineering. After his doctoral work, he became a member of the technical staff at the NASA Jet Propulsion Laboratory in Pasadena, California where he designed spacecraft control systems for NASA missions and performed research for the Mars robotics program. After joining academia, he began applying autonomous robotics to the study of animal behavior, cognition, and communication. From 2010-2011, he was Visiting Associate Professor in the Department of Neurology, Columbia University College of Physicians and Surgeons, New York City.

IT4 : Withstanding Asymmetric Situations in Distributed Dynamic Worlds

Dr. Peter S. Sapaty

Chief Research Scientist, Director of Distributed Simulation and Control of the Institute of Mathematical Machines and Systems, National Academy of Sciences of Ukraine, Ukraine

Abstract:

In our modern dynamic world we are meeting numerous irregular situations where proper reaction could save lives and wealth and protect critical infrastructures. For example, no secret that world powerful armies with traditional system organizations are often losing to terrorists, insurgents or piracy with primitive gadgets but very flexible structures making them hard to detect and fight. And delayed reaction to earthquakes or tsunamis is a result of inadequacy of system organizations too. A novel philosophy and supporting high-level networking technology will be revealed that can quickly react on irregular situations and threats and organize any available human and technical resources into operable systems providing global awareness, pursuing global goals and self-recovering from damages. The approach allows us at runtime, on the fly, to formulate top semantics of the needed reaction on asymmetric events in a special Distributed Scenario Language (DSL), shifting most of traditional organizational routines to automated up to fully automatic implementation, with effective engagement of unmanned systems. This technology, based on gestalt and holistic principles rather than traditional multi-agent organizations will be revealed in detail, with numerous DSL scenarios that can be executed by any mixture of human and robotic components. These include runtime investigation and classification of irregular situations in distributed air, land and maritime environments, launching effective relief or combat missions like fighting collective manned piracy by smart unmanned swarms, and many others. The technology offered provides a unified solution to human-robot interaction and multi-robot behaviors just as a derivative of parallel and distributed interpretation of DSL.

Biography:

Dr Peter Sapaty, Director of Distributed Simulation and Control at the Ukrainian Academy of Sciences, is with networked systems for more than 45 years. Received MSc on calculation and simulation of distributed power networks at Kiev Polytechnic Institute in 1971, and PhD in Computer Science from V.M. Glushkov Cybernetics Center in 1976. Created heterogeneous citywide computer networks from 1969 and parallel supercomputers from mid seventies, chaired international intelligent network management project and simulated dynamic systems like battlefields on distributed computer networks in 1990-98. Worked in Germany, UK, Canada, and Japan as Alexander von Humboldt Foundation fellow, project leader, research professor, department head, and special invited professor, chaired SIG on Mobile Technologies within Distributed Interactive Simulation project in the US. Published more than 150 scientific papers on simulations and management of networked systems. Invented higher-level networking technology used in different countries and resulted in a European Patent and two John Wiley books. Main area of interest: models and languages for coordination and simulation of distributed dynamic systems with application in cooperative robotics, emergency management, infrastructure protection, and terrorism and piracy fight. Peter's individual data is published in Marquis 2010 edition of Who's Who in the World, also in Cambridge 2000 Outstanding Intellectuals of the 21st Century.

IT5 : Human Interface of Robots or Agents via Facial and Word Expression

Prof. Kaoru Sumi

PhD Professor at Future University Hakodate, Hokkaido, Japan

Abstract:

To design an intelligent interactive system, it is necessary to consider how humans feel about the system and establish a good relationship with them. In human robot interaction or human agent interaction, to establish a fifty-fifty relationship between a technical artifact (such as a robot or an agent system) and a human, the power of conviction or influence of the artifact over the human is very important.

To develop an intelligent system using a robot or an agent such as a system that proactively interacts with a user and even changes the user's intention according to the user's circumstances, our project investigated reactions with the user under several situations, considering human robot interaction and human agent interaction using facial and word expressions. Accordingly, we established some rules for making the agent's reaction favorable to the user on the basis of facial expressions and words, and gained some insights into the differences between human robot interaction and human agent interaction.

In this talk, I introduce the possibility of human persuasion by a robot or an agent using facial expressions and emotion words, based on the experimental results.

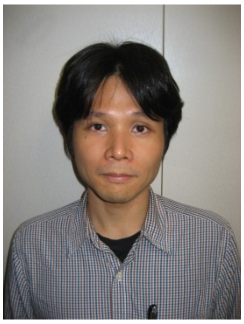
Biography:

Kaoru Sumi is a professor in the Department of Media Architecture, Future University Hakodate, Japan. Prof. Sumi received her PhD in engineering from the University of Tokyo. Her recent research interests are human computer interaction, persuasive technology, and an application for digital storytelling.

After she received her BS in physics from the Science University of Tokyo, she worked at a telecommunications company. She received her MS in systems management from the University of Tsukuba while she was working there.

She worked at ATR MI&C Research Laboratories, Communication Research Laboratory in Japan, Osaka University, where she researched human computer interaction, knowledge engineering and the application of artificial intelligence. She worked on media informatics and human agent interaction at the National Institute of Information and Communications Technology. She was an associate professor at Hitotsubashi University until last year.

Tutorial speaker:



Introduction to silicon neuron and neuronal networks

Dr. Takashi Kohno

M.D., Ph.D. Associate Professor, University of Tokyo, Japan

Abstract:

The silicon neuronal network is an electronic circuit system designed to mimic the biophysical functions in the nerve system, which is realized by interconnecting the silicon neurons and synapses, electronic counterparts to the neurons and the synapses. It has three major application fields; the hybrid system, the real-time neural network simulator, and the neuromorphic system. The hybrid system between the nerve system and the silicon neuronal networks have been playing crucial roles as neurophysiological research tools as well as are expected to realize novel biomedical devices. The neuromorphic system is expected to provide a robust, autonomous, and energy-efficient computation and controlling platform whose operating principle is similar to the nerve system.
Most of the silicon neurons are implemented using the Complementary Metal Oxide Semiconductor (CMOS) technology to simulate in real-time the activities of the membrane potential in neuronal cells. A wide variety of implementations have been tried in the aspect of their circuitry and the neuronal models they are based on. For the biomedical applications, a detailed ionic conductance neuron model has been implemented using ultra-low-power consuming circuitry, whereas more configurable models and circuitry with more precise operation were selected for the real-time simulators. Another most historical trend is to adopt an ultimately simplified model, the Leaky Integrage-and-Fire (LIF) model, to avoid difficulty of implementation and realize relatively large-scale network. Though it succeeded in the implementation aspect, the over-simplifed model seemed to provide very few functionality. In these years, several efforts based on the nonlinear mathematics are made to find the silicon neuron models with sufficient dynamics that are feasible for implementation of large-scale silicon neuronal networks.

Biography:

Takashi Kohno, M.D., Ph.D., received the B.E. degree in medicine and the Ph.D. degree in mathematical engineering from University of Tokyo, Japan, in 1996 and 2002, respectively. After experiencing designing of medical care information systems in Hamamatsu University School of Medicine, took the job of a group leader in Aihara Complexity Modeling Project, Exploratory Research for Advanced Technology (ERATO), Japan Science and Technology Agency (JST), Japan. He is currently an associate professor in Institute of Industrial Science, University of Tokyo, Japan.
His research interests include the construction of the silicon neuronal networks, an artificially realized nerve system, and nonlinear dynamics in the models of the neuronal cells and the synapses. Based on his knowledge over the three academic fields, applied nonlinear mathematics, neurophysiology, and electronic circuit design, he is realizing a simple, compact, and low-power consuming silicon neuron circuit whose dynamics are qualitatively equivalent to several classes of neuronal cells and can be selected at run-time. His main interest is moving to construction of small silicon neural networks and autonomous regulation of the silicon neuron circuit. The final goal of his research is to realize a brain-like computing system that is at least comparable to the human brain.
In his private life, he has a long history of developing digital circuits including an original microprocessor and electronic circuit development tools such as a logic analyzer and a ROM emulator. It started in the mid-1980s and his first personal FPGA device board was with him in the early 1990s. He has a number of contributions to Japanese industry journals on digital circuit design.

Technical paper index

January 19 (Thursday)

Room G
10:55-11:45 Plenary Speech
Chair: Hiroshi Tanaka (Tokyo Medical & Dental University, Japan)

PL1 *Modular Playware Technology*
Henrik Hautop Lund (Center for Playware, Technical University of Denmark, Denmark)

Room H
12:50-15:00 Invited Speech
Chair: Peter S. Sapaty (National Academy of Sciences of Ukraine, Ukraine)

IS1 *Future Technology and Market Developments for Unmanned Maritime Vehicles*
Bob Nugent (AMI International, USA)

IS2 *JAEA Robotics' Emergency Response to FUKUSHIMA-DAIICHI Accident*
Shinji Kawatsuma (Japan Atomic Energy Agency, Japan)

IS3 *Using Robots to Understand Natural Behavior (Genetic-Algorithms Produce Individual Robotic-Rat-Pup Behaviors that Match Norway-Rat-Pup Behaviors at Multiple Scales)*
Chris Sullivan, Sanjay S. Joshi, Jeffrey C. Schank (College of Engineering University of California, Davis, USA)

January 20 (Friday)

Room G
10:00-10:50 Plenary Speech
Chair: Ken Naitoh (Waseda University, Japan)

PL2 *Fundamentals of Neurodynamics: Statistical neurodynamics and Neural Field Theory*
Shun-ichi Amari (RIKEN Brain Science Institute, Japan)

Room H
11:10–12:40 Invited Session on Playware
Chair: Henrik Hautop Lund (Center for Playware, Technical University of Denmark, Denmark)

ISP1 *MagicTiles. ALife for Real and Virtual RoboMusic*
Luigi Pagliarini (Center for Playware, Technical University of Denmark, Denmark / Academy of Fine Arts of Macerata, Italy)
Henrik Hautop Lund (Center for Playware, Technical University of Denmark, Denmark)

ISP2 *Social Playware for Supporting and Enhancing Social Interaction*
Kenji Suzuki (University of Tsukuba / Japan Science and Technology Agency, Japan)
Kazuki Iida, Tomoya Shimokakimoto (University of Tsukuba, Japan)

ISP3 *Adapting Body and Behaviour: - learning and playing with a modular robotic platform -*
Patrizia Marti, Iolanda Iacono (University of Siena, Italy)

ISP4 *Adaptivity to Age, Gender, and Gaming Platform Topology in Physical MultiPlayer Games*
Davíð Þór Björnsson, Rafn Vídalín Friðriksson, Henrik Hautop Lund (Center for Playware, Technical University of Denmark, Denmark)

13:40-14:55 Tutorial

Tutorial *Introduction to silicon neuron and neuronal networks*
Takashi Kohno (University of Tokyo, Japan)

January 21 (Saturday)

Room H
13:00–15:10 Invited Speech
Chair: Ju-Jang Lee (KAIST, Korea)

IS4 *Withstanding Asymmetric Situations in Distributed Dynamic Worlds*
Peter S. Sapaty (National Academy of Sciences of Ukraine, Ukraine)

IS5 *Human Interface of Robots or Agents via Facial and Word Expression*
Kaoru Sumi (Future University Hakodate, Japan)

January 19 (Thursday)

Room A
08:45-10:15 GS3 Artificial life
Chair: Takaya Arita (Nagoya University, Japan)

GS3-1 *Two-dimensional cellular automata model of microorganism morphosis*
Takeshi Ishida (Nippon Institute of Technology, Japan)

GS3-2 *Control of water flow to avoid twining of artificial seaweed*
Jun Ogawa, Ikuo Suzuki, Masahito Yamamoto, Masashi Furukawa (Hokkaido University, Japan)

GS3-3 *Dealing with rounding error problems in evolutionary physical simulation*
Marcin L. Pilat, Reiji Suzuki, Takaya Arita (Nagoya University, Japan)

GS3-4 *Adaptive behavior to environmental changes: Emergence of multi-generational migration by artificial Monarch Butterfly*
Katsuya Suetsugu, Atsuko Mutoh, Shohei Kato, Hidenori Itoh (Nagoya Institute of Technology, Japan)

GS3-5 *Real-time generation of prime sequence by one-dimensional cellular automaton with 8 states*
Kunio Miyamoto (Japan Advanced Institute of Science and Technology, Japan)
Hiroshi Umeo (University of Osaka Electro-Communication, Japan)

12:50-15:00 GS2 Artificial intelligence
Chair: Hirokazu Taki (Wakayama University, Japan)

GS2-1 *Power saving parameter learning for light power control in public space*
Hiroaki Obana, Hirokazu Miura, Noriyuki Matsuda, Hirozumi Kaneko, Fumitaka Uchio, Hirokazu Taki (Wakayama University, Japan)

GS2-2 *Control of flock behavior by using tau-margin -Obstacle avoidance and reformation-*
Tatsuya Kon, Kazuyuki Ito (Hosei University, Japan)
Akira Yokokawa (SANYO Electric Co.,Ltd., Japan)

GS2-3 *A proposition of adaptive state space partition in reinforcement learning with Voronoi Tessellation*
Kathy Thi Aung, Takayasu Fuchida (Kagoshima University, Japan)

GS2-4 *Universal Creativity Engine: Real-time creation of melody and lyrics based on the Ant system*
Kenta Nishio, Takaya Arita (Nagoya University, Japan)

GS2-5 *Simple system for detecting sound localization based on the biological auditory system*
Takanori Tomibe, Kimihiro Nishio (Tsuyama National College of Technology, Japan)

15:20-16:20 OS17 Intelligent control
Chair: Yingmin Jia (Beihang University, P. R. China)
Co-Chair: Junping Du (Beijing University of Posts and Telecommunications, P. R. China)

OS17-1 *H_∞ consensus control for high-order multi-agent systems with disturbances*
Ping Wang, Yingmin Jia (Beihang University, P. R. China)
Junping Du (Beijing University of Posts and Telecommunications, P. R. China)
Fashan Yu (Henan Polytechnic University, P. R. China)

OS17-2 *Lane keeping control for 4WS4WD vehicles subject to wheel slip constraint*
Changfang Chen, Yingmin Jia (Beihang University, P. R. China)
Junping Du (Beijing University of Posts and Telecommunications, P. R. China)
Fashan Yu (Henan Polytechnic University, P. R. China)

OS17-3 *Robust exponential stabilization criteria for uncertain linear systems with interval time-varying delay*
Nan Xiao, Yingmin Jia (Beihang University(BUAA), P. R. China)
Junping Du (Beijing University of Posts and Telecommunications, P. R. China)
Fashan Yu (Henan Polytechnic University, P. R. China)

OS17-4 *Improved Rao-Blackwellized particle filtering algorithms for multi-target tracking in clutter*
Yazhao Wang, Yingmin Jia (Beihang University, P. R. China)
Junping Du (Beijing University of Posts and Telecommunications, P. R. China)
Fashan Yu (Henan Polytechnic University, P. R. China)

16:40-18:25 GS13 Genetic algorithms
Chair: Shigeru Nakayama (Kagoshima University, Japan)

GS13-1 *A hybrid evolutionary algorithm for the resource constrained project scheduling problem*
Arit Thammano, Ajchara Phu-ang (King Mongkut's Institute of Technology Ladkrabang, Thailand)

GS13-2 *Study on evolution of the artificial flying creature controlled by neuro-evolution*
Ryosuke Ooe, Ikuo Suzuki, Masahito Yamamoto, Masashi Furukawa (Hokkaido University, Japan)

GS13-3 *A new differential artificial bee colony algorithm for large scale optimization problems*
Takuya Kagawa, Akihide Utani, Hisao Yamamoto (Tokyo City University, Japan)

GS13-4 *A generation alternation model for user-system cooperative evolutionary computation*
Satoshi Ono, Kiyomasa Sakimoto, Shigeru Nakayama (Kagoshima University, Japan)

GS13-5 *A neutral evolutionary path-planner*
Eivind Samuelsen, Kyrre Harald Glette, Kazi Shah Nawaz Ripon (University of Oslo, Norway)

Room B

08:45-10:15 GS8 Control techniques I

Chair: Fusaomi Nagata (Tokyo University of Science, Japan)

GS8-1 *Attitude control of an airborne two wheeled robot*
Huei Ee YAP, Shuji Hashimoto (Waseda University, Japan)

GS8-2 *A new adaptive and flexible communication protocol for long-term operation of ubiquitous sensor networks with multiple sinks and multiple sources*
Satoshi Yasuda, Akihide Utani, Hisao Yamamoto (Tokyo City University, Japan)

GS8-3 *Data gathering scheme for area monitoring-based wireless sensor networks*
Kosuke Ikeda, Akihide Utani, Hisao Yamamoto (Tokyo City University, Japan)

GS8-4 *A centralized control system for ecological vehicle platooning using linear quadratic regulator theory*
Anan Kaku, Masakazu Mukai, Taketoshi Kawabe (Kyushu University, Japan)

GS8-5 *A feedback-trained robot task assignment system*
Jeremy Straub, Eunjin Kim (University of North Dakota, USA)

GS8-6 *A control method to suppress the rotational oscillation of a magnetic levitating system*
Toshimasa Nishino (Toshiba industrial products manufacturing corporation, Japan)
Yasuhiro Fujitani, Norihiko Kato, Yoshihiko Nomura, Hirokazu Matsui (Mie University, Japan)
Naoaki Tsuda (Wakayama National College of Technology, Japan)

12:50-15:00 GS9 Control techniques II

Chair: Kohji Higuchi (The University of Electro-Communications, Japan)

GS9-1 *Fuzzy servo control of an inverted pendulum system*
Mohd Khairi Bin Mohamed Nor, Shigenori Okubo (Yamagata University, Japan)

GS9-2 *A lightweight sensing method of tooth-touch sound for disabled person using remote controller*
Akira Yamawaki, Seiichi Serikawa (Kyushu Institute of Technology, Japan)

GS9-3 *Two-dimensional merging path generation using model predictive control*
Wenjing Cao, Masakazu Mukai, Taketoshi Kawabe (Kyushu University, Japan)

GS9-4 *Model predictive control of a power-split hybrid electric vehicle system*
Kaijiang Yu, Masakazu Mukai, Taketoshi Kawabe (Kyushu University, Japan)

15:20-16:20 OS28 Systems for defense of disaster
Chair: Masao Kubo (National Defense Academy of Japan, Japan)
Co-Chair: Hiroshi Sato (National Defense Academy of Japan, Japan)

OS28-1 *Estimation of Hazardous Area with Surveillance UAV*
Hiroshi Sato, Masao Kubo, Akira Namatame (National Defense Academy of Japan, Japan)
OS28-2 *Safety of ships evacuation from Tsunami-Survey Unit about the Great East Japan Earthquake-*
Saori Iwanaga, Yoshinori Matsuura (Japan Coast Guard Academy, Japan)
OS28-3 *Individual recognition-free target enclosure model*
Masao Kubo, Tatsurou Yoshimura, Hiroshi Sato (National Defense Academy of Japan, Japan)
Akihiro Yamaguchi (Fukuoka Institute of Technology, Japan)

16:40-18:25 GS16 Image processing I
Chair: Akira Yamawaki (Kyushu Institute of Technology, Japan)

GS16-1 *Hamming distance based gradient orientation pattern matching*
Prarinya Siritanawan, Toshiaki Kondo (Thammasat University, Thailand)
GS16-2 *Microscopic image restoration based on tensor factorization of rotated patches*
Masayuki Kouno, Ken Nakae, Shin Ishii (Kyoto university, Japan)
Shigeyuki Oba (Kyoto University / Japan Science and Technology Agency, Japan)
GS16-3 *Robotic applications of a defensible error-aware super-resolution technique*
Jeremy Straub (University of North Dakota, USA)
GS16-4 *A study on situation recognition in wide area by aerial image analysis*
Ganwen Jiang, Jun Yoshida, Masayuki Kashima, Kiminori Sato, Mutsumi Watanabe (Kagoshima University, Japan)

Room C
08:45-10:15 GS10 Data mining I
Chair: Daisuke Yamaguchi (Toin University of Yokohama, Japan)

GS10-1 *Web search support system for the smartphone using call and Web logs*
Takuya Ito, Hiroyuki Nishiyama (Tokyo University of Science, Japan)
GS10-2 *Sentiment analysis for domain-specific texts*
Hidekazu Yanagimoto, Michifumi Yoshioka (Osaka Prefecture University, Japan)
GS10-3 *A localization method for smart phones by detection of walking using an accelerometer in indoor environments*
Kunioki Hayashi, Hiroyuki Nishiyama (Tokyo University of Science, Japan)

GS10-4 *Batch fast update algorithm for incremental association rule discovery*
Araya Ariya, Worapoj Kreesuradej (King Mongkut's Institute of Technology Ladkrabang, Thailand)

15:20-16:20 GS4 Artificial mind research
Chair: Shohei Kato (Nagoya Institute of Technology, Japan)

GS4-1 *AGVs' control in autonomous decentralized FMS (AGVs' mind with neural networks)*
Hidehiko Yamamoto, Hiroaki Tashiro, Takayoshi Yamada (Gifu University, Japan)
GS4-2 *Modelling mental representation as evolved second order learning*
Solvi Fylgja Arnold, Reiji Suzuki, Takaya Arita (Nagoya University, Japan)
GS4-3 *How equity norms evolve? - an evolutionary game theory approach to distributive justice*
Kazuaki Kojima, Takaya Arita (Nagoya University, Japan)
GS4-4 *Dynamics of rules internalized in dynamic cognitive agents playing a multi-game*
Takashi Sato (Okinawa National College of Technology, Japan)

16:40-18:25 GS21 Multi-agent systems
Chair: Hidehiko Yamamoto (Gifu University, Japan)

GS21-1 *An implementation of firefly-inspired network synchronicity without leaders on a group of small wireless devices*
Fujio Yamamoto (Kanagawa Institute of Technology, Japan)
GS21-2 *An improved clustering based Monte Carlo Localization approach for cooperative multi-robot localization*
Guanghui Luo, Dan Wu (University of Windsor, Canada)
Libing Wu (Wuhan University, P. R. China)
GS21-3 *Soundscape partitioning to increase communication efficiency in bird communities*
Reiji Suzuki (Nagoya University, Japan)
Charles E. Taylor, Martin L. Cody (University of California, USA)
GS21-4 *A cooperative self-localization method based on group robot information sharing*
Yuichi Kitazumi, Noriyuki Shinpuku, Kazuo Ishii (Kyushu Institute of Technology, Japan)
GS21-5 *Dual layered multi agent system for intentional islanding operation of microgrids*
Asitha Lakruwan Kulasekera, Ranathunga Arachchilage Ruwan, Manjula Udayanga Hemapala, Nuwan Perera (University of Moratuwa , Sri Lanka)
Achala Pallegedara (Saga University, Japan)
GS21-6 *Multi-agent framework for kinematics process of redundant multi-link robots*
Shinya Haramaki (Ariake National College of Technology, Japan)
Akihiro Hayashi, Mochimitsu Komori (Kyushu Institute of Technology, Japan)
Toshifumi Satake (Asahikawa National College of Technology, Japan)

Room D
08:45-10:15 GS25 Robotics I
Chair: Jiwu Wang (Beijing Jiaotong University, P. R. China)

GS25-1 *Development of MEMS micro robot using piezoelectric actuator mechanism*
Tatsuya Ogiwara, Kazuto Okazaki, Yutaro Kezuka, Shinpei Yamasaki, Minami Takato, Ken Saito, Fumio Uchikoba (Nihon University, Japan)

GS25-2 *Development of an autonomous-drive personal robot "An environment recognition and the position detecting system that used image processing and an LRS"*
Katsuhiro Yamamoto, Hideki Ishimaru, Eiji Hayashi (Kyushu Institute of Technology, Japan)

GS25-3 *Design of robotic behavior that imitates animal consciousness: Construction of the user-recognition system*
Motoki Yoshida, Kei Ueyama, Eiji Hayashi (Kyushu Institute of Technology, Japan)

GS25-4 *An abductive environment enables teacher's intervention in a robotics class*
Ilkka Jormanainen, Erkki Sutinen (University of Eastern Finland, Finland)
Meurig Beynon (University of Warwick, UK)

GS25-5 *A simplified approach towards realizing a three dimensional fax based on claytronics*
Chetan J, Shrikrishna Upadhyaya (BMS Institute of technology, India)

15:20-16:20 GS5 Bioinformatics
Chair: Young Im Cho (The University of Suwon, Korea)

GS5-1 *On classification of interview sheets for ophthalmic examinations using self-organizing maps*
Naotake Kamiura, Ayumu Saitoh, Teijiro Isokawa, Nobuyuki Matsui (University of Hyogo, Japan)
Hitoshi Tabuchi (Tsukazaki Hospital, Japan)

GS5-2 *An electrophysiological model of the pharyngeal muscle in Caenorhabditis elegans*
Yuya Hattori (Hiroshima University / Japan Atomic Energy Agency, Japan)
Michiyo Suzuki, Yasuhiko Kobayashi (Japan Atomic Energy Agency, Japan)
Zu Soh (Osaka University, Japan)
Toshio Tsuji (Hiroshima University, Japan)

GS5-3 *Origin of the Chukchee-Kamchatkan language family from the Paiwan language in Formosa: Evidenced by Swadesh basic vocabulary comparison, providing basic knowledge for understanding DNA haplotype distributions*
Koji Ohnishi (Niigata University, Japan)

GS5-4 *A study on line length and direction perception via cutaneous sensation*
Syed Muammar Najib Syed Yusoh, Yoshihiko Nomura, Ryota Sakamoto, Kazuki Iwabu (Mie University, Japan)

16:40-18:25 GS22 Neural networks I
Chair: Eiichi Inohira (Kyushu Institute of Technology, Japan)

GS22-1 *Optimizing the thermoforming of polypropylene foam by an artificial neural network*
Shih-Jung Liu, Ting-Ting Wen, Yau-Zen Chang (Chang Gung University, Taiwan)

GS22-2 *Situational judgment system for a robot in complex environments using hierarchical neural network*
Anri Nishimoto, Hitoshi Sori (Tsuyama National College of Technology, Japan)

GS22-3 *Medical image diagnosis of lung cancer by multi-layered GMDH-type neural network self-selecting functions*
Tadashi Kondo, Junji Ueno, Shoichiro Takao (The University of Tokushima, Japan)

GS22-4 *The technique of the online learning method using SOM algorithm for nonlinear SVM*
Hiroki Tamura, Takeshi Yoshimatsu, Koichi Tanno (University of Miyazaki, Japan)

GS22-5 *Financial market forecasting by integrating wavelet transform and k-means clustering with support vector machine*
W.D.S Roshan, R.A.R.C Gopura, A.G.B.P Jayasekara, D.S.V Bandara (University of Moratuwa, Sri Lanka)

Room E
08:45-10:15 GS26 Robotics II
Chair: Nobuhiro Okada (Kyushu University, Japan)

GS26-1 *A method of teaching a new action to a communication robot through spoken commands*
Eiichi Inohira (Kyushu Institute of Technology, Japan)
Yudai Okuda (Hoshiden Kyushu Corporation, Japan)

GS26-2 *Evaluation of the teleoperation system based on force-free control and visual servo control by using different human operator perception: evidence verified by experiments and statistical analysis*
Achala Pallegedara, Yoshitaka Matsuda, Takeo Matsumoto, Kenta Tsukamoto, Takenao Sugi, Satoru Goto (Saga University, Japan)
Naruto Egashira (Kurume National College of Technology, Japan)

GS26-3 *Development of flexible joints for a humanoid robot that walks on an oscillating plane*
Takehiro Yoneyama, Kazuyuki Ito (Hosei University, Japan)

GS26-4 *Manually controlled manhole cleaning robotic system*
Gopal Joshi, Animesh Rana, Venkateshwar R (Vels University, India)

15:20-16:20 GS12 Evolutionary computations
Chair: Shih-Cheng Horng (Chaoyang University of Technology, Taiwan)

GS12-1 *Optimal base-stock policy of the assemble to order systems*
Shih-Cheng Horng (Chaoyang University of Technology, Taiwan)
Feng-Yi Yang (National Yang-Ming University, Taiwan)

GS12-2 *DNA sequencing by Max-Min Ant System and Genetic Algorithm*
Tao Liu, Michiharu Maeda (Fukuoka Institute of Technology, Japan)

GS12-3 *Advanced artificial bee colony algorithm detecting plural acceptable solutions*
Masaaki Nishimoto, Akihide Utani, Hisao Yamamoto (Tokyo City University, Japan)

GS12-4 *Multi-objective optimal path selection in the Electric Vehicles*
Umair Farooq Siddiqi, Yoichi Shiraishi (Gunma University, Japan)
Sadiq M. Sait (King Fahd University of Petroleum & Minerals, Saudi Arabia)

16:40-18:25 GS24 Pattern recognition
Chair: Mohd Rizon (King Saud University, Saudi Arabia)

GS24-1 *Handwriting character classification using Freeman's olfactory KIII model*
Masanao Obayashi, Shinnosuke Koga, Liangbing Feng, Takashi Kuremoto, Kunikazu Kobayashi (Yamaguchi University, Japan)

GS24-2 *A corner detection technique using unit gradient vectors*
Pramuk Boonsieng, Toshiaki Kondo, Waree Kongprawechnon (Thammasat University, Thailand)

GS24-3 *Human detection employing the HOG feature based on multiple scale cells*
Yusuke Ehara, Joo Kooi Tan, Seiji Ishikawa, Takashi Morie (Kyushu Institute of Technology, Japan)

GS24-4 *Hash based early recognition of gesture patterns*
Yoshiyasu Ko, Atsushi Shimada, Hajime Nagahara, Rin-ichiro Taniguchi (Kyushu University, Japan)

GS24-5 *Source recognition in acoustic sensor arrays using self-organizing hidden Markov models*
Edgar E. Vallejo, Julio G. Arriaga (ITESM Campus Estado de México, México)
Charles E. Taylor (University of California, USA)

GS24-6 *Japanese finger-spelling recognition using a chest-mounted camera*
Akira Nagasue, Joo Kooi Tan, Hyoungseop Kim, Seiji Ishikawa (Kyushu Institute of Technology, Japan)

Room F

08:45-10:15 OS18 Intelligent control & Modeling

Chair: Huailin Zhao (Shanghai Institute of Technology, P. R. China)

Co-Chair: Fengzhi Dai (Tianjin University of Science and Technology, P. R. China)

OS18-1 *System development of an artificial assistant suit*
Jianling Bian (Zhengzhou University, P. R. China)
Huailin Zhao (Shanghai Institute of Technology, P. R. China)
Xiaomin Liu (North China University of Water Resources and Electric Power, P. R. China)
Masanori Sugisaka (Nippon Bunri University, Japan)

OS18-2 *Fundamental research on the fuzzy control to the autonomous airship*
Long Li, Yuan Li, Fengzhi Dai, Dejin Wang (Tianjin University of Science and Technology, P. R. China)
Yutaka Fujihara (Matsue College of Technology, Japan)

OS18-3 *Fundamental research on the fingerprint recognition algorithm*
Binyao Li, Fengzhi Dai, Dejin Wang, Baolong Zhang (Tianjin University of Science and Technology, P. R. China)
Naoki Kushida (Oshima National College of Maritime Technology, Japan)

OS18-4 *Configuration of the Mckibben Muscles and action intention detection for the artificial assistant suit*
Xiaoqing Jia (Shanghai Institute of Technology / Shanghai Maritime University, P. R. China)
Huailin Zhao, Lixia Wang (Shanghai Institute of Technology, P. R. China)
Masanori Sugisaka (Nippon Bunri University, Japan)

15:20-16:20 GS27 Robotics III

Chair: Yoko Amano (Nihon University, Japan)

GS27-1 *An improved Bug-type navigation algorithm for mobile robots*
Yi Zhu, Tao Zhang, Jingyan Song, Xiaqin Li (Tsinghua University, P. R. China)
Xuedong Chen (Huazhong University of Science and Technology, P. R. China)
Masatoshi Nakamura (Research Institute of Systems Control, Saga University, Japan)

GS27-2 *Sound source detection robot inspired by water striders*
Hiroki Nakatsuka, Kazuyuki Ito (Hosei University, Japan)

16:40-18:25 GS28 Robotics IV

Chair: Chair: Yoko Amano (Nihon University, Japan)

GS28-1 *Stability of two-wheeled mobile robot using new combined pole-placement method*
Yoko Amano (Nihon University, Japan)

GS28-2 *Phrase and music search engine for musical data*
Kentarou Minowa, Eiji Hayashi (Kyushu Institute of Technology, Japan)
GS28-3 *Control of real world complex robots using a biologically inspired algorithm*
Fabio DallaLibera (Padua University, Italy / Osaka University, Japan)
Shuhei Ikemoto, Hiroshi Ishiguro, Koh Hosoda (Osaka University, Japan)
GS28-4 *Control method for a redundant robot using stored instances*
Yuya Okadome, Yutaka Nakamura, Hiroshi Ishiguro (Osaka University, Japan)
GS28-5 *Proposal of semiautonomous centipede-like robot for rubbles*
Shota Kashiwada, Kazuyuki Ito (Hosei University, Japan)

January 20 (Friday)

Room A
08:40-09:40 GS1 Artificial brain research
Chair: Hiroshi Tanaka (Tokyo Medical & Dental University, Japan)

GS1-1 *Binary MEMS optically reconfigurable gate array for an artificial brain system*
Yuichiro Yamaji, Minoru Watanabe (Shizuoka University, Japan)
GS1-2 *Synaptic redistribution and variability of signal release probability at hebbian neurons in a dynamic stocsastic neural network*
Subha Danushika Fernando, Koichi Yamada (Nagaoka University of Technology, Japan)
GS1-3 *Properties of Hopfield model with the zero-order synaptic decay*
Ryota Miyata, Toru Aonishi (Tokyo Institute of Technology, Japan)
Jun Tsuzuruki (Okayama University of Science, Japan)
Koji Kurata (University of the Ryukyus, Japan)
GS1-4 *Pulse-type hardware neural networks circuit for PWM servo motor control*
Ken Saito, Masahiko Kato, Minami Takato, Yoshifumi Sekine, Fumio Uchikoba (Nihon University, Japan)

15:15-17:00 OS10 Computer-Supported Learning Systems II
Chair: Kenneth J. Mackin (Tokyo University of Information Sciences, Japan)
Co-Chair: Daisuke Yamaguchi (Toin University of Yokohama, Japan)

OS10-1 *Educational effectiveness of the lecture using animated figures for beginner's programming course in the university*
Yorinori Kishimoto, Kazuhisa Kitakaze (Tokyo University of Information Sciences, Japan)
OS10-2 *Self-learning support system to increase motivation for learning*
Kei Ito, Tomoki Sato, Ayahiko Niimi (Future University Hakodate, Japan)

OS10-3 *A proposal of Web-Com API for e-learning contents creation services*
Yoshihiro Kawano (Tokyo University of Information Sciences, Japan)
Chao Zhou, Tatsuhiro Yonekura (Ibaraki University, Japan)

OS10-4 *Using smartphones in sports education*
Shinya Iwasaki, Kenneth J. Mackin, Masahiro Ishii (Tokyo University of Information Sciences, Japan)

OS10-5 *A vision-based motion-speed instruction method - Application to motion learning of underarm throw*
Akinobu Morikawa, Ryota Sakamoto, Yoshihiko Nomura (Mie University, Japan)

Room B
08:40-09:40 GS14 Human-machine cooperative systems
Chair: Kuu-young Young (National Chiao Tung University, Taiwan)

GS14-1 *Manipulating a multi-DOF robot manipulator for tasks in home-like environments*
Mu-Cheng Hsieh, Po-Ying Tseng, Ming-Shiun Jan, Kuu-young Young (National Chiao Tung University, Taiwan)

GS14-2 *An article retrieval support system that accepts arbitrary Kansei words*
Yuichi Murakami, Shingo Nakamura, Shuji Hashimoto (Waseda University, Japan)

GS14-3 *Design of a user-support system for vision information using a smart phone*
Hiroyuki Nishiyama, Fumio Mizoguchi (Tokyo University of Science, Japan)

GS14-4 *Producing text and speech from video images of lips movement photographed in speaking Japanese by using mouth shape sequence code - An experimental system to communicate with hearing impaired persons -*
Shiori Kawahata, Eiko Koyama, Tsuyoshi Miyazaki, Fujio Yamamoto (Kanagawa Institute of Technology, Japan)

OS13 Embracing Complexity in Natural Intelligence
Chair: Yoshiteru Ishida (Toyohashi University of Technology, Japan)
Co-Chair: Koji Harada (Toyohashi University of Technology, Japan)

OS13-1 *An analysis of spatial patterns in a spatial prisoner's dilemma*
Yuji Katsumata, Yoshiteru Ishida (Toyohashi University of Technology, Japan)

OS13-2 *Identifying cellular automata rules using local rule network from spatiotemporal patterns*
Takuya Ueda, Yoshiteru Ishida (Toyohashi University of Technology, Japan)

OS13-3 *Performance evaluations of adaptive strategies in self-repairing network*
Masahiro Tokumitsu, Yoshiteru Ishida (Toyohashi University of Technology, Japan)

OS13-4 *Solar Insolation simulation by cellular automata and applications to smart home*
Ken Matsuka, Yoshiteru Ishida (Toyohashi University of Technology, Japan)

OS13-5 *Toward development of a strategy to drive HIV-1 into self-extinction through the error catastrophe*
Koji Harada, Yoshiteru Ishida (Toyohashi University of Technology, Japan)

OS13-6 *A pattern formation mechanism of a cellular automaton evolving on a mutual determination rule of variables and a dynamics*
Koji Harada, Yoshiteru Ishida (Toyohashi University of Technology, Japan)

OS13-7 *Network rewiring in self-repairing network: from node repair to link rewire*
Yoshiteru Ishida, Kei-Ichi Tanabe (Toyohashi University of Technology, Japan)

Room C
08:40-09:40 GS18 Intelligent control & modeling I
Chair: Shigeru Nakayama (Kagoshima University, Japan)

GS18-1 *Reinforcement learning with phased approach for fast learning*
Norifumi Hodohara, Yuichi Murakami, Shingo Nakamura, Shuji Hashimoto (Waseda University, Japan)

GS18-2 *Identification of continuous-time Hammerstein systems using Gaussian process models trained by particle swarm optimization*
Tomohiro Hachino, Shouichi Yamakawa (Kagoshima University, Japan)

GS18-3 *Reinforcement learning in dynamic environment -Abstraction of state-action space utilizing properties of the robot body and environment-*
Yutaka Takeuchi, Kazuyuki Ito (Hosei University, Japan)

13:40-14:55 OS20 Intelligent Systems and Applications
Chair: Kuo-Lan Su (National Yunlin University of Science and Technology, Taiwan)
Co-Chair: Jie-Tong Zou (National Formosa University, Taiwan)

OS20-1 *A correction circuit of Hall sensor signal base speed measurement for BLDC motors*
Chung-Wen Hung, Jhih-Han Chen, Ke-Cheng Huang (National Yunlin University of Science & Technology, Taiwan)

OS20-2 *An image sensor based virtual mouse including fingertip detection in face mask algorithm*
Chung-Wen Hung, Hsuan T. Chang, Cheng-Yang Chen (National Yunlin University of Science & Technology, Taiwan)

OS20-3 *The modeling and implementation of tri-rotor flying robot*
Jie-Tong Zou, Haw Tso (National Formosa University, Taiwan)
Kuo-Lan Su (National Yunlin University of Science & Technology, Taiwan)

OS20-4 *Path planning of fire escaping system for intelligent building*
Hsu-Shan Su, Kuo-Lan Su (National Yunlin University of Science & Technology, Taiwan)

OS20-5 *Speech based formation control of multiple mobile robots*
Kuo-Lan Su, Bo-Yi Li, Jr-Hung Guo, Chih-Hung Chang (National Yunlin University of Science & Technology, Taiwan)

OS20-6 *Development of the residual power prediction system of mobile robots*
Jr-Hung Guo, Kuo-Lan Su, Cheng-Yun Chung (National Yunlin University of Science & Technology, Taiwan)
Jie-Tong Zou (National Formosa University, Taiwan)

OS20-7 *Development of tactile sensing system and evaluation for the application to the intelligent robot using the microbending fiber optic sensors*
Ju-Won Jeong, Jung-Ju Lee (Korea Advanced Institute of Science and Technology, Korea)
Heo-Jin Seok (Samsung Electronics company, Korea)

15:15-17:00 OS19 Intelligent System and Control
Chair: Kuo-Hsien Hsia (Far East University, Taiwan)
Co-Chair: Yen Liang Yeh (Far East University, Taiwan)

OS19-1 *Obstacle avoidance control of indoor patrol robots using image-sensing techniques*
Kuo-Hsien Hsia (Far East University, Taiwan)
Shao-Fan Lien, Juhng-Perng Su, Wei-Cheng Lin (National Yunlin University of Science & Technology, Taiwan)

OS19-2 *Twisting algorithm second order sliding mode control for a synchronous reluctance motor*
Wen-Bin Lin, Huann-Keng Chiang, Yi-Chang Chang (National Yunlin University of Science & Technology, Taiwan)

OS19-3 *The implementation of accelerometer and embedded system-based multi-functional pedometer*
Yi-Yu Lu (National Cheng Kung University / Far East University, Taiwan)
Kuo-Sheng Cheng (National Cheng Kung University, Taiwan)
Wen-Bin Lin (Far East University / National Yunlin University of Science & Technology, Taiwan)
Ji-Jer Huang (Southern Taiwan University of Technology, Taiwan)

OS19-4 *An efficient three-scan approach for mining high utility itemsets*
Guo-Cheng Lan, Vincent S. Tseng (National Cheng Kung University, Taiwan)
Tzung-Pei Hong (National University of Kaohsiung / National Sun Yat-Sen University, Taiwan)

OS19-5 *Thermal wave effect for living tissue with surface heating problems by differential transformation method*
Song-Yih Lin (National Cheng Kung University / Far East University, Taiwan)
Hsin-Yi Lai, Cha'o-Kuang Chen (National Cheng Kung University, Taiwan)

OS19-6 *The forming parameter analysis of the circular plate by using computer-aided engineering*
Yen-Liang Yeh, Kuo-Ying Chen, Chia-Hsing Shen (Far East University, Taiwan)

OS19-7 *Motion planning using memetic evolution algorithm for network robot systems*
Chien-Chou Lin, Wei-Ju Chuang, Kun-Cheng Chen (National Yunlin University of Science and Technology, Taiwan)

Room D
08:40-09:40 GS20 Learning
Chair: János Botzheim (Széchenyi István University, Hungary)

GS20-1 *Adaptive reinforcement learning based on degree of learning progress*
Akihiro Mimura, Shohei Kato (Nagoya Institute of Technology, Japan)
GS20-2 *Developing reinforcement learning for adaptive co-construction of continuous state and action spaces*
Masato Nagayoshi (Niigata College of Nursing, Japan)
Hajime Murao, Hisashi Tamaki (Kobe University, Japan)
GS20-3 *Reinforcement learning approach to multi-stage decision making problems with changes in action sets*
Takuya Etoh, Hirotaka Takano, Junichi Murata (Kyushu University, Japan)
GS20-4 *Reduction of learning space by making a choice of sensor information*
Yasutaka Kishima, Kentarou Kurashige, Toshinobu Numata (Muroran Institute of Technology, Japan)

11:10-12:40 GS11 Data mining II
Chair: Ikuo Yoshihara (University of Miyazaki, Japan)

GS11-1 *Proposal of method to extract location-related words and to classify location-dependent information*
Masaki Sakata, Hiroyuki Nishiyama (Tokyo University of Science, Japan)
GS11-2 *Advantages of flexible musculoskeletal robot structure in sensory acquisition*
Shuhei Ikemoto, Yoichi Nishigori, Koh Hosoda (Osaka University, Japan)
GS11-3 *Trend awareness by value senses in home energy consumption*
Jin Dai, Fei Wei, Shingo Aoki, Hiroshi Tsuji (Osaka Prefecture University, Japan)
Shuki Inoue (The Kansai Electric Power Co., Inc., Japan)

13:40-14:55 GS7 Complexity
Chair: Reiji Suzuki (Nagoya University, Japan)

GS7-1 *A potential model pruning in Monte-Carlo go*
Makoto Oshima, Koji Yamada, Satoshi Endo (University of the Ryukyus, Japan)
GS7-2 *Emergence of autocatalytic reaction in a meme propagation model based on particle motion*
Kengo Kobayashi, Reiji Suzuki, Takaya Arita (Nagoya University, Japan)

GS7-3 *Pre-historical multiple movements of modern humans from Old World to Americas: Evidence based on comparing basic body-part name words with Austronesian*

Koji Ohnishi (Niigata University, Japan)

GS7-4 *Bifurcation analysis in a silicon neuron*

Filippo Grassia, Timothée Levi, Sylvain Saighi (University of Bordeaux, France)

Takashi Kohno (University of Tokyo, Japan)

Room E

08:40-09:40 GS29 Robotics V

Chair: Jiwu Wang (Beijing Jiaotong University, P. R. China)

GS29-1 *Construction of a sense of force feedback and vision for micro-objects: Recreate the response and a sense of force of objects*

Tatsuya Domoto, Eiji Hayashi (Kyushu Institute of Technology, Japan)

GS29-2 *Estimate of current state based on experience in POMDP for Reinforcement Learning*

Yoshiki Miyazaki, Kentarou Kurashige (Muroran Institute of Technology, Japan)

GS29-3 *Evolution of locomotion in a simulated quadraped robot and transferral to reality*

Kyrre Glette, Gordon Klaus, Jim Torresen (University of Oslo, Norway)

Juan Cristobal Zagal (University of Chile, Chile)

GS29-4 *A study on the use of tactile instructions for developing robot's motions*

Fransiska Basoeki, Fabio DallaLibera, Hiroshi Ishiguro (Osaka University, Japan)

Takashi Minato (ATR Hiroshi Ishiguro Laboratory, Japan)

11:10-12:40 GS17 Image processing II

Chair: Hyoungseop Kim (Kyushu Institute of Technology, Japan)

GS17-1 *Visual IMU in Manhattan-like enviroments from 2.5D data*

Sven Olufs, Markus Vincze (Vienna University of Technology, Austria)

GS17-2 *Image texture analysis using second order statistical model*

Shahera Hossain, Seiichi Serikawa (Kyushu Institute of Technology, Japan)

GS17-3 *Study on the development of the log scaling system based on the machine vision*

Jiwu Wang, Weijie Gao, Fangbo Liao (Beijing Jiaotong University, P. R. China)

Masanori Sugisaka (Nippon Bunri University, Japan)

GS17-4 *Arterial hemodynamic analysis on non-enhanced magnetic resonance angiogram using optical flow*

Akiyoshi Yamamoto, Hyoungseop Kim, Joo Kooi Tan, Seiji Ishikawa (Kyushu Institute of Technology, Japan)

13:40-14:55 GS19 Intelligent control & modeling II
Chair: Nobuhiro Okada (Kyushu University, Japan)

GS19-1 *Intelligent control method for autonomous vehicle by fuzzy-neural network and self-position-azimuth Correction*
Ryunosuke Takauji, Peng Chen, Mitushi Yamashita (Mie University, Japan)

GS19-2 *Learning strategy with neural-networks and reinforcement learning for actual manipulator robot*
Shingo Nakamura, Shuji Hashimoto (Waseda University, Japan)

GS19-3 *A basic study on cooperative behavior of two butterflies inspired by quantum entanglement*
Masaki Maezono (Kagoshima National College of Technology, Japan)
Ichiro Iimura (Prefectural University of Kumamoto, Japan)
Shigeru Nakayama (Kagoshima University, Japan)

GS19-4 *Importing dynamic planner to BDI agent creating flexible dicision-making of policies for selecting robot actions in real world*
Megumi Fujita, Hiroko Katayama, Yuko Ojima, Naoyuki Nide (Nara Women's University, Japan)

15:15-17:00 OS24 Medical Science and Complex Systems
Chair: Ken Naitoh (Waseda University, Japan)
Co-Chair: Takashi Matsuo (Kanagawa Institute of Technology, Japan)

OS24-1 *Hyper-gourd theory: solving simultaneously the mysteries in particle physics, biology, oncology, neurology, economics, cosmology*
Ken Naitoh (Waseda University, Japan)

OS24-2 *Quasi-stability: Revealing the inevitability of biological molecules*
Hiromi Inoue, Kenji Hashimoto, Ken Naitoh (Waseda University, Japan)

OS24-3 *BioCell print utilizing PELID (Patterning with Electrostatically-Injected Droplet) method*
Shinjiro Umezu (Tokai University, Japan)

OS24-4 *Collective motions of Chases and Escapes*
Toru Ohira (Sony Computer Science Laboratories, Inc., Japan)

OS24-5 *Form and function of arterial bifurcations in the various parts of animal body*
Takashi Matsuo, Shin-ichi Watanabe, Masato Nakakubo, Hidenobu Takao (Kanagawa Institute of Technology, Japan)
Tatsuhisa Takahashi (Asahikawa Medical University, Japan)

Room F
08:40-09:40 OS9 Computer-Supported Learning Systems I
Chair: Kenneth J. Mackin (Tokyo University of Information Sciences, Japan)
Co-Chair: Daisuke Yamaguchi (Toin University of Yokohama, Japan)

OS9-1 *The PSP low layer practice support used on the android personal digital assistant*
Daisuke Yamaguchi (Toin University of Yokohama, Japan)
Ayahiko Niimi (Future University Hakodate, Japan)

OS9-2 *Development of game based learning features in programming learning support system*
Eiji Nunohiro, Kotaro Matsushita, Kenneth J Mackin, Masanori Ohshiro (Tokyo University of Information Sciences, Japan)

OS9-3 *Visualization of satellite data for educational use*
Kotaro Matsushita, Shun Koshikawa, Taito Endoh, Jong Geol Park,
Takashi Yamaguchi, Kenneth J. Mackin, Eiji Nunohiro (Tokyo University of Information Sciences, Japan)

OS9-4 *Programming learning support system with competitive gaming using monitoring and nicknames*
Masanori Ohshiro, Kotaro Matsushita, Kenneth J Mackin, Eiji Nunohiro (Tokyo University of Information Sciences, Japan)

11:10-12:40 GS23 Neural networks II
Chair: Jiann-Shing Shieh (Yuan Ze University, Taiwan)

GS23-1 *Medical image diagnosis of liver cancer by feedback GMDH-type neural network using knowlege base*
Tadashi Kondo, Junji Ueno, Shoichiro Takao (The University of Tokushima, Japan)

GS23-2 *Large database analysis of out-of-hospital cardiac arrest using ensembled neural networks*
Jiann-Shing Shieh (Yuan Ze University / National Central University, Taiwan)
Yuan-Jang Jiang (Yuan Ze University, Taiwan)
Huei-Ming Ma, Wei-Zen Sun (National Taiwan University, Taiwan)
Guan-Wu Jang (New Taipei City Government, Taiwan)

GS23-3 *Analog circuit for detecting position of smell based on pheromone source location of silkmoth*
Masaki Ihara, Kimihiro Nishio (Tsuyama National College of Technology, Japan)

GS23-4 *Discussion of stability of adaptive type neural network direct controller and its folding behavior*
Takayuki Yamada (Ibaraki University, Japan)

GS23-5 *A neural network strategy for process optimization*
Shiu-Wan Hung (National Central University, Taiwan)

15:15-17:00 GS15 Human-welfare Robotics
Chair: Takayasu Fuchida (Kagoshima University, Japan)

GS15-1 *Development of the electric wheelchair hands-free semi-automatic control system using the surface-electromygram of facial muscles.*
Yuki Yamashita, Hiroki Tamura, Koichi Tanno (University of Miyazaki, Japan)

GS15-2 *Upper extremity prosthetics: current status, challenges and future directions*
Sanjaya Vipula Bandara, Ruwan Chandra Gopura, Manjula Udayanga Hemapala (University of Moratuwa, Sri Lanka)
Kazuo Kiguchi (Saga University, Japan)

GS15-3 *Wire-driven two fingers robotic hand for operating a touch-sensitive panel*
Tatsuro Hakui, Yukiharu Yamauchi (Kitakyushu National College of Technology, Japan)
Sei-ichiro Kamata, Shinnosuke Nakao (Waseda University, Japan)

GS15-4 *Development of a singing robotic system from music scores in real time*
Shou Imamoto, Yukiharu Yamauchi (Kitakyushu National College of Technology, Japan)
Sei-ichiro Kamata, Naoto Ohta, Yusuke Murayama (Waseda University, Japan)

GS15-5 *Robotic system for reading Japanese characters on a written document in real time*
Narumi Habu, Yukiharu Yamauchi, Takahiro Kawabuchi (Kitakyushu National College of Technology, Japan)
Sei-ichiro Kamata, Youhei Shinfuku (Waseda University, Japan)

GS15-6 *Eye gesture controlled intelligent wheelchair using electro-oculography*
Satish Ravishankar, Govinda Ram Pingali, Niyanth Krishna Polisetty, Theja Ram Pingali, Padmaja K.V (R.V. College of Engineering, India)
Avinash Sista (Mahindra Satyam, India)

Room H
12:40-13:40 Poster Session
Chairs: Ju-Jang Lee (KAIST, Korea)
Masatoshi Nakamura (Research Institute of Systems Control, Saga University, Japan)
Peter S. Sapaty (National Academy of Sciences of Ukraine, Ukraine)

PS1-1 *An intelligent human behavior based automatic accessing control system*
ChinLun Lai (Oriental Institute of Technology, Taiwan)

PS1-2 *Non-contact physical activity estimation method based on electrostatic induction technique*
Koichi Kurita (Kochi National College of Technology, Japan)

PS1-3 *Genetic algorithm with cross paths detection for solving traveling salesman problems*
Shi-Jim Yen, Shih-Yuan Chiu (National Dong Hwa University, Taiwan)
Sheng-Ta Hsieh (Oriental Institute of Technology, Taiwan)

PS1-4 *Development of a mechanical safety device for service robots*
Yoshihiro Kai (Tokai University, Japan)
Tatsuya Adachi (Daitocacao Co., LTD., Japan)

PS1-5 *Improvement by the image processing of the certification of a reconstructed image from Computer-Generated Hologram picked up by digital watermark*
Yuki Hirama, Ken-ichi Tanaka (Meiji University, Japan)

PS1-6 *Improvement of digital halftoning*
Hiroki Takekawa, Ken-ichi Tanaka (Meiji University, Japan)

PS1-7 *An improved differential evolution for solving large scale global optimization*
Sheng-Ta Hsieh (Oriental Institute of Technology, Taiwan)
Shih-Yuan Chiu, Shi-Jim Yen (National Dong Hwa University, Taiwan)

PS1-8 *Calibration of networked laser range scanners in an intelligent space based on interactive SLAM*
Fumitaka Hashikawa, Kazuyuki Morioka (Meiji University, Japan)

PS1-9 *Development of person identification and tracking system with wearable acceleration sensors in intelligent space*
Tomoyasu Takigawa, Kazuyuki Morioka (Meiji University, Japan)

PS1-10 *Development of easy camera calibration tool under unified world coordinate system using online three-dimensional reconstruction*
Shintaro Kuroiwa, Kazuyuki Morioka (Meiji University, Japan)

PS1-11 *Development of a multi-purpose compact board for robot control systems*
Mitsuhiro Yamano, Shinya Takeda, Yu Kakuta (Yamagata University, Japan)
Yuichi Suzukawa (UD Trucks, Japan)

PS1-12 *'Cruise-and Collect' algorithm for an ARM-based autonomous robot*
Mohd. Noh Zarina, Md. Salim Sani Irwan, Mohamad Yatim Norhidayah, Ali Nur Alisa, Mohd. Said Muzalifah (Universiti Teknikal Malaysia Melaka, Malaysia)

PS1-13 *Blood vessel extraction for diabetic retinopathy*
Haniza Yazid (Universiti Malaysia Perlis, Malaysia)
Ali AlMejrad, Mohd Rizon (King Saud University, Saudi Arabia)
Hamzah Arof (University of Malaya, Malaysia)

PS1-14 *Decision tree approach for fault diagnosis of nonlinear systems*
In Soo Lee (Kyungpook National University, Korea)
Jung Hwan Cho (University of Massachusetts Lowell, USA)
Hae Moon Seo (Korea Electronics Technology Institute, Korea)
Yoon Seok Nam (Dongguk University, Korea)

PS1-15 *A design of a cost effective Fire Fighting Robot using intelligent system*
Shuddha Chowdhury, Shuva Paul (American International University Bangladesh, Bangladesh)
Istiaque Islam (Islamic University of Technology, Bangladesh)

PS1-16 *Gait analysis using inertial sensor and vision*
Tri Nhut Do, Young Soo Suh (University of Ulsan, Korea)

January 21 (Saturday)

Room A
08:40-10:10 GS6 Brain science
Chair: Timothée Levi (University of Bordeaux, France)

GS6-1 *Correlation-based competition regulated by nonlinear interspike interaction in STDP*
Shigeru Kubota (Yamagata University, Japan)
GS6-2 *Density map of attentional capacity allocation*
Satoshi Kambara (Kyoto University, Japan)
Shigeyuki Oba (Japan Science and Technology Agency, Japan)
GS6-3 *Development of a brain computer interface using inexpensive commercial EEG sensor with one-channel*
Masanao Obayashi, Kouji Watanabe, Takashi Kuremoto, Kunikazu Kobayashi (Yamaguchi University, Japan)
GS6-4 *A sparse regression method to estimate neuronal structure from spike sequence*
Syunsuke Aki, Ken Nakae (Kyoto university, Japan)
Shigeyuki Oba (Kyoto university / Japan Science and Technology Agency, Japan)
Shin Ishii (Japan Science and Technology Agency, Japan)

10:30-12:00 OS2 Aware Technologies for e-Services
Chair: Kiyota Hashimoto (Osaka Prefecture University, Japan)
Co-Chair: Sachio Hirokawa (Kyushu University, Japan)

OS2-1 *Visual chance discovery method of potential keys for innovations in tourism*
Kiyota Hashimoto, Makoto Okada (Osaka Prefecture University, Japan)
Kazuhiro Takeuchi (Osaka Electro-Communication University, Japan)
Sachio Hirokawa (Kyushu University, Japan)
OS2-2 *An improved method to extract landmarks information for the purpose of using maps and route*
Shunichiro Sugimori, Yuki Murai, Makoto Okada, Kiyota Hashimoto (Osaka Prefecture University, Japan)
OS2-3 *Automatic generation of tourism quiz using blogs*
Jun Zeng, Toshihiko Sakai, Chengjiu Yin, Takahiko Suzuki, Sachio Hirokawa (Kyushu University, Japan)

OS2-4 *Sharing knowlede and experience of search with SNS*
Xiaobin Wu, Jun Zeng, Chengjiu Yin, Sachio Hirokawa (Kyushu University, Japan)
OS2-5 *A method of sentiment analysis for online reviews containing values of multi-criteria evaluation*
Takaya Nishikawa, Makoto Okada, Kiyota Hashimoto (Osaka Prefecture University, Japan)

Room B
08:40-10:10 OS1 Advanced Vehicle Control
Chair: Shinichi Sagara (Kyushu Institute of Technology, Japan)
Co-Chair: Masahiro Oya (Kyushu Institute of Technology, Japan)

OS1-1 *Flight guidance and control of a winged rocket*
Tomoaki Shimozawa, Shinichi Sagara, Tomohiro Narumi, Koichi Yonemoto (Kyushu Institute of Technology, Japan)
OS1-2 *Position and attitude control of underwater vehicle-manipulator systems using a stereovision system*
Akihito Shigetomi, Shinichi Sagara, Tomoaki Shimozawa (Kyushu Institute of Technology, Japan)
OS1-3 *Adaptive control of underwater vehicle-manipulator systems using radial basis function networks*
Yuichiro Taira (National Fisheries University, Japan)
Masahiro Oya, Shinichi Sagara (Kyushu Institute of Technology, Japan)
OS1-4 *An improved adaptive controller in the presence of input saturation - In case of systems with available output derivatives up to the order of relative degree -*
Natsuki Takagi (Miyakonojo National College of Technology, Japan)
Masahiro Oya (Kyushu Institute of Technology, Japan)
OS1-5 *Development of a position control scheme for rotating sensor unit attached to in-pipe robot*
Hdeki Wada (Sin-Nippon Nondestructive Inspection Co., Japan)
Masahiro Oya (Kyushu Institute of Technology, Japan)
Katsuhiro Okumura (Fukuoka Industrial Technology Center, Japan)
OS1-6 *Adaptive oscillation control scheme for a wheeled mobile robot*
Bo Zhou, Tasuku Eto, Hiroshi Shibata, Masahiro Oya (Kyushu Institute of Technology, Japan)

10:30-12:00 OS5 Bio-inspired theory and applications II
Chair: Kunihito Yamamori (University of Miyazaki, Japan)
Co-Chair: Yuji Sato (Hosei University, Japan)

OS5-1 *Stochastic analysis of OneMax problem by using Markov chain*
QingLian Ma, Kiminobu Koga, Kunihito Yamamori, Makoto Sakamoto, Hiroshi Furutani (University of Miyazaki, Japan)
Yu-an Zhang (Qinghai University, P. R. China)

OS5-2 *High signal and power integrity design for VLSI packaging using genetic algorithms*
Moritoshi Yasunaga, Hiroki Shimada, Shohei Akita (University of Tsukuba, Japan)
Ikuo Yoshihara (Miyazaki University, Japan)

OS5-3 *Solving a multi-objective constraint satisfaction problem with genetic algorithms-Making a food menu with GAs-*
Hironori Fukamachi, Yuji Sato (Hosei University, Japan)

OS5-4 *Improvement of the reinforcement learning efficiency using individually reward value allotment of the soccer video game agent*
Daisuke Inami, Yuuki Sakaguchi, Yuji Sato (Hosei University, Japan)

15:30-16:45 OS21 Intuitive Human-System Interaction
Chair: Masao Yokota (Fukuoka Institute of Technology, Japan)
Co-Chair: Tetsushi Oka (Nihon University, Japan)

OS21-1 *Gesture detection based on 3D tracking for multimodal communication with a life-supporting robot*
Tetsushi Oka, Ryuuichi Kibayashi, Hirosato Matsumoto (Nihon University, Japan)

OS21-2 *Evaluation of some user interfaces for elderly persons*
Sinichi Inenaga, Kaoru Sugita, Masao Yokota (Fukuoka Institute of Technology, Japan)

OS21-3 *Toward artificial Kansei based on Mental Image Directed Semantic Theory*
Tzu-Hsuan Huang, Kaoru Sugita, Masao Yokota (Fukuoka Institute of Technology, Japan)

OS21-4 *A high-sensitivity 3-D shape measurement method with microscope*
Xueli Zhang, Kazuhiro Tsujino, Cunwei Lu (Fukuoka Institute of Technology, Japan)

OS21-5 *Tele-immersive environment with tiled display wall for intuitive operation and understanding in remote collaborative work*
Yasuo Ebara (Osaka University, Japan)

Room C
08:40-10:10 OS4 Bio-inspired theory and applications I
Chair: Ikuo Yoshihara (University of Miyazaki, Japan)
Co-Chair: Moritoshi Yasunaga (University of Tsukuba, Japan)

OS4-1 *Solving Sudoku with Bayesian optimization algorithm*
Shinichi Shirakami, Yuji Sato (Hosei Univercity, Japan)

OS4-2 *Parallelization of genetic operations that takes building-block linkage into account*
Hazuki Inoue, Naohiro Hasegawa, Yuji Sato (Hosei University, Japan)
Mikiko Sato (Tokyo University of Agriculture and Technology, Japan)

OS4-3 *A detection method for intronic snoRNA genes using extended-weight-updating SOM with appearance probability of bases*
Takuro Matsuo, Junichi Iwakiri, Kunihito Yamamori, Naoya Kenmochi, Ikuo Yoshihara (University of Miyazaki, Japan)

OS4-4 *A method to detect intronic snoRNA genes using characteristic base patterns of DNA sequences*
Chen Xue, Junichi Iwakiri, Kunihito Yamamori, Naoya Kenmochi, Ikuo Yoshihara (University of Miyazaki, Japan)

10:30-12:00 OS8 Computer Vision and Sound Analysis
Chair: Yasunari Yoshitomi (Kyoto Prefectural University, Japan)
Co-Chair: Masayoshi Tabuse (Kyoto Prefectural University, Japan)

OS8-1 *Pedestrian detection and tracking in near infrared images*
Masayoshi Tabuse (Kyoto Prefectural University, Japan)
Sayuri Kozawa (Sumitomo Forestry Archi Techno Co., Ltd., Japan)

OS8-2 *A system for facial expression recognition of a speaker using front-view face judgment, vowel judgment and thermal image processing*
Taro Asada, Yasunari Yoshitomi, Masayoshi Tabuse (Kyoto Prefectural University, Japan)

OS8-3 *Robust facial expression recognition of a speaker using thermal image processing and updating of fundamental training-data*
Yuu Nakanishi, Yasunari Yoshitomi, Taro Asada, Masayoshi Tabuse (Kyoto Prefectural University, Japan)

OS8-4 *A system for synchronizing nods of a computer-generated character and a speaker using thermal image processing*
Yasunari Yoshitomi, Ryota Kato, Taro Asada, Masayoshi Tabuse (Kyoto Prefectural University, Japan)

OS8-5 *Music recommendation aimed at improving recognition ability using collaborative filtering and impression words*
Chikoto Koro (ISI Software Corp., Japan)
Yasunari Yoshitomi, Taro Asada, Saya Yoshizaki (Kyoto Prefectural University, Japan)

15:30-16:45 OS22 Management of technology
Chair: Takao Ito (Ube National College of Technology, Japan)
Co-Chair: Rajiv Mehta (New Jersey Institute of Technology, USA)

OS22-1 *How does the network structure of standard-setter affect its standard-setting activity?*
Kensuke Ogata (University of Nagasaki, Japan)

OS22-2 *Simple model of economic Stability and Control*

S. Lu (Fudan University / Shandong University in Weihai, P. R. China)

Takao Ito (Ube National College of Technology, Japan)

OS22-3 *An efficiency analysis using the ICB model in Mazda's Keiretsu*

Seigo Matsuno, Takao Ito, Masayoshi Hasama (Ube National College of Technology, Japan)

Rajiv Mehta (New Jersey Institute of Technology, USA)

Makoto Sakamoto (University of Miyazaki, Japan)

OS22-4 *A note on three-dimensional probabilistic finite automata*

Makoto Sakamoto, Masahiro Yokomichi, Satoshi Ikeda, Hiroshi Furutani (University of Miyazaki, Japan)

Takao Ito, Yasuo Uchida (Ube National College of Technology, Japan)

Xia Qingquan (Harbin Institute of Technology, P. R. China)

Tsunehiro Yoshinaga (Tokuyama College of Technology, Japan)

OS22-5 *A Study on Factors Affecting the Degree of Bullwhip Effect and Inventory Cost to an optimal management strategy for information Sharing in Supply Chains*

Masayoshi Hasama, Seigo Matsuno, Takao Ito, Kouichi Saeki (Ube National College of Technology, Japan)

Yu Song (Fukuoka Institute of Technology, Japan)

Room D
08:40-10:10 OS12 Control Theory and its Application
Chair: Masahiro Yokomichi (University of Miyazaki, Japan)
Co-Chair: Nobuya Takahashi (University of Miyazaki, Japan)

OS12-1 *Propose of the use to alternative Gramian for the controller order reduction*

Shota Usui (Miyakonojo National College of Technology, Japan)

Tsutomu Nagado (University of the Ryukyus, Japan)

Michio Kono (University of Miyazaki, Japan)

OS12-2 *Classes of linear systems of difference equations with bounded solutions*

Naoharu Ito (Nara University of Education, Japan)

Reinhold Küstner (Universität Hannover, Germany)

Harald K. Wimmer (Universität Würzburg, Germany)

OS12-3 *Dynamic window-based obstacle avoidance in the presence of moving obstacles*

Hitomi Harada, Masahiro Yokomichi, Osamu Sato (University of Miyazaki, Japan)

OS12-4 *Multimodal MSEPF for visual tracking*

Masahiro Yokomichi, Yuki Nakagama (University of Miyazaki, Japan)

10:30-12:00 OS14 Embracing Complexity in System Sensing
Chair: Yoshiteru Ishida (Toyohashi University of Technology, Japan)
Co-Chair: Yuji Watanabe (Nagoya City University, Japan)

OS14-1 *A multipath immunity-based statistical en-route filtering in wireless sensor networks*
Yuji Watanabe, Tomotsugu Tamura (Nagoya City University, Japan)
OS14-2 *Extraction of operational behavior for user identification on smart phone*
Yuji Watanabe, Shunta Ichikawa (Nagoya City University, Japan)
OS14-3 *Continuous review model of mutual support supply system for disaster responses*
Nur Budi Mulyono, Yoshiteru Ishida (Toyohashi University of Technology, Japan)
OS14-4 *Network rewiring by matching automaton: from unit reliability to collective survivability*
Yoshiteru Ishida, Masahiro Tokumitsu (Toyohashi University of Technology, Japan)

13:00-15:10 OS15 Information Technology for Environmental Research I
Chair: Takashi Yamaguchi (Tokyo University of Information Sciences, Japan)
Co-Chair: Kenneth J. Mackin (Tokyo University of Information Sciences, Japan)

OS15-1 *Network Analysis of Input-Output Table* ***(withdrawal)***
Kousuke Yoshizawa, Xiang Gao, Shuhei Miyake, Naoko Sakurai, Takeshi Fujiwara, Zeyu Zheng, Kazuko Yamasaki (Tokyo University of Information Sciences, Japan)
OS15-2 *Network analysis of ecologocal footprint & CO2 emission based on Input-Output table for East Asia*
Xiang Gao, Takeshi Fujiwara, Naoko Sakurai, Kousuke Yoshizawa, Syuhei Miyake, Zeyu Zheng, Kazuko Yamasaki (Tokyo University of Information Sciences, Japan)
OS15-3 *The fluctuation in Carbon emission trading Market*
Zeyu Zheng, Naoko Sakurai, Takeshi Fujiwara, Kousuke Yoshizawa, Kazuko Yamasaki (Tokyo University of Information Sciences, Japan)

15:30-16:45 OS16 Information Technology for Environmental Research II
Chair: Takashi Yamaguchi (Tokyo University of Information Sciences, Japan)
Co-Chair: Kenneth J. Mackin (Tokyo University of Information Sciences, Japan)

OS16-1 *Development of Stream Data Platform in Satellite Image Data Analysis System*
Eiji Nunohiro, Hayao Mori, Masaki Hanada, Kenneth J Mackin, Jong Geol Park (Tokyo University of Information Sciences, Japan)
OS16-2 *Flood risk assessment using MLSWI by MODIS Time Series data*
Jonggeol Park, Eiji Nunohiro (Tokyo University of Information Sciences, Japan)
Youngjoo Kwak (International Center for Water Hazard and Risk Management, Japan)

OS16-3 *Application of transfer learning to PSO for similar image search*
Kazuma Mori, Takashi Yamaguchi, Kenneth J. Mackin, Yasuo Nagai (Tokyo University of Information Sciences, Japan)

OS16-4 *The maximum and minimum temperatures trends in Oita*
Masao Igarashi, Takahiro Yamazaki (Nihon University, Japan)
Eiji Nunohiro (Tokyo University of Information Sciences, Japan)

Room E
08:40-10:10 OS25 Network Dynamics in Biological Information Systems I
Chair: Hideyuki Suzuki (The University of Tokyo, Japan)
Co-Chair: Takashi Kohno (The University of Tokyo, Japan)

OS25-1 *Analytical approach to synchrony between populations of neurons with modulatory effects*
Yoichiro Hashizume, Osamu Araki (Tokyo University of Science, Japan)

OS25-2 *A computational model for multiple potential actions for inferred movement goals*
Takuro Fujimura, Yuta Kakimoto, Osamu Araki (Tokyo University of Science, Japan)

OS25-3 *An action planning model using short-term and long-term memory information during learning of sequential procedures*
Nao Tomoda, Yuta Kakimoto, Osamu Araki (Tokyo University of Science, Japan)

OS25-4 *Coherence patterns in neural fields at criticality*
Teerasit Termsaithong, Makito Oku, Kazuyuki Aihara (The University of Tokyo, Japan)

10:30-12:00 OS23 Mechatronics and Intelligent Systems
Chair: Maki K. Habib (American University in Cairo, Egypt)
Co-Chair: Ju-Jang Lee (KAIST, Korea)

OS23-1 *Modified local Gaussian Process Regression for inverse dynamics learning*
Seung-Yoon Cho, Sung-Soon Yim, Ju-Jang Lee (KAIST, Korea)

OS23-2 *Bioinspiration and modern actuators*
Maki K Habib (American University in Cairo, Egypt)
Keigo Watanabe (Okayama University, Japan)
Fusaomi Nagata (Tokyo University of Science, Japan)

OS23-3 *Ubiquitous system and its apapplication networks*
Young Im Cho (The University of Suwon, Korea)

OS23-4 *Simultaneous optimization of path planning and flow shop scheduling by bacterial memetic algorithm*
János Botzheim (Széchenyi István University, Hungary)
Yuichiro Toda, Naoyuki Kubota (Tokyo Metropolitan University, Japan)

OS23-5 *Lateral controller design for an unmanned vehicle via Kalman filtering*
Man Hyung Lee, Hyung Gyu Park, Kil Soo Lee, Young Chul Cha, Dong Jin Kim, Sinpyo Hong, Ho Hwan Chun, Bong Jin Lee, Yun Ja Lee (Pusan National University, Korea)
Byung Il Kim (Hyundai Motor Company, Korea)

OS23-6 *Unmanned container transporter via pseudolite ultrasonic system*
Man Hyung Lee, Kil Soo Lee, Young Chul Cha, Dong Jin Kim, Bong Jin Lee, Sung Mi Kim, Yun Ja Lee (Pusan National University, Korea)
Jung Hyun Moon (Aztechs Co., Ltd, Korea)
Fumio Harashima (Tokyo Metropolitan University, Japan)

13:00-15:10 OS3 Bioinformatics
Chair: Shigeru Omatu (Osaka Institute of Technology, Japan)
Co-Chair: Hideo Araki (Osaka Institute of Technology, Japan)

OS3-1 *Measurement system for metal oxide gas sensors*
Hideo Araki, Sigeru Omatu (Osaka Institute of Technology, Japan)

OS3-2 *Smell classification by using metal oxide gas sensors*
Sigeru Omatu, Hideo Araki (Osaka Institute of Technology, Japan)

OS3-3 *Measurement system for quarts crystal microbalance sensors*
Hideo Araki, Sigeru Omatu (Osaka Institute of Technology, Japan)

OS3-4 *Classification of mixed smells by using neural networks*
Toru Fujinaka (Hiroshima University, Higashihiroshima, Japan)
Sigeru Omatu, Hideo Araki (Osaka Institute of Technology, Japan)

15:30-16:45 OS11 Control Application
Chair: Osamu Sato (University of Miyazaki, Japan)
Co-Chair: Nobuya Takahashi (University of Miyazaki, Japan)

OS11-1 *Acquisition of rules for selecting suppliers of raw materials in distributed production systems by means of reinforcement learning*
Hisaaki Yamaba, Kayoko Takatsuka, Shigeyuki Tomita (University of Miyazaki, Japan)

OS11-2 *Analysis of manipulator in consideration of impact absorption between link and object*
Asaji Sato (Miyakonojo National College of Technology, Japan)
Osamu Sato, Nobuya Takahashi, Masahiro Yokomichi (University of Miyazaki, Japan)

OS11-3 *An application of guaranteed cost control to a 3-DOF model helicopter*
Erwin Susanto, Tatsuhiro Tamura, Mitsuaki Ishitobi, Sadaaki Kunimatsu (Kumamoto University, Japan)

OS11-4 *Robust control of a three-link RRR manipulator with structured uncertainty*
Nobuya Takahashi, Yoshiaki Nakamura, Osamu Sato (University of Miyazaki, Japan)
OS11-5 *Obstacle avoidance of snake robot by switching control constraint*
Yasunobu Hitaka, Toshikazu Yoshitake (Kitakyushu National College of Technology, Japan)

Room F
08:40-10:10 OS27 System sensing and control
Chair: Masafumi Uchida (The University of Electro-Communications, Japan)
Co-Chair: Hirotoshi Asano (Aoyama Gakuin University, Japan)

OS27-1 *The evaluation of the emotion by NIRS*
Hirotoshi Asano, Takanori Sagami, Hideto Ide (Aoyama Gakuin University, Japan)
OS27-2 *A reward allocation method for reinforcement learning in stabilizing control tasks*
Shu Hosokawa, Joji Kato, Kazushi Nakano (The University of Electro-Communications, Japan)
OS27-3 *Acquisition of stationary behavior based on Multiagent Enforced SubPopulations*
Joji Kato, Shu Hosokawa, Kazushi Nakano (The University of Electro-Communications, Japan)
OS27-4 *Robust digital control of DC-DC buck converter with various frequency samplings*
Yuji Fukaishi, Yoshihiro Ohta, Kohji Higuchi (The University of Electro-Communications, Japan)
Eiji Takegami, Satoshi Tomioka (TDK-LAMBDA K.K., Japan)
Kosin Chamnongthai (King Mongkut's University of Technology Thonburi, Thailand)
OS27-5 *EMG analysis accompanied by tactile apparent movement*
Ali Mokhtari, Masafumi Uchida (The University of Electro-Communications, Japan)

10:30-12:00 OS26 Network Dynamics in Biological Information System II
Chair: Hideyuki Suzuki (The University of Tokyo, Japan)
Co-Chair: Takashi Kohno (The University of Tokyo, Japan)

OS26-1 *A network consisting of phase adjusting units*
Masanori Shiro (AIST Human Technology Research Institute / University of Tokyo, Japan)
Syotaro Akaho (AIST Human Technology Research Institute, Japan)
Kazuyuki Aihara (University of Tokyo, Japan)
OS26-2 *Modeling of potential- and noise-induced intracellular dynamics with cell-cell communication*
Tomoyuki Yamada, Atsushi Kamimura (The University of Tokyo, Japan)
Tetsuya J. Kobayashi (The University of Tokyo / Japan Science and Technology Agency, Japan)
OS26-3 *Cholinergic top-down modulation based on the free-energy principle*
Masaaki Takada, Kazuyuki Aihara (The University of Tokyo, Japan)
OS26-4 *Dynamics of associative memory network with self-oscillatory and non-self-oscillatory oscillators*
Yusuke Okada, Yuichi Katori, Kazuyuki Aihara, Hideyuki Suzuki (The University of Tokyo, Japan)

13:00-15:10 OS6 Biomimetic Machines and Robots I
Chair: Keigo Watanabe (Okayama University, Japan)
Co-Chair: Kiyotaka Izumi (Saga University, Japan)

OS6-1 *Proposal and implementation of CAM system for industrial robot RV1A*
Sho Yoshitake, Fusaomi Nagata, Akimasa Otsuka (Tokyo University of Science, Yamaguchi, Japan)
Keigo Watanabe (Okayama University, Japan)
Maki K. Habib (American University in Cairo, Egypt)

OS6-2 *The adjustment of CPG parameters to realize continuous jumping movements for a six-legged robot*
Masaaki Ikeda, Keigo Watanabe (Okayama University, Japan)
Kiyotaka Izumi (Saga University, Japan)

OS6-3 *A proposal of experimental education system of mechatronics*
Naoki Kitahara, Fusaomi Nagata, Akimasa Otsuka (Tokyo University of Science, Yamaguchi, Japan)
Kaoru Sakakibara (C-TASK Co., Ltd., Japan)
Keigo Watanabe (Okayama University, Japan)
Maki K. Habib (American University in Cairo, Egypt)

OS6-4 *A discontinuous exponential stabilization law for an underactuated X4-AUV*
Zainah Binti Md. Zain, Keigo Watanabe, Isaku Nagai (Okayama University, Japan)
Kiyotaka Izumi (Saga University, Japan)

Abstract

In this paper, we present a shortened historical review of the building blocks concept. With the concept we show that three B's can lead to three A's: Building Bodies and Brains leads to applications for Anybody, Anywhere, Anytime. Hence, we outline how the inspiration from artificial life, especially regarding the relationship between the body and brain, leads to a building block concept based upon interactive, distributed parallel processing. The historical outline shows how biomimetic robotics and behavior-based robotics has inspired the development of modular playware. Application examples based upon the concept include LEGO I-Blocks, playgrounds, multi-sensory rooms, robomusic, etc. In the paper, we attempt to explore the theoretical characteristics of the concept and the lessons learned for playware application fields.

Introduction

Research into artificial life and robotics over the last few decades has provided background and insight for developing new kinds of interaction between human beings and physical electronic systems. The artificial life focus on living material provides a direction for the development of the physical systems (e.g. robotic systems) towards systems with "living" characteristics (growing systems, adaptive systems, flexible systems, social systems, etc.). We may speculate that such a focus may possibly allow for more natural interaction with such systems, since we as human beings are familiar with interaction with natural systems, hence we use the term 'natural' interaction. It is interesting to study if and how the artificial life inspiration to the creation of robotic system may lead to natural interaction for the users of such systems, and thereby expand the use of the technological systems to diverse users and diverse application fields.

Body and Brain

One of the main inspirations from artificial life to the field of robotics has been the understanding of the interplay between the body and the brain. Artificial life experiments in the form of biomimetic robotics [1, 2] have shown us how the brain structure and complexity to obtain certain behaviors is dependent on the physical body. For instance, by designing robotic ears and a robot mimicking female crickets, we [2] showed how cricket phonotaxis behavior could be obtained with a much simpler neural system than often hypothesized by biologists based on their behavioral experiments with crickets. Later, many other animal species have been mimicked in similar biomimetic robotic experiments. Such studies have enlightened both biological studies to enhance our fundamental scientific knowledge about nature, and they have enlightened robotics for the creation of intelligent robotic systems putting emphasis on creation of the right interplay between the body and the brain to achieve intelligent robotic systems.

Using artificial life as a means to understand and facilitate user interaction was initially performed as studies of simulation environments. For instance, we developed interactive evolutionary computation for users to express facial expressions and artistic design [3]. In this case, users were presented with a population of potential solutions (e.g. facial expressions or artistic design) on the computer screen, and the users would select a few of the most appealing to the user for reproduction. These selected examples would then reproduce with mutation (and possibly cross-over) to form the next generation presented on the computer screen, and the user would again select the most appealing ones. In this fashion, the user would select for generation after generation towards creating appealing solutions (e.g. facial expressions or artistic designs).

A similar approach of interactive evolutionary computation was used to allow users to develop their own controllers for simulated Khepera robots and LEGO robots. Indeed, in 1996-97 we developed interactive evolutionary robotics as a children's game for young children to make LEGO robots out of the Edinburgh LEGO robot platform [4]. With this approach, young children were able to simply select robot behaviors of their preference on the screen and make an evolutionary process to develop robot controllers that were afterwards downloaded to the physical LEGO robots. It demanded no technical knowledge to perform the selection for the development of robot controllers. Anybody would be able to express their preferences of the robot behaviors visualized on the computer screen and after an interactive evolutionary process download the developed controller to the physical LEGO robot.

This inspired us to engage in further collaboration with the LEGO company on the development of LEGO Mindstorms, e.g. with the development of the first public demonstration of LEGO Mindstorms during RoboCup 1998 [5], the pilot projects for the FIRST LEGO League, and the RoboCup Junior in 1999 [6]. Indeed, our invention of the RoboCup Junior in 1999 used the interactive evolutionary robotics approach and also a user-friendly behavior-based approach to allow even young children to develop LEGO robots for the soccer tournaments.

The behavior-based system allowed users to make the coordination of behaviors. A number of primitive behaviors (at a fairly high abstraction level) were shown on the computer screen, and the user could select among these and combine these to make up the overall soccer playing behavior and download this to the LEGO robots that would then play the robot soccer games [6].

This use of behavior-based robotics to allow non-expert users to develop fairly complex robot behaviors was the inspiration to make a physical version of the behavior-based approach. Indeed, in our LEGO Lab an approach to resistors in LEGO bricks was developed to allow the children to combine different bricks to make up behaviors for the robot. Here, the children would combine physical resistor bricks on top of a LEGO Mindstorms robot to make the overall behavior of the robot instead of combining the primitive behaviors on the computer screen [7].

Building Bodies and Brains

We can describe these examples of artificial life inspired approaches to facilitate user interaction as approaches based on distributed, parallel processing (populations with individuals running in parallel in the evolutionary computation approaches, and behaviors running in parallel in the behavior-based robot approaches). In a physical form, such distributed, parallel processing can manifest itself in a modular approach. Even though the interactive behavior-based approaches developed in the past with users combining primitive behaviors on the computer screen or physically in the form of resistor bricks entailed a somewhat serial processing, a distributed parallel processing version is an interesting possibility.

Based upon the exploration of the body and brain relationship and our exploration of this relationship in robotics, we developed a concept of physical and functional building blocks in order to explore interactive, distributed parallel processing in a physical form. We have explored this general concept since the mid-1990s and developed several physical platforms in order to test the concept in different use contexts.

Generally, the concept can be used to create self-reconfigurable modular robots [8], which autonomously change their physical shape, which we did later in the 2000's, but here we will focus on how the concept can be used to create *user-configurable modular interactive systems*. Here, the user constructs with the technological building blocks to create a physical entity and the functionality of this entity. By making changes to the physical shape of the entity, the user can change the functionality of the entity. This happens simply by attaching or detaching technological building blocks, and moving technological building blocks to different positions. Hence, in such a case, the user is making the physical configuration in a hands-on manner, and the user does not need to do traditional programming to change the functionality of the entity. Therefore, in some cases, it is believed that the building block approach may lead any user to develop solutions in a *simple* and very *flexible* manner. Further, the modularity and distributed processing of the building block approach means that the produced solutions are *robust to failure* of individual building blocks. If one building block fails then the rest will still be working, contrary to most traditional technological solutions with a central processing that makes everything fail if one component fails. Also, since there is no central processing and large infrastructure, but the system is composed of a set of individual building blocks (modules), these may potentially be easily transported around and set up anywhere.

Indeed, in 1995 we got the first idea on putting processing and communication capabilities into each individual LEGO brick. As one of the appealing research directions, at the time, together with Orazio Miglino we envisioned the possibilities for exploring neural networks in a physical form with this new building block concept. Even though the exact implementation was not done until the early 2000's, we explored the concept in several variations on the LEGO robot platforms in the 1995-2000, e.g. as the resistor bricks with LEGO Mindstorms mentioned above [7] and in co-evolution of bodies and brains experiments with the Edinburgh LEGO robot platform [9].

Finally in 2000, it became feasible from a technological point of view to start implementing processors, communication means, sensors, and actuators into the individual LEGO brick, though from a practical prototyping perspective we started making implementation in the LEGO DUPLO bricks [10]. The initial prototypes were based upon a PIC16 microprocessor and communication with two male connectors on the top and two female connectors on the bottom of each LEGO DUPLO brick.

Having processing and communication capabilities in the individual bricks allows both physical (body) and functional (brain) construction. Everything happens as soon as bricks are put together, contrary to e.g. the LEGO Mindstorms approach which imposes a certain sequential process and split of building, programming and testing in the real world. Hence, with LEGO Mindstorms there is a long way from conceiving ideas to actually testing in the real world, which may prevent the non-expert user from overcoming the abstract, cognitive challenge to develop his/her own robotic system. The building block approach is a response to the Mindstorms split processes, and it provides 'action in the interaction', where things happen as soon as the user puts two pieces together, and thereby get an *immediate feedback* (e.g. sound, light, motion) in the construction process.

Numerous tests showed that diverse child users were able to use the technological building block approach implemented in the LEGO bricks to physically confront abstract cognitive challenges e.g. in mathematics, language training, understanding emotions, etc. [11]. Later, cubic blocks – termed African I-Blocks and cubic I-Blocks - were developed as a response to some users' difficulty with building with the LEGO bricks.

Physical Interaction with Modules

The concept became the foundational technological concept when in 2001, Europe's largest producer of playgrounds, KOMPAN, engaged in the development of interactive electronic playgrounds [12]. Initially, sensors and actuators were distributed on traditional playground products, later wire-connected modular tiles were developed as the ground of playgrounds, and finally the ICONS product emerged on the market. The playground tiles became an implementation used for several studies of children's physical interactivity and of adaptation to the individual user.

Despite the relative success of the playground experiments, we wanted to push towards a more free use of modules. Some of the playground work was based on wired connection between modules, which essentially limited the reconfiguration of modules to be performed by the installation worker, and not to be performed by the user.

Therefore, we developed the modular interactive tiles. According to the concept, each tile is a self-contained module with processing power and communication to neighboring modules, and a number of these can be put together in any physical shape by the user within a minute. The tiles light up in different colors and can perceive the pressure when people press them with their hands or jump on them with their feet. Numerous games (exercises) are running on the tiles, and these games aim at providing high motivation for people to engage physically with the tiles. Therapists have used the tiles to provide treatment for a large number of patients who receive hospital, municipality or home care, although the tiles can as well be used for prevention with elderly or for fitness with normal people. The tiles have been tested extensively with cardiac patients, COLD patients and stroke patients in hospitals and in the private homes of patients and elderly, and it have been found that therapists are using the modular aspect of the tiles for personalized training of a vast variety of elderly patients modulating exercises and difficulty levels [13].

Modules and Applications – Some Lessons

In the mid 2000's, we started combining the different technological platforms to explore the building block concept for different user sensory modalities by combining heterogeneous building blocks. For instance, we combined the modular interactive tiles and cubic I-Blocks in the creation of a multi-sensory room in the HC Andersen children's hospital [14], we combined rolling pins and light&sound cylinders in the creation of a multi-sensory room for elderly with dementia [15], and we combined modular tiles, rolling pins, and light&sound cylinders for the first RoboMusic concert [16]. With the different kinds of technological building blocks, we were able to make applications and tests these in many different contexts. Some examples include:

- Neema Rehabilitation Unit, Iringa, Tanzania – therapy of handicapped children
- Orphanage Ilembula, Tanzania – play and education
- Pommern Secondary School, Tanzania – language and mathematics education
- Casa Protetta Albesani, Italy – elderly dementia patients therapy
- Ringe neurorehabilitation center, Denmark – stroke patient therapy
- OUH Hospital Svendborg, Denmark – cardiac and stroke patient physiotherapy
- Townships in South Africa – football competitions during FIFA World Cup 2010
- Winter Music Conference, Miami – RoboMusic performances

An important lesson learned from the many experiments with modular playware technology is that the building block concept facilitated users in engaging with modules with different sensory modalities, and that the concept made it easy to configure the technological systems to the users' preferred sensory modality or activity. Based on all these implementations of the concept, we can now summarize the types of modules and control used:

Modules:	Control:
arithmetic blocks, behavior blocks, language blocks, neural blocks, spiking neural blocks.	open loop, randomness based, rule based, user interaction based, AI and ALife based, morphology based.

Conclusion

We presented a shortened historical review of the building blocks concept. We believe that the concept has shown to be a general approach to facilitate user interaction. We can formulate this as with the building block concept three B's can possibly lead to three A's: **B**uilding **B**odies and **B**rains leads to applications for **A**nybody, **A**nywhere, **A**nytime.

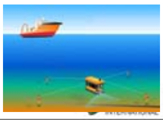
Defining Our Terms: UMS

- *"Unmanned Maritime Systems" refer to:*
- *"Unmanned Surface Vessels" (USV)*
- *Unmanned Underwater Vehicles (UUV)*
- *UUV further divided into*
  1. AUV (A=autonomous)
  2. ROV (R=Remote…tethered to the mothership)



Unmanned Surface Vessels: Comparative

Model	Common USV	Draco	Piranha	Spartan Scout
Manufacturer	AAI	GD	Zyvex	USMI
Snapshot				
Length (m)	11.9	11.0	16.3	11.0
Beam (m)	3.12	3.4	3.2	3.2
Endurance (hrs)	24+	24	96	48
Displacement (kg)	8000	10430	3856	8000
Max Payload (kg)	1200	2267	6804	2267
Max Speed (km/hr)	28	34	45+	40+

Small UUVs: Comparative

Name	Manufacturer	Weight (kg)	Diameter (cm)	Length (m)	Depth Max. (m)	Range (km)	Speed (m/sec)	Endurance
Electric Glider	Webb Research (Teledyne)	52	21.3	1.5	1000	1500	0.4	days
Thermal Glider	Webb Research (Teledyne)	60	21.3	1.5	2000	40000	0.4	5 years
Spray	Bluefin	52	n/a	n/a	1500	4000	n/a	6 months
Bluefin 9	Bluefin	50	23.5	1.7	198.12	n/a	2.57	13 hours
CETUS	Lockheed Martin	100	8	1.8	4000	40	2.57	n/a
REMUS 100	Hydroid (Kongsberg)	37	19	1.6	100	n/a	2.6	22 hours

Fetch 2.9	Sias Patterson (Prizm)	73	29	1.96	150	92.6	6.5	20 hours
Fetch 3.5	Sias Patterson (Prizm)	98	35	2.1	150	229	5	30 hours
Seaglider	iRobot	52	30	1.8	1000	4600	25	n/a

Range and Mission Demands for larger UMS

- *Commercial and Security/Military Customers seek larger UMS to for larger cargoes, longer ranges, deeper dives:*
  - **USV: From 7M RHIB to more robust/longer range hulls 11-16M…with new materials to lighten ship**
  - **UUV: From original torpedo form to "large diameter" UUVs**
- *Technical Challenges Limiting Vehicle Growth:*
  - **Launch/Recovery still the hardest bit**
  - **Followed closely by C2/autonomy**

AMI INTERNATIONAL

UMS Future Market Scenarios…

High: 8.8B 2008 USD total revenues (Military/Comm) by 2020

Bharat Book Bureau (India)

Mid: 1.8-3.7B annual market (Mil/Comm) 2018

Douglas-Westwood (UK)

Low: 500M annual sales (Mil) by 2017

Frost & Sullivan (US)

Our View: Most UMS Market Growth Forecasts Remain Overoptimistic …Especially WRT Military Market

Most Global Military UMS Spending will still be US…but procurement spending growing in Asia-Pacific region, which will become big UMS market by 2020

Current UMS Market Snapshot-UUV

- **UUVs: Existing Market Population = 6000+ ROV, 400+ AUV**
  - ✓ Commercial UUVs make up 70-80% of total existing market
  - ✓ ROVs in the oil and gas industry last 30 years
  - ✓ 3 UUV Types/Segments:
    - Large: Comm/Research/Oil & Gas
    - Medium: Research/Mil/Oil & Gas
    - Small: Research/Mil: Half of all AUVs are <50KG
    - Today's Military UUV market: mostly AUVs for Mine Warfare
- Military AUVs =25% of current global AUV inventory
- Military AUVs: portable and/or "Gliders"—torpedo heritage
- Industry seeing some growth potential—M&A up last 5 years:
  - **Hydroid (Kongsberg)**
  - **Bluefin (Batelle)**
  - **Sea Glider (iRobot)**
  - **Webb Research (Teledyne)**
  - **Sias Patterson (Prizm)**
  - **Seaeye (Saab)**

Identifying UMS Capability & Market Gaps

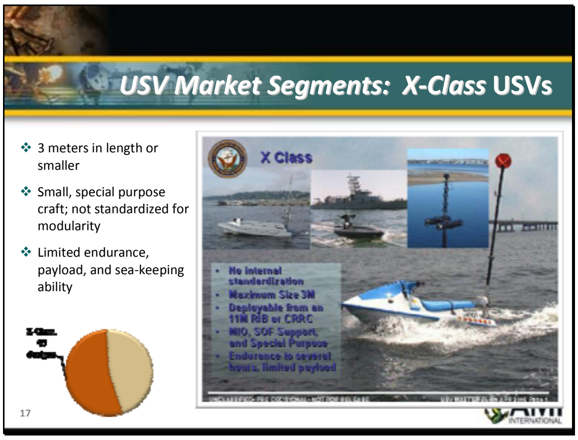
4 USV Classes as Defined by U.S. Navy

USV Mission	X-Class (small)	Harbor Class (7M)	Snorkeler Class (7M SS)	Fleet Class (11M)
Mine Countermeasures (MCM)		MCM Delivery, Search/Neutralization	MCM Search, Towed, Delivery, Neutralization	MCM Sweep, Delivery, Neutralization
Anti-Submarine Warfare (ASW)			Maritime Shield	Protected Passage & Maritime Shield
Maritime Security		ISR/Gun Payloads		7M Payloads
Surface Warfare (SUW)		SUW, Gun	SUW (Torpedo)	SUW, Gun & Torpedo
Special Operation Forces (SOF) Support	SOF Support	SOF Support		Other Delivery Missions (SOF)
Electronic Warfare		Other IO	High Power EW	High Power EW
Maritime Interdiction Operations (MIO) Support	MIO USV for 11M L&R	ISR/Gun Payloads		

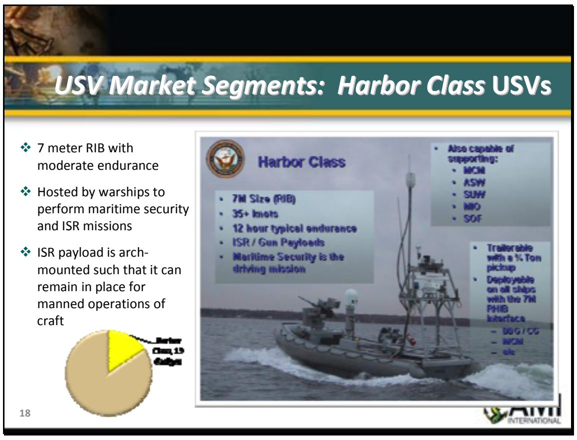
Primary Missions supported by

X-Class	Harbor Class	Snorkeler Class	Fleet Class
Secondary Missions of each class that are possible			

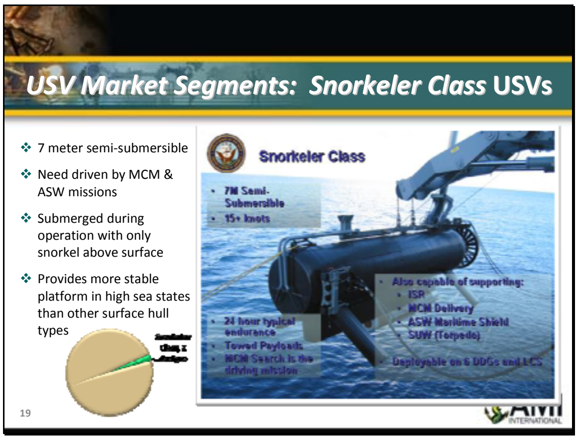
16



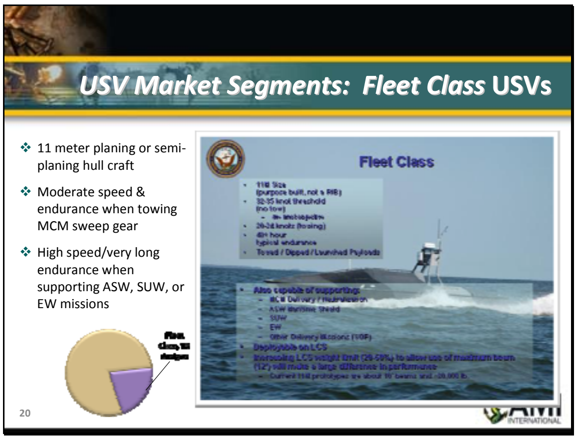
USV Market Segments: X-Class USVs
3 meters in length or smaller
Small, special purpose craft; not standardized for modularity
Limited endurance, payload, and sea-keeping ability
X Class
No internal standardization
Maximum Size 3M
Deployable from an 11M RIB or CRRC
MIO, SOF Support, and Special Purpose
Endurance to several hours, limited payload
17
INTERNATIONAL



USV Market Segments: Harbor Class USVs
7 meter RIB with moderate endurance
Hosted by warships to perform maritime security and ISR missions
ISR payload is arch-mounted such that it can remain in place for manned operations of craft
Harbor Class
7M Size (RIB)
35+ knots
12 hour typical endurance
ISR / Gun Payloads
Maritime Security is the driving mission
Also capable of supporting:
MCM
ASW
SUW
MIO
SOF
Trailerable with a ¾ Ton pickup
Deployable on all ships with the 7M RHIB interface
DDG / CG
MCM
etc
18
INTERNATIONAL



USV Market Segments: Snorkeler Class USVs
7 meter semi-submersible
Need driven by MCM & ASW missions
Submerged during operation with only snorkel above surface
Provides more stable platform in high sea states than other surface hull types
Snorkeler Class
7M Semi-Submersible
15+ knots
24 hour typical endurance
Towed Payloads
MCM Search is the driving mission
Also capable of supporting:
ISR
MCM Delivery
ASW Maritime Shield
SUW (Torpedo)
Deployable on 6 DDGs and LCS
19
INTERNATIONAL



USV Market Segments: Fleet Class USVs
11 meter planing or semi-planing hull craft
Moderate speed & endurance when towing MCM sweep gear
High speed/very long endurance when supporting ASW, SUW, or EW missions
Fleet Class
Also capable of supporting:
SUW
EW
Deployable on LCS
20

[1]kawatsuma.shinji@jaea.go.jp

Abstract: Japan Atomic Energy Agency developed Nuclear Disaster Response Robotics in 2001 after JCO criticality accidents occurred. It is very sorry that Nuclear Disaster Response Robotics could not work when the FUKUSHIMA-DAIICHI accident occurred by a big earthquake and a huge Tsunami on March 11th 2011. According to the situation and condition of the FUKU SHIMA-DAIICHI accident, JAEA has modified above mentioned Nuclear Disaster Response Robotics and prepared suppo rting equipments like as Robotics Control vehicles. JAEA has provided Robotics and Robotics Control vehicle to TEPCO and is continuously supporting TEPCO for plant restoration. This paper summarize JAEA ROBOTICS' Emergency Respo nse to FUKUSHIMA-DAIICHI Accident and describe lessons learned.

Keywords: FUKUSHIMA-DAIICHI, Emergency Response, Nuclear disaster Robotics, Robotics control vehicle.

1 INTRODUCTION

Japan Atomic Energy Agency (JAEA), former Japan Atomic energy Research Institute (JAERI) and Japan Nuclear Cycle development institute (JNC), had experienced on development for reactor vessel remote dismantling machine and bilateral servo-manipulator which has been used for maintenance task under extremely high radiation dose level. Nuclear Disaster Robotics, two RESQ-A, RESQ-B, RESQ-C and RaBOT had been developed after JCO criticality accident occurred on September 30th 1999. It is very sorry that those Nuclear Disaster Robotics could not work when the FUKUSHIMA-DAIICHI accident occurred by a big earthquake and a huge Tsunami on March 11th 2011.

JAEA modified existed Remote Operated Vehicle (ROV) which had been used cold test for Glove Box dismantling and two RESQ-A and prepared Robotics Control Vehicles and provides them to TEPCO for supporting FUKUSHIMA-DAIICHI restoration based on experiences obtained during above mentioned development.

2 Back Ground

2.1 reactor vessel remote dismantling system

JAERI developed reactor vessel remote dismantling machine based on single arm power manipulator 1981 to 1990, and deployed the system during decommissioning of The Japan Power Demonstration Reactor. See **Fig. 1**

2.2 Bilateral Servo-Manipulator System

JNC developed Bilateral Servo-Manipulator System 1982 to 1999 in order to deploy the system for maintenance in Tokai Vitrification Facility which has extremely high dose area. See **Fig. 2**.

Fig. 1

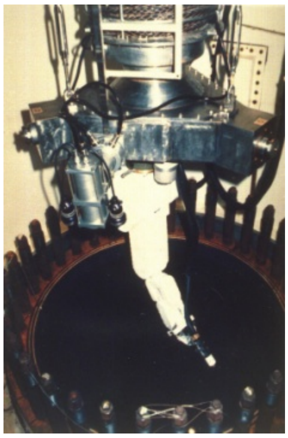

Fig. 2

2.3 Nuclear Disaster Robotics

JAERI developed nuclear Disaster Robotics, two RESQ-A, RESQ-B, RESQ-C and RaBOT in 2000 to 2001 with cooperation of some company, based on the lesson learned that operator could not access easily for repressing criticality during JCO criticality accident which was occurred on the September 30th.. See **Fig. 3**.

2.4 Remote Operated Vehicle for decommissioning

JAEA deploy Remote Operated Vehicle in cold test for dismantling Glove BOX which was use for Mixed Oxide

Fuel for Fast Breeder Reactors and an Advanced Thermal reactor. See **Fig. 4**.

Fig. 3

Fig. 4

3 Emergency response to FUKUSHIMA-DAIICHI accident

3.1 Outline

At the 2:46PM on March 11th 2011, the earthquake of the East Japan Pacific Ocean was occurred and following huge Tsunami attacked FUKUSHIMA-DAIICHI Nuclear Power Station, therefore Station black out occurred reactor coolant could not be maintained. As a result, hydrogen explosion was occurred. See **Fig. 5**.

At that time, RaBOT was already discarded, and RESQ-A, RESQ-B and RESQ-C were not able to work with some failure. It was requested to repair to the company which cooperated when developed, however the request was rejected by the company with reason why engaged engineer were had dissipated and the technology was not handed down.

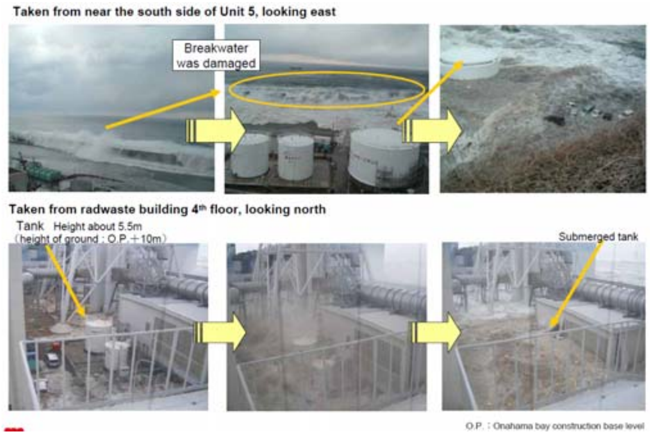

Fig. 5

3.2 Robotics Control Vehicle 1 (RC-1)

It is known that Robotics can't be used successfully without various supporting equipment. JAEA prepared Robotics Control Vehicle – 1 (RC-1) which is for JAEA-1 and JAEA-2 operation and is equipped with Steel shielded operation BOX, a gamma-camera, a teletecter, a viewing camera, a generator.

Based on request from Tokyo Electric Company (TEPCO), JAEA was provide the RC-1 to TEPCO for TALON operation which a robot has radiation mapping system and is provided by Idaho National Laboratory, DOE. Also, a thermo camera and a 3-D laser camera were equipped which were developed and provided by Tadokoro Laboratory of Tohoku University. See **Fig. 6**.

Fig. 6

RC-1 was supplied to FUKUSHIMA-DAIICHI on May 1st and have been used for radiation measurement. The picture taken by gamma camera was shown in **Fig.7**, and the hot point was indicated clearly.

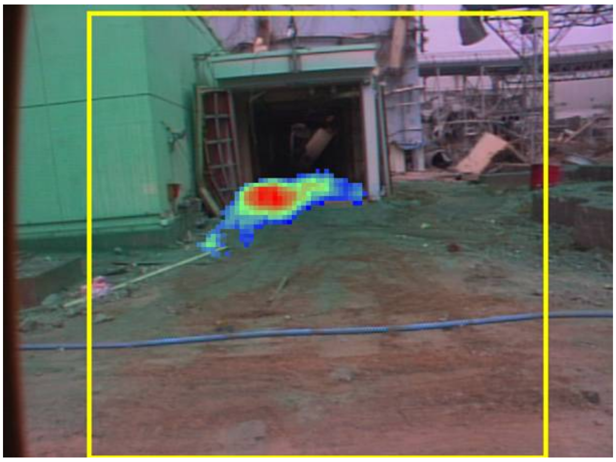

Fig. 7

3.3 JAEA-1

JAEA-1 was modified based on Remote Operated Vehicle used for cold test for Globe BOX dismantling, and is for cleanup of rubbles Rubble scattered by the explosions. See **Fig. 8**.

Fig. 8

3.4 JAEA-2

JAEA-2 was modified based on RESQ-A and equipped with 6 MPa high pressure water spray for decontamination. See **Fig. 9**.

3.5 JAEA-3

JAEA-3 was modified based on RESQ-A and equipped with a prototype of gamma camera which was made based on the experiences on the gamma camera which was equipped on RC-1. See **Fig. 10**.

3.6 Robotics Control Vehicle 2 (RC-2)

As a result of RC-1 preparation, TEPCO requested a new Robotic Control Vehicle. **Fig 11** shows the steel shielded BOX which was not fitting yet.

Fig. 9

Fig. 10

Fig. 11

4 Consideration

4.1 Organization and Scheme for operation and maintenance

It is most important lesson learned that an organization and scheme for operation and maintenance of Emergency response Robotics and accessories like as Robotics control vehicle.

This issue had been pointed out and discussed when Nuclear Disaster Robotics were developed after JCO criticality accident, however conclusion had not been reached.

If such organization and scheme had been established other lessons learned mentioned below could have been pointed out and solved.

4.2. Systematization

As mentioned above, it was known that a Robotics itself can't be used successfully without accessories. Accessories like as Robotic Control Vehicles, gamma cameras, teletecters lights, cooler/heater, generators and others should be prepared in advance and should be systematization. Especially, generators were difficult to obtain after the earthquake and Tsunami attacked.

4.3. Optimization under emergency

As experienced, maker cannot be always depended, under the emergency situation. Minimum tasks like as to optimize Robotic systems in accordance to the situation of the accidents should be performed by operators of the organization.

Therefore, Platform and tool systems should be recommended. Platform is mobile mechanism and should be prepared two or three type according to size and weight of tools. Tools should be prepared or modified based on conventional equipment on the shelf.

4.4 Mobility

Even if an organization established, it is very difficult to prepare logistics in the damaged area just after earthquakes and Tsunamis attacked, so the organization should cooperated with the Defense Forces of Japan. Also Robotics Control Vehicles should be designed and prepared in accordance with transport plane and helicopter of Defense Force of Japan.

5 CONCLUSION

We are TEAM NIPPON.

We shall overcome!

Abstract: We designed cognitive architectures for individual robotic rat pups using genetic algorithms, with the aim of achieving insight into Norway rat pup behavior. Our genetic algorithms were evolved using only metrics of Norway rap pup behavior (e.g., percent of time spent in corners, along walls, and center of an arena during animal experiments). Robotic rat pups quantitatively matched Norway rat pups at the macro level and additionally qualitatively matched Norway rat pup behavior at the micro behavior scales (corner snooping, punting). The complexity of the resulting deterministic controllers may lend support to previous studies that show random-like control codes (possibly emerging from complex underlying interactions) can produce apparently realistic rat pup behavior below a certain age.

Keywords: genetic algorithm, behavior, biorobotics

1 INTRODUCTION

We combine robotic models of infant Norway rats (robopups), with computer simulation and animal experimentation to study rat pup behavior (Fig. 1). In past work, we showed the remarkable result that simply choosing robopup movement directions at random, regardless of sensory input, produced quite intentional-looking emergent behavior patterns that matched rat pups in both individuals and groups, somewhere in-between 7-10 days of age [1]. Our analysis revealed that body morphology and arena topology interacted with the random control architecture to produce emergent complex behavior. We could not conclude, however, from these results that rat pups in an arena move purely randomly, because we did not investigate the full space of possible deterministic sensorimotor rules. In our current work, we use genetic algorithms to investigate the space of possible sensorimotor rules by artificially designing sensory-dependent deterministic robopup controllers using macro-level topological fitness metrics (e.g., percent of time spent in various regions of an arena during animal experiments). The genetic algorithms allow us to explore a wide range of possible deterministic control solutions. In this paper, we review past work and explain our methods to evolve cognitive codes with genetic algorithms to study a variety of solutions.

2 BACKGROUND

Behavior is influenced by the nervous system, body morphology, physiology, the environment (including the social environment), and interactions among all these elements. Thus, our basic schematic view of behavior is defined in equation (1). Autonomous robots and associated simulations allow systematic variation of the variables of (1) in ways that are often impossible in live animals.

Behavior = *F*(*Internal State*, *Sensorimotor Rules*, *Biomechanics*, *Environment*) (1)

Equation (1) is a schema for developing animal and robotic models and, by including the environment (broadly construed), it is a schema that is likely to result in emergent behavior.

2.1 Rat Pup Experiments

An individual rat-pup experiment consists of placing a single pup in the middle of an arena and videotaping its behavior from above. Figure 1 illustrates a 7-day old rat pup in an arena. Arenas could be manipulated in a variety of ways and the test chamber was configured to study the effects of specific environmental stimuli (e.g., heat, inclines, and light). The video recordings of rats moving in the arena, were then analyzed by extracting digitized video frames at specified time intervals (i.e., 5 secs.) to record the position of the tip of the nose and base of the tail [2].

Fig. 1. 7-day old Norway rat pup during animal observation experiments.

Algorithms were then used to extract metrics from these measurements [3]. Animal experiment results for individual 10-day old pups were reported in Schank et al., 2004 [4]. Rat pups spent time in corners, near walls, and in the center of the arena. In addition, some rat pups visited one corner, some two corners, and others 3 or 4 corners. Sometimes, a rat pup spent an extended period of time in a limited region of the arena. Playback of video from these pup experiments revealed "micro" behaviors, which were limited in time and space. Micro behaviors were easily identified in video playback, but hidden in 2-dimensional trajectory plots. For example, rat pups repeatedly burrowed their nose into corners for variable periods of time (i.e., *corner-snooping*, e.g., see Fig. 1). Rat pups sometimes turned in place in the open or in a corner for periods of time, which is called *punting*. Rat pups also followed walls for periods of time, which we called *wall-following*. These individual rat-pup behavior features also hold for 7-day old pups [1]. We therefore categorized all rat pup behavior as either: (1) macro-level behavior (those relating to overall trajectories which occur on the order of 10 minutes over extended arena space), or (2) micro-level (those that relate to detailed micro-behaviors as described above which occur on the order of seconds to minutes over limited arena space).

2.2 Robotic Rats and Dynamic Simulator

In parallel with the animal experiments, we conducted experiments with robotic rat pups (robopups). The current generation of robopup is shown in Fig. 2. The design of the robopup incorporated biologically inspired and robotic aspects, such as body shape, sensor and actuator location, and computational needs [4]. In brief, the robot's shape was designed to model the basic shape of a rat pup 7-10 days of age. The robot had the same 3:1 length to width ratio as Norway rat pups in the 7 to 10-day age range, and had a similar curved snout (Fig. 1). Rat pups have limited mobility at these ages and primarily use their back legs to push their bodies forward [2]. To model this type of movement, two rear rubber wheels propelled the robot and a supporting passive wheel stabilized the front of the robot.

Before 13 to 14 days of age, rats are blind, deaf, and have limited olfactory capabilities [3]. Thus, infant rat pups rely largely on tactility at these early ages. Robopups incorporated tactility by placing 14 micro-switches at various positions around the robot's perimeter. Most of the sensors were placed near the front of the robopup because a rat pup's primary tactile sensitivity is around the snout area [2]. To detect contact at points where there were no switches, brass strips were connected to the micro switches. Sensorimotor rules were programmed in the robot's microprocessor (Parallax 25 MHz Java stamp 24-pin DIP module). Robots were tested in arenas proportional to the arenas in which rat pups were tested (Fig. 1), and we applied the exact same data extraction and analysis tools for both the robopups and rat pups.

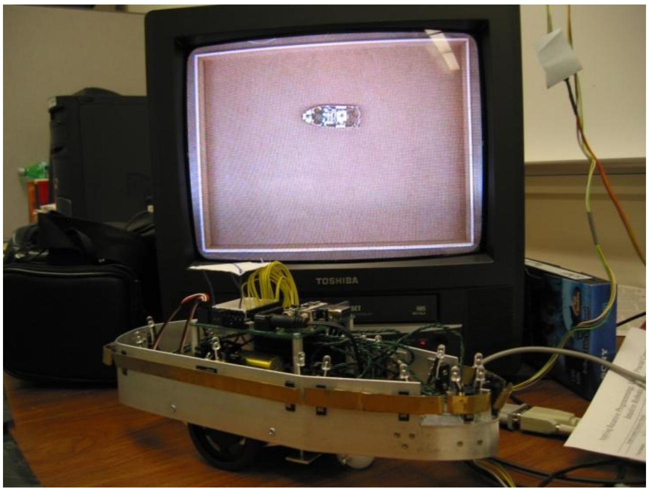

Fig. 2. Robotic model of infant rat pup (foreground), and another robot in testing arena (on monitor).

A MATLAB/Simulink based individual-robot simulation was used in the current study [5]**.** Just as in the actual robots, sensorimotor rules are programmed into the robot simulator. The only differences are the programming language and the computing platform. Model validation studies showed that the simulation produced results very similar to robopups [5].

Several robot controllers were developed for the robopup project to accomplish the goal of modeling rat-pup sensory behavior. Each controller took in information from the robot's tactile sensors and then used that information to send commands to the two robot wheels. The robopup could move forward, back up, or turn (or some combination thereof), depending on the command sent to each wheel.

2.3 Random Control Architectures

In May et al., 2006 [1], we implemented a *random* control architecture as a type of null model to compare to other sensor-driven architectures. In this null model, robots did not use their sensors at all. Instead, every two seconds, robopups *randomly* chose one of ten movements with equal probability: stop moving or one of the seven forward or two back-up directions depicted in Fig. 3.

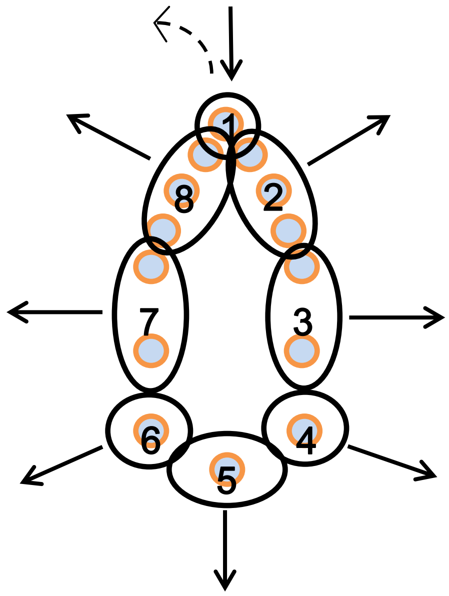

Fig. 3. Illustration of tactile sensor groups on robot, and possible movement directions.

Rat pups can flex their body and turn away from a corner. Rigid-body robopups cannot escape a corner in this way. Therefore, to model the ability of rat pups to escape corners, we implemented *back-up* directions of movement. When moving, the random architecture distributed movements such that a robopup moved forward 78% of the time and backed up 22% of the time. It was surprising and remarkable how well the trajectory plots of "random" robots matched the plots for both 7 and 10 day-old pups. Further analysis showed that the random architecture resulted in good matches somewhere in-between 7-day old and 10-day old rat pups in key macro-level topological metrics, such as the proportion of time spent in corners, near walls, and in the center of the arena [1]. The robopups also exhibited all the micro-level behaviors commonly seen in rat pups including corner-snooping, wall-following, and punting. This surprising result could be explained by the complex interaction of body-shape, arena constraints, and simple cognitive codes all working in unison to allow behavior to emerge.

3 GENETIC ALGORITHM METHODOLOGY

In May et al., 2006 [1], we first designed the controller and then analyzed the ability of the controller to match certain macro-level topological quantitative metrics and micro-level behaviors. In the current work, we reversed the procedure by *imposing* (through artificial selection) the matching of macro-level quantitative topological numerical metrics (percent of time spent in various regions of an arena during animal experiments), and then studied the resulting variety of controllers and their subsequent qualitative micro-level detailed behaviors.

Given that the *random* control architecture, using no sensory information, produced results very similar to the rat pups, a natural question to ask was how well *any* sensory-dependent *deterministic* control architecture could perform in matching pup behavior. To explore the large space of possible deterministic control designs, we employed a genetic algorithm (GA). The evolutionary method used to design controllers depended on three components: (i) macro-level behavior metrics that could be numerically quantified (e.g., percent of time spent in various regions of an arena during animal experiments), (ii) creation of *fitness functions* that evaluated behavioral metrics to score the quality of control designs, and (iii) a method of varying and combining high-scoring control designs to create new control designs (called a *generation* of control designs).

Employing a relatively high-fidelity dynamics model [5] placed computational constraints on our ability to simulate thousands of solutions over hundreds of generations, as is commonly done in GA studies. However, the evolutionary method was still extremely successful at automatically constructing and comparing thousands of computer-designed control codes, many of which closely matched our performance goals and rat pup behavior.

3.1 Control Designs

In this study, the physical design of the robot was held constant; only the motor responses to sensor contact were able to evolve from generation to generation. For each of the eight touch sensor groups on the robot (Fig. 3), a motor response could support up to three consecutive wheel commands (Fig. 4). A wheel command consisted of a left wheel *speed*, a right wheel *speed*, and a time variable to define *duration* of wheel operation. Each sensor's motor response therefore had nine degrees of freedom, bringing the total potential number of variables to 74 (eight sensor groups and an additional two variables to define default left and right wheel speeds when no sensors were currently activated).

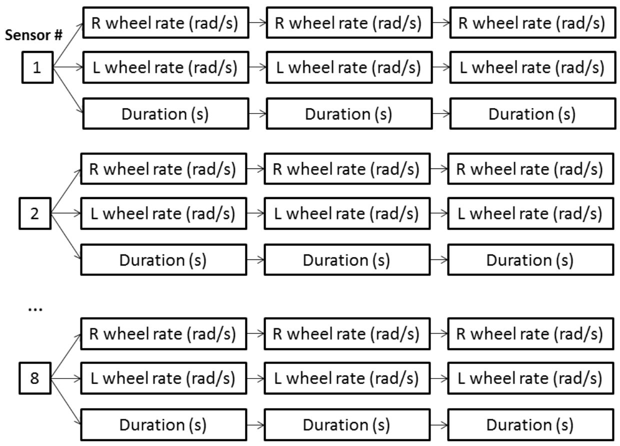

Fig. 4. Variables representing sensori-motor mapping on robotic pup.

It is important to note that a controller design was *not* required to have more than one response for each sensor group. If a controller design consisted of more than one response for a sensor group, the second and third responses were executed sequentially in order, for the amount of time defined in their duration variable (Fig. 4). It was up to the genetic algorithm to select the best combination of the 74 variables that would lead to the most realistic rat pup behavior. The controller genome was then simply a matrix of floating numbers precise to the 2nd decimal place.

3.2 Topological Metric

The underlying fitness metric matched was based on a topological analysis of where infant rat pups spend time in an arena. An average profile of 113 10-day old pups was reported in Schank et al., 2004 by comparing the percentage of total time spent next to walls, in corners, and in the center of the arena during rat pup testing [4]. Every 5 secs during a 10 minute experiment, a pup's position was classified as a *wall event*, *corner event*, or *center event*. A wall event was defined as a snout point next to a wall. A corner event was defined as a snout point within a square area delineated by a corner. A center event was a snout point in the inner arena. We found that rat pups, on average, spent ~60% of time near a corner, ~22% near a wall, and ~18% in the center (Fig. 5). Note that this metric of rat pup behavior does not describe micro behaviors that rat pups exhibited including corner snooping and punting.

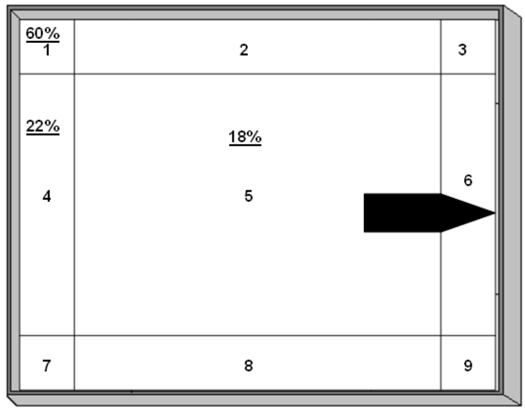

Fig. 5 Topological fitness metrics. Percentages indicate location distributions among all corners (~60%), walls (~22%), and center (~18%) areas averaged over 113 rat pups [4].

3.3 Fitness Function

A linear fitness function was defined as in Eqn. 2, where c is the percent distribution of corner samples (in range from 0-100), c_0 is the desired target percent distribution of corner samples (60% in our case), and the variables w, a, represent the walls and center areas, respectively. The goal then was to maximize this fitness function (c_0 =60, w_0 =22, a_0 =18). Note that the overall fitness function is in the range from 0-1. Even though we refer to the fitness function as linear, the function in (2) is piecewise linear

$$f_{avg} = 1 - \left[\left(\left| \frac{c - c_0}{c_0} \right| \right) + \left(\left| \frac{w - w_0}{w_0} \right| \right) + \left(\left| \frac{a - a_0}{a_0} \right| \right) \right] \Big/ 3 \tag{2}$$

3.4 Genetic Algorithm (GA)

The GA would initially generate 12 controller genomes at random for the first generation of simulated robots. The simulation stored the (x,y) locations of the nose of the robot every 5 seconds to maintain consistency with the original rat pup observations (Section 3.2). For each controller design, three simulation trials were run with different initial headings for a robot initially placed in the center of the arena, since initial orientation often resulted in a substantial difference in robot paths for both deterministic and random architectures. The fitness scores were computed for each simulation and averaged to obtain an average fitness value.

The genetic algorithm employed one of two selection methods to vary control design each generation. Both single parent and crossbreeding techniques were used.

Once the GA evaluated the average fitness of all the simulated robots in a given generation, the top three designs from the population of 12 were selected as a basis for the next generation in the single parent cases. Each of the chosen parent designs created four (slightly varied) versions of itself to produce the 12 children needed for the next generation. In the crossbreeding trials, the process was different. New genomes were created by choosing two parents from the previous generation to essentially blend motor response features of the two parents. Rather than averaging motor responses, the child design would instead pick several motor responses from each parent and the resulting design would be tried. The percentage of cases in which a particular design would be chosen as a parent was proportional to its fitness score.

Mutations could occur at the level of an individual response element ("point" mutations), or an entire sensor response ("bulk" mutations). The mutation rates were 25% for point mutations, and 15% for bulk mutations. Our chosen mutation rates ensured that the children genomes would vary significantly from the parents, but hopefully not so significantly that natural selection was neutralized. Point mutations could modify a single wheel speed by roughly ten percent, or wheel duration by up to 0.1 second. After the new generation of controller designs was mutated, the simulation and fitness function evaluation process started over and repeated for 20 generations.

4 RESULTS

The linear fitness function (2) frequently evolved a control scheme that invoked punting or flailing movement of the robot when a wall was contacted by a sensor. This caused the robot to move across the arena in unpredictable trajectories. In some cases, a no-sensor-contact default curved movement would lead the robot into another wall or corner across the arena, at which point the robot would again spin away from the wall and head out into the arena again (Fig. 6).

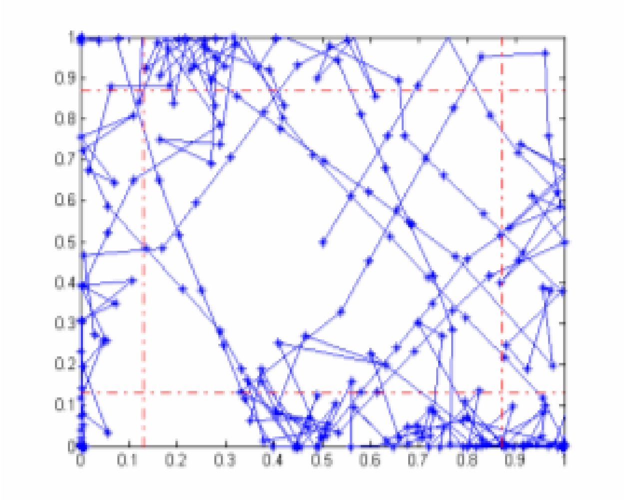

Fig. 6. Representative trajectory of robotic rat pup using a GA solution. This controller achieved an average corner behavior of ~65%, average wall behavior of ~21%, and average center behavior of ~14%.

The best (fully deterministic) linear fitness controller trajectories were quantitatively and visually similar to both infant rat pup trajectories (Schank et al., 2004 [4]) and the previously reported (May et al. 2006 [1]) random robopup trajectories in that the controller produced:

- trajectories that closely matched the macro-level topological corner, wall, and center distributions (by selection with the fitness functions);
- a wide variety of trajectories for a single controller, including trajectories that visited a varying number of corners (depending on a simulated robopup's initial heading);
- typical rat-pup micro-level sub-behaviors like corner snooping, wall-following, and punting
- many trajectories that traversed the center of the arena and crossed the length of the arena to the other side, and whose paths crossed over each other multiple times.

Only the first item above was explicitly designed-for in the GA methodology. The other three items were emergent.

5 CONCLUSIONS

The best GA solutions (in terms of the macro-level topological fitness metric and micro-level rat pup behaviors) incorporated a repeated thrashing at wall contact and a 'random-looking' projection of the robot into the center of the arena, which is interesting for two reasons. First, it supports the idea that a 'random-like' component is needed to match observed behavior, regardless of whether the random-like behavior was created by a truly random controller as in May et al., 2006 [1] or a complex deterministic controller as evolved in this study. As discussed in May et al. 2006 [1], random-like behavior need not result from truly random commands, but in biological organisms, it could be, for example, the result of developing motor systems. Secondly, our results illustrate the potential complexity of sensory-dependent controllers that may be required to produce realistic behavior. The controllers we evolved were complex, with each sensor contact followed by possibly three motor commands in succession. In effect, this work and our past work bounds the rat-pup controller problem at the controller extremes, from a simple random controller (May et al. 2006 [1]) to a complex deterministic controller (current study). Indeed, we have shown that both extremes can produce apparently realistic rat-like behavior for individuals. A promising future line of study would mix deterministic and stochastic controllers. Finally, more investigation needs to be conducted into group behavior. May et al. 2006 [1] showed random-robot behavior metrics intermediate between 7-10 day old pups in individuals and groups. However, a recent study by May et al. 2011 [6], which studied only group behavior, showed metrics that match random-robot group behavior and 7-day old group behavior. But, random-robot group behavior and 10-day old group behavior did not match. This may imply that near 10-days of age, behavior shifts depending on isolation vs. group contexts [3]. However, more investigation with both random and non-random models, and different age rat pups needs to be conducted before any conclusions can be drawn.

Abstract: A high-level ideology and technology will be revealed that can effectively convert any distributed system (manned, unmanned, or mixed) into a globally programmable spatial machine capable of operating without central resources. Compact mission scenarios in a special high-level language can start from any point, runtime covering & grasping the whole system or its parts needed, setting operational infrastructures, and orienting local and global behavior. The approach offered can be particularly useful for quick reaction on asymmetric situations and threats the world is facing, paving the way to massive use of cooperative robotics and gradual transition to unmanned systems for solving critical problems in unpredictable environments.

Keywords: distributed dynamic worlds, asymmetric situations and threats, Spatial Grasp Technology, Distributed Scenario Language, parallel networked interpretation, multi-robot systems.

1 INTRODUCTION

In our modern dynamic world we are meeting numerous irregular situations and threats where proper reaction could save lives and wealth and protect critical infrastructures. For example, no secret that world powerful armies with traditional system organizations are often losing to terrorists, insurgents or piracy with primitive gadgets but very flexible structures making them hard to detect and fight. And delayed reaction to earthquakes or tsunamis is a result of inadequacy of system organizations too.

A novel philosophy and supporting high-level networking technology will be described that can quickly react on irregular situations and threats and organize any available human and technical resources into operable systems providing global awareness, pursuing global goals and self-recovering from damages.

The approach allows us at runtime, on the fly, formulate top semantics of the needed reaction on asymmetric events in a special Distributed Scenario Language (DSL), shifting most of traditional organizational routines to automated up to fully automatic implementation, with effective engagement of unmanned systems.

The details of this technology, based on gestalt and holistic principles [1] rather than traditional multi-agent organizations [2, 3] will be revealed in this paper, with explanation of different DSL scenarios that can be effectively executed by self-organized robotic groups. These scenarios include collective navigation of distributed spaces, coastline patrols, outlining and impacting forest fire zones, and swarm-against-swarm solutions where highly organized robotic swarms can fight another, manned, groups related, say, to piracy intrusions.

The technology offered provides a unified solution to human-robot interaction and multi-robot behaviors just as a derivative of parallel and distributed interpretation of system scenarios in DSL.

2 TRADITIONAL SYSTEM ORGANIZATIONS AND THEIR PROBLEMS

2.1 From system structure to system function

The traditional approach to system design, development and management is when the system structure and system organization are primary, created in advance, and global function with overall behavior are secondary, as in Fig. 1.

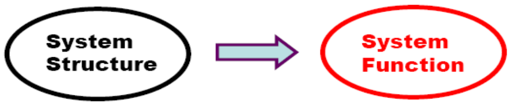

Fig. 1. Traditional approach to system design

Typical examples of the traditional approach are multi-agent organizations [2, 3], where global system behavior is the result of work and interaction of predetermined parts (agents). In this respect we can name the 4D/RCS Model Architecture [4], with its block diagram shown in Fig. 2.

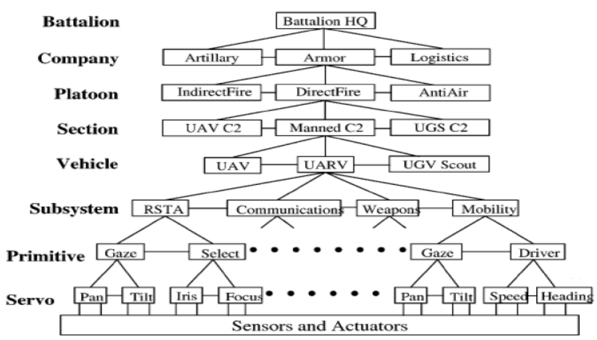

Fig. 2. 4D/RCS model architecture

4D/RCS prescribes a hierarchical control principle, where commands flow down the predefined hierarchy, and status feedback and sensory information flows up. Large amounts of communication may also occur between nodes at the same level, particularly within the same subtree of the command tree. Future Combat Systems (FCS) project [5] was ideologically and technologically based on this organizational (as well as artificial intelligence) hierarchical model.

2.2 The problems with classical organizations

The related systems, where we first formalize and build the system structure and organization and then try to get from these the global behavior needed, are usually static, and may often fail to adapt to highly dynamic and asymmetric situations. If the initial goals change, the whole system may have to be partially or even completely redesigned and reassembled. Adjusting the already existing system to new goals and functionality needed may result in a considerable loss of system's integrity and performance.

3 AN ALTERNATIVE: THE SPATIAL GRASP TECHNOLOGY (SGT)

3.1 SGT basic idea

Within the approach offered (also known as "overoperability" [6, 7] in contrast to the conventional *interoperability*) the global function and overall behavior are considered, as much as possible, to be primary. Whereas system structure and organization (command and control including) are secondary, with the latter as a derivative of the former, as in Fig. 3.

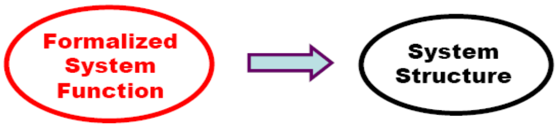

Fig. 3. SGT basic idea of system creation and organization

The advantages of this (actually, the other way round) approach include high potential flexibility of runtime system creation and organization, especially in quick responses to asymmetric events, and enhanced opportunities for automated up to fully automatic (unmanned) solutions.

3.2 Parallel spatial grasp of distributed worlds

SGT is based on a formalized wavelike seamless navigation, coverage, penetration, and grasping of distributed physical and virtual spaces, as shown in Fig. 4.

a) b)

Fig. 4. Incremental integral grasping of distributed worlds: a) virtual interpretation, b) symbolic physical analogy

This top mode of system vision has strong psychological and philosophical background, reflecting, for example, how humans (top commanders) mentally plan, comprehend, and control complex operations in distributed environments.

3.3 Distributed scenario interpretation

The approach in practice works as follows. A network of universal control modules U, embedded into key system points, collectively interprets system scenarios expressed in DSL, as shown in Fig. 5. System scenarios, based on the spatial grasp idea (representing any parallel and distributed algorithms, spatial cycles including), can start from any node, subsequently covering the system at runtime.

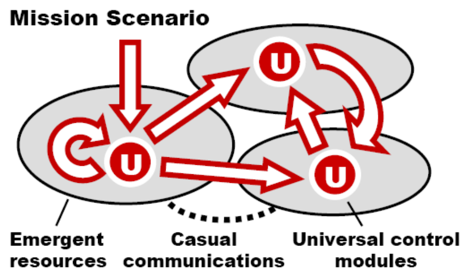

Fig. 5. Scenario execution in dynamic environments

DSL scenarios are very compact and can be created on the fly. Different scenarios can cooperate or compete in a networked space (depending on real control or distributed simulation mode) as overlapping fields of solutions. Self-spreading scenarios can also create runtime knowledge infrastructures distributed between system components (robots, sensors, humans). These infrastructures can effectively support distributed databases, command and control, situation awareness, and autonomous decisions, as well as any other computational or control models.

More details on the SGT, its core language DSL, and its distributed interpreter can be found elsewhere [8-16], with some key features (necessary for explanation of the chosen here applications) being briefed in the following sections.

4 DISTRIBUTED SCENARIO LANGUAGE, DSL

DSL differs radically from traditional programming languages. It allows us to directly move through, observe, and make any actions and decisions in fully distributed environments. DSL directly operates with:

- *Virtual World* (VW), finite and discrete, consisting of nodes and semantic links between them.
- *Physical World* (PW), infinite and continuous, where each point can be identified and accessed by physical coordinates.
- *Virtual-Physical World* (VPW), finite and discrete, similar to VW but associating virtual nodes with certain PW coordinates.

4.1 DSL basic features

Any sequential or parallel, centralized or distributed, stationary or mobile algorithm operating with information and/or physical matter can be written in DSL on a high level. Its top level recursive structure is shown in Fig. 6.

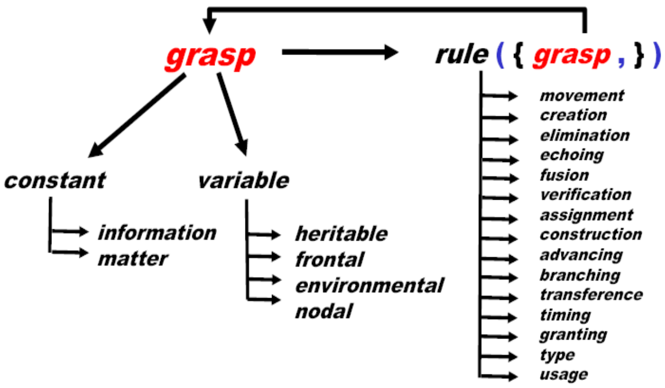

Fig. 6. DSL top level syntax

DSL main features may be summarized as follows:

- A DSL scenario develops as parallel transition between sets of progress points (*props*).
- Starting from a prop, an action may result in other props.
- Each prop has a resulting *value* and a resulting *state*.
- Different actions may evolve *independently or interdependently* from the same prop.
- Actions may also spatially *succeed each other*, with new ones applied in parallel from all props reached by the previous actions.
- Elementary operations may directly use *values of props obtained from other actions* whatever complex and remote.
- Any prop can associate with a *node* in VW or a *position* in PW, or *both* -- when dealing with VPW.
- Any number of props can simultaneously link with the same points of the worlds.
- Staying with the world points, it is possible to *directly access and impact* local world parameters, whether virtual or physical.

4.2. DSL rules

The basic construct, *rule*, of the language can represent any action or decision and can, for example, be as follows (this list is far from being complete):

- Elementary arithmetic, string or logic operation.
- Hop in a physical, virtual, or combined space.
- Hierarchical fusion and return of (remote) data.
- Distributed control, both sequential and parallel.
- A variety of special contexts for navigation in space, influencing operations and decisions.
- Type or sense of a value, or its chosen usage, guiding automatic interpretation.
- Creation or removal of nodes and links in distributed knowledge networks.

4.3 Spatial variables in DSL

Working in fully distributed physical or virtual environments, DSL has different types of variables, called *spatial*, effectively serving multiple cooperative processes:

- *Heritable variables* – these are starting in a prop and serving all subsequent props, which can share them in both read & write operations.
- *Frontal variables* – are an individual and exclusive prop's property (not shared with other props), being transferred between the consecutive props, and replicated if from a single prop a number of other props emerge.
- *Environmental variables* – are accessing different elements of physical and virtual words when navigating them, also a variety of parameters of the internal world of DSL interpreter.
- *Nodal variables* – allow us to attach an individual temporary property to VW and VPW nodes, accessed and shared by all props associated with these nodes.

These variables allow us to create spatial algorithms working *in between components* of distributed systems rather than *in* them, thus allowing for highly flexible, robust and capable of self-recovery solutions, even though different components may fail indiscriminately. Such algorithms can freely move in distributed processing environments (partially or as an *organized whole*), always preserving global integrity and overall control.

Traditional abbreviations of operations and delimiters can be used too, substituting some rules, as in following examples throughout this text, in order to shorten DSL programs (but always remaining within the general recursive syntactic structure shown in Fig. 6).

5 THE DSL INTERPRETER

5.1 Distributed interpreter organization

The DSL interpreter consists of specialized modules (which can work in parallel) handling and sharing specific language interpretation data structures [10, 13-16]. The network of the interpreters (the latter encircled as modules U in Fig. 7) can be mobile and open, changing the number of nodes and communication structure at runtime. Communicating copies of the interpreter can be concealed, if needed (say, for operation in hostile environments).

The heart of the distributed interpreter is its spatial *track system*. The dynamically crated track forests are used for supporting (or removing) spatial variables and echoing and merging different types of control states and remote data.

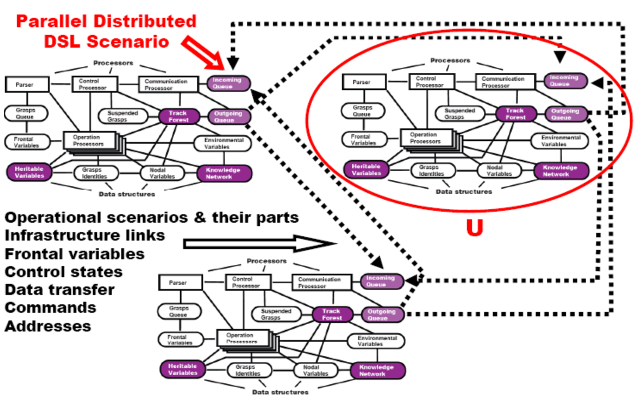

Fig. 7. Networked DSL interpreter organization

Being self-optimized in the echo processes, the track forests are dynamically covering the systems in which DSL scenarios evolve, keeping the overall parallel and distributed process integrity as well as local and global control. They also route further grasps to the positions in physical, virtual or combined spaces reached by the previous grasps, uniting them with the frontal variables left there by preceding grasps.

5.2 Integrating interpreter with usual robotic functionality

Installing DSL interpreters (as universal modules U, see Fig. 8) into mobile robots (ground, aerial, surface, underwater, space, etc.) allows us to organize effective group solutions (incl. any swarming) of complex problems in distributed physical spaces in a clear and concise way, effectively shifting traditional management routines to automatic levels. Human-robot interaction and gradual transition to fully unmanned systems are essentially assisted too.

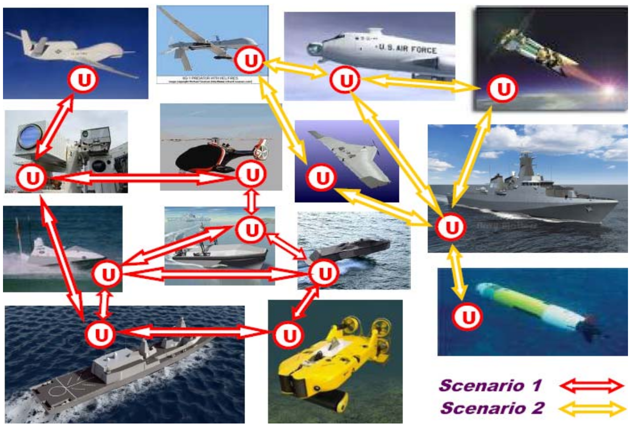

Fig. 8. Examples of cooperative robotic scenario skeletons

Any groups of manned-unmanned devices with DSL interpreters implanted into them, with any communication networks in between, can serve as universal spatial machines capable of doing any jobs together, under a unified control automatically emerging from high-level DSL scenarios.

6 EXAMPLE OF SEMANTIC, TASK LEVEL

By embedding DSL interpreters into robotic vehicles we can task them on a higher, *semantic* level, skipping numerous traditional details of management of them as a group -- fully delegating these to an automatic solution. An exemplary semantic level tasking may be as follows.

Go to physical locations of the disaster zone with coordinates: (x1, y1), (x2, y2), (x3, y3); evaluate radiation level at each location; return its maximum value with attached exact coordinates of the respected location to the headquarters; and launch from the latter a massive cleanup operation at this location.

The DSL program will strictly follow this scenario:

```
Location = maximum(move(x1_y1, x2_y2, x3_y3);
  attach(evaluate(radiation), WHERE));
move(Location[2]); massive_cleanup(radiation)
```

This (inherently parallel and fully distributed) scenario can be executed with any available number of mobile robots (practically from one to four), and the number of robots may change at runtime. Distributed DSL interpreter automatically creates the needed operational and command and control infrastructures of the robotic group and guarantees full task execution under any variations [8, 9].

7 PATROLLING COASTAL WATERS

This scenario may be suitable for both surface and varying depth underwater search of intrusions in the coastline zone, but for simplicity we will be assuming here only two dimensional space to be navigated.

At the beginning let us create a coastal waypoint map in the form of a semantic network, as in Fig. 9 (where `r` is chosen as an arbitrary name of links between the nodes-waypoints). The corresponding DSL solution is as follows.

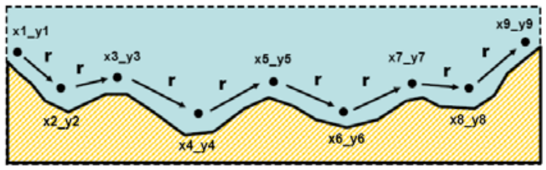

Fig. 9. Coastal waypoint map

```
create(
 #x1_y1; +r#x2_y2; +r#x3_y3; ... +r#x9_y9)
```

A single USV (or UUV) solution repeatedly navigating all coastal area by the map created is shown in Fig. 10 and DSL program that follows (searching the water space for alien objects by the `depth` available by vehicle's sensors).

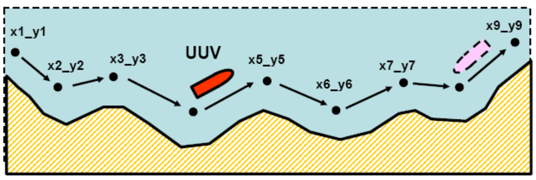

Fig. 10. Patrolling coastal waters with a single vehicle

```
move(hop(x1_y1)); R = +r;
repeat(repeat(move(hop(R));
         check_report(depth)); invert(R))
```

Two-vehicle parallel solution is shown in Fig. 11 and by the following program, with vehicles are moving according to the coastal map independently, assuming each having embedded automatic procedures for avoiding possible collisions with the other vehicle.

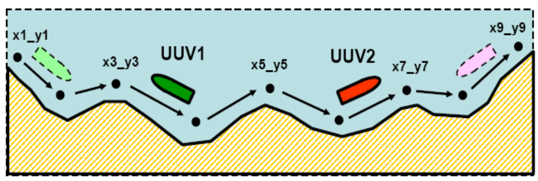

Fig.11. Patrolling coastal waters with two vehicles

```
(move(hop(x1_y1)); R = +r),
(move(hop(x9_y9)); R = -r);
repeat(repeat(move_avoid(hop(R));
          check_report(depth)); invert(R))
```

Another solution for the two-vehicle case may be when each vehicle turns back if discovers another patrol vehicle on its way, checking for this its vicinity by `depth2`).

```
(move (hop(x1_y1)); R = +r),
(move (hop(x9_y9)); R = -r);
repeat(repeat(none(depth2); move(hop(R));
           check_report(depth)); invert(R))
```

For the both latter cases, the whole coastline will always be searched in full if at least a single vehicle remains operational.

8 BATTLING FOREST FIRES

We will consider a solution where distributed physical space is randomly searched by simultaneous propagation of multiple reconnaissance units, which when discover irregularities (e.g. forest fires) move further and encircle respected zones, collect their perimeter coordinates, transfer them to the headquarters (HQ), and ultimately initiate massive impact on the zones under fire.

The zones with fires and initial positions of reconnaissance units are shown in Fig. 12*a*, and intermediary positions of robotic unites moving randomly-oriented (repeatedly shifting their positions within certain coordinate sector) are in Fig. 12*b*.

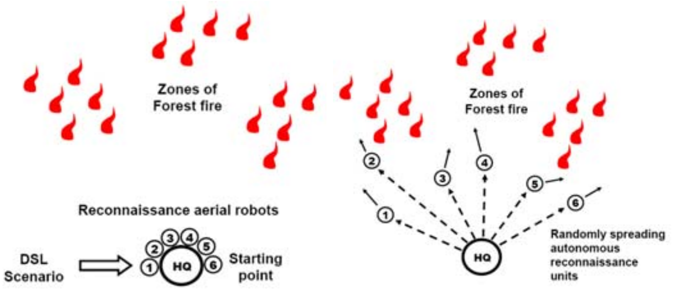

Fig.12. Initial scenario injection (a) and robots movement (b)

After detecting fire locations, the reconnaissance units that reached them begin moving around the fire zones, having initially randomly chosen the encirclement orientation (i.e. clockwise or anticlockwise). In each step they accumulate coordinates of the periphery of fire zones, and upon termination of the encirclement send the completed zone coordinates to the headquarters (HQ). Getting the latter, the HQ is launching a massive direct impact on the zones outlined, as shown in Fig. 13, which may be manned, unmanned, or mixed. The full DSL scenario for this task may be as follows.

```
move(HQ); create_nodes(1,2,3,4,5,6);
repeat(shift(random(limits));
 if(check(fire),
    (Zone = WHERE; Direction =
      random(clockwise, anticlockwise);
      repeat(
       move_around(fire, Direction, depth);
       append(Zone, WHERE);
       if(distance(WHERE,Zone[1])<threshold,
          (hop(HQ); impact(Zone); done)))))
```

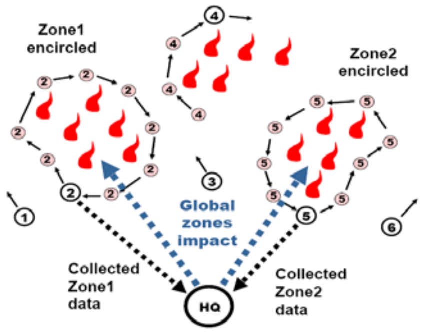

Fig.13. Encircling fire zones followed by global impact

Other interpretations of this scenario may be dealing with radiation zones, environment pollution, zones of terrorist activities, zones of fish concentration, etc., with aerial, ground, surface or underwater robots engaged.

9 SWARM AGAINST SWARM SCENARIO

As a more complex scenario example in DSL we will consider here the case where an unmanned swarm is opposing other (possibly, manned) group/swarm, as in Fig. 14. This may relate, for example, to fighting piracy in maritime environment where aerial, surface and underwater unmanned vehicles, working cooperatively under a unified control, can be used for withstanding this negative activity taking place worldwide.

Fig. 14. Fighting group targets with unmanned swarms

Main features of this scenario are as follows:

- Initial launch of the swarmed chasers (shown in red in Fig. 14, with DSL interpreters embedded, which can communicate with each other) into the expected piracy area.
- Discovering targets and forming their priority list by their positions in physical space where maximum priority is assigned to topologically central targets as potential control units of the intruders.
- Other targets are sorted out by their distance from the topological center of their group, estimated previously.

- Most peripheral targets (those in maximum distance from the topological center, as potentially having more chances to escape, are being of higher priority too.
- Assigning available chasers to targets, classifying them as engaged, with chasing and neutralizing targets, and subsequently returning them into status free after performing mission.
- The vacant chasers are again engaged in the targets selection & impact.

This entire advanced swarm-against-swarm scenario may be expressed in DSL in a very compact form, as follows.

```
frontal(Next);
sequence(
 start_launch(all_free_chasers,targets_area),
 repeat(
  hop(any_free_chaser);
  All_targets = merge(hop(all_free_chasers);
  coordinates(targets_seen));
  nonempty(All_targets);
  Center = average(All_targets);
  List = min_max_sort(split(All_targets);
      attach(distance(VALUE,Center),VALUE);
  List = append(withdraw(List, last), List);
  loop(nonempty(List); Next =
   element(withdraw(List, first), second);
   Chaser =
    element(min(hop(all_free_chasers);
      attach(distance(WHERE,Next),ADDRESS),
       second);
   release(hop(Chaser); STATUS = engaged;
    pursue_investigate_neutralize(Next);
    STATUS = free))));
```

It is worth noting that all the chaser swarm management expressed or automatically induced by the above program is done exclusively within the swarm itself, without any external intervention, which dramatically simplifies external control of this multi-robot operation.

10 CONCLUSION

A brief summary of advantages of the approach offered may be as follows.

- The Spatial Grasp ideology and technology can dramatically simplify application programming in distributed dynamic systems.
- Setting multi-robot solutions in DSL may often be comparable in complexity to routine data processing in traditional languages.
- External management of multi-robot systems may not depend on the number of components in them due to their internal self-organization and automatic command and control inside robotic groups.
- Formalization of mission scenarios in DSL can make human-robot interaction and transition to fully unmanned systems natural and straightforward.
- Spatial swarm intelligence in DSL can successfully compete with human collective intelligence, outperforming the latter in time critical situations.

In addition to the features listed above, we can state that in comparison with other systems, DSL interpreter represents an *embedded universal intelligence* common to all applications. Any scenario can be executed by a network of such intelligences. In other approaches, most of the system intelligence has to be programmed *explicitly for each application*, thus enormously complicating mission planning and management.

All communications among unmanned units, also between manned and unmanned ones, are on a high, semantic level in DSL. They are *very compact* (often hundreds times shorter than in other languages) which may be essential for maritime (especially underwater) operations with casual and limited data channels.

Human Interface of Robots or Agents via Facial and Word Expression

Kaoru Sumi[1]

[1]Future University Hakodate, Hakodate, Hokkaido 041-8655, Japan
kaoru.sumi@acm.org

Abstract: To design an intelligent interactive system, it is necessary to consider how humans feel about the system and establish a good relationship with them. In human robot interaction or human agent interaction, to establish a fifty-fifty relationship between a technical artifact (such as a robot or an agent system) and a human, the power of conviction or influence of the artifact over the human is very important. To develop an intelligent system using a robot or an agent such as a system that proactively interacts with a user and even changes the user's intention according to the user's circumstances, our project investigated reactions with the user under several situations, considering human robot interaction and human agent interaction using facial and word expressions. Accordingly, we established some rules for making the agent's reaction favorable to the user on the basis of facial expressions and words, and gained some insights into the differences between human robot interaction and human agent interaction. In this talk, I introduce the possibility of human persuasion by a robot or an agent using facial expressions and emotion words, based on the experimental results.

Keywords: Facial expression, word expression, persuasive technology

1 INTRODUCTION

Nowadays, there are many systems that use virtual agents to mediate between a user and the system. Character agents make the user feel the presence of an assistant to access the system and also give him or her feeling of affinity with the system. According to Media Equation [1], people treat computers, television, and new media as real people and places, thereby making the users uncomfortable if an agent behaves in a disagreeable manner. In the field of persuasive technology research [2] it is said that if a user recognizes the presence of something in a computer, he or she will respond to it according to the normal social rules. However, there are still many things that we do not know about how an agent's response affects a user during their interaction.

In the development of intelligent systems, it is important to consider how best a feeling of affinity with the system and show the presence of the system that has human-like intelligent functions such as recommendation or persuasion. Therefore, evaluating the interpersonal impressions conveyed by agents is very important.

Our research group performed an experiment to evaluate how the facial expressions of an agent and the words used by the agent affected users during agent-user interaction [3]. In this paper, I introduce our evaluation of the user's impression of agents in emotion-arousing scenarios set up to see how users react to various patterns of agent reactions. In particular, after setting up situations that evoke feelings of "joy", "anger", "sadness", "disgust", "fright", and "surprise" and matching up the agent's reaction with the combination of facial and verbal expressions, we asked users about their impressions of the agent.

There have been some studies using character agents as the interface of a system. However, it is not known how and there has been no evaluation of how the agents affect the users. Interactive patterns of the combination of the agents' facial expressions and words have not yet been evaluated.

The situation in which a message and its contradiction are both presented simultaneously is called a double-bind situation [4]. There has been research on information processing by the memory and the feelings perceived by humans in double bind situation. However, it is not clear what impression the speaker conveying the messages of double-bind situation gives to the receiver.

2 EXPERIMENT ON IMPRESSIONS OF REPLIES FROM THE AGENT

We chose six kinds of feelings. From the total of 216 combinations, covering multiple feelings that the user felt (6 patterns) and the facial expressions for the agent's interaction with the user (6 patterns) and word expressions used by the agent (6 patterns), we selected 96 patterns in this experiment. These covered 16 patterns in each feeling: empathetic words and consistent facial expressions, nonempathetic words and consistent facial expressions, word consistent and facial inconsistent, and word inconsistent and facial consistent. This is because the conditions of nonempathetic and both inconsistent word and facial expressions are nonsensical in normal communication. This is the condition where the word and facial expressions are inconsistent, which is the condition for double bind communication, but it can be considered as either word or facial being empathetic to the user. The case of nonempathetic condition and inconsistent word and facial expressions can be considered as pathological. A total of 1236 people, 568 male and 668 female (AV. age 38.0, SD age 11.5), were assigned 96 contents. More than ten users were assigned to each content.

- Experimental Materials

"Joy", "anger", "sadness", "disgust", "fright", and "surprise" scenarios were selected as scenarios with a high concordance rate in a preliminary experiment as emotion-arousing scenarios for each emotion. These scenarios were described by a male reader reading in a neutral manner.

A female character agent was used to react to the user's emotion. Faces representing "joy", "anger", "sadness", "disgust", "fright", and "surprise" were selected as faces with a high concordance rate in a preliminary experiment as emotional faces.

The agent dialog was read by a female reader with emotions conveyed. At first, as empathetic dialogue, "I think so, too" or "I don't think so" as nonempathetic dialog were spoken. Then, emotionally, the dialogue of "that's nice", "that's aggravating", "that's sad", "that's disgusting", "that's scary", and "that's a big surprise" were spoken.

In this experiment, we use nine factors: three factors for interpersonal impression evaluation [5] were "affable-inaffable","serious-unserious","conversable-inconversable" and original six factors.

" reliable-unreliable", "gentle-bitter", "egotistic-humble", "empathetic-unempathetic", "authoritative-unauthoritative", and "offensive-inoffensive".

We prepared 96 contents to cover the combination of emotions that a user feels, the facial expressions of the agent, and the word expressions used by the agent. These contents were developed using the Bot3D Engine [6], which displays an agent on web pages. The Bot3D Engine is an embedded engine for developing software using the Web3D plug-in and ActiveX component. Users can use the 3D agent program only to access web pages that have the program embedded.

- Procedure

The examination was conducted in the form of a questionnaire on the Web. The content was displayed on user's own PC monitor after the user accessed the target URL.

The users were asked about their sex, age, marital status, occupation, intended purpose of using the PC, and for how long they had been using a PC.

Next, the following teaching sentences were presented.

"This examination aims to discover what emotions people feel in various cases. There is no correct answer, so please say exactly what you think and feel. This examination is not a test of your personal abilities. The answers will be analyzed statistically and private information will not be released. First, please consider the given scenario and then select from the alternatives the emotions that you feel. Next, an animated character will respond to your selected answer. Please answer the question by giving your impression of the character. Your answer should relate only to this scenario. Please do not include feeling from previous scenarios, but think scenario by scenario."

Each user was presented with one of 96 contents. One of the emotion-arousing scenarios was read by a male voice. It then asked: "What kind of emotion do you feel?" and prompted the user to select from the alternatives "joy", "anger", "sadness", "disgust", "fright", and "surprise". On the other hand, the female agent on the screen responded with facial and word expressions.

Users were asked: "How do you feel about this person? Please answer using the degrees listed in the questionnaire." Five conditional moods in nine answers, "conversable-inconversable", "reliable-unreliable", "gentle-bitter", "egotistic-humble", "empathetic-unempathetic", "authoritative-unauthoritative", "offensive-inoffensive", "serious-unserious", "affable-inaffable" were given and the user selected a suitable answer. The order of the terms was kept constant throughout the questions.

3 Result and Discussion

We conducted the experiment on how the user felt about the agent's reaction by setting up an emotion-arousing scenario for the user. Four factors were extracted by using factor analysis. Eight clusters were indicated by cluster analysis by using four factors as the dependent variable. Favorable, intermediate, and unfavorable impressions fell in category of higher-level clusters among these eight clusters. Therefore, we focused on the relationship between agent reaction and the higher clusters.

The synchronization of the agent's words with the user's emotion has a major impact on the impression of the agent as perceived by the user. However, the synchronization of facial expressions of the agent with the user's emotion does not have a major impact on the creation of an impression.

First, we predicted that words and facial expressions reflected on the emotions aroused by the scenario would lead to the most favorable impression, so we set these data as the control group. In fact, there were more favorable impressions than those obtained for the control group. For example, the words and facial expressions were "joy" when the user's emotion was "joy" for the control group. It is very interesting that when the user's emotion was "joy", the agent's words for "joy" with facial expressions of "surprise", "sadness", or "fright" were most favorable. On the other hand, when the user's emotion was "fright", the agent's words for "fright" with facial expressions of "disgust" or "sadness" were the most favorable.

These facial expressions were recognized as the emotion conveyed by the words and were more empathetic and somewhat meaningful emotions. For example, when the user's emotion was "joy", the agent's words of "joy" with facial expressions of "surprise" or "fright" might have been recognized as the agent being exaggeratedly surprised at the "joy" scenario. When the user's emotion was "joy", the agent's words of "joy" with facial expressions of "sadness" might have been recognized as the agent being highly pleased from the heart at the "joy" scenario. When the user's emotion was "fright", the agent's words of "fright" with facial expressions of "sadness" might have been recognized as the agent grieving deeply at the user's "fright" scenario. When the user's emotion was "fright", the agent's words of "fright" with facial expressions of "disgust" might have been recognized as the agent feeling deep hate at the user's "fright" scenario.

Through these observations, we concluded that there is a rule for facial expressions: in a certain scenario, synchronizing foreseen emotion of the user caused by the situation will make a favorable impression. For example, when the user has the emotion of "joy", he/she wants someone to be surprised or highly pleased. Then, showing surprised or highly pleased face expression make the user feels favorable impression. When the user has the emotion of "fright", he/she wants someone to grieve deeply or disgust. Then, showing grieved or disgust face expression make the user feels favorable impression. Users want the agent to ooze synchronized their foreseen emotion by hearing the news instead of simply showing synchronized reaction according to emotion at present time.

The ability to do this is known as the emotional intelligence quotient (EQ) [7], which is a measure of the ability to understand the feelings of the partner and maintain human relations well.

This facial expression rule is a kind of EQ rules as we can often see service-minded persons show their sympathy with very sad face when they on hearing bad news. In this case, the emotional situation was "disgust", their word is "disgust" with facial expressions of "sad". These patterns are consistent with the cluster of favorable impressions in the result of the experiment. These persons favorably impress, as we often see them employed as salesmen having some technical know-how in order to make themselves look good. We often see this type of person in our country and they are accepted as favorable. However, this facial expression might be considered as a specific feature of Japanese culture. It needs more examination, taking into account diverse nationalities.

This facial expression rule is a technique of foreseeing the other's emotion and the agent can behave proactively by reading the other's feelings.

5 CONSLUSION

As a purpose of developing intelligent system using virtual agent which interacts with a user proactively according to the user's circumstances, we evaluated the user's impression of agents by setting up an emotion-arousing scenario and observed how the users reacted to various patterns of agent reactions. The results of the experiment reveal the rule for creating an agent which reacts proactively using facial expressions.

For the next step of this research, our research group have evaluated human robot interaction using facial expression.

Abstract

In this paper, we define and trace the contours of a new cross-modal and cross-media approach to robotic systems. In particular, our system is based on the use of electronic tiles and oriented to the use of ALife based interactive robotic modules that can be either virtual or real. This approach, which relies on interactive parallel and distributed processing algorithmics, can be thought and used on many different domains, though in the specific experience presented here, it has been applied to music composition and remix. In details, we describe the initial MagicTiles product prototype and show, as an example, a musical application with which any user can create and perform RoboMusic. We show how the combination of the Modular Interactive Tiles and the MagicTiles tools might lead to a broader vision of robotic systems with a fluid flow between the physical and virtual. Fluidity between the physical and virtual, end-user authoring, and ALife control is conceived to open up technology to ordinary users as a tool for creativity. Finally, in this paper, we attempt to explore the theoretical characteristics of such an approach and exploit the possible playware application fields.

Introduction

In this paper we present the "MagicTiles" application, an ALife software based on and derived from our previous work on the Modular Interactive Tiles [1] and RoboMusic [2]. This attempt to move a hardware based paradigm to a software based one is due to a couple of main beliefs.

The first of these is that the social media are changing and are showing a strong demand for a mobile electronics representation (i.e. applications) of any given device and/or activity. Indeed it seems to be expected that any future playware [3] and/or robotics tool will require - for a proper and common use within a large community of people - to get somehow connected to a mobile phone, tablet (or similar) control system or, alternatively, have a given instance of it, as for example a simulated version of the tool/activity itself. This is because the new virtual media may allow users an easy access to social interaction, for instance mediated by the physical media.

Hence, the physical media is enhanced by the social, virtual media. On the other hand, the social, virtual media is also used to promote the users' interest in the physical media. Indeed, today users' access to the virtual is easy and cheap, and it allows the users to experience their own interest for the specific real technology (e.g. the physical media). Thereby, there is a bidirectional use of the social, virtual media (on smart phones, tablets, etc.) and the physical media, which can be seen as complementary, and to be integrating and promoting each other.

The second belief is that by realizing a software-based representation of the Modular Interactive Tiles, we can easily explore many different new algorithmic solutions and easily access a larger number of users. Therefore, it gives the chance to test both efficiency and popularity of our "games" and the concept of Modular Interactive Tiles itself.

As a starting point, we chose music as the application domain, building upon the concept of RoboMusic.

RoboMusic

The RoboMusic concept [2] was developed to allow any user to interact with a professional music performance through the interaction with physical, intelligent objects. For instance, in the first RoboMusic concert, the interaction happened with modular interactive tiles, rolling pins and cylinders [2] (see Fig. 1), and the Center for Playware later made RoboMusic versions using cubes [4, 5] and tiles. When interacting with these physical, intelligent objects, the user activates, changes or de-activates a sound (Fig. 2).

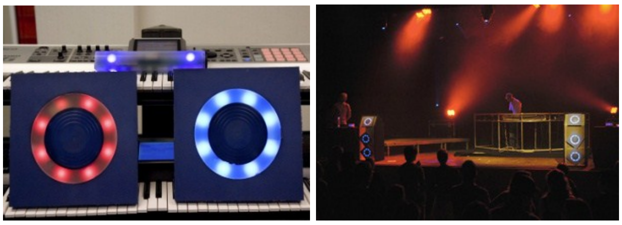

Figure 1. Left: Two Tiles and a RollingPin used as robotic instruments. Right: The RoboMusic live concert set-up, with Funkstar De Luxe and his control station in the center, and the robotic instruments on the left and right side of the stage.

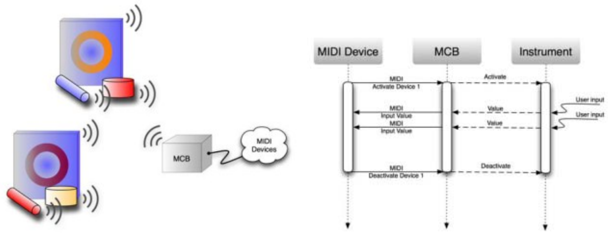

Figure 2. For the first RoboMusic concert, we used an interaction pattern in which physical objects as tiles, rolling pins, and cylinders ("Instruments") are communicating to a MIDI Control Box ("MCB"), which is connected to a PC running Cubase or Ableton Live ("MIDI Device"). Note that the original RoboMusic concept allows also communication in the direction from PC ("MIDI Device") to tiles ("Instruments") through the MIDI Control Box ("MCB").

The sound can be more or less complex. In order to produce an appealing sound, it is of crucial importance to create a RoboMusic soundscape which fits the RoboMusic concept of allowing the user to interact with the music, e.g. as in the behavior-based approach, where the programmer is designing the default music behavior, and the user provokes smaller behavioral deviations by the physical interaction [2].

Indeed, as a kind of *user-guided behavior-based system*, in RoboMusic, the design challenge is to create primitive 'robotic' behaviours and to coordinate these primitive behaviours in order for the music piece to emerge as the coordination of primitive behaviours. Thereby, a music composition emerges from the way the composer, musicians or audience interact with the 'robotic' instruments that provide the primitive behaviours.

Each 'robotic' instrument is used to trigger a particular primitive behaviour dependent on the interaction with the instrument(s). In RoboMusic, the primitive behaviours can be anything from a volume or a cut-off to a small sequence of tones. The music composer designs the way in which the primitive behaviours that are triggered should interact with each other.

Hence, as is the case when designing behaviour-based robots such as mobile robots (e.g. [6, 7]), the robot designer (in this case the music composer) designs the primitive behaviours and the coordination scheme. And, as is the case with *user-guided behaviour based robotics* [8, 9], if non-expert users (e.g. live concert audience) are supposed to manipulate and become creative with the systems, it is crucial that the designer (music composer) creates primitives on a fairly high abstraction level that allows the non-expert user to understand and have positive feedback from the human-robot interaction within a very short time frame.

The RoboMusic concept was applied on cubic I-BLOCKS [4, 5] which each represents an instrument or group of instruments. The individual I-BLOCKS orientation - which side is facing down - determines the variation of that specific instrument. The I-BLOCK LEDs change colour depending on their orientation, in order to make it possible for the user to remember and activate specific variations.

The musical setup can be seen in Figure 3. Note the black XBEE-enabled I-BLOCK, which communicates wirelessly with the MIDI Box. When instrument blocks are connected to this, music starts playing depending on the actual I-BLOCK's colour and orientation. The music is loop-based, meaning that when active, each variation of each instrument is playing for a certain time and then repeating itself over and over until it is finally deactivated when the user removes the current instrument I-BLOCK from the structure or shifts its orientation.

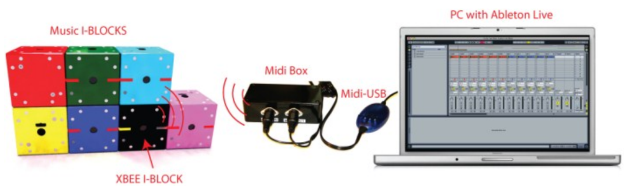

Figure 3. Music setup with I-BLOCKS, MIDI-box and PC.

The pieces of music that was made for the cubic I-BLOCKS were all constructed using these rules: There are five or six predefined instruments or groups of instruments, varying in type according to genre, and within each piece of music there are up to six variations per instrument type, and there can be an unspecified number of different instruments. Later, we also applied this approach to other intelligent building blocks such as the modular interactive tiles [1], where the color of the tiles LEDs would indicate the instrument, and the number of LEDs indicates the variation of the instrument type.

MagicTiles Interface

The MagicTiles application is a new, funny, musical app, which as RoboMusic can be used by users of different musical competencies - from precipitants to musician to expert composers - to both remix songs or experiment with new tunes. The initial MagicTiles app runs on iPads and iPhones. The MagicTiles application is made of a small number (i.e. more than 3 less than 10) of virtual music tiles. Generally, each single tile embodies a single instrument (although it can be programmed and used in many different ways), and each instrument-tile is capable of expressing seven different musical solution (i.e. loops) or variation of the same one. Every instrument of a MagicTiles song is wrapped inside a single tile and, therefore, we can have a tile for vocals, one for the rhythm guitar, one for the bass, one for the piano, etc.

Figure 4. MagicTiles for iPad.

At the start, the user is presented with all the tile-instruments of a given song inside the tiles board with the tile-instruments being disconnected from each other (see Fig. 4). Since a tile is disconnected from other tiles, it is not active and will not play.

Once the user drags and attaches a tile to another (see Fig. 5 left) the two tiles get synchronized and are able to play together.

To actually start the music, the user has to press the play/stop icon, positioned at the bottom-right side of the screen (see Fig. 4). At this point, the music will keep playing and the remaining music tiles can be connected to the former two enriching the music scenario of the song running. In the same way, by dragging the tiles around and rearranging their geometry, the user changes the music sequence and flow.

Figure 5. Left: Connecting two tiles. Right: 2-sides connection example.

Every tile has 7 music loops, one for each side (north side, east side, south side and west side) plus 3 extra music loops which will play when a tile is connected on, respectively, two, three or four sides. In this way, as in Fig. 5 left, the Drum tile will play the East Side loop and the Guitar tile will play the West Side loop, and as in Fig. 5 right, the Drum tile will play the *2 Sides* loop, the Guitar tile will play the West Side loop and the Choir tile will play the North Side loop.

Likewise, as in Fig. 6 the Drum tile will play *3 Sides* loop, the Choir tile the North Side loop, the Guitar tile will play the West Side loop, and the Bass tile the East one.

Figure 6. A *3 Sides* connection example.

Growing the number of instruments/tiles impressively increase the number of possible combinations and out of these simple rules, one obtains an extraordinary number of musical possibilities (e.g. by using 6 tiles, and just counting the 1-side connections, we reach 4^(6-1)=1024 music variations of the same song).

MagicTiles' usability has already been pilot-tested with 5 years old children and can be considered simple to use, and to be an effective and funny instrument to play with. Further, this first version of the MagicTiles app has two more exciting features, which enhance the user interactivity and possibility: the *Loop Recorder* and the *SkipBar Tool*.

The Loop Recorder

The previous section described the so-called *Pre-recorded* loops tiles, trying to understand their meaning and logic. Differently from that, MagicTiles also features two other kinds of music tiles, the *Pre-recorded* loops tiles and the *User-recording* loops tiles (see Fig. 7).

The *User-recording* tiles differ from *Pre-recorded* tiles for two specific characteristics:

1. The music loops are not given and have to be recorded by the user (e.g. at run-time);
2. The number of different loops a *User-recording* tile can express are only four (i.e. north, east, south and west side loops).

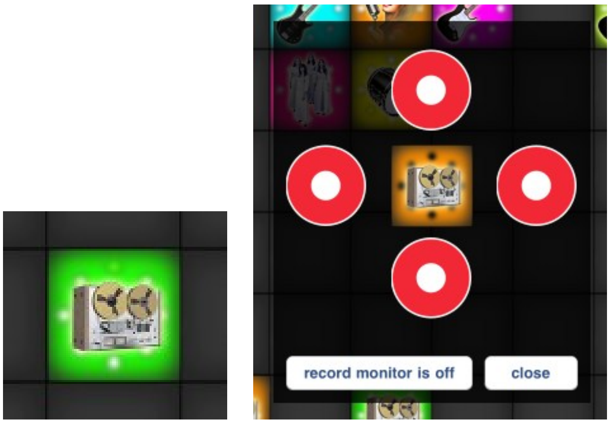

Figure 7 Left: The *User-recording* tile icon. Right: The loop recorder menu.

When the user double touches one of the User-recording tiles (see Fig. 7 left), the MagicTiles app shows the loop recorder menu (see Fig. 7 right). The loop recorder menu allows the user to record a loop for each side of the user-recording tile through the iPhone or iPad built-in microphone. The application shapes the recordings to exactly fit to the length of all the other pre-recorded tile loops of the actually running song. Such process gives the user the great advantage of always being on the beat. As a consequence, the ability of recording a proper music sequence/loop will simply rely on the user musicality, itself. Technically speaking, such a feature works at the lowest possible latency, because it relies on the powerful audio framework that the native iOS devices comes with.

Another tool for user interactivity is the SkipBar Tool that allows the user to skip the current (playing) bar and to repeat it or use it like for real sampler. The bottom of Fig. 4 shows the SkipBar with 8 buttons/areas (i.e. one for each single bar). When pressing one of them, the user let the music flow to jump or repeat one single bar music.

MagicTiles Algorithms

The Sound Patterns

Every single tile can activate seven different music loops. Each sound is activated accordingly to the following rules.

If only one side of the tile is connected, the tile itself reproduces one out of four available loops, which is:

1. One for the North side
2. One for the East side
3. One for the South side
4. One for the West side.

Besides the above sounds, there are three extra music loops, which are activated when:

5. Two sides of the given tile are connected simultaneously;
6. Three sides of the given tile are connected simultaneously;
7. Four sides of the given tile are connected simultaneously.

(See Fig. 5 and Fig. 6 for visual examples).

Sound Files Specifications

To be used with the MagicTiles app, sound files must be:

1. of an uncompressed sound format (e.g. AIF or .WAV);
2. same length (at the moment, 8 bars for every musical loop, independently from the song metronome).

Further, the sound files should preferably only be *monophonic files*, since stereo files may demand too much memory.

Loops may be denominated in any way. For example, a good practice would be to name loops with a specific *Song/AuthorName_* plus *InstrumentName_* plus the *SideNames*, to keep track of the musical meanings, as shown here:

The Drums Tile of the Bob Marley Remix files could be denominated:

1. MARLEY_DRUM_N
2. MARLEY_DRUM_E
3. MARLEY_DRUM_S
4. MARLEY_DRUM_W
5. MARLEY_DRUM_2
6. MARLEY_DRUM_3
7. MARLEY_DRUM_4

Meaning that the first 4 loops are denominated accordingly to the activated side, and the remaining 3 loops are the extra loops for "2 sides connected", "3 sides connected", "4 sides connected".

Synchronization of audio files

With MagicTiles, we developed a novel way for getting rid of a metronome. First of all, we made the music loops have a fixed length (i.e. a parameter that you can tune inside your audio editor, like Ableton Live, Logic, Cubase, etc.). Every single loop is stored inside a *C* programming language structure variable defined with the keyword "*struct*" that contains some variables. As in Fig. 8 one of those variables is sampleNumber. This var contains the current sample number of a music loop, this *struct* is filled during the app startup where all the files are red and stored into memory. The sampleNumber is updated during playback continuously.

```
// Data structure for mono or stereo sound, to pass to the application's render callback function,
//    which gets invoked by a Mixer unit input bus when it needs more audio to play.
typedef struct {
    BOOL                 isStereo;          // set to true if there is data in the audioDataRight member
    UInt32               frameCount;        // the total number of frames in the audio data
    UInt32               sampleNumber;      // the next audio sample to play
    AudioUnitSampleType  *audioDataLeft;    // the complete left (or mono) channel of audio data read from an audio file
    AudioUnitSampleType  *audioDataRight;   // the complete right channel of audio data read from an audio file
    BOOL                 isRecording;
    UInt32               startSample;
} soundStruct, *soundStructPtr;
```

Figure 8. The audio files C struct.

Now, suppose that the drum tile is playing and we want to add the guitar tile. When the user connects the guitar tile to the drum tile, it is known that the drum tile is playing the "x" sample number, so the system simply updates the sampleNumber variable inside the guitar struct to get them synchronized.

ALife in MagicTiles

The MagicTiles app is both inspired and aiming at the use of ALife paradigms. Indeed, as software conception it was deeply inspired by cellular automata research, from which it inherits part of the cells interactive logic. The MagicTiles algorithm could be properly defined as a User Based Interactive Cellular Automata algorithm where - for the moment being - the basic cell rules are predefined (see the MagicTile Algorithm section for further explanations). In this cellular automata like approach the *User* - intended either as the one who "composes the musical units" or the one who "manipulate the software" by arranging them in the virtual space – plays a major role in leading the (musical) output flow.

Further, the MagicTiles conception effectively derives from Music Cubes and Modular Interactive Tiles, and by doing so, it largely expresses and inherits principles coming from embodied artificial life. As a consequence, the musical outcome the MagicTiles, as for the Embodied ALife algorithms, implements a form of intelligence without either a static or a physical representation. As Brooks enounced [10], in MagicTiles the so-called musical intelligence is approached in an incremental manner, and it is given a strict reliance on interfacing to it through perception and action, letting the reliance on representation gradually disappear.

Apart from improving the interface and the interactivity, as an experimental platform the MagicTiles opens up for future research that goes deeper in incorporating ALife paradigms. An intelligent serve-routine may be defined to learn from the user activity and to build a user profile – a personalized fitness formula – which may facilitate users to manipulate music elements and reach their desired goal. In addition, the MagicTiles app can be introduced as a social component that by connecting its own community of users - through the use of classical interactive genetic algorithms – may implement a refined form of collective Evolutionary Music.

Discussion and Conclusion

In this paper, we presented a new RoboMusic application, MagicTiles, which aims at exploring a new cross-modal and cross-media approach to robotic systems. Through such an application any user can create and perform RoboMusic by assembling a number of interactive virtual tiles on the screen. After our past efforts in building physical interfaces, we decided to conceive the MagicTiles platform to show how the combination of the physical interface (i.e. Music Cubes and Modular Interactive Tiles) and the virtual interface (i.e. MagicTiles) tools might lead to a broader vision of robotic systems with a fluid and bidirectional flow between the physical and virtual. Indeed we believe that such a fluid and multifaceted representation of a single tool/activity may widely enhance the user immersion into a *one reality* that combines the physical and virtual.

It is interesting to observe a similar trend in robotics with the current development of cloud robotics, which combines the physical with the virtual. This may be in the form of physical robots connected to the cloud, which performs the computing such as object recognition, speech recognition, etc. for the physical robot.

Differently from most other modular interactive systems, the MagicTiles application allows end-user authoring of the contents of the individual modules, therefore enabling a high level of personalization – that even can be applied run-time – of the outcome. Our concept is inspired by ALife control systems (e.g. Cellular Automata, Embodied AI, etc.) and aims at using further traditional ALife resources to open up to single and ordinary users, as well as, building a new collective and evolutionary tool for creativity.

Abstract: Social Playware is regarded as cyber-physical systems to support and enhance the experiences on play and social interaction among people by measuring and presenting physical contacts, spatial movement and facial expression. Several wearable or modular devices are used in this study, which enable behavior and affective measurements based on augmented human technology. It is aimed not only to integrate cyber and physical spaces by using developed wearable devices but also to show the possibility to help people develop their social ability throughout case studies.

Keywords: Playware, Wearable Device, Body Area Network, Heart Beat, Physiotherapy Application

1 INTRODUCTION

Several attempts have been done for playful physiotherapy, which is supposed to motivate patients to engage in and perform physical training and exercising for preventing potential health problems or rehabilitation. Researchers recently have been paid attention to playful therapeutic applications with the aid of recent advancement of sensing devices and display. For example, input devices by measuring body gesture such as Wii (Nintendo) and Eyetoy (SONY) are typical cases used for rehabilitation or clinical trials. Camera or sensors are used to measure human bodily movement, and visual and / or auditory feedback is given to people by using virtual / mixed reality technology.

In this domain, social interaction plays an important role in different situations during these physical training and exercising. There have been reported that the motivation is a critical factor at the physical therapy and rehabilitation, but it is not easy for people to keep it on performing physical exercising. There is another difficulty to establish a different level of communication between patients, or patient and therapist. In this matter, toys are interesting and playful tools to each other mediated through the interaction. Several studies about toys have been done, for example, it is known that children have general preferences on visual stimuli with warm-color lights, auditory stimuli with tones and scales, haptic and somatosensory feedback to the whole body. Also they have positive response to toy's movement itself.

In order to understand social interaction among people, several kinematic and physiological cues among people are investigated in these case studies, such as facial expression, gaze direction, head orientation, body gesture, physical touch, space / location, physical distance among people and objects, as illustrated in Fig. 1. We introduce several wearable or modular devices, which enable behavior and affective measurements based on augmented human technology.

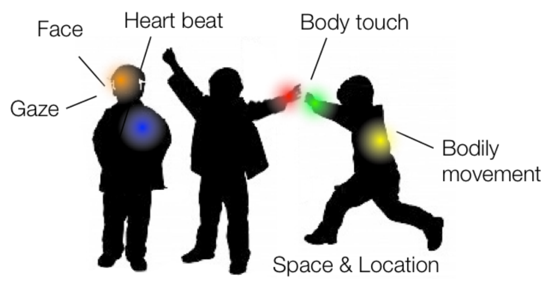

Fig. 1. Social Playware: Cyber-physical system to support and enhance the experiences on play and social interaction.

The concept of "Playware" is proposed and several works have been done so far in order to realize the playful interaction with interactive tools (see also [1, 2]). It is defined as intelligent hardware and software that creates play and playful experiences for users of all ages, and social playware is also defined as playware which aims at creating playful social interaction between several users.

In this paper, we introduce two examples of Social Playware; (i) Enhanced Touch: Sensing touches and identifying others can be done by the wearable device, (ii) HOTARU ("firefly" in Japanese): LED lights up in synchronization with the heart beat, and the color changes according to the calculated heart beat rate.

2 CASE STUDY I: ENHANCED TOUCH

We propose a novel bracelet-type device for sensing physical contact among people in order to support direct communication between people by inducing touching with appropriate visual feedbacks. The device detects and records the touches of users by simply wearing the device on their wrists (See Fig. 3).

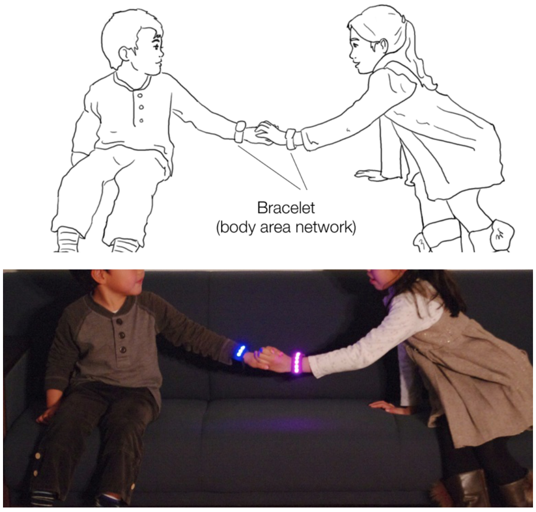

Fig. 2. Enhanced Touch: Sensing touches and identifying others can be done by the wearable device with electrodes.

Fig. 3. The six full color LEDs are installed in the bracelet, which are lit up when handshake occurs.

Physical touch is a fundamental element of human communication and several benefits and positive effects were reported at the communication and therapeutic domain such as Positive Touch and Deep Touch Pressure, for instance [3]. Typical symptoms of autism among children include avoiding direct touch with other people in addition to the tendency to lone activities. Some studies reported that training of touching by therapists contributes in the alleviation of these symptoms. Till now, human coders tried to observe their activity via recorded video but it is not objective measure and time consuming for checking all touches among people in a session. Measuring the time of touching, partner, frequency are desirable data, but there is no practical equipment for this purpose. Similar technology is used for the instrumental device [5], but users needed to grasp and hold the same device together.

2.1 System Overview

We use the communication technology based on body area network [4] in order to detect touching between people communication through human body. This technology was known as alternative solution of communication between humans and objects. Since the information is transferred via human body, it can be utilized for sensing physical contact among people. The developed device is used for sensing touches and identifying others, which can be performed by the wearable device with electrodes. The six full color LEDs are installed in the bracelet, which are lit up when handshake occurs. The pair of electrodes is located on the inside of the case as to fit the wrist. The device communicates with another device using a specific communication protocol. The received conducted signal is first amplified and demodulated, and then handled by the microprocessor. Every microprocessor tries to transmit a synchronous signal at random intervals within $10\,[\mathrm{ms}]$ to detect if touching has occurred and to synchronize with other device.

Several visual effects are programmed to visualize not only the physical touch but also the touching condition such as duration of physical touch and history of past touching. For example, colour blending is implemented for effective visual feedback to show the duration of touching. A unique color is assigned to each device; the three primary colors (Red, green, blue).

When a user wears the devices and touch to another person with the developed device by their hands, both devices light up LEDs with its unique color. While keeping the shake-hands, Two different colors change and are then blended gradually as long as the touching lasts. In other words, the degree of color blending represents the duration of the touching time. The LED colors in the two devices in touch become the same color. This manner of lighting allows our proposed method to measure the duration of physical contact along with the device's ability to identify other devices.

Table 1. Time during different style of physical touch

Style of physical touch	Time (S.D.) [ms]
Hand Clap	50.7 (12.1)
High Touch (Normal)	44.8 (10.9)
High Touch (Slow)	187.5 (22.1)

2.2 Touching and response time

In order to confirm the performance of the developed device, we first conducted a simple experiment to measure the time during different style of physical touch. Fig. 1 shows the averaged times in [ms]. We obtained that the averaged touching time is $94.3\,[\mathrm{ms}]$ at different style of physical touch such as hand clap and high touch.

Due to the characteristics of communication protocol, the response time of the developed device has some variance. The response time is regarded as the period of time from the moment the touching occurs to the moment the LEDs of the device are lit up. Two subjects touched fifty times by the tip of the fingers and these touches was recorded by a high-

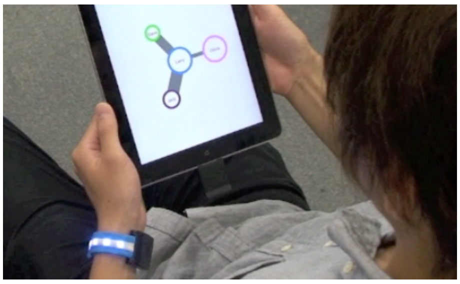

Fig. 4. A correlation diagram among users by exporting the data to another device with a Tablet device.

speed camera with 1200 [fps]. The response time was calculated from the number of frames between those two actions. From the experimental results, we obtained that the average of response time is 27.7 [ms], and the standard deviation is 19.2 [ms]. The minimum value is 6.7 [ms], which is almost equal to the transmitting time plus receiving time, thus the value is valid. The maximum value is 80.0 [ms]. These results show that the response is signitifant for recording daily life touching or for games that include touching activity, even in the worst case of response time.

2.3 Correlation Diagram on a Tablet Device

The device is be able to record and show the physical contact log among people, such as the number of shake-hands and/or amount of touching time over a long term. These logs show the degree of friendship or relationship among people. We developed a Tablet device with electrode in order to show a correlation diagram among users by exporting the data to it. A correlation diagram is shown in Fig. 4. This diagram appears when the user touch and hold the device. Where the circles indicate users, and the lines show the relationship among these users as the line's width indicates the degree of friendship between two users. Such application will provide a new measuring method of relationship in an easily understandable way.

3 CASE STUDY II: HOTARU

In this study, we propose a novel method of heart beat tracking and develop a wearable device to visualize the heart beat, namely *HOTARU* ("firefly" in Japanese). These are a number of systems and devices for heart beat measurement, which can be used to measure heart function or exercise volume, psychological barometer such as stress or relaxes. However, since the measurement of biological signals are not stable due to the unexpected several noises, the user is asked to firmly attach the sensor, for example electrode, and also to keep quiet even for the measurement of the heart beat rate, Fast Fourier Transform (FFT) is used as the traditional method of the measurement of heart beat rate, while the signals with unexpected noises in the measured signal are ignored.

Fig. 5. HOTARU ("firefly" in Japanese): The conceptual image of using the developed device.

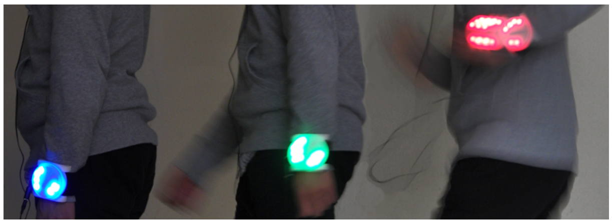

Fig. 6. The developed device in use. LED lights up in synchronization with the heart beat, and the color changes according to the calculated heart beat rate.

3.1 System Overview

A wearable device is developed to indicate the heart beat in real time with different color of LED. The color changes according to the heart beat rate, and blinks in synchronization with the heart beat pulse. The developed system is able not only to track the heart beat but also to interpolate it from the noisy signals in real time. The heart beat is extracted from the original signal of the photoplethysmographic (PPG) sensor, which contains the noise delivered by body movement or other unexpected causes. In the proposed method, when the system is not able to determine the heart beat due to the sensor 's alignment or temporary no pulse, the heart beat is interpolated based on the past signal and liner prediction algorithm.

3.2 System Overview

The developed device *HOTARU* consists of a microprocessor, LEDs display, and PPG sensor that can measure heart beat pulse by using optical absorptance of human body. The user is asked to attache PPG sensor that is a clip-type interface on the ear, and to wear a bracelet-type interface with LEDs on his or her wrist. The brightness of LEDs changes in synchronizion heart beat and its colors corresponds to the heart beat rate (HBR). As shown in left of Fig. 6, blue means that heart beat rate is less than 60, green means that heart beat rate is from 60 to 80, and red means more than 80.

3.3 Methodology: Real Time Heat Beat Tracker

Traditionally, since the measurement of heart beat is focused on the heart beat pulse itself, but the tracking accuracy depends upon the environment. It is usually not stable because of the noise, and users are asked to rest during the measurement. The intervals of heart beat pulse are low frequency from about 0.5 to 2.0 [Hz] and these intervals is assumed not rapidly change. But precise intervals are difficult to be recognized from the measured signals only by using peak detection due to the noises, which are usually impulse noise and look like heart beat pulse. FFT is used as the analysis of it.

On the other hand, we propose a novel method of heart beat tracking. The pattern-matching is carried out between the measured signal $\mathbf{P}(x, t)$ and the ideal heart beat pulse $\mathbf{Pc}(x)$, which is prepared in advance. The cross-correlation $\mathbf{z}(x, t)$ is calculated with the fixed time window which is the same as the length of the ideal heart beat pulse. The matching result $\mathbf{z}$ is expected to be a periodical signal, and it is synchronized with the real heart beat pulse. The computational cost to obtain the coefficients of all possible cross-correlation values is very high and not suitable for real time calculation, only limited coefficients are used in this process. In addition, in order to reduce the computational cost, the cross-correlation values are obtained only at the certain time, which is estimated at the linear prediction process.

Then, a modified peak detection algorithm is employed by combining Kalman filter to predict the intervals of heart beat, which is based on the linear prediction and uniform distribution function. Assuming that these intervals do not rapidly change, next heart beat interval can be estimated from transition of previous several intervals. And center value of probability density function (PDF) is solely used for detection of peak candidate in $\mathbf{P}$. The peaks are detected within the $\mathbf{z}$ time range of reliability based on this PDF.

3.4 Experiments

We conducted an experiment to compare the proposed heart beat tracker with electrocardiograph (ECG) signal from 10[s] data in different situations of user's resting and moving. The experimental result shows 100% accuracy for resting state and 94% for moving situation where traditional FFT or peak detection algorithm does not give any significant heart beat tracking.

4 DISCUSSION AND CONCLUSIONS

In this paper, we introduced two examples of social playware. It is aimed not only to integrate cyber and physical spaces by using developed wearable devices but also it can be used to help people develop their social ability throughout case studies.

The devices for sensing the human contact can be used to recognize the social network based on physical contacts. The bracelet-type device lights up - with a different color for each - when the wearer shakes hands with another wearer. Not only sensing the contact but also the electrical communication is also used to identify and share the device ID. We believe that the proposed device could provide a novel playful interaction method between humans. We now plan to verify if the device contributes to motivate touching among users by lighting LEDs or by playing interactive social games. On the other hand, we presented another device for presenting current heart beat with different color. LED lights up in synchronization with the heart beat, and the color changes according to the calculated heart beat rate. The developed device allows users to freely move and play without attaching the sensor or electrode firmly. Potential applications include the tool for kids to promote social interaction. The user testing with several people is planned. We also will implement the sound feedback according to heart beat pulse for computer games and VR avatar.

Throughout these case studies, we would like to expand the playware technology for supporting and enhancing the experiences on play and social interaction among people by using playful devices. The device mediates between humans without missing fundamental properties of human activities. We consider that social playware is a cyber-physical system by measuring and presenting human physical activities such as physical contacts, spatial movement and facial expression, where psychological and social aspect of human activities could also be enhanced.

Abstract: The paper illustrates the design of Iromec, a robotic platform developed to engage disabled children in exploring play scenarios and thereby in learning through play. Key features of the system are: *modularity*, provided both at physical and functional level; *configurability*, to allow the teacher to make the physical and functional rearrangement of the robot configuration, *construction* to modify, enrich and adapt play activities to different and evolving needs of the disabled children. Furthermore the platform offers the possibility for the teacher/therapist to design new play scenarios addressing different educational objectives**.** The paper shows how the adopted design enables multiple robot configurations and play scenarios, and exemplifies the use of the robot in the school context.

Keywords: modularity, play, learning, disability, game creation.

1 INTRODUCTION

In the last decade the technology evolution has produced a remarkable change in children's and adults' play offering new kinds of play experiences and equipments. From the humble beginnings of Pong, Pac-man, Tetris, and video pinball computer games, the game industry has moved to more realistic virtual worlds, more interactive environments and competitive play. A number of challenges guided this evolution: to increase the realism of virtual worlds, to turn "finger athletes" in sport and fitness people, to penetrate different areas of the industrial and public sector other than entertainment, like business (simulation games), education, professional training, health care. While some of these challenges have been successfully addressed by launching on the market physical and virtual games of increasing popularity, 3D representations used in courtrooms, interactive learning environments for the school and museum context, simulations for building designs and military systems, however a limited attention has been paid in making interactive games and equipments accessible for all, and in particular for disabled people to support them in improving their quality of life, their learning and development opportunities. Moving, exchanging, experimenting and learning through play are fundamental activities that should be exercised from childhood, according to the cognitive and physical abilities that an individual may have.

Unfortunately, disabled children are often prevented from playing due to their cognitive or physical impairment. Interactive games rarely adapt to the abilities of disabled children and therefore are far from being accessible for them.

Iromec (Interactive RObotic social MEdiators as Companions) is a robotic platform that addresses play as a medium for disabled children's learning, development and enjoyment. The platform is composed of passive and interactive hardware modules and configurable interfaces to enable the creation of play scenarios adapted to fit the needs of children with different kinds of disabilities [1].

Key features of the system are: *modularity* (passive and interactive modules can assembled to modify the robot appearance and its behaviour), *configurability* (the platform allows two main configurations, stationary and mobile), *construction* (the construction and deconstruction of modules allows to modify, enrich and adapt play activities to children with different abilities in different contexts). Furthermore the platform allows the creation of new games that can be implemented through "play script".

2 THE ROBOTIC PLATFORM

IROMEC is a modular mobile robotic platform developed to support children with cognitive and physical impairment to learn through play. The platform is conceived as a modular system equipped with different components: a mobile platform, an application module and some additional pluggable components used to modify the robot's appearance and behaviour [1].

The mobile platform developed by Robosoft (www.robosoft.fr) controls all the commands related to the movement, localization and navigation. It is equipped with

13 ultrasound and 18 infrared sensors and a laser scanner to allow obstacle detection, navigation in the space and reaction to external stimuli. Movement and speed are controlled through a motor/gearbox/encoder ensemble that makes the movement safe and suitable for the interaction with children. The platform contains also a video camera for colour tracking. It weights around 10 kgs.

The application module developed by Profactor (www.profactor.at) manages the user interaction through a set of digital components and interfaces. It can be plugged/-unplugged on/from the mobile platform through hooks that safely and invisibly fastener the two modules. The interaction module measures 35x55x17 cm and weights around 8 kgs. The module is composed of two parts: the body and the head. The body displays graphical interface elements related to different play scenarios on a 13 inch digital touch screen. For example, the body screen can represent the features of an imaginary cartoon-like character displaying a digital fur which moves according to the direction of the platform's movement. When the robot stops, fur clumps appear that extend when it moves again. The head is constituted of a 8 inch digital screen that displays the robot's facial expressions. The head rotates along a vertical axis from right to left (and vice versa) to simulate the robot's attention towards a specific direction. The head movements are controlled by an additional micro-controller that it also in charge for controlling the camera system.

A number of additional components were designed to modify the appearance of the robot and its behaviours. Some of these modules are interactive and affect the robot's behaviour. For example luminescent fabric covers are plugged on the lateral sides of the robot and light up when the robot moves. They are fixed on the interaction module through magnets. Different groups of luminescent fibers are weaved into the fabric and can be managed independently being controlled by one inverter each. Different light patterns can be obtained are used to reinforce the feedback on the robot status during movements and coordination games. Another example of interactive module embedding smart textile is "interactive fur" is made of a soft woolen cover with static and moving hairs. This is a stand alone module which is plugged on top of the interaction module through an interlocking mechanism. The moving hairs are fixed to the copper fabric but their lower part is connected to a Nitinol spring.

Each Nitinol spring is connected in their central part to an electric wire wrapping the hairs. The Nitinol springs are fixed to the inner part of the dome shell by means of screws, and the electric wires are inserted through holes in the shell itself. When electricity passes from one extremity of the spring to the center, the other extremity contracts. The movement of the hair can be controlled in timing, intensity and form. This makes the effect of the moving hairs seem quite natural, similar to the fur of an animal [2].

Some other modules of the platform are passive and are used to modify the appearance of the robot. For example, a mask can be mounted on the robot's head to hide part of the digital face and reduce the robot's expressivity. The mask is composed of a fixed smiling mouth, nose and removable eyes.

Fig. 1. The robotic platform

The platform can be assembled in two main robot configurations, vertical (**Fig. 2.** left) and horizontal (**Fig. 2**. right). In the vertical configuration, the robot is stationary and the interaction module is mounted on a dedicated support that provides stability and maintains a fixed position. The mobile platform is not used in this configuration. The head is rotated on the vertical axe to fit the vertical position of the body and the head display automatically adapts the face with the correct orientation. In this configuration the robot has a human-like stance. A dedicated mask can be mounted on the head to hide part of the face if required. This configuration supports imitation scenarios that require the children to reproduce basic movements, like turning the head. The robot can also assume the horizontal configuration to support activities requiring wider mobility and dynamism. In the horizontal configuration the interaction module in plugged in the mobile platform and the head is rotated upside down. Also in this case the head display automatically adapts the face with the correct orientation.

Fig. 2. Vertical (left) and horizontal (right) configuration

The covering modules contribute to modify the appearance of the robot in both configurations (**Fig. 3.**).

Fig. 3. Interactive fur cover (left), mask (right)

2.2 Interfaces

The application module is featured with a high level control system (Game Control) that provides editing of "play scripts" through the GUI, by means of XML-description. The Game Control programming software is written in java programming language and it is easy to modify. An game editor is currently under development to allow the teachers to implement new scenarios autonomously. "Play script" allow to implement GUIs for different play scenarios, so that the robot can turn from an imaginary animal covered by a fur (**Fig. 4.**) into a creeping snake, or an agile tiger or a quite turtle (**Fig. 5.**). Currently the robot can show facial expressions that incorporate the mouth, nose, eyes and eyebrows, as well as different levels of expressiveness and emotional states. Smooth transitions are used to provide a life-like impression.

Fig. 4. Imaginary animal-like character

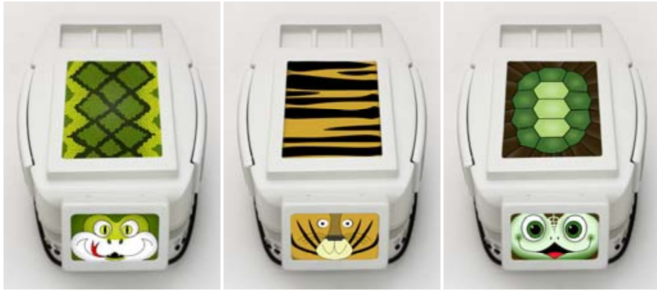

Fig. 5. Snake (left), Tiger (centre), Turtle (right)

The interfaces are enriched by original sounds to structure and articulate the play experience. They have been designed in collaboration with experts, therapists and teachers to give the impression of a living entity without any specific human or animal connotation. A library of sounds was created so that different sounds can be associated to various games through "play scripts".

3 CREATION OF PLAY SCENARIOS

The robotic platform can be configured to engage in a number of play scenarios [3] [1] including turn taking and imitation games, cause and effect games, coordination games, sensory stimulation games. Each scenario is designed to address detailed educational and therapeutic objectives and can be adapted to the specific needs and ability of the child. For example, the *Tickle* scenario (**Fig. 6.**) consists of an exploration of the robot's body to discover where it is sensitive to being tickled. The game can be played in different configurations: either by tickling the robot in correspondence of "digital fur knots" appearing and disappearing on the touch screen display; or by stroking a pressure sensitive fabric cover mounted on the robot's body: whenever the child strokes a sensitive area the robot laughs emitting sounds. The tickling zones change dynamically and children have fun in trying to guess where the robot is more sensitive.

Fig.6. Two configurations for the Tickle scenario

The game is designed to improve the perceptual functions (auditory, visual, tactile and visuo-spatial perception) as a basic form of communication. This is important to the learner since the tactile sense can help to provide awareness of one's own self and each other, to build trust, and to give or receive support in order to develop social relationships during play.

The scenario was experimented in a primary school in Siena (Italy) with children with physical and cognitive impairments. As an example, we briefly present an excerpt of an experiment conducted with M., a 6 year old girl with Pierre Robin syndrome. Because of her disease, M. has a poor speech and difficulties in performing movements that require coordination of the upper and lower limbs, such as sitting down and getting up, and eye-hand coordination. She is emotionally fragile and needs to be constantly reassured during the execution of a task. She is in trouble in playing games that require the production of simultaneous mental schemes and the presence of co-occurrence of variables such as several moving objects at the same time. M. was involved in an experimental study conducted in a primary school in Siena (Italy) for 3 months with 3 sessions per week [4].

Fig. 7. shows the child playing the *Tickle* game. The child explores the robot's body (**Fig. 7**. up left), she observes the interface and the "fur knots" appearing on the digital screen (**Fig. 7.** up right), she executes the task (**Fig. 7.** bottom left) and at the same time monitors the robot's expressions in reaction to tickling (**Fig. 7.** bottom right). The sequence shows that M. is very engaged in playing with the robot. She carefully touches the fur knots showing a certain degree of eye-hand coordination and a correct understanding of the cause-effect relations of her actions. Furthermore, she attributes emotional states to the robot showing empathic engagement with the play companion. These behaviours are examples of social competence that the child can develop, exercise and reinforce in interaction with the robot.

Fig. 7. Experimenting the *Tickle* scenario

4 CONCLUSIONS

Iromec is a robotic platform that supports disabled children in exploring play styles. The platform has a number of key features that make the robot a suitable support in learning and therapeutic activities. The modularity is achieved both at hardware and software level: it allows to configure the robot by changing its appearance, and to create new games to address the specific needs of disabled children. Thereby, the platform can be used in a flexible manner by allowing the teacher/therapist to design educational activities. The design leads to solutions such as utilising the material properties of the platform to facilitate understanding of behavioural characteristics and to exercise creativity. These features further make it possible to create inclusive games which are adapted to children with different physical and cognitive abilities. Indeed, the platform has been used with autistic, motor impaired children, and children with mild cognitive impairment in the school context with the classmates with typical development [4].

ACKNOWLEDGMENTS

The authors would like to thank the children and their families for their enthusiasm in experimenting with the robot. Thanks also to Sara Gioiosa for designing the tiger, turtle and snake games.

Abstract

In games where players are competing against each other, it can be of interest to ensure that all players are challenged according to their individual skills. In order to investigate such adaptivity to the individual player in physical multi-player games, we developed a game on modular interactive tiles which can be used in both single-player and multi-player mode. We implemented simple adaptivity methods and tested these with different user groups including children and adults of both genders. The results show statistically significant differences in the game interactions between children and adults, and between male and female players. Also, results show statistically significant differences in the game interactions between different physical set-ups of the modular interactive tiles, i.e. the interaction depended on the topology of the modular tiles set-up. Changing the physical set-up of the physical game platform changes the interaction and performance of the players.

Introduction

Physical games can be both fun and physical challenging, as is seen with numerous physical gaming platforms currently emerging on the market, including Nintendo Wii, Microsoft Kinect, etc. (an overview of such physical gaming platforms and their history is presented in [1]). If we want the games to be challenging to a variety of users, it is important that the games can challenge the users at different levels appropriate to the individual user. In the physical games, we may imagine that a young child is at a different level than an older child, we may imagine that young adults are at a different level than most elderly, we may imagine that fully able users are at a different level than physical disabled users, etc.

Hence, it is interesting to investigate how different users perform differently, and based on this investigate how physical games may possibly adapt to match the physical capabilities of the individual user. In other words, it is interesting to investigate how to develop adaptive physical games. For instance, for modular playware [2, 3], it has been outlined that there exist different possibilities for such adaptation: "(1) *Hardware adaptation*, e.g. the user changes the physical form or size of the playware tool to fit the user level, (2) *Software adaptation*, e.g. the game automatically changes level to fit the user at run-time, (3) *Hardware and software adaptation*, e.g. the user builds a desired playware tool and software adapts to the built playware tool (e.g. to its topology) and the user interactions" [4]. In the present work, we will therefore make experiments with a platform that allows both hardware and software adaptation, though focusing on the software adaptation.

As introduced by Derakhshan et al. [5], an adaptation approach to playware is a run-time iteration of observation, classification, and adaptation. Related to the classification of users in physical playware games, Derakhshan et al. [5] classified the users into simple categories (young/old child, playing/not playing, continuous/discontinuous behavior, etc.) using an artificial neural network, whereas Yannakakis et al. [6, 7] introduced an approach for estimating expressed player satisfaction in real-time through physiological signals (e.g. heart rate) measured during physical gameplay. Lund and Thorsteinsson [4] used a simple approach of a run-time classification and adaptation based upon the reaction speed of the user. Likewise, we will use such an approach in the present work.

Experimental Set-up

In order to make experiments on different user groups' physical performance and impression of adaptive physical games of different difficult level, we developed the adaptive double mole game for the modular interactive tiles.

Modular Interactive Tiles

The modular interactive tiles are a distributed system where the tiles can be attached to one another to form the overall system. Each tile is self sufficient of processing power and each one has a battery that lasts approximately 30 hours in use. This makes the usage of the tiles very flexible because they do not need a computer or external power source. When connected to one another to form a playfield, they communicate to their neighbors through four infra-red (IR) transceivers located on the sides. In a set of tiles one tile usually differs slightly from the others and that is the master tile which has a XBee radio communication chip. The master tile is capable of communicating to other devices that have a XBee chip for example a game selector box or a PC that has an USB XBee dongle connected.

Figure 1: Left: The interior of the modular interactive tiles.
Right: A tile playfield being assembled.

When playing on the tiles, the player provides the tiles with an input in the form of pressure measured by a single force sensitive resistor which is located in the center of each tile. The tile can then react by turning on 8 RGB LEDs which are mounted with equal spacing between each other in a circle inside the tile. On the back side of the tiles there are four magnets which can be used to place the tiles vertically on a magnetic surface. The tiles have the means to detect whether they are placed horizontally or vertically with a 2 axis accelerometer. This feature can be used to change game parameters on the fly when the tiles are, for example, moved from a floor to a wall.

Double Mole

The game developed for the present work found inspiration from the well known game „Whack-A-Mole“ where the objective is to hit the moles with a hammer before they go back into their holes. The game was implemented on the modular interactive tile platform in such a way that each tile was considered as a hole for a mole to appear in. Appearing moles were represented by 8 LEDs lighting up in either green or blue color and they appeared randomly around the tile set. The tiles count down by turning off the LEDs one by one until all the LEDs have been turned off, which means that the mole has escaped. However if the player steps on a lit up tile before it finishes the countdown, the player is considered to have hit the mole and receives one point. The game can either be played in single-player or multi-player mode where the two modes differ slightly. The difference is due to the chance of a bonus tile/mole appearing in the multi-player mode. The players compete for this bonus and the player who wins it, receives a certain amount of points (e.g. 10 points). This tile counts up from 0 to 8 LEDs in red and yellow until a player hits it, but then the red color randomly changes to either blue or green. Then with each hit, the color switches between green and blue until the count up finishes. In the present tests, the tiles are arranged in a rectangle, in 2x3, 2x4, or 4x4 set-ups. Depending on the set-up the amount of tiles each player has to hit changes. In the 2x3 set-up each player has one tile to hit while in 2x4 and 4x4 each player has 2 tiles to hit at each time. When playing, players are most often standing outside the tile platform facing each other in the 2x3 and 2x4 set-ups and stretch their leg inside the platform to hit the lit up tiles. This game-play relies on the reaction of the players and their ability to keep the balance while stretching their leg inside the tile platform. The 4x4 tile set-up requires the players to stand on top of the platform which alters the game-play quite considerably because now size and strength of the player also plays a big role in how they perform in the game.

Adaptivity

Due to the nature of the game, being fast paced and competitive in the multi-player mode, the game was made in such a way that it would adapt the countdown speed of the tiles depending on the number of remaining LEDs lit when a tile was hit. The values used to adapt the countdown speed can be seen in the following table:

Countdown		
LEDs (no.)	LEDs (ms)	Tile (ms)
8	-80	-640
7	-40	-320
6	0	0
⋮	⋮	⋮
3	0	0
2	10	80
1	20	160
0	30	240

Table 1: Countdown speed adaptation values where negative values are an increase in speed and positive a decrease.

In both single- and multi-player mode the game adapts the countdown speed to each individual depending on his performance. This feature possibly allows two players in different physical shape to play a game against each other. The challenge may be to make the game challenging enough to keep each player motivated but at the same time make each of the two players able to win the match. The bonus tile was implemented as a test to see whether it could be used to slow down the faster player.

Tests

User tests were made on two different age groups. One group consisted of children aging 6-8 year old, 3 boys and 3 girls and the other group consisted of adults aging 20-35 year old, 10 males and 10 females.

Single-player
First a single player test was conducted where each player played a 60 second game alone and where the adults played both in 2x3 and 2x4 tile set-ups while the children only played in the 2x3 tile set-up. Comparisons were made between the 10 males and 10 females to determine whether any significant difference was in their performance in the game. Figure 2 shows the performance of males and females in the 2x3 tile set-up, displaying how the countdown time adapts over game time.

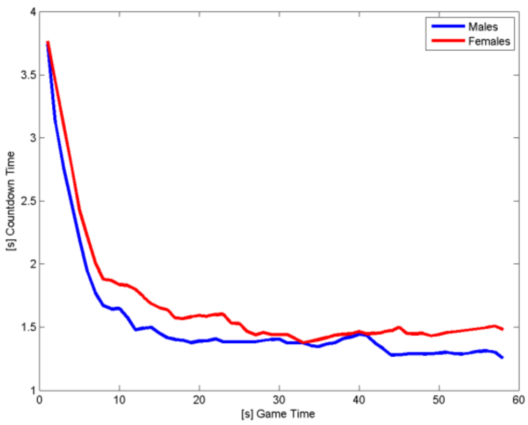

Figure 2: The average values of tile countdown time. A comparison between males and females in 2x3 tile set-up.

The males appear to reach faster countdown time than the females. Comparing the two sets of data consisting of the countdown time at each second of game time, a Mann Whitney U-test returns the P-value 5.6098e-008. At the 0.05 critical alpha level, this concludes that there is a statistically significant difference between the performance of males and females. The game statistics can be seen in the following table.

2x3 – Males vs. Females		
Gender	Tiles hit	Reaction time [s]
Males	82.80	0.446
Females	75.20	0.530
MW-U (P)	0.0881	0.0452

Table 2: Game statistics, average values.

The difference in countdown time observed on Figure 2 is related to the significant difference in reaction speed observed in Table 2.

Similarly a comparison was made between males and females in the 2x4 tile set-up, see figure 3.

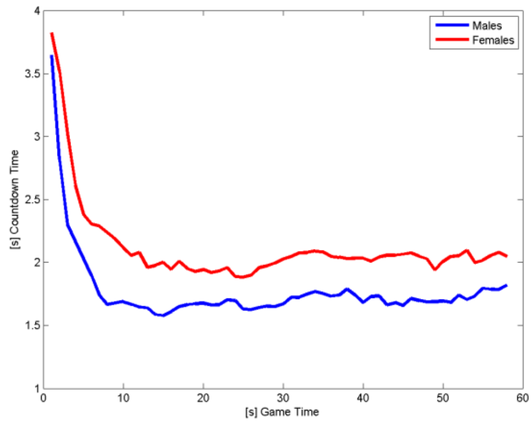

Figure 3: The average values of tile countdown time. A comparison between males and females in 2x4 tile set-up.

For the game on the larger 2x4 tiles platform, the difference between the countdown time of the tiles for the two genders increases from what was observed in the 2x3 tile set-up. A Mann Whitney U-test with the 0.05 critical alpha level was used to determine if the difference could be considered significant. The test returned the P-value 1.6521e-015 so the difference is considered significant.

2x4 – Males vs. Females		
Gender	Tiles hit	Reaction time [s]
Males	127.80	0.612
Females	113.8	0.734
MW-U (P)	0.1117	0.0312

Table 3: Game statistics, average values.

When examined, the game statistics revealed that changing from 2x3 tile set-up to 2x4 tile set-up slowed the reaction time (remember that in this game the user now has two tiles lighting up at a time), and the reaction time difference between the two genders is, as before, statistically significant.

A comparison between adults and children was also made where the averages of all the adults were compared to the averages of all the children, as shown in figure 4.

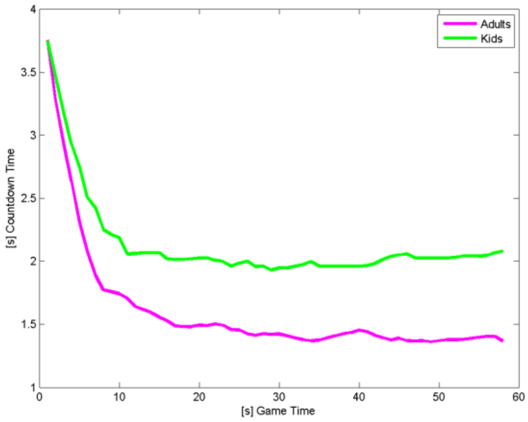

Figure 4: The average values of countdown time. A comparison between adults and children in 2x3 tile set-up.

It can be seen that the adults reached a much faster countdown time on average than the children did. A Mann Whitney U-test returned the P-value 5.4814e-014 so the difference is considered significant.

2x3 – Adults vs. Children		
Group	Tiles hit	Reaction time [s]
Adults	79.00	0.488
Children	61.83	0.684
MW-U (P)	0.0028	0.0038

Table 4: Game statistics, average values.

By examining Table 4 it can be seen that the adults seem to have much faster reactions than the children do. The difference was determined, with the Mann Whitney U-test, to be significant.

Finally for the single-player user tests, a comparison was made between two different tile set-ups, namely 2x3 and 2x4, see figure 5. This comparison was made between the average values of the adults that participated.

It can be observed that the adults reached a faster countdown time in the 2x3 set-up. This difference is explained by the increased number of lit tiles that the players have to hit in the 2x4 set-up.

Game statistics show a significant difference in both tiles hit and reaction time. This is explained as before by that an increase in amount of tiles the players have to hit at each time is increased from one to two.

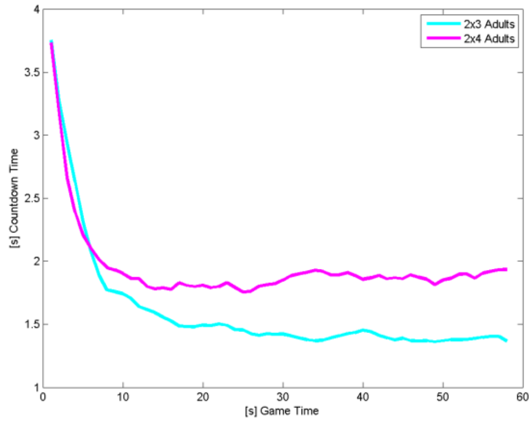

Figure 5: The average values of countdown time. A comparison between adults playing in 2x3 and 2x4 tile set-ups.

2x3 vs. 2x4 – Adults		
Setup	Tiles hit	Reaction time [s]
2x3	79.00	0.488
2x4	117.25	0.673
MW-U (P)	0.0000	0.0000

Table 5: Game statistics, average values.

Multi-player

In the multi-player tests, 16 of the 20 adults were tested. They were split into 4 groups where 2 fast players of each gender were matched against 2 slow player of each gender. The players were categorized as fast or slow depending on how they performed in the single-player test. The same 6 children as before were also tested in 2x3 tile set-up though no performance classification was made.

To see how changing the tile set-up would affect the performance of the adult players, the average values of all adults were put on a single graph for comparison, see figure 6.

When Figure 6 is examined it can be seen that the games adapt to the users at different speeds. The 4x4 tile set-up has by far the slowest game-play. This is due to altered game interaction where the players are now standing on top of the tile set resulting in more disturbances from the other player.

Figure 7 shows the results from the matching of fast and slow players in the 2x4 tile set-up. The other games (2x3 and 4x4) show similar patterns, though with either faster (2x3) or slower (4x4) countdown time. In all games, Mann-Whitney U-tests show (P-values of 1.5085e-009, 3.9221e-013, and 2.7131e-013) a statistically significant difference between the fast and slow players.

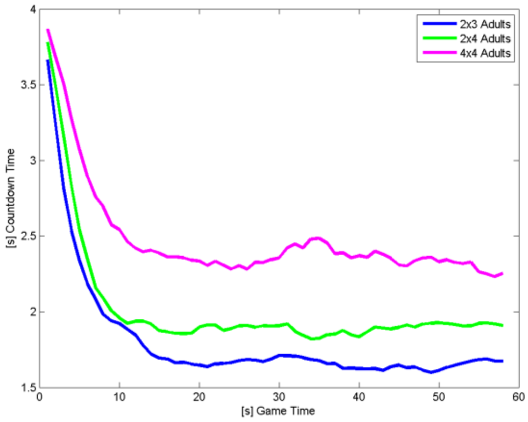

Figure 6: The average values of countdown time. A comparison between adults playing in 2x3, 2x4 and 4x4 tile set-ups.

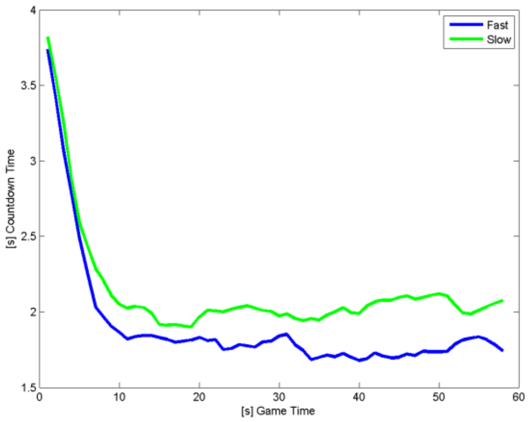

Figure 7: The average values of countdown time. A comparison between fast and slow players playing in 2x4 tile set-up.

2x3 – Fast vs. Slow - Adults			
Group	Tiles hit	Bonus tiles	Reaction time [s]
Fast	59.44	2.13	0.570
Slow	52.50	1.69	0.653
MW-U (P)	0.0258	0.3644	0.0438

2x4 – Fast vs. Slow – Adults			
Group	Tiles hit	Bonus tiles	Reaction time [s]
Fast	73.69	1.94	0.706
Slow	61.94	1.75	0.794
MW-U (P)	0.0039	0.7132	0.0302

4x4 – Fast vs. Slow – Adults			
Group	Tiles hit	Bonus tiles	Reaction time [s]
Fast	61.38	1.31	0.893
Slow	50.13	2.06	1.091
MW-U (P)	0.0066	0.0111	0.0044

Table 6: Game statistics, average values.

For all the game set-ups, the game statistics show a significant difference according to the Mann Whitney U-test both in the amount of tiles hit and the reaction time. In the case of 4x4, there is also a statistically significant difference in bonus tiles hit favoring the slower players.

If the game scoring system is set so that one point is awarded for hitting a regular tile and 3 points for winning a bonus tile, the fast player wins in all three tile set-ups as seen in table 7. On the other hand, if the bonus tile was set to give 15 points, then the slower players would obtain a higher score than faster players in the 4x4 game.

Adults – Scores			
Group	2x3	2x4	4x4
Fast	65.81	79.50	65.31
Slow	57.56	67.19	56.31

Table 7: Adults, average scores in multi-player.

After playing each game, the players answered a questionnaire including the three following questions:

Q1: How was the game ? (1 Boring / 5 Fun)
Q2: How was the speed ? (1 Slow / 5 Fast)
Q3: Was the game difficult ? (1 Not / 5 Very)

The answers were given on a 5-step Lickert Scale. The answers to the questions revealed that both player groups thought the game was entertaining (average 4 on the 1-5 scale) and moderately challenging (speed average 3.5, difficulty average 3). Interestingly, in all cases, the difference in answers between the fast and slow players was not considered statistically significant according the Mann Whitney U-test. Hence, despite the statistically significant differences in reaction speed (and thereby difference in number of tiles hit during each game), the players found the adaptive game equally fun and challenging.

Finally a comparison between adults and children was made to see if there was a difference in how children and adults compete, see figure 8. As can be seen in Table 8, the adults hit significantly more tiles and their reaction time is almost twice as of the children. Interestingly, the amount of bonus tiles hit is similar.

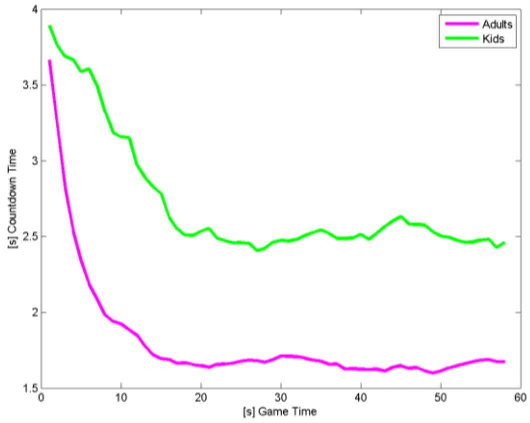

Figure 8: The average values of countdown time. A comparison between adults and children playing the multi-player version in 2x3 tile set-up.

2x3 – Adults vs. Children			
Group	Tiles hit	Bonus tiles	Reaction time [s]
Adults	55.97	1.91	0.611
Children	38.83	1.50	1.046
MW-U (P)	0.0012	0.4996	0.0000

Table 8: Game statistics, average values.

Discussion and Conclusion

With the present work, we have seen how different users have different reaction speed in single and multiplayer physical games. The work shows that there are statistical significant differences between different players and between different game set-ups. Indeed, in the single player game we observed statistical significant differences between male and female players, between adult and children, and between play on a 2x3 tiles platform and a 2x4 tiles platform. A similar change in performance due to different tiles set-ups (2x3, 2x4, and 4x4) was observed with the multiplayer game. Further, the multiplayer games showed that there was statistical significant difference in reaction speed and number of tiles hit between the fast players and the slow players, who were coupled to play against each other. Despite this difference, both fast players and slow players found the games equally fun and challenging.

In our point of view, it is an important result to be able to create physical games which players with different physical abilities can play together with equal fun and challenge. We believed that we obtained this here by the creation of adaptive games that run-time adapts to the reaction speed of individual players. Even in the multiplayer game, the game adapts differently to the two individual players, and thereby they each become challenged at their own particular level.
This can be important for instance in welfare technology for elderly, where we have observed a need for physical training/rehabilitation equipment to easily adapt to the individual elderly [8, 9]. Therefore, in future, we will investigate the adaptive playware as a welfare technology, and adaptive in other games potentially suitable for elderly (e.g. see [10]).

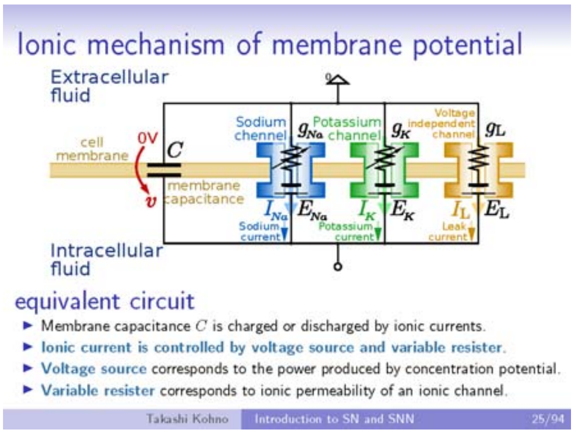
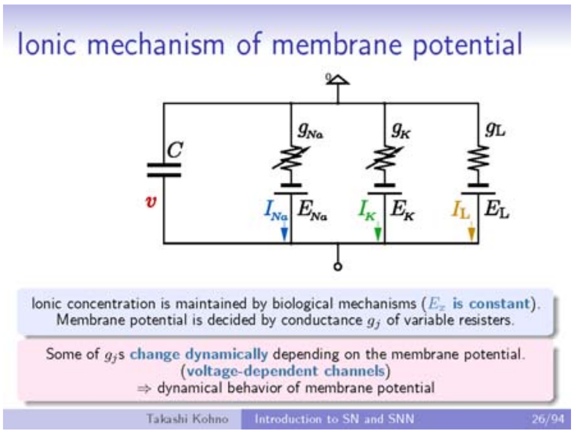
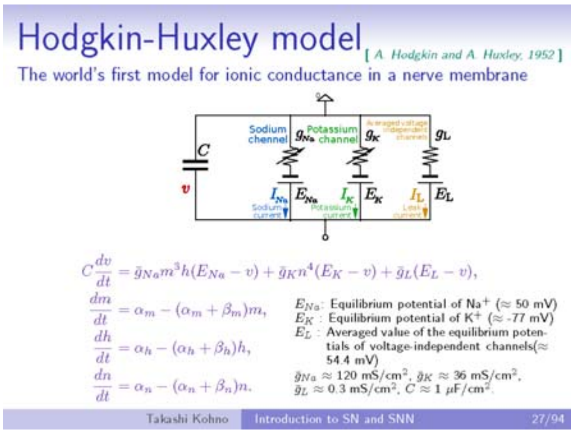
Leak current
membrane capacitance: cell membrane is an insulator.
Ionic concentration is different between intracellular and extracellular fluids.
Ionic channels passively transmit specific ionic particles.
⇒ ionic current (e.g. sodium current, ...)
Membrane capacitance is charged or discharged by ionic currents.
⇒ membrane potential
Takashi Kohno Introduction to SN and SNN 24/94



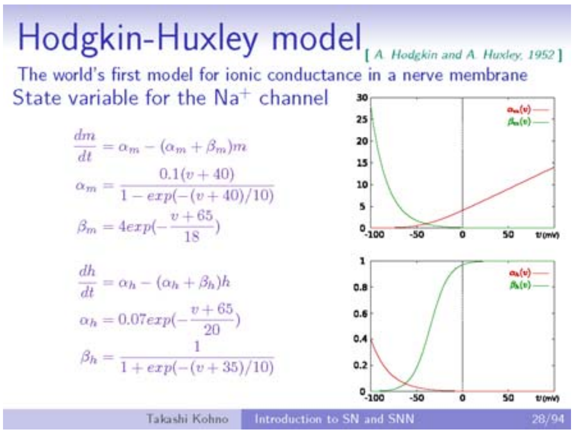
Ionic mechanism of membrane potential
Extracellular fluid
Intracellular fluid
cell membrane
membrane capacitance
Sodium chennel
Potassium channel
Voltage independent channel
equivalent circuit
Membrane capacitance C is charged or discharged by ionic currents.
Ionic current is controlled by voltage source and variable resister.
Voltage source corresponds to the power produced by concentration potential.
Variable resister corresponds to ionic permeability of an ionic channel.
Takashi Kohno Introduction to SN and SNN 25/94



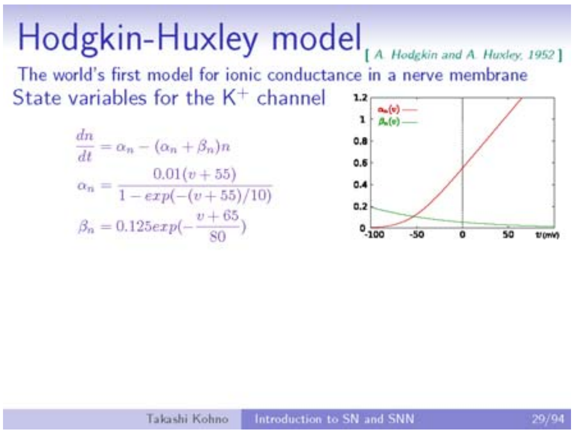
Ionic mechanism of membrane potential
Ionic concentration is maintained by biological mechanisms (E_x is constant).
Membrane potential is decided by conductance g_j of variable resisters.
Some of g_js change dynamically depending on the membrane potential.
(voltage-dependent channels)
⇒ dynamical behavior of membrane potential
Takashi Kohno Introduction to SN and SNN 26/94



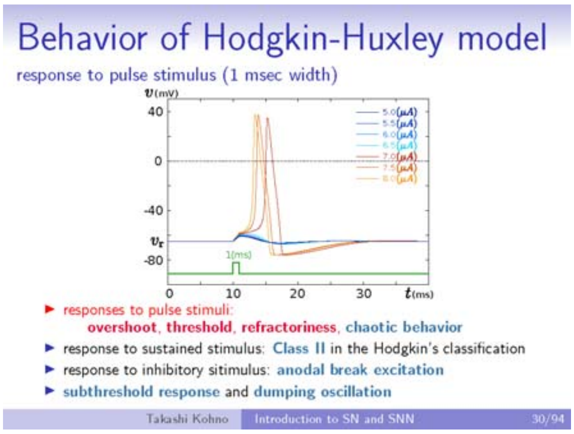
Hodgkin-Huxley model [A. Hodgkin and A. Huxley, 1952]
The world's first model for ionic conductance in a nerve membrane
$C\frac{dv}{dt} = \bar{g}_{Na}m^3h(E_{Na}-v) + \bar{g}_K n^4(E_K - v) + \bar{g}_L(E_L - v),$
$\frac{dm}{dt} = \alpha_m - (\alpha_m + \beta_m)m,$
$\frac{dh}{dt} = \alpha_h - (\alpha_h + \beta_h)h,$
$\frac{dn}{dt} = \alpha_n - (\alpha_n + \beta_n)n.$
E_{Na}: Equilibrium potential of Na+ (≈ 50 mV)
E_K: Equilibrium potential of K+ (≈ -77 mV)
E_L: Averaged value of the equilibrium potentials of voltage-independent channels(≈ 54.4 mV)
$\bar{g}_{Na} \approx 120$ mS/cm², $\bar{g}_K \approx 36$ mS/cm², $\bar{g}_L \approx 0.3$ mS/cm², $C \approx 1$ μF/cm².
Takashi Kohno Introduction to SN and SNN 27/94



Hodgkin-Huxley model [A. Hodgkin and A. Huxley, 1952]
The world's first model for ionic conductance in a nerve membrane
State variable for the Na+ channel
$\frac{dm}{dt} = \alpha_m - (\alpha_m + \beta_m)m$
$\alpha_m = \frac{0.1(v+40)}{1-exp(-(v+40)/10)}$
$\beta_m = 4exp(-\frac{v+65}{18})$
$\frac{dh}{dt} = \alpha_h - (\alpha_h + \beta_h)h$
$\alpha_h = 0.07exp(-\frac{v+65}{20})$
$\beta_h = \frac{1}{1+exp(-(v+35)/10)}$
Takashi Kohno Introduction to SN and SNN 28/94



Hodgkin-Huxley model [A. Hodgkin and A. Huxley, 1952]
The world's first model for ionic conductance in a nerve membrane
State variables for the K+ channel
$\frac{dn}{dt} = \alpha_n - (\alpha_n + \beta_n)n$
$\alpha_n = \frac{0.01(v+55)}{1-exp(-(v+55)/10)}$
$\beta_n = 0.125exp(-\frac{v+65}{80})$
Takashi Kohno Introduction to SN and SNN 29/94



Behavior of Hodgkin-Huxley model
response to pulse stimulus (1 msec width)
responses to pulse stimuli:
overshoot, threshold, refractoriness, chaotic behavior
response to sustained stimulus: Class II in the Hodgkin's classification
response to inhibitory stimulus: anodal break excitation
subthreshold response and dumping oscillation

A conductance-based silicon neuron
[Simoni et al., IEEE Biomed. Eng., 2004]
[Simoni, 2004]
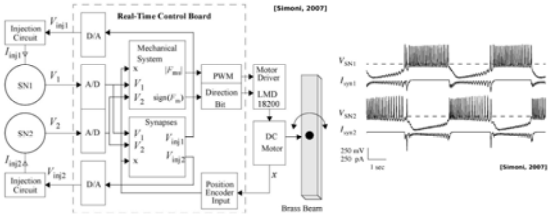
A number of parameter voltages (~ 40) to be applied externally.
Differnt values are required for each silicon neuron circuit because of fabrication variation.
Equips measurement circuits for $m_{\infty,j}, h_{\infty,j}, I_j$.
Takashi Kohno
Introduction to SN and SNN
38/94

A conductance-based silicon neuronal network

[Simoni et al., IEEE Biomed. Eng., 2007]

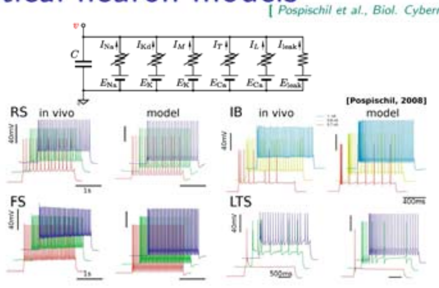


- A silicon half-center oscillator
  - Half-center oscillator: the simplest biological motion pattern generator
  - Two neurons are connected each other via inhibitory synapses.
- Synapses are emulated by ADC, PC, and DAC (dynamic clamp)

Takashi Kohno | Introduction to SN and SNN | 39/94

Cortical neuron models

[Pospischil et al., Biol. Cybern., 2008]

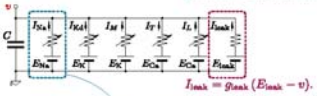


- Composed of 5 voltage-dependent and 1 voltage-independent ionic channels

Takashi Kohno | Introduction to SN and SNN | 40/94

A conductance-based silicon cortical neuron

[Grassia et al., Frontiers Neurocsi., 2011]



$$I_{leak} = g_{leak}(E_{leak} - v).$$

$$I_j = \bar{g}_j m_j^{p_j} h_j^{q_j}(E_j - v),$$

$$\frac{dm_j}{dt} = \frac{m_{\infty,j}(v) - m_j}{\tau_{m_j}(v)}, \quad \frac{dm_j}{dt} = \frac{m_{\infty,j}(v) - m_j}{\tau_{m_j}},$$

$$\frac{dh_j}{dt} = \frac{h_{\infty,j}(v) - h_j}{\tau_{h_j}(v)}, \quad \frac{dh_j}{dt} = \frac{h_{\infty,j}(v) - h_j}{\tau_{h_j}},$$

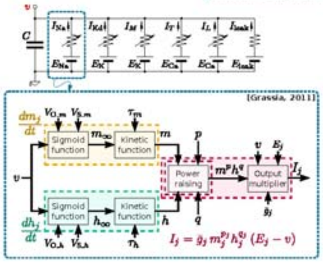
$$m_{\infty,j}(v) \equiv \frac{1}{1+\exp((V_{m_j} - v)/V_{s,m_j})}, \quad h_{\infty,j}(v) \equiv \frac{1}{1+\exp((V_{h_j} - v)/V_{s,h_j})}$$

- Equations were modified for simplification of circuitry.

Takashi Kohno | Introduction to SN and SNN | 41/94

A conductance-based silicon cortical neuron

[Grassia et al., Frontiers Neurocsi., 2011]

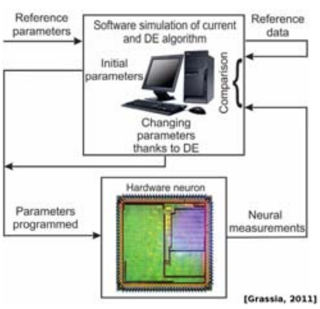


- Several nFs of capacitors are required: off-chip capacitor.
- Parameter voltages are stored in on-chip dynamic analog memory.
- 0.35μm BiCMOS SiGe process, total power consumption 550mW (5 neurons)

Takashi Kohno | Introduction to SN and SNN | 42/94

A conductance-based silicon cortical neuron

[Grassia et al., Frontiers Neurocsi., 2011]



Configuration

- Numbers of parameter voltages to be tuned (maximum 28).
- Fabrication variation is inevitable:
  ⇒ Each instance of silicon neurons requires different parameter voltages.

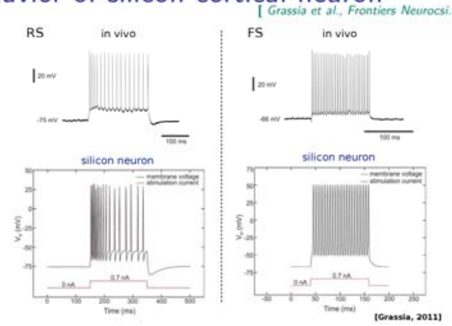
Automated configuration

- Parameter voltages are tuned up by differential evolution algorithm.
- Minimize behavioral difference to the target cortical neuron models.
- Requires about a day.

Takashi Kohno | Introduction to SN and SNN | 43/94

Behavior of silicon cortical neuron

[Grassia et al., Frontiers Neurocsi., 2011]

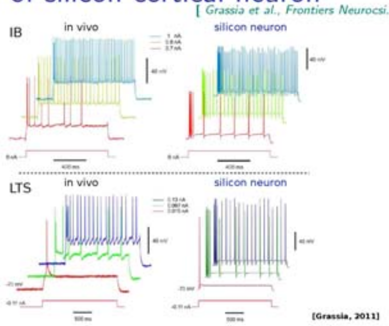


- Successfull automated tuning system.

Takashi Kohno | Introduction to SN and SNN | 44/94

Behavior of silicon cortical neuron

[Grassia et al., Frontiers Neurocsi., 2011]



- Successfull automated tuning system.

Takashi Kohno | Introduction to SN and SNN | 45/94

Qualitative neuron models

Ionic conductance models are too complex to explain the mechanism of the neuronal behaviors.

Simple models with similar dynamics were developed by techniques in nonlinear mathematics.

FitzHugh-Nagumo model
Similar dynamics to the Hodgkin-Huxley model

$$\frac{du}{dt} = c(-v + u - \frac{u^3}{3} + I(t)),$$
$$\frac{dv}{dt} = u - bv + a.$$

Hindmarsh-Rose model
A simplest burst firing model

$$\frac{dx}{dt} = y - x^3 + 3x^2 - z,$$
$$\frac{dy}{dt} = 1 - 5x^2 - y,$$
$$\frac{dz}{dt} = r(s(x - x_1) - z).$$

Reduction of the Hodgkin-Huxleymodel by Rinzel

$$h = b - an.$$

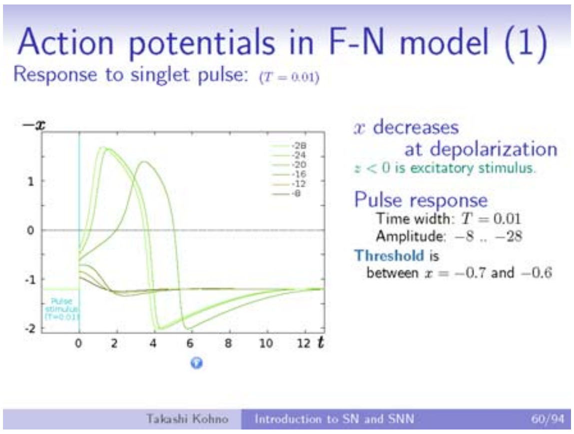
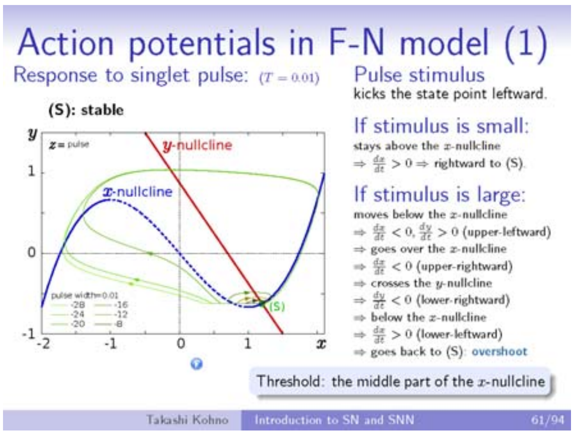
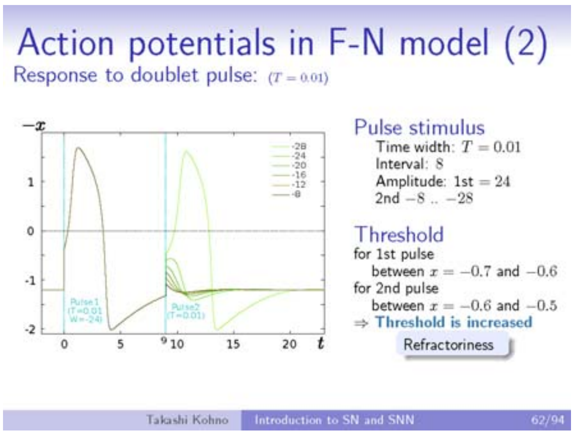
Action potentials in F-N model (1)
Response to singlet pulse: $(T = 0.01)$
x decreases at depolarization
$z < 0$ is excitatory stimulus.
Takashi Kohno
Introduction to SN and SNN
59/94



Action potentials in F-N model (1)
Response to singlet pulse: $(T = 0.01)$
x decreases at depolarization
$z < 0$ is excitatory stimulus.
Pulse response
Time width: $T = 0.01$
Amplitude: -8 .. -28
Threshold is between $x = -0.7$ and -0.6
Takashi Kohno
Introduction to SN and SNN
60/94



Action potentials in F-N model (1)
Response to singlet pulse: $(T = 0.01)$
(S): stable
Pulse stimulus
kicks the state point leftward.
If stimulus is small:
stays above the x-nullcline
$\Rightarrow \frac{dx}{dt} > 0 \Rightarrow$ rightward to (S).
If stimulus is large:
moves below the x-nullcline
$\Rightarrow \frac{dx}{dt} < 0$, $\frac{dy}{dt} > 0$ (upper-leftward)
$\Rightarrow$ goes over the x-nullcline
$\Rightarrow \frac{dx}{dt} < 0$ (upper-rightward)
$\Rightarrow$ crosses the y-nullcline
$\Rightarrow \frac{dy}{dt} < 0$ (lower-rightward)
$\Rightarrow$ below the x-nullcline
$\Rightarrow \frac{dx}{dt} > 0$ (lower-leftward)
$\Rightarrow$ goes back to (S): overshoot
y-nullcline
x-nullcline
Threshold: the middle part of the x-nullcline
Takashi Kohno
Introduction to SN and SNN
61/94

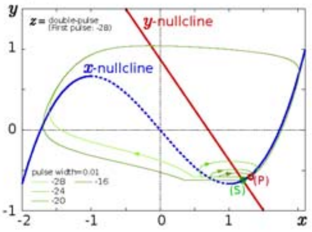


Action potentials in F-N model (2)
Response to doublet pulse: $(T = 0.01)$
Pulse stimulus
Time width: $T = 0.01$
Interval: 8
Amplitude: 1st $= 24$
2nd -8 .. -28
Threshold
for 1st pulse
between $x = -0.7$ and -0.6
for 2nd pulse
between $x = -0.6$ and -0.5
$\Rightarrow$ Threshold is increased
Refractoriness
Takashi Kohno
Introduction to SN and SNN
62/94

Action potentials in F-N model (2)

Response to doublet pulse: $(T = 0.01)$

(S): stable



The 2nd pulse is given when the state point is at (P)

(8 timeunit after the 1st pulse) ⇒ jumps leftward from (P)

Threshold: the middle part of the x-nullcline

[The x coordinate of threshold for (P)] $\vee$ [The x coordinate of threshold for (S)]

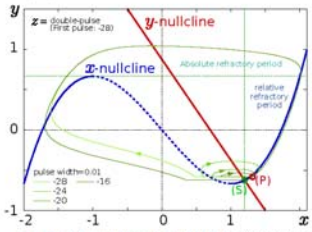
Refractoriness

Takashi Kohno | Introduction to SN and SNN | 63/94

Action potentials in F-N model (2)

Response to doublet pulse: $(T = 0.01)$

(S): stable



- Absolute refractory period: No threshold exist
- Relative refractory period: Threshold is high

The 2nd pulse is given when the state point is at (P)

(8 timeunit after the 1st pulse) ⇒ jumps leftward from (P)

Threshold: the middle part of the x-nullcline

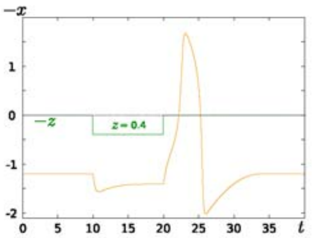
[The x coordinate of threshold for (P)] $\vee$ [The x coordinate of threshold for (S)]

Refractoriness

Takashi Kohno | Introduction to SN and SNN | 64/94

Anodal break excitation in F-N model

Response to inhibitory stimulus: $(z = 0.4, T = 10)$



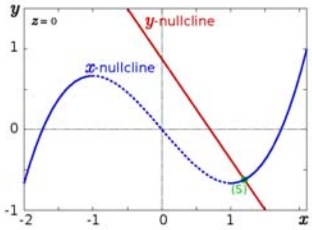
Sufficiently long inhibitory stimulus invokes an action potential at its end.

Takashi Kohno | Introduction to SN and SNN | 65/94

Anodal break excitation in F-N model

Response to inhibitory stimulus: $(z = 0.4, T = 10)$

(S): stable



Sufficiently long inhibitory stimulus invokes an action potential at its end.

- Inhibitory stimulus $z = 0.4$ ⇒ x-nullcline is displaced downward

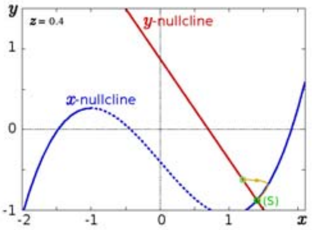
($\because$ x-nullcline: $y = -x + \frac{x^3}{3} - z$) ⇒ (S) moves lower-rightward

Takashi Kohno | Introduction to SN and SNN | 66/94

Anodal break excitation in F-N model

Response to inhibitory stimulus: $(z = 0.4, T = 10)$

(S): stable



Sufficiently long inhibitory stimulus invokes an action potential at its end.

- Inhibitory stimulus $z = 0.4$ ⇒ x-nullcline is displaced downward

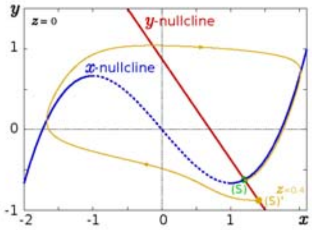
($\because$ x-nullcline: $y = -x + \frac{x^3}{3} - z$) ⇒ (S) moves lower-rightward

Takashi Kohno | Introduction to SN and SNN | 67/94

Anodal break excitation in F-N model

Response to inhibitory stimulus: $(z = 0.4, T = 10)$

(S): stable



Sufficiently long inhibitory stimulus invokes an action potential at its end.

- Inhibitory stimulus $z = 0.4$ ⇒ x-nullcline is displaced downward

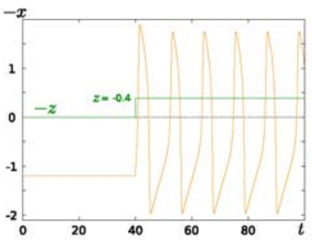
($\because$ x-nullcline: $y = -x + \frac{x^3}{3} - z$) ⇒ (S) moves lower-rightward

- Stimulus ends $z = 0$ ⇒ The system state is below the x-nullcline, where $\frac{dx}{dt} < 0$ ⇒ it moves leftward and action potential starts.

Takashi Kohno | Introduction to SN and SNN | 68/94

Periodic firing in F-N model (1)

Response to sustained stimulus: $(z = 0 \to -0.4)$



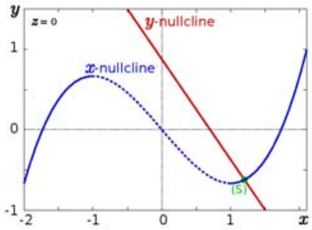
Excitatory sustained stimulus invokes periodic firing.

Takashi Kohno | Introduction to SN and SNN | 69/94

Periodic firing in F-N model (1)

Response to sustained stimulus: $(z = 0 \to -0.4)$

(S): stable

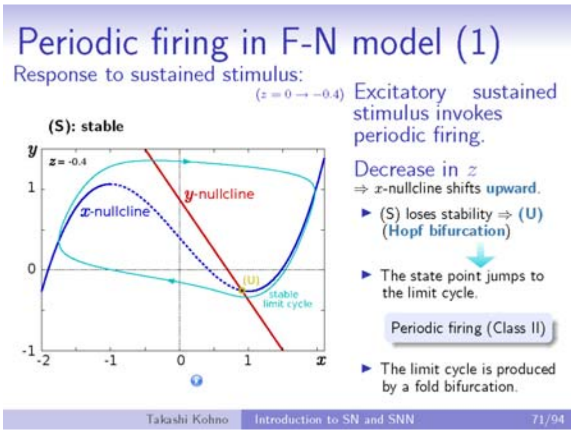


Excitatory sustained stimulus invokes periodic firing.

Decrease in z ⇒ x-nullcline shifts upward.

x-nullcline: $y = -x + \frac{x^3}{3} - z$

Takashi Kohno | Introduction to SN and SNN | 70/94



Periodic firing in F-N model (1)
Response to sustained stimulus:
Excitatory sustained stimulus invokes periodic firing.
(S): stable
y-nullcline
x-nullcline
(U)
stable limit cycle
Decrease in z
⇒ x-nullcline shifts upward.

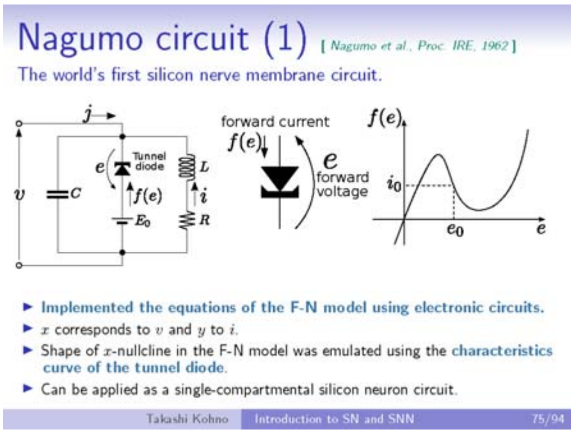
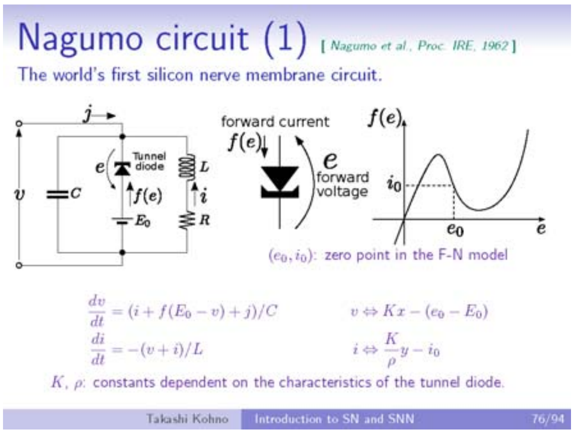
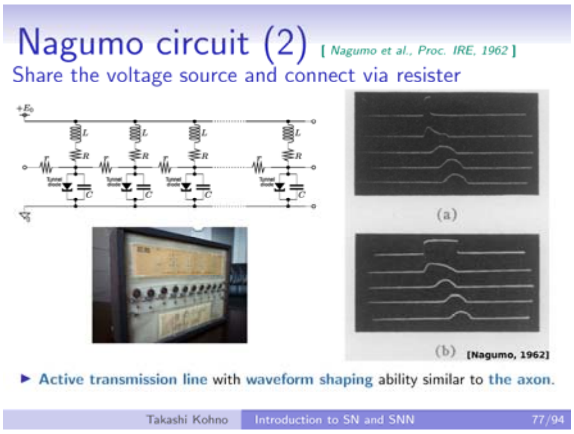
Comparison with H-H model
Projection of the H-H model to a plane [FitzHugh, Biophys. J., 1961]
Porjected H-H model
F-N model
H-H Eqns.
BVP Eqns.
[FitzHugh, 1961]
In H-H h + n ~ 0.85 is known to be true in most of the activities.
⇒ h can be assumed to depend directory on n.
Time constant of m is sufficiently small.
⇒ m can be assumed to depend directory on v.
Oribits in both planes are similar: F-N model approximates H-H model
Takashi Kohno Introduction to SN and SNN 74/94



Nagumo circuit (1) [Nagumo et al., Proc. IRE, 1962]
The world's first silicon nerve membrane circuit.
Tunnel diode
forward current
forward voltage
Implemented the equations of the F-N model using electronic circuits.
x corresponds to v and y to i.
Shape of x-nullcline in the F-N model was emulated using the characteristics curve of the tunnel diode.
Can be applied as a single-compartmental silicon neuron circuit.
Takashi Kohno Introduction to SN and SNN 75/94



Nagumo circuit (1) [Nagumo et al., Proc. IRE, 1962]
The world's first silicon nerve membrane circuit.
Tunnel diode
forward current
forward voltage
(e_0, i_0): zero point in the F-N model
$\frac{dv}{dt} = (i + f(E_0 - v) + j)/C$
$\frac{di}{dt} = -(v + i)/L$
$v \Leftrightarrow Kx - (e_0 - E_0)$
$i \Leftrightarrow \frac{K}{\rho}y - i_0$
K, ρ: constants dependent on the characteristics of the tunnel diode.
Takashi Kohno Introduction to SN and SNN 76/94



Nagumo circuit (2) [Nagumo et al., Proc. IRE, 1962]
Share the voltage source and connect via resister
(a)
(b) [Nagumo, 1962]
Active transmission line with waveform shaping ability similar to the axon.

Abstract: Since Reusable Launch Vehicles (RLVs) operate in a wide range of flight conditions, the values of the parameters of the RLVs' dynamic equations are not constant. Therefore, some adaptive control methods for RLVs have been proposed. We have proposed a digital adaptive feedback linearization control method with time-scale separation to a winged rocket. In this paper, we propose a digital adaptive feedback linearization control method using unscented Kalman filter. The simulation results with a guidance using genetic algorithm show the effectiveness of the proposed control systems.
Keywords:Adaptive Control, Flight Control

1 Introduction

In late years space development is performed lively all over the world, and the research of space transportation systems to enable them is performed. Especially, Reusable Launch Vehicles (RLVs) are expected for the systems because the RLVs are the low-cost and highly reliable transport system instead of the conventional disposable rockets.

Since the RLVs have wide range flight conditions, the values of parameters of the dynamic model of the RLVs are not constant. Therefore, gain scheduling control method has been applied for the RLVs [1]. However, when the air traffic window expands, the number of required gains to be designed becomes very large and the method can only correspondence to the known change; the control performance becomes worse for the unpredictable change in the flight condition such as the abort flight.

For the change of the flight conditions, adaptive control methods using approximated linear dynamic equation of the RLVs have been researched [2–5]. However, the control performance decreases when the nonlinearity strengthens though a linear adaptive control has an excellent performance when the nonlinearity of the controlled system can be disregarded. Then, a feedback linearization method for deleting the nonlinear term by the state feedback for the nonlinear equation of motion of the RLV have been researched [6]. In addition, the method for dividing time-scale by a fast motion and a slow motion is researched for the simplification of the structure of the control system [7]. We have also proposed a digital adaptive feedback linearization control method with time-scale separation to a winged rocket [8] which is one of the RLVs.

Here, the air data obtained from a pitot tube etc. contains many noises. Therefore, in order to guarantee the good control performance of RLVs, it is necessary to estimate the state variables. For estimation of the parameters and state variables of the nonlinear systems, Unscented Kalman Filter (UKF) is researched [9]. The UKF was developed as approximating a Gaussian distribution instead of linear approximating for a nonlinear system such as Extended Kalman Filter (EKF). Therefore, it is said that UKF is more effective than EKF for the estimation of a nonlinear system [10].

Fig. 1 Winged rocket

In this paper, we propose a digital adaptive feedback linearization control method using UKF to a winged rocket, and to validate the effectiveness of the control systems in wide range flight conditions, guidance and control simulations are done. The simulation results show that the control system has a good control performance.

2 Model of Winged Rocket

Fig. 1 shows an outline of a winged rocket [11] which is one of the RLVs. The body length is assumed to be 2.5[m] and the mass is 241[kg]. The rocket has two elevons and two rudders as aerodynamic control surfaces. Here, the equation of motion of the winged rocket divided into fast motion and slow motion is shown. Since the configuration of the winged rocket shown in Fig. 1 is similar for general airplanes [12]. Roll, pitch and yaw rotational rates with a fast response are assumed to be fast time scale variables $\boldsymbol{x} = [p,\ q,\ r]^T$, and angle of attack, sideslip angle and bank angle with a slow response are assumed to be slow time scale variables $\boldsymbol{y} = [\alpha,\ \beta,\ \phi]^T$. Therefore, equations of motion are expressed as follows:

$$\dot{\boldsymbol{x}}(t) = \boldsymbol{A}(\boldsymbol{x})\boldsymbol{x}(t) + \boldsymbol{B}(\boldsymbol{x})\boldsymbol{u}(t) + \boldsymbol{C}(\boldsymbol{x})\boldsymbol{w}(t), \quad (1)$$

$$\dot{\boldsymbol{y}}(t) = \boldsymbol{D}(\boldsymbol{y})\boldsymbol{x}(t) + \boldsymbol{E}(\boldsymbol{y})\boldsymbol{h}(t) + \boldsymbol{g}(t) \quad (2)$$

where

$$\boldsymbol{u}(t) = [\delta_{ac},\ \delta_{ec},\ \delta_{rc}]^T,$$

$$\boldsymbol{w}(t) = [pq,\ qr,\ rp,\ r^2 - p^2,\ \alpha,\ \beta]^T,$$

$$\boldsymbol{h}(t) = \left[\frac{1}{V_{TAS} C_\beta},\ \frac{1}{V_{TAS}}\right]^T,$$

$$\boldsymbol{g}(t) = \begin{bmatrix} \dfrac{g(C_\phi C_\alpha C_\theta + S_\alpha S_\theta)}{V_{TAS} C_\beta} \\ \dfrac{g(S_\theta\ C_\alpha S_\beta + C_\theta S_\phi C_\beta - C_\theta C_\phi S_\alpha S_\beta)}{V_{TAS}} \end{bmatrix},$$

$$\boldsymbol{A}(\boldsymbol{x}) = \boldsymbol{I}_d^{-1} \begin{bmatrix} L_p & 0 & L_r \\ 0 & M_q & 0 \\ N_p & 0 & N_r \end{bmatrix},\ \boldsymbol{B}(\boldsymbol{x}) = \boldsymbol{I}_d^{-1} \begin{bmatrix} L_{\delta_a} & 0 & L_{\delta_r} \\ 0 & M_{\delta_e} & 0 \\ N_{\delta_a} & 0 & N_{\delta_r} \end{bmatrix},$$

$$\boldsymbol{C}(\boldsymbol{x}) = \boldsymbol{I}_d^{-1} \begin{bmatrix} I_{xz} & I_{yy} - I_{zz} & 0 & 0 & 0 & L_\beta \\ 0 & 0 & I_{zz} - I_{xx} & I_{xz} & M_\alpha & 0 \\ I_{xx} - I_{yy} & -I_{zz} & 0 & 0 & 0 & N_\beta \end{bmatrix},$$

$$\boldsymbol{D}(\boldsymbol{y}) = \begin{bmatrix} -C_\alpha \tan\beta & 1 & -S_\alpha \tan\beta \\ S_\alpha & 0 & -C_\alpha \\ 1 & S_\phi \tan\theta & C_\phi \tan\theta \end{bmatrix},$$

$$\boldsymbol{E}(\boldsymbol{x}) = \begin{bmatrix} -\frac{L}{m} & 0 \\ 0 & \frac{Y}{m} \\ 0 & 0 \end{bmatrix},\ \boldsymbol{I}_d = \begin{bmatrix} I_{xx} & 0 & I_{xz} \\ 0 & I_{yy} & 0 \\ I_{xz} & 0 & I_{zz} \end{bmatrix}$$

and θ is pitch angle, m is mass, I_{ij} is moment/product of inertia, g is gravitational acceleration, V_{TAS} is true airspeed, L_*, M_* and N_* are aerodynamic rolling, pitching and yawing moments, δ_a, δ_e and δ_r are aileron, elevator and rudder deflection angles, and $S_* = \sin *,\ \ C_* = \cos *$.

When $\dot{\boldsymbol{x}}$ and $\dot{\boldsymbol{y}}$ are discretizaed for forward difference by a sampling period T, Eqs. (1) and (2) are expressed as follows:

$$\boldsymbol{x}(k+1) = \boldsymbol{A}_T(\boldsymbol{x})\boldsymbol{x}(k) + \boldsymbol{B}_T(\boldsymbol{x})\boldsymbol{u}(k) + \boldsymbol{C}_T(\boldsymbol{x})\boldsymbol{w}(k) \quad (3)$$

$$\boldsymbol{y}(k+1) = \boldsymbol{y}(k) + \boldsymbol{D}_T(\boldsymbol{y})\boldsymbol{x}(k) + \boldsymbol{E}_T\boldsymbol{h}(k) + T\boldsymbol{g}(k) \quad (4)$$

where $\boldsymbol{A}_T(\boldsymbol{x}) = \boldsymbol{I} + T\boldsymbol{A}(\boldsymbol{x})$, $\boldsymbol{B}_T(\boldsymbol{x}) = T\boldsymbol{B}(\boldsymbol{x})$, $\boldsymbol{C}_T(\boldsymbol{x}) = T\boldsymbol{C}(\boldsymbol{x})$, $\boldsymbol{D}_T(\boldsymbol{y}) = T\boldsymbol{D}(\boldsymbol{y})$, $\boldsymbol{E}_T = T\boldsymbol{E}$ and $\boldsymbol{I}$ is identity matrix.

3 Control System

In this section, the structure of a control system for Eqs. (3) and (4) in case the value of parameters are known is shown. Moreover, adaptive estimation using UKF which inhibits the suppress of a sensor noise and can respond to wide range flight environment flexibly is described.

3.1 Known parameter case

In the case that the value of parameters of Eqs. (3) and (4) are known the control commands for Eqs. (3) and (4) are defined as follows [8]. First, the rotational rate command for the slow state, i.e. control input to Eq. (4) is defined as

$$\begin{aligned} \boldsymbol{x}_c(k) = \boldsymbol{D}_T^{-1}\{&\boldsymbol{y}_d(k+1) - \boldsymbol{y}(k) - \boldsymbol{E}_T(\boldsymbol{y})\boldsymbol{h}(k) \\ &- T\boldsymbol{g}(k) - \boldsymbol{P}[\boldsymbol{y}_d(k) - \boldsymbol{y}(k)]\} \end{aligned} \quad (5)$$

where $\boldsymbol{P} = \mathrm{diag}\{p_i\}$ $(i = \alpha,\ \beta,\ \phi)$ is the gain matrix and $\boldsymbol{y}_d$ is the value which filtered $\boldsymbol{y}_c$ by a low pass filter. From Eqs. (4) and (5), the equation of the output error $\boldsymbol{e}_s(k) = \boldsymbol{y}_d(k) - \boldsymbol{y}(k)$ is

$$\boldsymbol{e}_s(k+1) = \boldsymbol{P}\boldsymbol{e}_s(k). \quad (6)$$

And if p_i is selected to satisfy $0 < p_i < 1$, the output error $\boldsymbol{e}_s(k)$ tends to zero as k tends to infinity.

Second, the control input for the fast state (Eq. (3)) is defined as

$$\begin{aligned} \boldsymbol{u}(k) = \boldsymbol{B}_T^{-1}\{&\boldsymbol{x}_d(k+1) - \boldsymbol{A}_T(\boldsymbol{x})\boldsymbol{x}(k) \\ &- \boldsymbol{C}_T(\boldsymbol{x})\boldsymbol{w}(k) - \boldsymbol{\Lambda}[\boldsymbol{x}_d(k) - \boldsymbol{x}(k)]\} \end{aligned} \quad (7)$$

where $\boldsymbol{\Lambda} = \mathrm{diag}\{\lambda_i\}$ $(i = p,\ q,\ r)$ is the gain matrix and $\boldsymbol{x}_d$ is the value which filtered $\boldsymbol{x}_c$ by a low pass filter. From Eqs. (3) and (7), the equation of the output error $\boldsymbol{e}_f(k) = \boldsymbol{x}_d(k) - \boldsymbol{x}(k)$ is

$$\boldsymbol{e}_f(k+1) = \boldsymbol{\Lambda}\boldsymbol{e}_f(k). \quad (8)$$

And if λ_i is selected to satisfy $0 < \lambda_i < 1$, the output error $\boldsymbol{e}_f(k)$ tends to zero as k tends to infinity.

3.2 Estimation by unscented Kalman filter

In the case of unknown parameters, we introduce the matrices $\hat{\boldsymbol{A}}_T(\boldsymbol{x})$, $\hat{\boldsymbol{B}}_T(\boldsymbol{x})$, $\hat{\boldsymbol{C}}_T(\boldsymbol{x})$, etc. those coefficients are estimated values of the coefficients in $\boldsymbol{A}_T(\boldsymbol{x})$, $\boldsymbol{B}_T(\boldsymbol{x})$, $\boldsymbol{C}_T(\boldsymbol{x})$, etc., respectively. Moreover, these matrices include the state variables. Therefore, states and parameters are estimated for the improvement of the control performance. For estimation of the parameters and state variables of nonlinear systems, UKF is used [9]. The UKF calculates the covariance of estimation by using the finite sample point that is called a sigma point around the mean. Then, sigma points are propagated through the nonlinear functions, and statistic is approximated, nonlinear system is estimated. Because the correction by the sample point is done, error margins are smaller than EKF. A detailed explanation of the UKF is omitted for want of space.

For Eqs. (5) and (7), the augmented state vector $\bar{\boldsymbol{x}}$ to estimate the parameters at the same time by

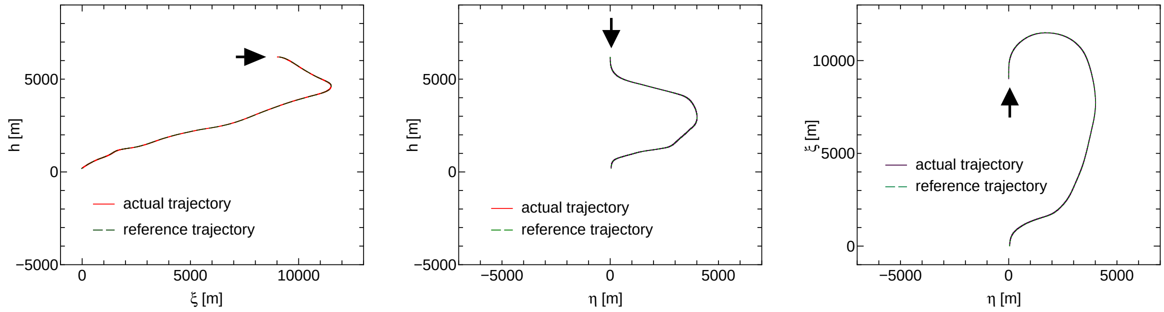

Fig. 2 Flight trajectory

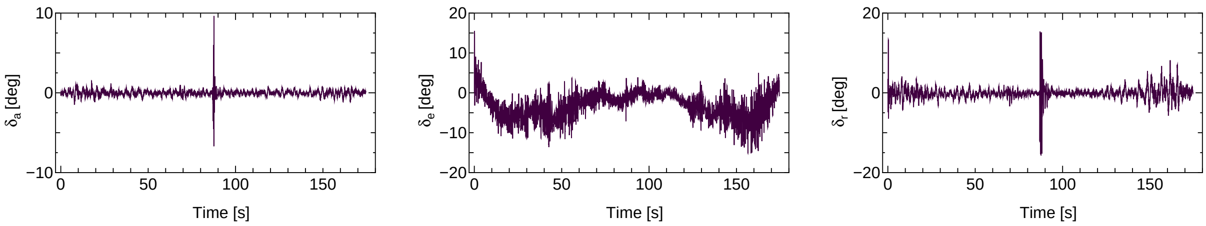

Fig. 3 Input

the UKF is introduced as follows:

$$\begin{aligned}\bar{\boldsymbol{x}}(k) =& [p\ q\ r\ \alpha\ \beta\ \phi\ \theta\ V_{TAS}\ I_{xx}\ I_{yy}\ I_{zz}\ I_{xz} \\ & L_p\ L_r\ M_q\ N_p\ N_r\ L_{\delta_a}\ L_{\delta_r}\ M_{\delta_e}\ N_{\delta_a}\ N_{\delta_r} \\ & L_\beta\ M_\alpha\ N_\beta\ \frac{X}{m}\ \frac{Y}{m}\ \frac{Z}{m}]^T \end{aligned} \tag{9}$$

And the augmented measurement vector is $\bar{\boldsymbol{y}}(k) = [p\ q\ r\ \alpha\ \beta\ \phi\ \theta\ V_{TAS}]^T$.

4 Simulation

To validate the adaptive control system described above, computer simulations for a 6-DOF nonlinear winged rocket model [13] considering the atmospheric fluctuation are performed.

The simulation condition is follows. When the winged rocket is in level flight those velocity is 93[m/s], the guidance is started at $h = 6200$[m], $\xi = 9000$[m] and $\eta = 0$[m] in altitude, downrange and crossrange, respectively. Moreover, the wind shear that the wind velocity in a downrange direction rapidly changes from -10[m/s] to 10[m/s] while flying was generated by about the 2500[m] in altitude. The guidance to the target point uses optimal trajectory generation using a genetic algorithm (GA) [14] which is a real-time guidance method. This method performs orbital optimization using GA, in order to suit flight environment without a preplanned reference trajectory and to generate a flexible trajectory, and it outputs an angle of attack command and a bank angle command required in order to realize the trajectory. The guidance is updated every 1[s]. The aerodynamic coefficient of the winged rocket uses the value obtained from the wind tunnel examination result. The actuators of elevons and rudders are used that the attenuation coefficient $\zeta = 0.7$ and the natural frequency $\omega_n = 72$[rad/s]. The sampling period of the control system is $T = 0.01$[s]. The gains are $\lambda_p = 0.94$, $\lambda_q = 0.92$, $\lambda_r = 0.94$, $p_\alpha = 0.95$, $p_\beta = 0.96$ and $p_\phi = 0.97$. The time constants of the low-pass filters for p, q, r, α and β are 0.2, 0.3, 0.5, 0.5 and 0.5[s], respectively. The UKF [9] is utilized for state and parameter estimation.

Fig. 2 shows the flight trajectory. From Fig. 2, we can see that the winged rocket can follows the reference trajectory. Fig. 3 shows the time history of the control input commands to the actuators. And Fig. 4 shows the time history of the output $\boldsymbol{y}$ and the estimated error $e_* = * - \bar{*}$. In Fig. 4 a dashed lines show the desired value obtained from the guidance. Since the wind shear is considered in this simulation, from Fig. 3 we can see that the input commands have vibrations with small amplitude. However, from Fig. 4, it can be seen that the estimation by the UKF is performed good and the output $\boldsymbol{y}$ follows the desired value. From the simulation result, it can be confirmed that the applied control method is effective for the flight control of the winged rocket.

5 Conclusion

In this paper, we propose a digital adaptive feedback linearization control method using UKF to a winged rocket. From the numerical simulation, we showed that the control system of the winged rocket has a good control performance.

Abstract: Underwater Vehicle-Manipulator Systems (UVMS) are expected to make important roles in ocean exploration. The manipulator operations in underwater need information of position between an object of capture and the vehicle. Therefore, sensors that measure position and attitude of the objects must be mounted on UVMS. We have been developing a stereovision system for UVMS. In this paper, to verify the effectiveness of the proposed stereovision system equipped to a floating UVMS, experiments on position and attitude control of the UVMS are done.

Keywords: Underwater Robot, Manipulator, Stereovision System

1 Introduction

Underwater robots are expected to make important roles in ocean exploration and many studies on Underwater Vehicle-Manipulator Systems (UVMS) are performed in recent years [1–5]. However there are only a few experimental studies. We have proposed digital Resolved Acceleration Control (RAC) methods for UVMS [6,7] and the effectiveness of the RAC methods has been demonstrated by using a floating underwater robot with vertical planar 2-link manipulator.

Here, underwater robots having small size manipulators have been used in real situations. Manipulator operations in underwater need information of position between object of capture and vehicle. Therefore, sensors that measure position and attitude of the objects must be mounted on UVMS.

We have been developing a stereovision system for UVMS. In this paper, to verify the effectiveness of the proposed stereovision system equipped to a floating UVMS, experiments on position and attitude control of the UVMS are done. The experimental results show the effectiveness of the stereovision system.

2 Configuration of Experimental System

2.1 UVMS

The underwater robot used in this paper is shown in Fig. 1. The robot has a robot base (vehicle) and a 2-link manipulator. By six thrusters equipped in the robot base, three-dimensional movement is possible. In addition, two waterproof cylinders has been equipped on front and rear of the robot. The one of cylinders is for a stereovision system and the other is for balance weights.

	Base	Link 1	Link 2
Mass [kg]	104.52	4.65	4.65
Volume [$\times 10^{-3}$ m^3]	108.04	3.3	3.1
Moment of inertia [kgm^2]	2.40	0.075	0.075
Link length (x axis) [m]	0.870	0.35	0.28
Link length (y axis) [m]	0.640	-	-
Link length (z axis) [m]	0.335	-	-
Link diameter[m]	-	0.13	0.13
Added mass(x) [kg]	73.19	0.35	0.35
Added mass(y) [kg]	30.57	3.31	3.31
Added mass(z) [kg]	99.54	3.31	3.31
Added moment of inertia [kgm^2]	1.28	0.06	0.06
Drag coefficient(x)	1.2	0	0
Drag coefficient(y)	1.2	1.0	1.0
Drag coefficient(z)	1.2	1.0	1.0

Fig. 1 2 link underwater robot

2.2 Stereovision system

Fig. 2 shows our developing stereovision system for UVMS. The size of the system is 540×140×136[mm] and the mass is 2.2[kg].

The stereovision system is equipped with two CCD cameras that can pan and tilt individually by

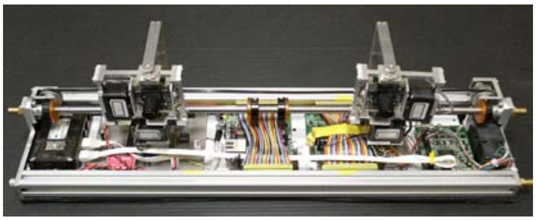

Fig. 2 Stereovision system

Table 1 Motor specification

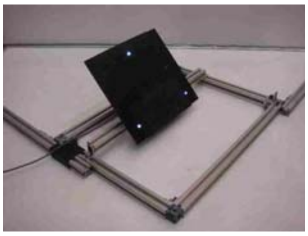

Fig. 3 LED marker

servo actuators. Moreover, the stereovision system has a slide mechanism by one stepping motor; it is possible to vary the distance between the cameras for avoiding occlusions. Table 1 shows specifications of the motors. Moving from side to side two cameras, the stereovision system control pan/tilt angle of the cameras to track the measurement object at the center of image surface. By doing this, the position and attitude can be obtained from that angles and measuring coordinates on the pixel surface of the cameras. the specification of the CCD camera to shoot object is shown in Table 2. In this paper, measurement object is flat object that has three radiants. Fig. 3 shows the LED marker for measurement. The cameras change of each pan/tilt angle to track the centroid of the three radiants.

3 Measurement Method

In this section, we explain the position and attitude measurement method using the stereovision system shown in Fig. 2.

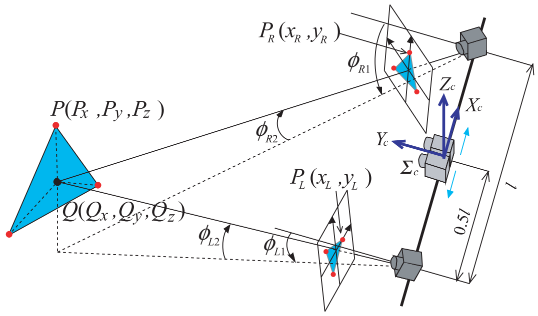

Fig. 4 Measurement model

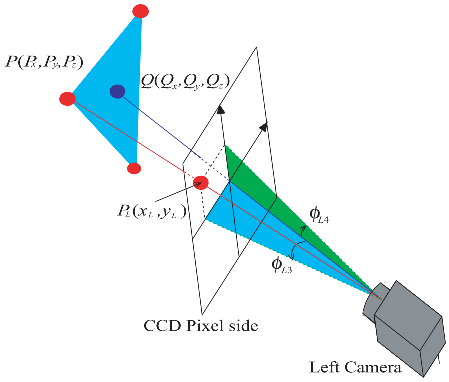

Fig. 5 Camera coordinate system

Fig. 4 shows the measurement model of Fig. 2. From Fig. 4, position of centroid of the object, $Q(q_x, q_y, q_z)$, can be calculated from the geometric relationship as follows:

$$\left.\begin{aligned} q_x &= 0.5l - k\sin\theta_{R_1}, \\ q_y &= k\cos\theta_{R_1}, \\ q_z &= k\tan\theta_{R_2} \end{aligned}\right\} \tag{1}$$

where

$$k = \frac{\cos\theta_{L_1}}{\sin(\theta_{R_1} - \theta_{L_1})}l, \quad \theta_{*_1} = \phi_{*_1}, \quad \theta_{*_2} = \phi_{*_2}.$$

Fig. 5 shows the camera coordinate system of the left camera. In Fig. 5, position of a radiant on the pixel surface is defined as $P_L(x_L, y_L)$. In the similar manner, $P_R(x_R, y_R)$ for the right camera is also defined. Positions of three radiants $P_i(x_i, y_i, z_i)$ $(i = 1, 2, 3)$ are similarly obtained by transforming Eq. (1) as follows:

$$\begin{gathered} \theta_{*_1} = \phi_{*_1} - \phi_{*_3}, \quad \theta_{*_2} = \phi_{*_2} + \phi_{*_4}, \\ \phi_{*_3} = \tan^{-1}\left(\frac{x_*}{f}\right), \quad \phi_{*_4} = \tan^{-1}\left(\frac{y_*}{f}\right) \end{gathered} \tag{2}$$

where f is the focal length. Using $P_i(x_i, y_i, z_i)$ the normal vector of the plane through three points, $\boldsymbol{m} = [u, v, w]^T$, can be obtained:

$$\boldsymbol{m} = \begin{bmatrix} (y_2 - y_1)(z_3 - z_1) - (y_3 - y_1)(z_2 - z_1) \\ (z_2 - z_1)(x_3 - x_1) - (z_3 - z_1)(x_2 - x_1) \\ (x_2 - x_1)(y_3 - y_1) - (x_3 - x_1)(y_2 - y_1) \end{bmatrix}. \tag{3}$$

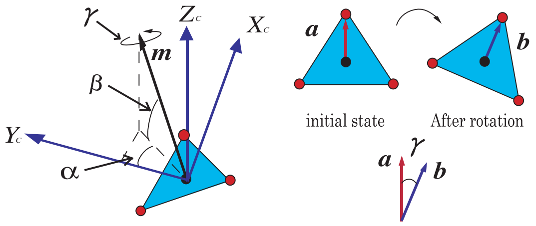

Fig. 6 Attitude

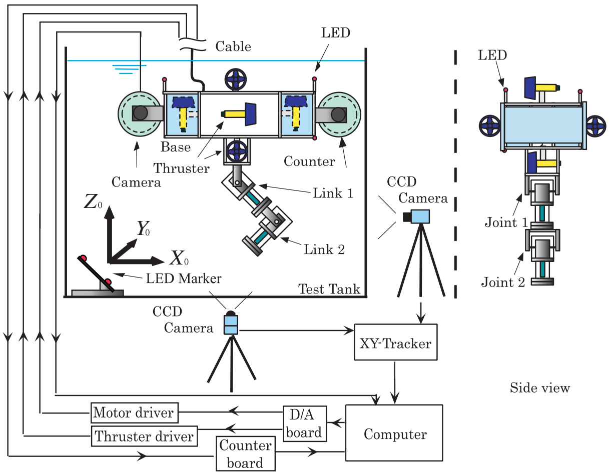

Fig. 7 Configuration of experimental system

The attitude of the measurement object is defined by the angle between the normal vector and the coordinate plane as shown in Fig 6. From Fig 6, attitude angles α and β are described as follows:

$$\alpha = -\text{atan2}\,(u,\ v)\,,\quad \beta = \text{atan2}\left(w,\ \sqrt{u^2+v^2}\right). \tag{4}$$

Moreover, in the initial state, $\boldsymbol{a}$ is defined as vector between Q and P_1, and $\boldsymbol{b}$ is defined as vector between Q and P_1 after rotation. From $\boldsymbol{a}$ and $\boldsymbol{b}$, the third attitude angle γ is described as follows:

$$\gamma = \cos^{-1}\left(\frac{\boldsymbol{a}^T\boldsymbol{b}}{||\boldsymbol{a}||||\boldsymbol{b}||}\right). \tag{5}$$

4 Experiments

In this section, PI control experiments are done to verify the effectiveness of the stereovision system for control of UVMS using the experimental system shown in Fig. 7.

The origin of the inertial coordinate frame is defined to the center of gravity of the LED marker. The LED marker is fixed to the bottom of the water tank. Position and attitude of the UVMS are calculated by measured information of the LED marker obtained from the stereovision system. Also, the pose of UVMS can be obtained by two CCD cameras (XY-Tracker) have been located outside of the tank. We compare the experimental results that controlled by stereovision system with the other controlled by XY-Tracker.

The experiments are carried out under the following condition. Two experimental conditions are the same. The sampling period is T=1/30[s]. The initial position is set up $(X,\ Y,\ Z)$ = $(0.4,\ 0,\ 0.9)$[m] on the inertial coordinate frame and the desired position and attitude of the base is set up $(X,\ Y,\ Z)$ = $(0.4,\ 0,\ 0.75)$[m]. The proportional and integral gains of the controller are $(P_x,\ P_y,\ P_z,\ P_r,\ P_p,\ P_y)$ = $(1.0,\ 1.5,\ 3,\ 1,\ 2,\ 1)$ and $(I_x,\ I_y,\ I_z,\ I_r,\ I_p,\ I_y)$ = $(0.8,\ 0.8,\ 0.9,\ 0.6,\ 0.6,\ 0.4)$.

Fig. 8 and 9 show experimental results. From results, the stereovision system of the present work similar to XY-Tracker. Therefore, the use of stereovision system to UVMS is considered to be effective.

5 Conclusion

In this paper, we proposed a stereovision system for UVMS. The effectiveness of the proposed stereovision system was demonstrated by using a floating underwater robot. The experimental results show the effectiveness of the stereovision system.

Abstract: This paper deals with a control scheme for underwater vehicle-manipulator systems with the dynamics of thrusters in the presence of uncertainties in system parameters. We have developed a regressor-based adaptive and a robust controller that overcome thruster nonlinearities, which cause an uncontrollable system. However, the structure of the adaptive controller is very complex due to the feedforward terms including the regressors of dynamic system models, and the error feedback gains of the robust controller with a good control performance are excessively high due to the lack of feedforward terms. In this paper we develop an adaptive controller that uses radial basis function networks instead of the feedforward terms. The replacement leads to a moderately high gain controller whose structure is simpler than that of the regressor-based adaptive controller.

Keywords: adaptive control, radial basis function network, thruster dynamics, underwater vehicle-manipulator system

1 INTRODUCTION

Adaptive or robust control schemes for autonomous underwater vehicles with manipulators, referred to as underwater vehicle-manipulator system (UVMS), have recently been developed in the presence of uncertainties in system parameters [1, 2]. In a general type of UVMS, the vehicle is propelled by marine thrusters, whereas the manipulator is driven by electrical motors. Despite such a different actuator system, the existing control schemes in [1, 2] were designed based on the dynamic system models without the thruster dynamics to obtain a simply structured controller. In each control scheme, furthermore, a high gain control system is constructed in order to achieve a good control performance. However, the vehicle propelled by marine thrusters generally has a considerably slower time response than the manipulator driven by electrical motors [2], and hence the high gains may excite the ignored thruster dynamics, which degrades a control performance and may even cause instability.

In order to overcome the problem, we have developed a regressor-based adaptive controller for UVMS with the thruster dynamics [3]. The adaptive control inputs are composed of adaptive feedforward signals including the regressors of the dynamic system models, and error feedback signals. Since the slow thruster dynamics is taken into consideration in the controller development, the control performance can be improved by the high gain feedback terms. However, the structure of the adaptive controller is very complex due to the regressors. On the other hand, we have developed a robust controller where the adaptive term is removed completely [4]. Although it has a much simpler structure than that of the adaptive controller, the removal leads to an excessively high gain controller, which may cause saturation or oscillations in the control inputs, to achieve a good control performance.

In this paper we develop an adaptive controller that uses radial basis function (RBF) networks, a type of neural network, instead of the adaptive terms including the regressors (see Fig. 1). The replacement leads to a moderately high gain controller whose structure is simpler than that of the regressor-based adaptive controller [3].

2 UVMS MODEL

Consider an underwater vehicle equipped with a Dm link manipulator with revolute joints. Let Dv and De be the numbers of dimensions for the vehicle's and the manipulator end-effector's motions, respectively. We assume without loss of generality that $Dm = De$.

As in [1, 5], the mathematical model of a UVMS with thruster dynamics is expressed as

$$\left.\begin{aligned} &M(\phi)\ddot{x}(t) + f(\phi, u) = J(\phi)^{-T}\begin{bmatrix} \bar{R}(\phi)\bar{K}D(v)v(t) \\ \tau_m(t) \end{bmatrix} \\ &\dot{v}(t) = -\frac{1}{2}AD(v)v(t) + \frac{1}{2}B\tau_b(t) \end{aligned}\right\} \quad (1)$$

$$\left.\begin{aligned} &M(\phi) = J(\phi)^{-T}\bar{M}(\phi)J(\phi)^{-1} \\ &f(\cdot) = J(\phi)^{-T}[\bar{f}(\phi, u) - \bar{M}(\phi)J(\phi)^{-1}\dot{J}(\phi, u)u(t)] \\ &D(v) = \mathrm{diag}\{|v_1|, \ldots, |v_{Dv}|\} \end{aligned}\right\} \quad (2)$$

where $D(\cdot) \in R^{Dv\times Dv}$, $v_i(t)$ is the ith element of $v(t)$, and the explanation of the main symbols is shown in Table 1.

In this paper, the backstepping control technology is used to develop an adaptive controller. To this end, the state $v(t)$ has to be replaced by the new one $z(t) = D(v)v(t)$. Rewriting the signal $D(v)v(t)$ as $z(t)$ in the model (1), we obtain the new representation

$$\left.\begin{aligned} &M(\phi)\ddot{x}(t) + f(\phi, u) = H(\phi)^T K\begin{bmatrix} z(t) \\ \tau_m(t) \end{bmatrix} \\ &\dot{z}(t) = -AD(v)z(t) + BD(v)\tau_b(t) \end{aligned}\right\} \quad (3)$$

$$\left.\begin{aligned} &H(\phi) = R(\phi)^T J(\phi)^{-1} \\ &R(\phi) = \begin{bmatrix} \bar{R}(\phi) & 0 \\ 0 & I_m \end{bmatrix}, \quad K = \begin{bmatrix} \bar{K} & 0 \\ 0 & I_m \end{bmatrix} \end{aligned}\right\} \quad (4)$$

where $R(\cdot),\ K \in R^{Dn\times Dn}$ and $I_m \in R^{Dm\times Dm}$ is an identity matrix.

The model (3) has the following properties useful for our controller development [1, 5]:

P1) The diagonal elements of A, B and $\bar{K}$ are positive constants, and there exists a positive constant c_B such that $c_B\|\bar{y}\|^2 \le \bar{y}^T B\bar{y}$ for any $\bar{y} \in R^{Dv}$.

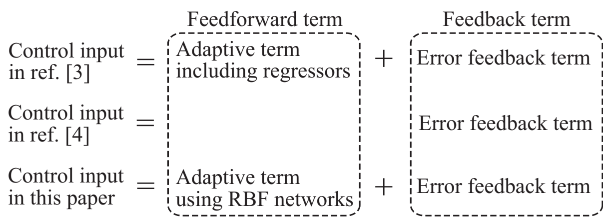

Fig. 1. Comparison of our controllers

Table 1. Symbols in the model (1)

Da	Number of dimensions for vehicle's orientation and manipulator's joint angles
Dn	Number of dimensions $Dv + De = Dv + Dm$
$x(t)$	Signal composed of vehicle's and manipulator end-effector's positions and orientations ($\in R^{Dn}$)
$\phi(t)$	Signal composed of vehicle's orientation and manipulator's joint angles ($\in R^{Da}$)
$u(t)$	Signal composed of vehicle's translational velocity and $\dot\phi(t)$ ($\in R^{Dn}$)
$\tau_m(t)$	Joint torques of manipulator ($\in R^{Dm}$)
$J(\phi)$	Jacobian matrix in the equation $\dot x(t) = J(\phi)u(t)$ ($\in R^{Dn\times Dn}$)
$\bar R(\phi)$	Transformation matrix from thrust forces to force and torque concerning inertial coordinate system ($\in R^{Dv\times Dv}$)
$\bar M(\phi)$	Inertia matrix ($\in R^{Dn\times Dn}$)
$\bar f(\cdot)$	Signal composed of centrifugal, Coriolis, gravitational and buoyant forces, and fluid drag ($\in R^{Dn}$)
$v(t)$	Shaft velocities of thruster's propellers ($\in R^{Dv}$)
$\tau_b(t)$	Shaft torques of thruster's propellers ($\in R^{Dv}$)
A, B, $\bar K$	Diagonal matrices composed of thruster's system parameters ($\in R^{Dv\times Dv}$)

P2) Each of $J(\phi)$ and $R(\phi)$ is composed of kinematic parameters and the functions of $\phi(t)$. Moreover, if each of $J(\phi)$ and $R(\phi)$ has a full rank, then there exists a positive constant c_{H2K} such that $c_{H2K}\|\bar x\|^2 \le \bar x^T H(\phi)^T K H(\phi)\bar x$ for any $\bar x \in R^{Dn}$.
P3) If $J(\phi)$ has a full rank, then $M(\phi)$ is symmetric and positive definite, and there exists a positive constant c_M such that $\|M(\phi)\| \le c_M$.

3 CONTROLLER DESIGN

The control objective is to develop a controller so that all the signals in the closed loop system can be bounded and the state $x(t)$ can track the desired trajectory $x_r(t)$ under the condition that the dynamic and hydrodynamic parameters (e.g., mass and a drag coefficient) are unknown constants.

In order to meet the objective, we make the following assumptions about the model (3) and the reference model (i.e., the desired trajectory $x_r(t)$):
A1) The signals $\phi(t)$, $x(t)$, $u(t)$ and $v(t)$ are available.
A2) The kinematic parameters in (3) (e.g., length) are known constants.
A3) Each of the matrices $J(\phi)$ and $R(\phi)$ in (3) has a full rank.
A4) The desired trajectory $x_r(t)$ and the derivatives $\dot x_r(t)$, $\ddot x_r(t)$ and $x_r^{(3)}(t)$ exist and are bounded.
It follows from the property P2 and the assumptions A1 and A2 that $J(\phi)$ and $R(\phi)$ are known matrices, and hence $\dot x(t)$ is available by using the equation $\dot x(t) = J(\phi)u(t)$.

In the following subsections we develop a controller that achieves the control objective by using a two-step backstepping procedure, as shown in Fig. 2. The first step is the design of an adaptive controller for the inputs $z(t)$ and $\tau_m(t)$, called Adaptive Controller I in this paper. The second step is the design of an adaptive controller for the input $\tau_b(t)$, called Adaptive Controller II in this paper. In this step we first replace $z(t)$, determined in the first step, by the desired trajectory $z_r(t)$, and then design the control input $\tau_b(t)$ so that $z(t)$ can track $z_r(t)$.

3.1 Adaptive Controller I

According to the design procedure shown in Fig. 2, we make the following assumption in the design of Adaptive Controller I:
A5) The control inputs are $z(t)$ for vehicle control and $\tau_m(t)$ for manipulator control.

In order to achieve the control objective described above, we use the tracking errors

$$\tilde s(t) = \dot{\tilde x}(t) + \alpha\tilde x(t), \quad \tilde x(t) = x(t) - x_r(t) \tag{5}$$

where $\alpha > 0$ is a constant design parameter. Using the first equations of (3) and (5), we have the error models

$$\left.\begin{aligned} M(\phi)\dot{\tilde s}(t) &= H(\phi)^T K\begin{bmatrix} z(t) \\ \tau_m(t)\end{bmatrix} - \frac{1}{2}\dot M(\cdot)\tilde s(t) \\ &\qquad - H(\phi)^T K f_x(n_x) - \tilde x(t) \\ \dot{\tilde x}(t) &= -\alpha\tilde x(t) + \tilde s(t) \end{aligned}\right\} \tag{6}$$

$$\begin{aligned} f_x(n_x) = K^{-1}H(\phi)^{-T}\{f(\cdot) - \frac{1}{2}\dot M(\cdot)\tilde s(t) \\ - M(\phi)[\alpha\dot{\tilde x}(t) - \ddot x_r(t)] - \tilde x(t)\} \end{aligned} \tag{7}$$

where $n_x(\cdot) \in R^{5Dn+Da}$ is composed of $\phi(t)$, $x(t)$, $x_r(t)$, $\dot x_r(t)$, $\ddot x_r(t)$ and $u(t)$. In a subsequent analysis, the control input $z(t)$ will contain $n_x(t)$. Moreover, the time derivative of $z(t)$ (i.e., the time derivative of $n_x(t)$) will have to be used in the control input $\tau_b(t)$ of Adaptive Controller II. However, the signal $n_x(t)$ includes $u(t)$ whose time derivative is not directly available, and hence we divide $n_x(t)$ into $u(t)$ and $n_{x1}(t)$ composed of $\phi(t)$, $x(t)$, $x_r(t)$, $\dot x_r(t)$ and $\ddot x_r(t)$ whose time derivatives are directly available.

In this paper, the nonlinear term $f_x(n_x)$ in the error model (6) is replaced by the following RBF network and compensated by Adaptive Controller I:

$$f_x(n_x) = \Theta_x\omega_x(n_x) + \delta_x(n_x) \tag{8}$$

where $\Theta_x \in R^{Dn\times Dx}$ is a constant parameter, $\delta_x(n_x)$ is an approximation error, and $\omega_x(\cdot) \in R^{Dx}$ is a signal whose ith element is given by

$$\omega_{xi}(n_x) = e^{-\|n_x(t)-\bar n_{x1i}\|^2/\bar n_{x2i}^2} \tag{9}$$

where $\bar n_{x1i} \in R^{5Dn+Da}$ and $\bar n_{x2i} \in R$ are constant design parameters. In order to obtain an adequate approximation accuracy, the network dimensions Dx is chosen to be sufficiently high so that the following assumption can be satisfied:
A6) There exists a positive constant $c_{\delta x}$ such that $\|\delta_x(n_x)\| \le c_{\delta x}$ for any $n_x(\cdot) \in \bar R_x$, where $\bar R_x$ is a compact subset of R^{5Dn+Da}.
The assumption A6 is a reasonable assumption because it is shown in [6] that an RBF network can approximate any continuous function on a compact set.

The adaptive control law for the error model (6) subject to the assumptions A1 to A6 is given by

$$\begin{bmatrix} z(t) \\ \tau_m(t)\end{bmatrix} = \hat\Theta_x(t)\omega_x(n_x) - \alpha H(\phi)\tilde s(t) \tag{10}$$

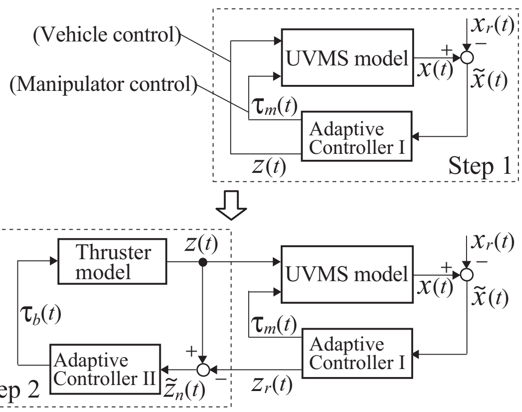

Fig. 2. Controller design procedure

where $\hat{\Theta}_x(t)$, the estimate of Θ_x, is generated by the adaptive law

$$\dot{\hat{\Theta}}_x(t) = -\sigma_{x1}\hat{\Theta}_x(t) - \sigma_{x2}H(\phi)\tilde{s}(t)\omega_x(n_x)^T \qquad (11)$$

where $\sigma_{x1},\,\sigma_{x2} > 0$ are constant design parameters. It can be shown that the adaptive controller (10) and (11) guarantees an ultimate boundedness of the tracking error $\tilde{x}(t)$.

3.2 Adaptive Controller II

According to the design procedure shown in Fig. 2, we make the following assumption instead of the assumption A5 in the design of Adaptive Controller II:

A7) The control inputs are $\tau_b(t)$ for vehicle control and $\tau_m(t)$ for manipulator control.

As shown in Fig. 2, we first replace the input $z(t)$ in (10) by the desired trajectory $z_r(t)$, i.e.,

$$\begin{bmatrix} z_r(t) \\ \tau_m(t) \end{bmatrix} = \hat{\Theta}_x(t)\omega_x(n_x) - \alpha H(\phi)\tilde{s}(t) \qquad (12)$$

and then design Adaptive Controller II by using the tracking error of $z(t)$. When we choose the error as the normal one $\tilde{z}_n(t) = z(t) - z_r(t)$, the error model is written as $\dot{\tilde{z}}_n(t) = -AD(v)z(t) - \dot{z}_r(t) + BD(v)\tau_b(t)$. This model has a situation where the system is uncontrollable due to the lack of the rank of $BD(v)$ when some of $v_i(t)$ equal zero. This situation is caused by the thruster nonlinearities. In order to avoid the situation, we propose the following error instead of the normal one $\tilde{z}_n(t)$:

$$\tilde{z}(t) = z(t) - z_r(t) + \frac{2}{\epsilon}\,l(v) \qquad (13)$$

$$\left.\begin{array}{l} l(v) = \{I_v - E(v)\}\,\bar{v}(v) \\ E(v) = \mathrm{diag}\left\{e^{-|v_1|}, \ldots, e^{-|v_{Dv}|}\right\} \\ \bar{v}(v) = [\mathrm{sgn}(v_1), \ldots, \mathrm{sgn}(v_{Dv})]^T \end{array}\right\} \qquad (14)$$

where $\bar{v}(\cdot) \in R^{Dv}$, $E(\cdot) \in R^{Dv\times Dv}$, $I_v \in R^{Dv\times Dv}$ is an identity matrix, and $\epsilon > 0$ is a design parameter. It should be noted that $l(v)$ is bounded for all $v(t)$. As a result of adding the term $l(v)$, the error model of $\tilde{z}(t)$ is expressed as

$$\dot{\tilde{z}}(t) = BL(v)\tau_b(t) - Bf_z(n_z) - \bar{I}^TKH(\phi)\tilde{s}(t) \qquad (15)$$

$$\left.\begin{array}{l} L(v) = D(v) + \frac{1}{\epsilon}E(v), \quad \bar{I} = \begin{bmatrix} I_v \\ 0 \end{bmatrix} \\ f_z(n_z) = B^{-1}[AL(v)z(t) - \bar{I}^TKH(\phi)\tilde{s}(t) + \xi(t) \\ \qquad + \bar{I}^T\{Y(\dot{u})y_2(t) - \alpha H(\phi)J(\phi)\dot{u}(t)\}] \\ \xi(t) = \bar{I}^T\{y_1(t) + \dot{\hat{\Theta}}_x(t)\omega_x(n_x) - \alpha\dot{H}(\cdot)\tilde{s}(t) \\ \qquad -\alpha H(\phi)[\dot{J}(\cdot)u(t) - \ddot{x}_r(t) + \alpha\dot{\tilde{x}}(t)]\} \\ y_1(t) = -2\,\hat{\Theta}_x(t)\bar{Y}_1(n_x)\dot{n}_{x1}(t) \\ y_2(t) = -2\begin{bmatrix} \bar{Y}_2(n_x)^T\hat{\theta}_{x1}(t) \\ \vdots \\ \bar{Y}_2(n_x)^T\hat{\theta}_{xDn}(t) \end{bmatrix} \\ \bar{Y}_1(n_x) = \begin{bmatrix} \bar{\omega}_1(n_x)[n_{x1}(t) - \bar{n}_{x111}]^T \\ \vdots \\ \bar{\omega}_{Dx}(n_x)[n_{x1}(t) - \bar{n}_{x11Dx}]^T \end{bmatrix} \\ \bar{Y}_2(n_x) = \begin{bmatrix} \bar{\omega}_1(n_x)[u(t) - \bar{n}_{x121}]^T \\ \vdots \\ \bar{\omega}_{Dx}(n_x)[u(t) - \bar{n}_{x12Dx}]^T \end{bmatrix} \\ Y(\dot{u}) = \begin{bmatrix} \dot{u}(t)^T & & 0 \\ & \ddots & \\ 0 & & \dot{u}(t)^T \end{bmatrix}, \; \bar{\omega}_i(n_x) = \dfrac{\omega_{xi}(n_x)}{\bar{n}_{x2i}^2} \end{array}\right\} \qquad (16)$$

$$\hat{\Theta}_x(t) = \begin{bmatrix} \hat{\theta}_{x1}(t)^T \\ \vdots \\ \hat{\theta}_{xDn}(t)^T \end{bmatrix}, \; \bar{n}_{x1i} = \begin{bmatrix} \bar{n}_{x11i} \\ \bar{n}_{x12i} \end{bmatrix} \qquad (17)$$

where $\bar{I} \in R^{Dn\times Dv}$, $Y(\cdot) \in R^{Dn\times(Dn)^2}$, $\bar{n}_{x11i} \in R^{4Dn+Da}$, $\bar{n}_{x12i} \in R^{Dn}$, $\bar{Y}_1(\cdot) \in R^{Dx\times(4Dn+Da)}$, $\bar{Y}_2(\cdot) \in R^{Dx\times Dn}$, $\hat{\theta}_{xi} \in R^{Dx}$, and $\bar{\omega}_i \in R$. In the derivation of (15), we use the equation

$$\hat{\Theta}_x(t)\dot{\omega}_x(n_x, \dot{n}_x) = y_1(t) + Y(\dot{u})y_2(t), \qquad (18)$$

which is modified so that $\hat{\Theta}_x(t)\dot{\omega}_x(\cdot)$ in $\dot{z}_r(t)$ can be separated into the unavailable signal $\dot{u}(t)$ and the available ones $y_1(t)$ and $y_2(t)$. It is noteworthy that the coefficient matrix $BL(v)$ of the input $\tau_b(t)$ in the error model (15) has a full rank for all $v(t)$, and hence the error model is controllable in spite of the thruster nonlinearities.

The nonlinear term $f_z(n_z)$ in the error model (15) is replaced by an RBF network in a way similar to the design of Adaptive Controller I. For the replacement of a function (e.g., $y = f(x)$) by an RBF network, it is necessary to identify not the structure but the arguments of a function replaced (i.e., x of $f(x)$). In view of the fact that the arguments of the unavailable signal $\dot{u}(t)$ are $\phi(t)$, $u(t)$, $v(t)$ and $\tau_m(t)$ (i.e., $\dot{u}(\phi, u, v, \tau_m)$), it can be seen from the third equation of (16) that the argument $n_z(t)$ of $f_z(n_z)$ is composed of $\phi(t)$, $u(t)$, $\tilde{s}(t)$, $v(t)$, $\tau_m(t)$, $y_2(t)$ and $\xi(t)$. The nonlinear term $f_z(n_z)$ is replaced by the following RBF network:

$$f_z(n_z) = \Theta_z\omega_z(n_z) + \delta_z(n_z) \qquad (19)$$

where $\Theta_z \in R^{Dv\times Dz}$ is a constant parameter, $\delta_z(n_z)$ is an approximation error, and $\omega_z(n_z) \in R^{Dz}$ is a signal whose ith element is given by

$$\omega_{zi}(n_z) = e^{-\|n_z(t) - \bar{n}_{z1i}\|^2/\bar{n}_{z2i}^2} \qquad (20)$$

where $\bar{n}_{z1i} \in R^{(Dn+3)Dn+Da+Dv}$ and $\bar{n}_{z2i} \in R$ are constant design parameters. We make the following assumption in common with the assumption A6:

A8) There exists a positive constant $c_{\delta z}$ such that $\|\delta_z(n_z)\| \le c_{\delta z}$ for any $n_z(\cdot) \in \bar{R}_z$, where $\bar{R}_z$ is a compact subset of $R^{(Dn+3)Dn+Da+Dv}$.

The adaptive control law for the error model (15) subject to the assumptions A1 to A4, A7 and A8 is given by

$$\tau_b(t) = L(v)^{-1}[\hat{\Theta}_z(t)\omega_z(n_z) - \alpha\tilde{z}(t)] \qquad (21)$$

where $\hat{\Theta}_z(t)$, the estimate of Θ_z, is generated by the adaptive law

$$\dot{\hat{\Theta}}_z(t) = -\sigma_{z1}\hat{\Theta}_z(t) - \sigma_{z2}\,\tilde{z}(t)\omega_z(n_z)^T \qquad (22)$$

where $\sigma_{z1},\,\sigma_{z2} > 0$ are constant design parameters.

For Adaptive Controller I and II, the following theorem holds:

Theorem 1 Consider the adaptive controller (11), (12), (21) and (22) for the error models (6) and (15) subject to the assumptions A1 to A4 and A6 to A8. This controller guarantees that signals in the closed loop system are bounded, and that the tracking error $\tilde{x}(t)$ satisfies the inequality

$$\|\tilde{x}(t)\|^2 \le \rho_1\,e^{-\gamma\alpha t} + \frac{\rho_2}{\alpha^2\bar{\epsilon}} \qquad (23)$$

where $\rho_1,\,\rho_2 > 0$ are positive constants, $\bar{\epsilon} = \min\{1, \epsilon^2\}$, and $\gamma = \min\{c_{H2K}/(2\,c_M),\,1,\,c_B\}$.

Proof: We can prove Theorem 1 in a way similar to the proofs of the main theorems in [3, 4].

4 SIMULATION EXAMPLE

In order to confirm the usefulness of the adaptive controller (11), (12), (21) and (22), we performed numerical simulations. Typical simulation results are presented in this paper. The UVMS simulated here was an underwater vehicle with a two-link manipulator, as shown in Fig. 3. The values of its system parameters (excepting thruster's parameters) were the same as those used in [3, 4]. In this figure, only the values of the main parameters are shown. The system parameters of the thrusters were given by $A = (1/T)I_3$, $B = (612.5/T)I_3$, $\bar{K} = 0.0408I_3$, where $I_3 \in R^{3\times 3}$ is an identity matrix and T is a positive constant. These values were determined so that the steady state responses could be roughly the same as those of the experimental results in [7], whereas the transient responses are changed by the parameter T. It should be noted that the time responses of the thrusters become slower with an increase in the parameter T. The design parameters of the proposed adaptive controller were chosen as $\alpha = 100$, $\sigma_{x1} = \sigma_{z1} = 0.01$, $\sigma_{x2} = \sigma_{z2} = 1$, $\epsilon = 10$, $Dx = Dz = 50$, $\bar{n}_{x2i} = \bar{n}_{z2j} = 3$, $\hat{\Theta}_{xki}(0) = \hat{\Theta}_{zhj}(0) = 0$ where $\hat{\Theta}_{xki}(\cdot)$ and $\hat{\Theta}_{zhj}(\cdot)$ are the (k, i)th and the (h, j)th element of $\hat{\Theta}_x(\cdot)$ and $\hat{\Theta}_z(\cdot)$, respectively. In addition, the design parameters $\bar{n}_{x1i}$ and $\bar{n}_{z1j}$ were set as points into which the interval of each variable corresponding to $n_x(t)$ and $n_z(t)$ is divided equally. Each of the desired trajectories of the vehicle's and the manipulator end-effector's position was set up along a straight path. Each of the velocities was given by a filtered trapezoidal function. In these simulations, the time at which each of the desired trajectories reaches a target point was about 15 seconds. On the other hand, the desired trajectory of the vehicle's orientation is selected to remain at the initial value.

In order to investigate an effect of thruster dynamics on a control performance, we performed simulations using a controller for UVMS without thruster dynamics, called Static Controller in this paper. Static Controller is composed of (11), (12) and the static model $\tau_b(t) = B^{-1}Az_r(t)$, which is obtained from the second equation of (3) when $\dot{z}(t) = 0$. Figure 4 shows the tracking errors of Static Controller for $T = 0.01, 0.1, 1$. It is worth noting that an unstable robot motion was observed when $T > 1$. It can be seen from this figure that the tracking error increases with an increase in the parameter T. This means that a slow thruster dynamics degrades a control performance when Static Controller is used. On the other hand, Fig. 5 shows the tracking errors of the adaptive controller (11), (12), (21) and (22) for $T = 1, 10, 100$. As shown in this figure, the tracking errors are roughly the same and remain small in the three cases, irrespective of the parameter T.

In order to compare the proposed adaptive controller with the robust controller developed in [4], we performed simulations using the robust controller. Figure 6 shows the tracking errors of the adaptive and the robust controller for $T = 1$. It can be seen from this figure that the tracking error of the proposed adaptive controller is smaller than that of the robust controller. It is noteworthy that the steady state error of the adaptive controller is considerably reduced, particularly after the desired trajectories reach the target points.

5 CONCLUSION

In this paper we developed an adaptive controller for underwater vehicle-manipulator systems with thruster dynamics. In the controller development we presented a new tracking error model that overcomes uncontrollability caused by the thruster dynamics, and then designed the adaptive controller with radial basis function networks. Furthermore, the usefulness of the proposed controller was demonstrated by the simulation results.

Abstract: We have proposed a model reference adaptive control scheme (conventional control scheme) for continuous time single-input single-output linear systems with an input saturation in which i-th derivatives of the output signal ($i = 1, \cdots$, relative degree) are available. In the conventional scheme, a condition for the initial states of the controlled object has to be satisfied. In this paper, the main attention is focused on the relaxation of the condition. To achieve the objective, we propose an improve adaptive control scheme. As a result of analyzing stability of the closed loop system using the improved adaptive control scheme, a new condition for the initial states is derived. It should be emphasized that we can apply the new control scheme in a larger region of initial states compared with the conventional one.

Keywords: adaptive control, input saturation, order of systems, improvement of control performance, relaxation of restrict condition

1 INTRODUCTION

In practice, the values of the system parameters, that are coefficients of dynamic equations describing behavior of physical systems, vary due to aged deterioration or environmental changes. For the systems, adaptive control schemes [1]-[3] were useful. However, input saturation was ignored in the early works. To overcome the problem, various adaptive control schemes have been developed for single-input single-output (SISO) linear systems [4]-[16]. These schemes guarantee boundedness of all signals in the closed loop systems. But most of them could not assure asymptotical stability of a tracking error between the output of the controlled object and a desired trajectory. Although there exist some schemes that can assure asymptotical stability of the tracking error, they have a problem that controlled objects are restricted to asymptotically stable systems. Moreover, in all proposed schemes, there exists a problem that a method to improve tracking performance have not been provided.

To struggle against these problems, for the first step, the authors proposed an adaptive output tracking control scheme for SISO linear systems with an input saturation in which full states can be measured [17]. The closed loop system using the proposed controller has the following properties: 1) Stability of all signals in the closed loop systems can be guaranteed; 2) Convergence of the tracking error to zero is assured even for unstable controlled objects; 3) Setting only one design parameter, the control performance can be easily improved. For the next step, to decrease measurement signals, for n-th degree systems with an input saturation and the relative degree n_r, we proposed an extended scheme satisfying 1)-3) in which i-th derivatives of output signal ($i = 1, \cdots, n_r$) are only required [18]. However, to achieve the good properties 1)-3), the condition for the initial states of the controlled object has to be satisfied.

In this paper, the main attention is to relax the condition for the initial states derived in [18]. We propose an improved adaptive controller for SISO linear systems with an input saturation in which the output derivatives up to the order of relative degree n_r are available. In the proposed adaptive controller, it is shown theoretically that the same good properties 1)-3) can be assured under a new condition for the initial states. Moreover, it can be shown theoretically that the improved adaptive controller can be utilized in a larger region of initial states compared with the adaptive control scheme proposed in [18].

2 PROBLEM STATEMENT

In this paper, we consider the controlled objects described by

$$\left.\begin{aligned} Y(s) &= \frac{b_m B_p(s)}{A_p(s)}F(s) + \frac{C_p(s)}{A_p(s)} \\ A_p(s) &= s^n + a_{n-1}s^{n-1} + \cdots + a_1 s + a_0 \\ B_p(s) &= s^m + b_{m-1}s^{m-1} + \cdots + b_1 s + b_0 \\ C_p(s) &= c_{n-1}s^{n-1} + \cdots + c_1 s + c_0 \end{aligned}\right\} \tag{1}$$

where $A_p(s)$ and $B_p(s)$ are coprime. $f(u) = \mathcal{L}[F(s)]^{-1} \in \mathbb{R}$ is a saturation function given by

$$f(u) = \begin{cases} \sigma & \text{for} \quad u(t) > \sigma \\ u(t) & \text{for} \quad |u(t)| \le \sigma \\ -\sigma & \text{for} \quad u(t) < -\sigma \end{cases} \tag{2}$$

where $u(t) \in \mathbb{R}$ is the control input and the positive constant σ is an amplitude saturation level of the actuator.

The reference model is given by

$$\left.\begin{aligned} Y_M(s) &= \frac{B_M(s)}{A_M(s)}R(s) \\ A_M(s) &= s^{n_M} + a_{M(n_M-1)}s^{n_M-1} + \cdots + a_{M1}s + a_{M0} \\ B_M(s) &= b_{Mm_M}s^{m_M} + \cdots + b_{M1}s + b_{M0} \end{aligned}\right\} \tag{3}$$

where $y_M(t) = \mathcal{L}^{-1}[Y_M(s)]$ is the reference output, $r(t) = \mathcal{L}^{-1}[R(s)]$ is the reference input, $A_M(s)$ is Hurwitz polynomia, and $n_M - m_M \ge n - m$. The reference input $r(t)$ is a deterministic signal given by

$$\left.\begin{aligned} R(s) &= \frac{B_R(s)}{A_R(s)} \\ A_R(s) &= s^{n_r} + a_{R(n_r-1)}s^{n_r-1} + \cdots + a_{R1}s + a_{R0} \\ B_R(s) &= b_{Rm_r}s^{m_r} + \cdots + b_{R1}s + b_{R0} \end{aligned}\right\} \tag{4}$$

where $A_R(s)$ and $B_R(s)$ are known polynomials, and $n_r - m_r \ge 0$.

The tracking error is defined as $y_e(t) = y(t) - y_M(t)$. Then, using the polynomials

$$\left.\begin{array}{l} A_p(s) = A_{pq}(s)B_p(s) + A_{pr}(s) \\ A_{pq}(s) = s^{n-m} + a_{q(n-m-1)}s^{n-m-1} + \cdots + a_{q1}s + a_{q0} \\ A_{pr}(s) = a_{r(m-1)}s^{m-1} + \cdots + a_{r1}s + a_{r0} \end{array}\right\}, \quad (5)$$

the following state space description can be derived [18].

$$\left.\begin{array}{l} \dot{\boldsymbol{x}}_e(t) = \boldsymbol{A}\boldsymbol{x}_e(t) + b_m\boldsymbol{b}\left(f(u) - \boldsymbol{c}_z^\top \boldsymbol{z}(t) - \boldsymbol{\theta}_r^\top \boldsymbol{x}_r(t) + \phi(t)\right) \\ \boldsymbol{x}_e(t) = \left[y_e(t),\ \dot{y}_e(t),\ \cdots,\ y_e(t)^{(n-m-1)}\right]^\top \\ \boldsymbol{A} = \overline{\boldsymbol{A}} - \boldsymbol{b}\boldsymbol{a}_q^\top,\ \boldsymbol{b}^\top = [0, \cdots, 0, 1] \\ \overline{\boldsymbol{A}} = \left[\begin{array}{c|c} \boldsymbol{0} & \boldsymbol{I} \\ \hline 0 & 0 \cdots 0 \end{array}\right],\ \boldsymbol{a}_q^\top = [a_{q0}, \cdots, a_{q(n-m-1)}] \\ \boldsymbol{c}_z^\top = [a_{r0}, \cdots, a_{r(m-1)}] \\ \dot{\boldsymbol{x}}_r(t) = \boldsymbol{A}_r\boldsymbol{x}_r(t),\ \boldsymbol{x}_r(0) = \boldsymbol{x}_{r0} \end{array}\right\} \quad (6)$$

$$\left.\begin{array}{l} \dot{\boldsymbol{z}}(t) = \boldsymbol{A}_z\boldsymbol{z}(t) + \boldsymbol{h}\boldsymbol{c}_x^\top \boldsymbol{x}_e(t),\ \boldsymbol{z}(0) = \boldsymbol{0} \\ \boldsymbol{A}_z = \left[\begin{array}{c|c} \boldsymbol{0} & \boldsymbol{I} \\ \hline -b_0 & -b_1 \cdots - b_{m-1} \end{array}\right] \\ \boldsymbol{h}^\top = [0, \cdots, 0, 1/b_m],\ \boldsymbol{c}_x^\top = [1, 0, \cdots, 0] \end{array}\right\} \quad (7)$$

Where $\phi(t)$ is an unknown bounded exponential damping function, $\boldsymbol{\theta}_r$ is an unknown parameter, $\boldsymbol{A}_r$ is known constant matrix, and $\boldsymbol{x}_r(t) \in \mathbb{R}^{n_M+n_r}$ is a known state with respect to the reference model.

Using a known constant vector $\boldsymbol{d} \in \mathbb{R}^{n-m}$, the Hurwitz matrix $\boldsymbol{A}_e$ is defined as $\boldsymbol{A}_e = \overline{\boldsymbol{A}} - \boldsymbol{b}\boldsymbol{d}^\top$. Then, defining the signal $\ell(t) = \boldsymbol{c}_z^\top \boldsymbol{z}(t)$, the tracking error system (6) can be rewritten as

$$\left.\begin{array}{l} \dot{\boldsymbol{x}}_e(t) = \boldsymbol{A}_e\boldsymbol{x}_e(t) + b_m\boldsymbol{b}\left(f(u) - q(t)\right) \\ q(t) = \boldsymbol{\theta}(t)^\top \boldsymbol{\omega}(t) + \ell(t),\ \ell(t) = \boldsymbol{c}_z^\top \boldsymbol{z}(t) \\ \boldsymbol{\theta}(t)^\top = \dfrac{1}{\varepsilon}\left[\phi(t),\ \boldsymbol{\theta}_e^\top,\ \boldsymbol{\theta}_r\right],\ \varepsilon \geq 1 \\ \boldsymbol{\omega}(t)^\top = \varepsilon\left[-1,\ \boldsymbol{x}_e(t),\ \boldsymbol{x}_r(t)\right] \\ \boldsymbol{\theta}_e = \dfrac{1}{b_m}(\boldsymbol{a}_q - \boldsymbol{d}) \end{array}\right\} \quad (8)$$

where $\boldsymbol{\theta}(t)$ and $\ell(t)$ are unknown signals. The design parameter ε is a positive constant. The design parameter ε is introduce to reduce the initial value $\|\boldsymbol{\theta}(0)\|$.

The controlled objective is that the tracking error becomes asymptotically stable even if a controlled object is not asymptotically stable. To achieve the controlled objective, the following assumptions are made:

A1 Coefficients of polynomials $A_p(s)$, $B_p(s)$ and $C_p(s)$ are unknown constants.
A2 The plant is minimal phase.
A3 Sign of b_m is known. It is assumed that the sign is positive hereafter.
A4 Relative degree $n - m$ is known.
A5 $y(t)^{(i)},\ i = 0, \cdots, n - m - 1$ are available.
A6 There exists a known positive constant δ_z such that $\overline{\boldsymbol{A}}_z = \boldsymbol{A}_z + \delta_z\boldsymbol{I}$ is Hurwitz matrix.
A7 There exists bounded positive constant $\overline{\rho}_{M1}$ and $\overline{\rho}_{M2}$ such that $|\boldsymbol{\theta}_r\boldsymbol{x}_r(t) - \phi(t)| \leq \overline{\rho}_{M1}$ and $\|\boldsymbol{x}_r(t)\| \leq \overline{\rho}_{M2}$.
A8 The relation $\sigma - \overline{\rho}_{M1} > 0$ holds.
A9 The saturation level σ is known.

The assumptions A1 ~ A4 are the same assumptions made in conventional adaptive control scheme. From the assumption A2, $\boldsymbol{A}_z$ becomes Hurwitz. Since $\phi(t)$ is bounded exponential damping function, it is also seen that there exist positive constants ρ_ϕ, δ_ϕ such that $\left\|\dot{\phi}(t)\right\| \leq \rho_\phi \exp(-\delta_\phi t)$. The assumptions A5 ~ A9 are introduced to develop the adaptive controller mentioned later. From the assumption A5, the signal $\boldsymbol{x}_e(t)$ is available.

3 DEVELOPMENT OF ADAPTIVE CONTROLLER

3.1 Conventional adaptive controller

In [18], the controller developed under the assumptions A1~A9 is given by

$$\left.\begin{array}{l} u(t) = \hat{q}(t) = \hat{\boldsymbol{\theta}}(t)^\top \boldsymbol{\omega}(t) + \hat{\ell}(t) \\ \hat{\boldsymbol{\theta}}(t) = \left[\hat{\theta}_\phi(t),\ \hat{\boldsymbol{\theta}}_e(t)^\top,\ \hat{\boldsymbol{\theta}}_r(t)\right]^\top \end{array}\right\}, \quad (9)$$

$$\left.\begin{array}{l} \dot{\hat{\boldsymbol{\theta}}}(t) = -\alpha^3 g(t)\tilde{\boldsymbol{x}}_e(t)^\top \boldsymbol{P}\boldsymbol{b}\boldsymbol{\Gamma}\boldsymbol{\omega}(t),\ \boldsymbol{\Gamma} > 0 \\ \dot{\hat{\ell}}(t) = -\delta_z\hat{\ell}(t) - \dfrac{1}{\rho_\ell}\alpha^3 g(t)\tilde{\boldsymbol{x}}_e(t)^\top \boldsymbol{P}\boldsymbol{b},\ \hat{\ell}(0) = 0 \\ \tilde{\boldsymbol{x}}_e(t) = \boldsymbol{x}_e(t) - \hat{\boldsymbol{x}}_e(t) \\ \dot{\hat{\boldsymbol{x}}}_e(t) = \boldsymbol{A}_e\hat{\boldsymbol{x}}_e(t) + \alpha^2\tilde{\boldsymbol{x}}_e(t),\ \hat{\boldsymbol{x}}_e(0) = \boldsymbol{x}_e(0) \\ g(t) = 1 - (1-\beta)(1 - \delta_{\tilde{e}f}(t)),\ 1 \geq \beta > 0 \\ \delta_{\tilde{e}f}(t) = \begin{cases} 1 & \text{for} \quad \tilde{\boldsymbol{x}}_e(t)^\top \boldsymbol{P}\boldsymbol{b}\tilde{f}(u) \leq 0 \\ 0 & \text{for} \quad \tilde{\boldsymbol{x}}_e(t)^\top \boldsymbol{P}\boldsymbol{b}\tilde{f}(u) > 0 \end{cases} \\ \tilde{f}(u) = f(u) - u(t) \end{array}\right\}, \quad (10)$$

where $\hat{\theta}_\phi(t)$, $\hat{\boldsymbol{\theta}}_e(t)$ and $\hat{\boldsymbol{\theta}}_r(t)$ are estimate values corresponding to the unknown signal $\phi(t)/\varepsilon$ and constants $\boldsymbol{\theta}_e/\varepsilon$ and $\boldsymbol{\theta}_r/\varepsilon$, respectively. $\hat{\boldsymbol{x}}_e(t)$ and $\hat{\ell}(t)$ are estimates of $\boldsymbol{x}_e(t)$ and $\ell(t)$, respectively. The design parameters α and β are positive constants, $\boldsymbol{\Gamma}$ is a positive definite matrix. The design parameter ρ_ℓ is a positive constant satisfying

$$\left.\begin{array}{l} \rho_\ell \leq \dfrac{\delta_z}{b_m}\left\{\left(\dfrac{4}{\underline{\alpha}} + \dfrac{6}{\rho_{\tilde{e}}}\right)\dfrac{\|\boldsymbol{c}_z^\top \boldsymbol{h}\boldsymbol{c}_x^\top\|^2}{\lambda_{\min}[\boldsymbol{Q}]} + \dfrac{4\|\boldsymbol{c}_z^\top \overline{\boldsymbol{A}}_z\|^2}{\rho_z\lambda_{\min}[\boldsymbol{Q}_z]}\right\}^{-1} \\ \rho_z = \left(\dfrac{4}{\underline{\alpha}} + \dfrac{6}{\rho_{\tilde{e}}}\right)^{-1}\dfrac{\lambda_{\min}[\boldsymbol{Q}_z]}{4}\dfrac{\lambda_{\min}[\boldsymbol{Q}]}{\|\boldsymbol{P}_z\boldsymbol{h}\boldsymbol{c}_x^\top\|^2} \\ \rho_{\tilde{e}} = \dfrac{\lambda_{\min}[\boldsymbol{Q}]}{6}\left(\dfrac{\|\boldsymbol{P}\|}{\underline{\alpha}}\right)^{-1} \end{array}\right\}, \quad (11)$$

where $\underline{\alpha}$ denotes a lower bound of the design parameter α such that $\alpha > \underline{\alpha} > 0$, design parameters $\boldsymbol{Q}$ and $\boldsymbol{Q}_z$ are positive definite matrices. $\boldsymbol{P}$ and $\boldsymbol{P}_z$ are the solutions of the following Lyapunov equations.

$$\left.\begin{array}{l} \boldsymbol{A}_e^\top \boldsymbol{P} + \boldsymbol{P}\boldsymbol{A}_e = -\boldsymbol{Q},\ \boldsymbol{Q} > 0 \\ \boldsymbol{A}_z^\top \boldsymbol{P}_z + \boldsymbol{P}_z\boldsymbol{A}_z = -\boldsymbol{Q}_z,\ \boldsymbol{Q}_z > 0 \end{array}\right\} \quad (12)$$

The estimated signal $\hat{\boldsymbol{x}}_e(t)$ and the design parameter α is introduced to improve performance of the estimators for $\hat{\boldsymbol{\theta}}(t)$ and $\hat{\ell}(t)$. The design parameter β is introduced to guarantee tracking performance between the control input signal $\hat{q}(t)$ and the ideal input signal $q_d(t) = \boldsymbol{\theta}(t)^\top \boldsymbol{\omega}(t) + \ell(t)$. The switch function $\delta_{\tilde{e}f}(t)$ is introduced to assure stability of the closed loop system with the input saturation.

To show the property of the closed loop system, we define the following Lyapunov function candidate

$$\left.\begin{array}{l} V(t) = V_1(t) + \rho_{v2}V_2(t) \\ V_1(t) = \alpha^3\tilde{\boldsymbol{x}}_e(t)^\top \boldsymbol{P}\tilde{\boldsymbol{x}}_e(t) + V_e(t) \\ \qquad + \rho_z\boldsymbol{z}(t)^\top \boldsymbol{P}_z\boldsymbol{z}(t) + b_m\rho_\ell\tilde{\ell}(t)^2 \\ \qquad + b_m\tilde{\boldsymbol{\theta}}(t)^\top \boldsymbol{\Gamma}^{-1}\tilde{\boldsymbol{\theta}}(t) \\ V_2(t) = \dfrac{2\rho_\phi\sqrt{b_m}\left\|\boldsymbol{\Gamma}^{-\frac{1}{2}}\right\|}{\varepsilon\delta_\phi}\exp(-\delta_\phi t) \\ \rho_{v2} = \dfrac{V_2(0) + \sqrt{V_2(0)^2 + 4V_1(0)}}{2} + \delta_v \\ \tilde{\ell}(t) = \ell(t) - \hat{\ell}(t),\ \tilde{\boldsymbol{\theta}}(t) = \boldsymbol{\theta}(t) - \hat{\boldsymbol{\theta}}(t) \end{array}\right\}, \quad (13)$$

$$V_e(t) = \rho_{\hat{e}} \hat{\boldsymbol{x}}_e(t)^\top \boldsymbol{P} \hat{\boldsymbol{x}}_e(t) \tag{14}$$

where $\tilde{\boldsymbol{\theta}}(t)$ and $\tilde{\ell}(t)$ are the parameter estimation errors, and δ_v is a design parameter of a positive constant.

Define a input estimation error $\tilde{q}(t)$ as $\tilde{q}(t) = q_d(t) - \hat{q}(t) = \tilde{\boldsymbol{\theta}}(t)^\top \boldsymbol{\omega}(t) + \tilde{\ell}(t)$. In the closed loop system using the conventional adaptive controller, the following theorem holds [18].

Theorem 1 If the initial states satisfy

$$\left.\begin{aligned}
&\rho_v^2 \geq V(0) \\
&\quad = \rho_{\hat{e}} \boldsymbol{x}_e(0)^\top \boldsymbol{P} \boldsymbol{x}_e(0) + b_m \tilde{\boldsymbol{\theta}}(0)^\top \boldsymbol{\Gamma}^{-1} \tilde{\boldsymbol{\theta}}(0) \\
&\qquad + \rho_{v2} V_2(0) \\
&\rho_v = \frac{1}{2\beta\rho_{u3}} \Big\{ -(\rho_{u1} + \beta\rho_{u2}) \\
&\qquad + \sqrt{(\rho_{u1} + \beta\rho_{u2})^2 + 4(\sigma - \bar{\rho}_{M1})\beta\rho_{u3}} \Big\} \\
&\rho_{u1} = \sqrt{2 \max\left\{ \frac{\|\boldsymbol{\theta}_e\|^2}{\rho_{\hat{e}} \lambda_{\min}[\boldsymbol{P}]}, \frac{\|\boldsymbol{c}_z\|^2}{\rho_z \lambda_{\min}[\boldsymbol{P}_z]} \right\}} \\
&\rho_{u2} = \sqrt{\frac{2}{b_m}} \max\left\{ \frac{\varepsilon \bar{\rho}_{M2}}{\lambda_{\min}\left[\boldsymbol{\Gamma}^{-\frac{1}{2}}\right]}, \frac{1}{\sqrt{\rho_\ell}} \right\} \\
&\qquad + \frac{\varepsilon}{\sqrt{b_m} \lambda_{\min}\left[\boldsymbol{\Gamma}^{-\frac{1}{2}}\right]} \\
&\rho_{u3} = \sqrt{\frac{2}{b_m \lambda_{\min}\left[\boldsymbol{\Gamma}^{-1}\right] \lambda_{\min}[\boldsymbol{P}]} \max\left\{ \frac{1}{\underline{\alpha}^3}, \frac{1}{\rho_{\hat{e}}} \right\}}
\end{aligned}\right\}, \tag{15}$$

in addition, the lower bound of the design parameter $\underline{\alpha}$ is given by

$$\underline{\alpha}^2 \geq 2 b_m \|\boldsymbol{\theta}_e\| \sqrt{\boldsymbol{b}^\top \boldsymbol{P} \boldsymbol{b} \lambda_{\min}[\boldsymbol{P}^{-1}]}, \tag{16}$$

the closed loop system using the controller (9) – (12) becomes stable, and the error signals $\boldsymbol{x}_e(t)$, $\tilde{\boldsymbol{x}}_e(t)$, $\boldsymbol{z}(t)$, $\tilde{\ell}(t)$ and $\tilde{q}(t)$ converge to zero. When the design parameters are fixed except for the design parameter α, the following relation holds.

$$\tilde{q}(t)^2 \leq \exp\left(-\alpha \bar{\rho}_{q1} t\right) \tilde{q}(0)^2 + \alpha^{-1} \bar{\rho}_{q2} \tag{17}$$

Where $\bar{\rho}_{qi},\ i = 1, 2$ are bounded positive constants independent of the design parameter α. ■

From Theorem 1, we have the following remarks.

Remark 1 It is seen from Theorem 1 that $\tilde{q}(t)$ converges to zero rapidly as the design parameter α increases. Then, the control input signal (9) becomes close to the ideal input $u(t) = q_d(t)$. Therefore, it can be expected that if the value of the design parameter α is large enough, the oscillations caused by the estimator of unknown parameters are hard to occur in the control input signal.

Remark 2 Consider the case when $\tilde{q}(t)$ converges to zero rapidly. Since $\boldsymbol{x}_e(t)$ converges to zero, from the assumption A8, it is seen that there exists $t_1 \geq 0$ such that $|q(t)| \leq \sigma,\ t_1 \geq t$. Then, for $t \geq t_1$, $\boldsymbol{x}_e(t)$ converges to zero at the convergent rate specified by the system matrix $\boldsymbol{A}_e$.

Remark 3 From (15), ρ_v becomes large as the desing parameter β decreases. The upper bound of ρ_v is

$$\lim_{\beta \to 0} \rho_v = \frac{\sigma - \bar{\rho}_{M1}}{\rho_{u1}}. \tag{18}$$

From this fact, it can be seen that if the condition

$$\left.\begin{aligned}
&\frac{(\sigma - \bar{\rho}_{M1})^2}{2} \min\left(\frac{\lambda_{\min}[\boldsymbol{P}]}{\|\boldsymbol{\theta}_e\|^2}, K_1 K_2 \right) > \boldsymbol{x}_e(0)^\top \boldsymbol{P} \boldsymbol{x}_e(0) \\
&K_1 = \frac{\lambda_{\min}[\boldsymbol{Q}_z] \lambda_{\min}[\boldsymbol{Q}] \lambda_{\min}[\boldsymbol{P}_z]}{16 \|\boldsymbol{P}_z \boldsymbol{h} \boldsymbol{c}_x^\top\|^2 \|\boldsymbol{c}_z\|^2} \\
&K_2 = \frac{6}{9 + \dfrac{\lambda_{\min}[\boldsymbol{Q}]}{\|\boldsymbol{P}\|}}
\end{aligned}\right\} \tag{19}$$

is satisfied, for any initial condition of the parameter estimation error $\tilde{\boldsymbol{\theta}}(0)$ and $V_2(0)$, there exist design parameters ε, $\boldsymbol{\Gamma}$, and β such that the first equation of (15) holds.

3.2 Improved adaptive controller

If the left side of the first equation in (19) can become large, the region of the initial states satisfying Theorem 1 can be expanded. To achieve this, the Lyapunov function candidate is redefined as (13) and

$$V_e(t) = \boldsymbol{x}_e(t)^\top \boldsymbol{P} \boldsymbol{x}_e(t). \tag{20}$$

Analyzing the derivative of (13) and (20), the improved adaptive controller is developed as (9) and

$$\left.\begin{aligned}
&\dot{\hat{\boldsymbol{\theta}}}(t) = -\alpha^3 g(t) \bar{\boldsymbol{x}}_e(t)^\top \boldsymbol{P} \boldsymbol{b} \boldsymbol{\Gamma} \omega(t),\ \boldsymbol{\Gamma} > 0 \\
&\dot{\hat{\ell}}(t) = -\delta_z \hat{\ell}(t) - \frac{1}{\rho_\ell} \alpha^3 g(t) \bar{\boldsymbol{x}}_e(t)^\top \boldsymbol{P} \boldsymbol{b},\ \hat{\ell}(0) = 0 \\
&\bar{\boldsymbol{x}}_e(t) = \tilde{\boldsymbol{x}}_e(t) + \frac{1}{\alpha^3} \boldsymbol{x}_e(t) \\
&\tilde{\boldsymbol{x}}_e(t) = \boldsymbol{x}_e(t) - \hat{\boldsymbol{x}}_e(t) \\
&\dot{\hat{\boldsymbol{x}}}_e(t) = \boldsymbol{A}_e \hat{\boldsymbol{x}}_e(t) + \alpha^2 \tilde{\boldsymbol{x}}_e(t),\ \hat{\boldsymbol{x}}_e(0) = \boldsymbol{x}_e(0) \\
&g(t) = 1 - (1 - \beta)(1 - \delta_{\tilde{e}f}(t)),\ 1 \geq \beta > 0 \\
&\delta_{\tilde{e}f}(t) = \begin{cases} 1 & \text{for} \quad \bar{\boldsymbol{x}}_e(t)^\top \boldsymbol{P} \boldsymbol{b} \tilde{f}(u) \leq 0 \\ 0 & \text{for} \quad \bar{\boldsymbol{x}}_e(t)^\top \boldsymbol{P} \boldsymbol{b} \tilde{f}(u) > 0 \end{cases} \\
&\tilde{f}(u) = f(u) - u(t)
\end{aligned}\right\}, \tag{21}$$

where the design parameter ρ_ℓ satisfies

$$\left.\begin{aligned}
&\rho_\ell \leq \frac{\delta_z}{4 b_m} \left\{ \frac{\|\boldsymbol{c}_z^\top \boldsymbol{h} \boldsymbol{c}_x^\top\|^2}{\lambda_{\min}[\boldsymbol{Q}]} + \frac{\|\boldsymbol{c}_z^\top \bar{\boldsymbol{A}}_z\|^2}{\rho_z \lambda_{\min}[\boldsymbol{Q}_z]} \right\}^{-1} \\
&\rho_z = \frac{\lambda_{\min}[\boldsymbol{Q}_z]}{16} \frac{\lambda_{\min}[\boldsymbol{Q}]}{\|\boldsymbol{P}_z \boldsymbol{h} \boldsymbol{c}_x^\top\|^2}
\end{aligned}\right\}. \tag{22}$$

Then, for the closed-loop system using the improved adaptive controller, the following theorem holds.

Theorem 2 If the initial states satisfy

$$\left.\begin{aligned}
&\rho_{v_m}^2 \geq V(0) \\
&\quad = \boldsymbol{x}_e(0)^\top \boldsymbol{P} \boldsymbol{x}_e(0) + b_m \tilde{\boldsymbol{\theta}}(0)^\top \boldsymbol{\Gamma}^{-1} \tilde{\boldsymbol{\theta}}(0) \\
&\qquad + \rho_{v2} V_2(0) \\
&\rho_{v_m} = \frac{1}{2\beta\rho_{u3}} \Big\{ -(\rho_{u1} + \beta\rho_{u2}) \\
&\qquad + \sqrt{(\rho_{u1} + \beta\rho_{u2})^2 + 4(\sigma - \bar{\rho}_{M1})\beta\rho_{u3}} \Big\} \\
&\rho_{m1} = \sqrt{\max\left\{ \frac{\|\boldsymbol{\theta}_e\|^2}{\lambda_{\min}[\boldsymbol{P}]}, \frac{\|\boldsymbol{c}_z\|^2}{\rho_z \lambda_{\min}[\boldsymbol{P}_z]} \right\}} \\
&\rho_{m2} = \frac{1}{\sqrt{b_m}} \max\left\{ \frac{\varepsilon(\bar{\rho}_{M2} + 1)}{\lambda_{\min}\left[\boldsymbol{\Gamma}^{-\frac{1}{2}}\right]}, \frac{1}{\sqrt{\rho_\ell}} \right\} \\
&\rho_{m3} = \frac{1}{\sqrt{b_m \lambda_{\min}\left[\boldsymbol{\Gamma}^{-1}\right] \lambda_{\min}[\boldsymbol{P}]}}
\end{aligned}\right\}, \tag{23}$$

the closed loop system using the controller (9), (12), (21), and (22) becomes stable, and the error signals $\boldsymbol{x}_e(t)$, $\tilde{\boldsymbol{x}}_e(t)$, $\boldsymbol{z}(t)$, $\tilde{\ell}(t)$ and $\tilde{q}(t)$ converge to zero. When the design parameters are fixed except for the design parameter α, there exist the bounded positive constant $\overline{\rho}_{qi}$, $i = 1, 2$ independent of the design parameter α satisfying (17). ■

For the lack of space, the proof is omitted. □

From Theorem 2, it can be ascertained that the properties stated in Remark 1 and Remark 2 hold. Moreover, we have the following remark for initial states.

Remark 4 From (23), ρ_{v_m} becomes large as the desing parameter β decreases. The upper bound of ρ_{v_m} is

$$\lim_{\beta\to 0}\rho_{v_m} = \frac{\sigma - \overline{\rho}_{M1}}{\rho_{m1}}. \tag{24}$$

From this fact, it can be seen that if the condition

$$(\sigma - \overline{\rho}_{M1})^2 \min\left(\frac{\lambda_{\min}[\boldsymbol{P}]}{\|\boldsymbol{\theta}_e\|^2},\ K_1\right) > \boldsymbol{x}_e(0)^{\mathrm{T}}\boldsymbol{P}\boldsymbol{x}_e(0) \tag{25}$$

is satisfied, for any initial condition of the parameter estimation error $\tilde{\boldsymbol{\theta}}(0)$ and $V_2(0)$, there exist design parameters $\varepsilon, \boldsymbol{\Gamma}$, and β such that the first equation of (23) holds.

From Remark 3 and Remark 4, we have following fact. Comparing with the value of (19) and (25), since the parameter K_2 becomes $K_2 < 1$, it can be easily ascertained that the value of the left hand side of (25) becomes at least two times larger than and equal to the value of the left side of (19). This means that the improved adaptive controller can be applied to the larger region of the initial states compared with the conventional one proposed in [18].

Therefore, it can be concluded that the improved adaptive controller can achieve good properties mentioned in Remark 1 and Remark 2 and the relaxation of the condition of the initial states.

4 CONCLUSION

In this paper, the main attention was to relax the condition for the initial states of the closed loop system using the conventional adaptive control scheme proposed in [18], we proposed the improved adaptive control scheme. Using the proposed adaptive controller, it is shown theoretically that the following properties can be achieved: 1) Stability of all signals i the closed loop systems can be guaranteed; 2) The tracking error can converges to zero even for unstable controlled objects; 3) Tracking performance can be improved by setting the only one design parameter α. Moreover, it was shown that we can apply the improved adaptive control scheme in the larger region of the initial states compared with the control scheme proposed in [18].

Abstract: In this paper, we propose a position control scheme for the rotation axis of a rotating ultrasonic sensor unit with a position adjustment mechanism. The control objective is that the position of the rotation axis can become equal to the center of a pipe. To realize the control objective, we provide a method to measure the vertical and horizontal position of the rotation axis. Using the measurements, we propose a position controller for the rotation axis. By carrying out experiments, we investigate the usefulness of the developed mechanism and the proposed position controller. As a result, it is shown that the proposed position control scheme has good performance.

Keywords: In-pipe Robot, Thickness measurement of the pipe, Ultrasonic sensor

1 INTRODUCTION

In the power generation plants, chemical plants and steel mills, the pipes may be deteriorated over time. Since these pipes have enormous length, it is a difficult task for human to inspect the deterioration state of the pipes [1]. Here, the deterioration state of the pipes means the decrease of the thickness of the pipes. To address the problem, we have developed inspection robots [2-8]. Those robots move on the outside of the pipes. Since most of such pipes are buried undergrounds or covered with the heat insulator, the high precision inspection can not be expected. For the reason, we have developed an in-pipe robot which can inspect the deterioration state from the inside of the pipes [9]. The robot has the inspection sensor unit in which ultrasonic sensors can be rotated in the circumferential direction of the pipe. However, there is a serious problem that the rotation axis in the inspection sensor unit may deviate from the center of the pipe while the in-pipe robot is moving inside the pipe. In such a case, the scanning speeds of the ultrasonic sensors are not constant and unknown. Then, the measurement precision of the thickness of the pipes may become worse.

To overcome this problem, we develop a new inspection sensor unit with a position adjustment mechanism for the rotation axis, and we propose a position control scheme. Namely, we provide a method to measure the vertical position and horizontal position of the rotation axis. Using the measurements, we propose a controller so that the position of the rotation axis can stay at the center of the pipe even if the in-pipe robot is moving inside the pipe.

2 OVERVIEW OF THE INSPECTION SYSTEM

Fig. 1 shows the overview of the in-pipe robot developed in [9]. The inspection sensor unit is attached to the front of the in-pipe robot (see the right hand side of Fig. 1). The inspection sensor unit has four inspection arms, and one ultrasonic sensor is attached on the top of the each inspection arm. Fig. 2 shows the details of the inspection arm. The inspection arm is composed of the holder part and the sliding part. Using a ball screw and a motor, the sliding

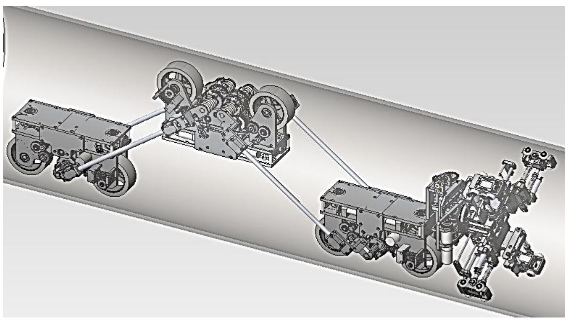

Fig. 1 Overview of the in-pipe robot.

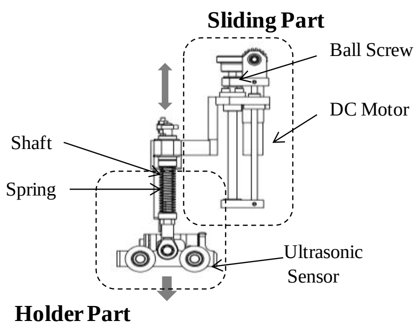

Fig. 2 Inspection arm.

part can move the holder part. There is a spring in the holder part. The ultrasonic sensor is pushed on the inner surface by the spring force. Moving the in-pipe robot and rotating the inspection arms, the all pipe thickness can be measured.

Fig. 3 shows the schematic of the initial configuration of the inspection sensor unit. The symbols l_{si} , i =1~4 are the spring strokes that are the distance from the rotation axis to the inner surface of the pipe. The symbol l_{sp} denotes the fixed stroke of the sliding part. In the initial configuration, the rotation axis corresponds to the center of the pipe. In this situation, all of the spring strokes l_{si} become same and the scanning speeds of the ultrasonic sensors become a known constant speed. Then, the high precision inspection can be expected. However, while the in-pipe robot is moving inside the pipe, the center of the in-pipe robot may move due to the influence of disturbances. In that case, the rotation axis of the inspection arms deviates from the center of the pipe. Fig. 4 shows the displacements x_p, y_p of the rotation axis. The scanning speeds of the ultrasonic sensors on the inner surface are not constant when the inspection arms are rotated. Furthermore, because of a lack of information of the position of the

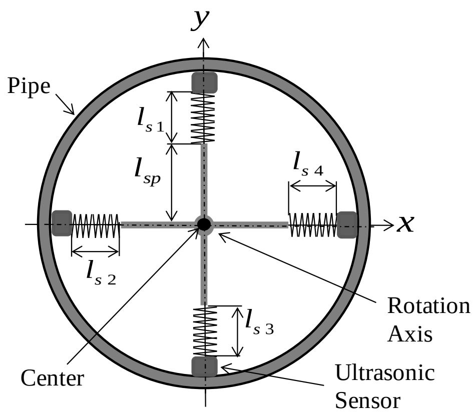

Fig. 3 Schematic of initial configuration.

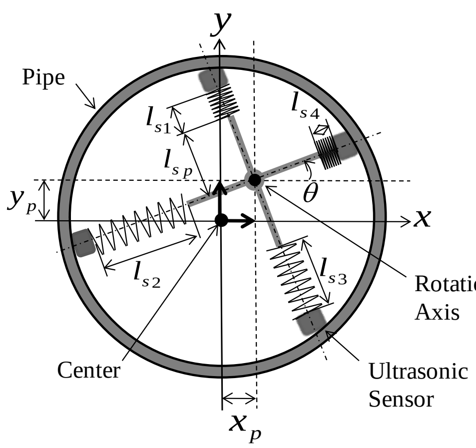

Fig. 4 Schematic in the presence of the deviation of the rotation axis.

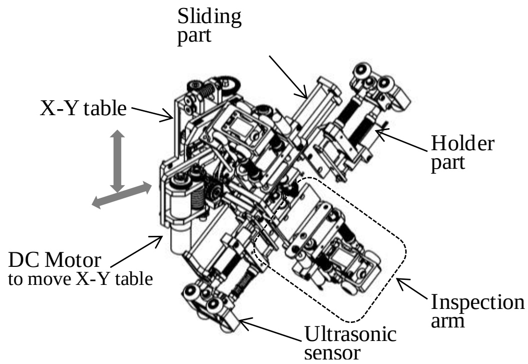

Fig. 5 Movable inspection unit.

rotation axis, the accurate location of the ultrasonic sensor cannot be obtained. Due to the influence, the measurement precision of the thickness may become worse.

3 MOVABLE INSPECTION SENSOR UNIT

To overcome the problem stated in the section 2, we develop an inspection sensor unit with a position adjustment mechanism for the rotation axis. Hereafter, the sensor unit is called the movable inspection unit. Fig. 5 shows the developed movable inspection unit. As shown in Fig. 5, the unit contains an adjustment mechanism (X-Y table) to move the rotation axis of the inspection arm. In order to make the position of the rotation axis be equal to the position of the center of the pipe, we require the displacement of the rotation axis from the center of the pipe.

3.1 Measurement of displacement of rotation axis

Fig. 6 shows the displacements x_p, y_p of the rotation axis. In Fig. 6, l_i , i =1~4 are the distances from the rotation axis to the inner surface of the pipe. The symbol θ is the rotation angle of the inspection arms. In Fig.6, x_θ and y_θ can be written by

$$x_\theta = \frac{l_4 - l_2}{2}, \quad y_\vartheta = \frac{l_3 - l_1}{2} \tag{1}$$

Using the equation (1), we have the following

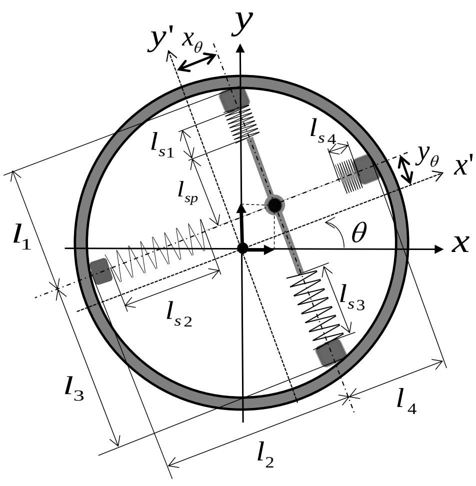

Fig. 6 The displacement of the rotation axis.

displacement of the rotation axis.

$$\begin{bmatrix} x_p \\ y_p \end{bmatrix} = \begin{bmatrix} \cos\theta & -\sin\theta \\ \sin\theta & \cos\theta \end{bmatrix} \begin{bmatrix} x_\theta \\ y_\theta \end{bmatrix} = \begin{bmatrix} \cos\theta & -\sin\theta \\ \sin\theta & \cos\theta \end{bmatrix} \begin{bmatrix} \frac{l_4 - l_2}{2} \\ \frac{l_3 - l_1}{2} \end{bmatrix} \quad (2)$$

Since the initial length of l_{sp} is fixed, the displacement of the rotation axis can be rewritten as

$$\begin{bmatrix} x_p \\ y_p \end{bmatrix} = \begin{bmatrix} \cos\theta & -\sin\theta \\ \sin\theta & \cos\theta \end{bmatrix} \begin{bmatrix} \frac{l_{s4} - l_{s2}}{2} \\ \frac{l_{s3} - l_{s1}}{2} \end{bmatrix} \quad (3)$$

In the developed movable inspection unite, the rotation angle θ and the spring strokes l_{si} can be measured. Using the measurements, we can calculate the displacements x_p, y_p of the rotation axis.

3.2 Position control of the rotation axis

To simplify the construction of the position controller, we derive a simplified model of the movable inspection sensor unit. Fig.7 shows the block diagram of the simplified model I for x axis direction. We can obtain the similar block diagram for y axis direction. In Fig. 7, u_x denotes the input signal (duty ratio ± 100%) added to DC motor to move the X-Y table, T_x is the equivalent time constant and K_x is the equivalent gain from the input to velocity $\dot{x}_p$ .The symbol d_x denotes the disturbance corresponding to the reaction force of springs which are attached to the holder parts in the inspection arms (see Fig.2). It is assumed that the equivalent time constant T_x is very short. Then, we propose a simplified model II shown in Fig. 8. Based on simplified model II, the following position controller is developed.

$$\begin{bmatrix} u_x \\ u_y \end{bmatrix} = -100 \begin{bmatrix} \operatorname{sgn} x_p \\ \operatorname{sgn} y_p \end{bmatrix} \quad (4)$$

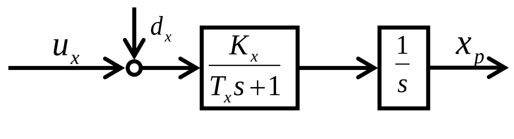

Fig. 7 Simplified model I.

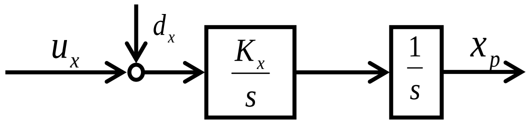

Fig. 8 Simplified model II.

4 EXAMINATIONS

4.1 Measurement of the displacement x_p, y_p

Fig. 9 shows the test equipment for the experiment of the position measurement of the rotation axis. The test equipment consists of ϕ350 acrylics pipe, the movable inspection sensor unit and the support base to fix the movable inspection sensor unit. The support base has the mechanism that the whole movable inspection sensor unit can be moved to top and bottom(y_M), right and left(x_M) by the handle operation. Using the mechanism, the position of the rotation axis can be moved from the center of pipe. The accurate displacements x_M , y_M of the rotation axis of the movable inspection unit is measured by using high precision encoders.

In the initial configuration, the position of the rotation axis and the center of the pipe are the same, and the rotation angle θ was fixed to be a certain angle. Then, the rotation axis is moved by using the handle attached to the support base, and the displacements x_p and y_p of the rotation axis are measured based on the equation (3).

The results of measurements of the displacements are shown in Figs 10-13. In Figs. 10 and 12, the horizontal axis denotes the accurate displacement x_M of the rotation axis which is moved by the handle operation. The accurate displacement y_M is fixed as $y_M = 0$. The vertical axis denotes the displacements x_p and y_p. In Figs. 11 and 13, the horizontal axis denotes the accurate displacement y_M of the rotation axis. The accurate displacement x_M is fixed as $x_M = 0$. The vertical axis denotes the displacement x_p and y_p.

As shown in Figs. 10-13, x_p and y_p are mostly same with the accurate displacements x_M and y_M . However, there exit small errors between the measurement displacements x_p , y_p and the accurate displacements x_M , y_M due to the low rigidity of the used acrylic pipe and the effect of gravity.

4.2 Position control position of the rotation axis

As with the measurement experiments of the displacement of the rotation axis, the test equipment shown

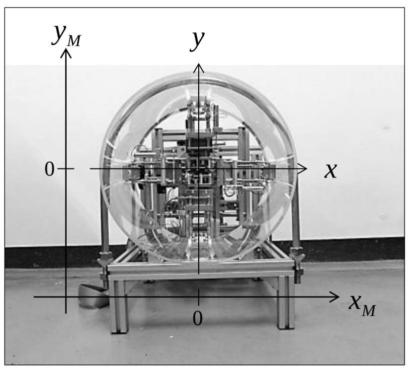

Fig. 9 The test equipment.

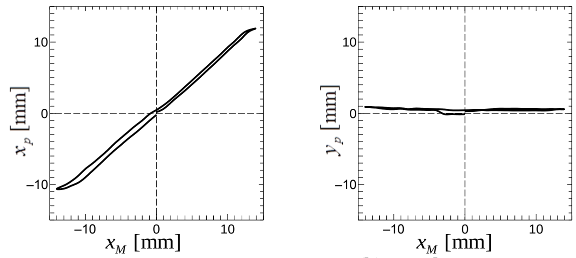
in Fig.9 is used in the position control experiments. In the initial configuration, the position of the rotation axis and the center of the pipe are the same, and the rotation angle θ was fixed to be zero. Next, the rotation axis is moved by the handle operation, and the inspection arms are rotated repeatedly within ±90[deg]. Then, the position control (4) is carried out.



(a) Displacement x_p (b) Displacement y_p

(a) x_p Response (b) y_p Response

Fig.14 Responses of the rotation axis.

Fig. 14 shows the responses of the displacements of the rotation axis. As shown in Fig. 14, the displacements x_p, y_p of the rotation axis converge to zero. Because of the effect of gravity, the convergence time of y_p becomes more quickly than that of x_p.

5 CONCLUSION

We develop an adjustment mechanism for the position of the rotation axis, and we propose the simple position controller for the adjustment mechanism. Carrying out experiments, it has been shown that the proposed position controller is very useful.

Abstract: In the case when wheeled mobile robots run fast on rough terrain, due to the robot body acceleration and oscillation, sensors mounted on the robot body may be destroyed. In this paper, we propose a scheme to reduce the body acceleration at any specified location on the robot body. In the proposed scheme, a combined ideal model is designed so that the location where acceleration performance becomes best can be moved easily by setting only two design parameters. Then, an adaptive controller is developed so that the behavior of the actual mobile robot tracks that of the combined ideal model. It is ascertained by numerical simulations that the body acceleration at any specified location can be improved easily.

Key Words: Wheeled mobile robot, Oscillation, Adaptive control.

1. INTRODUCTION

In extreme environment, for example, disaster areas and minefields, there are many dangerous tasks for human. Recently, in the environment, mobile robots working instead of human have been developed [1]-[4]. In the case when robots go over steps, due to the vertical acceleration of the robot body, sensors mounted on the robot body may be destroyed or the measurement accuracy of sensors becomes worse. Nevertheless, the problem had not been considered yet. If the acceleration at each location on the robot body is controlled so as to be zero, that problem can be resolved. However, in such a case, the mobile robot cannot go over a slope. Therefore, the controllers are designed by using trial and error method so that the body acceleration can be suppressed at only one specified location on the robot body. In this case, well oscillation suppression of the acceleration can be realized for a sensor mounted on the robot body. If measurement accuracy is required for the other sensor, we have to redesign the controller. However, it will cost a lot of time.

To overcome the problem stated above, we proposed a robust oscillation control scheme [5] that can suppress the vertical acceleration at a specified location on the robot body without any redesigning of controllers. For uncertainties of the system parameters, the excellent robust performance can be also achieved. However, there is a problem that the scheme still requires accurate information of some parts of system parameters.

In this paper, we propose an adaptive oscillation control scheme. The controller does not require any information of system parameters. At first, a combined ideal model is designed based on the state space description containing the body acceleration. In the combined ideal robot model, the location where the acceleration becomes small can be moved easily by setting only two design parameters. Next, an adaptive tracking controller is developed so that the actual robot can track the behavior of the designed combined ideal robot model. In the proposed adaptive tracking control system, for any uncertainties of system parameters, it is shown that the tracking performance can be improved by setting design parameters. At last, the usefulness of the proposed controller is shown by carrying out numerical simulations.

2. WHEELED MOBILE ROBOT

The wheeled mobile robot is shown in Fig. 1, and Fig. 2 shows the simplified model of the wheeled mobile robot. To simplify the explanation below, each large wheel is labeled as 1, 2, and 3. Each large wheel has three small wheels. In the large wheels labeled 1 and 2, the small wheels are driving wheels. The wheeled mobile robot has the mechanism that each large wheel can be rotated by the motors set at the center axis of the large wheels 1, 2 and 3. The explanations of parameters are shown in Table 1.

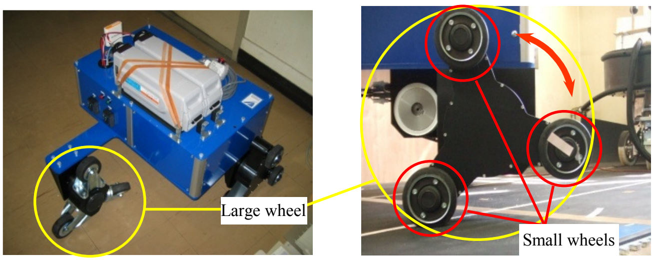

Fig. 1 Mobile robot and wheels.

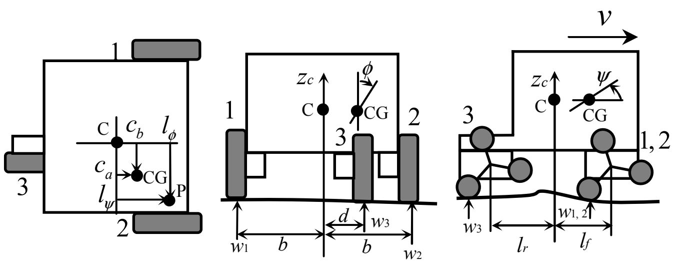

Fig. 2 Mobile robot model

Table. 1 Notation of wheeled mobile robot

C,CG	center and center of gravity of mobile robot body
z_c	vertical displacement at C
P	location on the robot body
ψ, ϕ	pitch and roll angle
x_1, x_2, x_3	vertical displacement at the center of large wheels
w_1, w_2, w_3	vertical displacement of road disturbance added to large wheels
v	longitudinal velocity of mobile robot
g	acceleration of gravity
m, i_ψ, i_ϕ	robot mass, pitch and roll moment of inertia of robot body
l_f, l_r, b, d	distance from C to large wheels
c_a, c_b	distance from C to CG
l_ψ, l_ϕ	distance from C to P
l_w	distance from the center of large wheel to the center of small wheel
k_a	voltage and torque conversion constant
r, k_G	reciprocal of armature resistance and gear ratio
j_{mL}, d_{mL}	moment of inertia and viscous damping constant between a motor and wheel center axis

It is assumed that the pitch angle ψ(t) and the roll angle ϕ(t) are small. Then, the dynamic equation of the wheeled mobile robot is given as follows.

$$\left.\begin{aligned} &M_p(t)\ddot{\boldsymbol{x}}(t) + K_d(t)\dot{\boldsymbol{x}}(t) = -K_b(t)\boldsymbol{u}(t) + D_p(t)\ddot{\boldsymbol{w}}(t) - \boldsymbol{g}_a \\ &\boldsymbol{x}(t) = \begin{bmatrix} x_1(t), & x_2(t), & x_3(t) \end{bmatrix}^T \\ &\boldsymbol{w}(t) = \begin{bmatrix} w_1(t), & w_2(t), & w_3(t) \end{bmatrix}^T \end{aligned}\right\} \quad (1)$$

$$\left.\begin{aligned} &M_c = \mathrm{diag}\begin{bmatrix} m, & i_\psi, & i_\phi \end{bmatrix} \\ &M_p(t) = \left(\left(HT_h\right)^T\right)^{-1} M_c \left(HT_h\right)^{-1} + K_j(t) \\ &D_p(t) = K_j(t) - M_p(t) \\ &H = \begin{bmatrix} 1 & l_f & -b \\ 1 & l_f & b \\ 1 & -l_r & d \end{bmatrix}, \quad T_h = \begin{bmatrix} 1 & -c_a & -c_b \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{bmatrix} \\ &K_d(t) = \theta_{kj} K_{j\theta}(t) \\ &K_j(t) = \theta_{kd1} K_{d\theta 1}(t) + \theta_{kd2} K_{d\theta 2}(t) \\ &K_b(t) = \theta_{kb} K_{d\theta}(t) \\ &\theta_{kj} = \frac{j_{mL}}{l_w^2}, \theta_{kd1} = \frac{j_{mL}}{l_w^3}, \theta_{kd2} = \frac{k_G^2 d_{mL} + r k_a^2}{k_G^2 l_w^2}, \theta_{kb} = \frac{r k_a}{k_G l_w} \\ &K_{j\theta}(t) = K_{d\theta 2}(t) = \mathrm{diag}[S_1^{-2}, S_2^{-2}, S_3^{-2}] \\ &K_{d\theta 1}(t) = \mathrm{diag}[C_1 S_1^{-4}\dot{x}_1(t), C_2 S_2^{-4}\dot{x}_2(t), C_3 S_3^{-4}\dot{x}_3(t)] \\ &K_{d\theta}(t) = \mathrm{diag}[S_1^{-1}, S_2^{-1}, S_3^{-1}] \\ &S_i = \sin(\theta_{wi}(t) + \cos^{-1}\frac{3}{4}) \\ &C_i = \cos(\theta_{wi}(t) + \cos^{-1}\frac{3}{4}) \\ &(i = 1,2,3) \end{aligned}\right\} \quad (2)$$

Where $\boldsymbol{g}_a$ is the constant vector including the gravity g and $\boldsymbol{u}(t)$ denotes an input voltage added to the motors set at the center axis of the large wheels 1, 2 and 3. In order to add a suspension characteristic to the wheeled mobile robot (1), the input voltage is given by

Table. 2 Nominal values of parameters

$$\left.\begin{aligned} &\boldsymbol{u}(t) = -\bar{K}_b^{-1}(t)(\boldsymbol{u}_a(t) - k_p \boldsymbol{x}(t) - \bar{K}_j(t)\ddot{\boldsymbol{w}}(t) + \bar{\boldsymbol{g}}_a) \\ &\bar{K}_b(t) = \bar{\theta}_{kb} K_{b\theta}(t), \bar{K}_j(t) = \bar{\theta}_{kj} K_{j\theta}(t) \end{aligned}\right\} \quad (3)$$

where $\boldsymbol{u}_a(t)$ is the new input signal introduced to control the acceleration of the robot body. The parameter $\bar{\bullet}$ denotes the parameters$\bullet$ in which the values of element are nominal values shown in table 2.

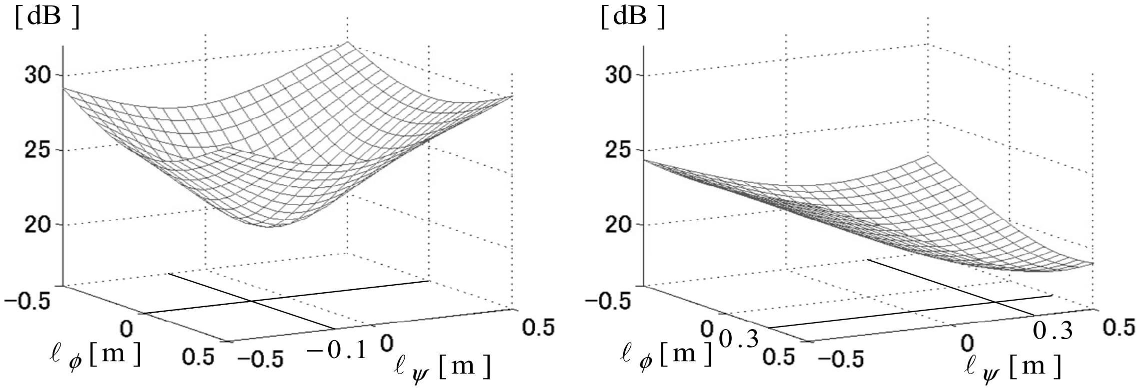
To develop a controller achieving a small acceleration of the robot body, the state space description including the acceleration of the robot body is introduced as follows. The symbols O_n, I_n used below denote $n\times n$ zero matrix and $n\times n$ unit matrix.

$$\left.\begin{aligned} &\dot{\xi}(t) = (\Gamma - B_\xi M_p^{-1}(t) F(t)^T)\xi(t) + B_\xi M_p^{-1}(t)\frac{\theta_{kb}}{\bar{\theta}_{kb}}\boldsymbol{\mu}(t) \\ &\quad + D_1(t)\ddot{\boldsymbol{w}}(t) + D_2(t)\dddot{\boldsymbol{w}}(t) - B_\xi M_p^{-1}(t)\left(\boldsymbol{g}_a - \frac{\theta_{kb}}{\bar{\theta}_{kb}}\bar{\boldsymbol{g}}_a\right) \\ &\boldsymbol{\mu}(t) = \dot{\boldsymbol{u}}_a(t) + \boldsymbol{u}_a(t), \\ &\xi(t) = \begin{bmatrix} \boldsymbol{x}(t)^T & \dot{\boldsymbol{x}}(t)^T & (H\ddot{\boldsymbol{q}}(t))^T \end{bmatrix}^T, \ddot{\boldsymbol{q}}(t) = \begin{bmatrix} \ddot{z}_c(t) & \ddot{\psi}(t) & \ddot{\phi}(t) \end{bmatrix}^T \end{aligned}\right\} \quad (4)$$

$$\left.\begin{aligned} &\Gamma = \begin{bmatrix} O_3 & I_3 & O_3 \\ O_3 & O_3 & I_3 \\ O_3 & O_3 & O_3 \end{bmatrix}, F(t) = \begin{bmatrix} k_p \frac{\theta_{kb}}{\bar{\theta}_{kb}} I_3 \\ \dot{K}_d(t) + K_a(t) + k_p \frac{\theta_{kb}}{\bar{\theta}_{kb}} I_3 \\ M_p(t) + \dot{K}_j(t) + K_d(t) \end{bmatrix} \\ &D_1(t) = \begin{bmatrix} O_3 \\ -I_3 \\ M_p^{-1}(t)(\dot{K}_j(t) + K_j(t) + K_d(t) - \frac{\theta_{kb}}{\bar{\theta}_{kb}}\left(\dot{\bar{K}}_j(t) - \bar{K}_j(t)\right) \end{bmatrix} \\ &D_2(t) = \begin{bmatrix} O_3 & O_3 & M_p^{-1}(t)\left(K_j(t) - \frac{\theta_{kb}}{\bar{\theta}_{kb}}\bar{K}_j(t)\right) \end{bmatrix}^T \\ &B_\xi = \begin{bmatrix} O_3 & O_3 & I_3 \end{bmatrix}^T \end{aligned}\right\} \quad (5)$$

Where $\boldsymbol{\mu}(t) = \dot{\boldsymbol{u}}_a(t) + \boldsymbol{u}_a(t)$ is the virtual input. The wheeled mobile robot with $\boldsymbol{\mu}(t) = 0$ is called the passive robot.

The control objective is to develop an adaptive controller so that the vertical acceleration at any specified location on the robot body can be reduced to a small value easily. To meet the objective, the following assumptions are made for the actual mobile robot (4).



(a) Maximum gain surface of the passive robot (b) Maximum gain surface of the combined ideal robot model

Fig. 3 Properties of the passive robot and the combined ideal robot model

A1 The body acceleration $\ddot{\boldsymbol{q}}(t)$ can be measured.

A2 The vertical displacements $\boldsymbol{x}(t)$ at the center of large wheels and its velocity $\dot{\boldsymbol{x}}(t)$ can be measured.

A3 The acceleration $\ddot{w}(t)$ of road disturbance is bounded and can be measured

3. COMBINED IDEAL ROBOT MODEL

A combined ideal robot model that achieves the control objective is given by [5]

$$\left.\begin{aligned} &\dot{\boldsymbol{\xi}}_m(t) = \Gamma\boldsymbol{\xi}_m(t) - B_\xi \bar{M}_p^{-1} k_b \boldsymbol{f}_m(t) + \bar{D}\ddot{\boldsymbol{w}}(t) \\ &\boldsymbol{\xi}_m(t) = \left[\boldsymbol{x}_m(t)^T,\ \ \dot{\boldsymbol{x}}_m(t)^T,\ \ (H\ddot{\boldsymbol{q}}_m(t))^T\right]^T \end{aligned}\right\} \quad (6)$$

$$\left.\begin{aligned} &\bar{D}(t) = \left[O_3,\ \ -I_3,\ \ \bar{M}_p^{-1}k_d\right]^T \\ &f_m(t) = \sum_{i=1}^{2}\gamma_{\phi i}\sum_{j=1}^{2}\gamma_{\psi j}F_{m(2i+j-2)}(t)\boldsymbol{\xi}_{m(2i+j-2)}(t) \\ &\gamma_{\phi i} = \frac{(-1)^i l_{\phi p} + l_{\phi m}}{2l_{\phi m}},\ \gamma_{\psi i} = \frac{(-1)^{i-1} l_{\psi p} + l_{\psi m}}{2l_{\psi m}},\ i = 1,2 \\ &\boldsymbol{\xi}_{mi}(t) = \Omega_i\boldsymbol{\xi}_{di}(t),\ i = 1,2,3,4 \\ &F_{mi}(t) = \bar{M}_p H T_i H^{-1}\bar{M}_p^{-1}(\bar{F} - G_i)\Omega_i^{-1},\ i = 1,2,3,4 \\ &\Omega_i = \mathrm{diag}\left[HT_iH^{-1},\ \ HT_iH^{-1},\ \ HT_iH^{-1}\right],\ \ i = 1,2,3,4 \\ &T_i = I_3 - \boldsymbol{b}\left[0,\ \ l_{\psi p} - l_{\psi m},\ \ l_{\phi p} + (-1)^{i-1}l_{\phi m}\right],\ i = 1,2 \\ &T_i = I_3 - \boldsymbol{b}\left[0,\ \ l_{\psi p} + l_{\psi m},\ \ l_{\phi p} + (-1)^{i-1}l_{\phi m}\right],\ i = 3,4 \\ &\dot{\boldsymbol{\xi}}_{di}(t) = (\Gamma + \bar{B}(\bar{F} - G_i))\boldsymbol{\xi}_{di}(t) + \bar{D}_w\ddot{\boldsymbol{\omega}}(t) \\ &\boldsymbol{\xi}_{di}(t) = \left[\boldsymbol{x}_{di}(t)^T,\ \ \dot{\boldsymbol{x}}_{di}(t)^T,\ \ (H\ddot{\boldsymbol{q}}_{di}(t))^T\right]^T,\ \ i = 1,2,3,4 \end{aligned}\right\} \quad (7)$$

where the design parameters $l_\psi = l_{\psi p}, l_\phi = l_{\phi p}$ are introduced to the specified location where the vertical acceleration becomes minimum. Hereafter, the location where the vertical acceleration becomes minimum is called the best location. The feedback gains $G_i, i = 1 \sim 4$ are designed by using the optimal control theory so that the vertical acceleration of ideal robot models $\xi_{di}(t), i = 1 \sim 4$ become small at the specified locations $l_\psi = -l_{\psi m}, l_\phi = (-1)^i l_{\phi m}, i = 3,4$ and $l_\psi = l_{\psi m}$, $l_\phi = (-1)^i l_{\phi m}, i = 1,2,$ respectively. $\Omega_i, i = 1 \sim 4$ are transformation matrixes that are introduced to specified the best location.

Fig. 3 shows the properties of the passive robot and the designed combined ideal robot model. To show the gain characteristics relating to the vertical acceleration on the robot body, the maximum value of the norm of transfer function vector from the road disturbance $\dot{\boldsymbol{w}}(t)$ to the vertical acceleration at a location (l_ψ, l_ϕ) is plotted. Hereafter, the curve surface such as shown in Fig. 3 (a) is called the maximum gain surface. Fig.3 (a) shows the maximum gain surface of the passive robot and Fig. 3 (b) shows that of the combined ideal robot model. The two design parameters l_ψ, l_ϕ are set as $l_\psi = 0.3\mathrm{m}, l_\phi = 0.3\mathrm{m}$.

As shown in Fig. 3 (b), the combined ideal robot model has better performance in suppression of the vertical acceleration than the passive robot, and the best location is corresponding to the specified location $l_\psi = 0.3\mathrm{m}, l_\phi = 0.3\mathrm{m}$. From this fact, it can be concluded that the control objective can be achieved if the behavior of the actual mobile robot can track that of the combined ideal robot model.

4. ADAPTIVE TRACKING CONTROLLER

To develop a tracking controller, the tracking error between the actual mobile robot (4) and the combined ideal robot model (6) is defined as $\tilde{\xi}(t) = \xi(t) - \xi_m(t)$, and the new signal is defined by $\boldsymbol{\eta}(t) = [2I_3\ \ 3I_3\ \ I_3]\tilde{\xi}(t) = L^T\tilde{\xi}(t)$. Then, the error equation is given by

$$\begin{aligned} \dot{\boldsymbol{\eta}}(t) = &-d\boldsymbol{\eta}(t) - \frac{1}{2}M_p^{-1}(t)\dot{M}_p(t)\boldsymbol{\eta}(t) \\ &+ \frac{\theta_{kb}}{\bar{\theta}_{kb}}M_p^{-1}(t)\left\{\boldsymbol{\mu}(t) + \Theta\boldsymbol{\omega}_\eta(t) + \boldsymbol{\omega}_k(t) + \left(K_j(t) - \frac{\theta_{kb}}{\bar{\theta}_{kb}}\tilde{K}_j(t)\right)\ddot{\boldsymbol{w}}(t)\right\}, \end{aligned} \quad (8)$$

$$\left.\begin{array}{l}\Theta=\dfrac{1}{\theta_{kb}}\left[\left(\left(HT_h\right)^T\right)^{-1} M_c\left(HT_h\right)^{-1} \quad \theta_{kj}I_3 \quad \theta_{kd1}I_3 \quad \theta_{kd2}I_3 \quad \boldsymbol{g}_a\right] \\ \boldsymbol{\omega}_\eta(t)=\bar{\theta}_{kj}\left[\boldsymbol{\omega}_1(t)^T \quad \boldsymbol{\omega}_{j\theta}(t)^T \quad \boldsymbol{\omega}_{d\theta1}(t)^T \quad \boldsymbol{\omega}_{d\theta2}(t)^T \quad -1\right]^T \\ \boldsymbol{\omega}_{j\theta}(t)=K_{j\theta}(\boldsymbol{\omega}_1(t)+\boldsymbol{\omega}_2(t))+\dot{K}_{j\theta}\boldsymbol{\omega}_3(t) \\ \boldsymbol{\omega}_{d\theta1}(t)=K_{d\theta1}\boldsymbol{\omega}_4(t)+\dot{K}_{d\theta1}\boldsymbol{\omega}_5(t), \quad \boldsymbol{\omega}_{d\theta2}(t)=K_{d\theta2}\boldsymbol{\omega}_4(t)+\dot{K}_{d\theta2}\boldsymbol{\omega}_5(t) \\ \boldsymbol{\omega}_1(t)=L^T\Gamma\tilde{\boldsymbol{\xi}}(t)+d\boldsymbol{\eta}(t)-H\ddot{\boldsymbol{q}}(t)+\bar{M}_p^{-1}\left(\bar{K}_b\boldsymbol{f}_m-\bar{K}_d\ddot{\boldsymbol{w}}(t)\right) \\ \boldsymbol{\omega}_2(t)=\ddot{\boldsymbol{w}}(t), \boldsymbol{\omega}_3(t)=\ddot{\boldsymbol{w}}(t)-H\ddot{\boldsymbol{q}}(t)+\dfrac{1}{2}\dot{M}_p(t)\boldsymbol{\eta}(t) \\ \boldsymbol{\omega}_4=-\dot{\boldsymbol{x}}(t)+\ddot{\boldsymbol{w}}(t)-H\ddot{\boldsymbol{q}}(t), \boldsymbol{\omega}_5=-\dot{\boldsymbol{x}}(t) \\ \boldsymbol{\omega}_k(t)=-k_p\dot{\boldsymbol{x}}(t)-k_p\boldsymbol{x}(t)-\left(\dot{\bar{K}}_j(t)+\bar{K}_j(t)\right)\ddot{\boldsymbol{w}}(t)+\bar{\boldsymbol{g}}_a\end{array}\right\} \quad (9)$$

where Θ is unknown constant matrix, $\boldsymbol{\omega}_\eta(t)$ and $\boldsymbol{\omega}_k(t)$ are known signal vectors and d is design parameter.

We developed the following adaptive tracking controller based on the error equation (8).

$$\dot{\hat{\Theta}}(t)^T=\Gamma_\eta\boldsymbol{\omega}_\eta(t)\boldsymbol{\eta}(t)^T-\delta\hat{\Theta}^T(t), \qquad \delta>0 \quad \Gamma_\eta>0 \quad (10)$$

$$\boldsymbol{\mu}(t)=-\beta\boldsymbol{\eta}(t)-\hat{\Theta}(t)\boldsymbol{\omega}_\eta(t)-\boldsymbol{\omega}_k(t) \quad \beta>0 \quad (11)$$

Where $\hat{\Theta}(t)$ is the estimated matrix of the unknown matrix Θ . δandβ are positive design parameters and $\Gamma\eta$ is a positive definite matrix.

The following theorem holds in the mobile robot using controller (10) and (11).

Theorem 1

The adaptive wheeled mobile robot using the controller (10) and (11) becomes stable. In addition, there are positive values $\bar{\rho}_1, \bar{\rho}_2$ independent of β such that

$$\|\boldsymbol{\eta}(t)\|^2 \le \bar{\rho}_1 e^{-\beta t}+\frac{\bar{\rho}_2}{\beta^2}. \quad (12)$$

5. NUMERICAL SIMULATION

We show numerical simulation results to confirm the effectiveness of the proposed controller.

The mobile robot is running at the speed 0.5[m/s], and the left front wheel runs over the road disturbance with the amplitude 0.03m and the frequency 2Hz. The design parameters are set as $\beta=50^2$, $\Gamma_\eta=50^3 I_3$, $d=10$, δ=0.01 . The specified location was set as $l_\psi=0.3\text{m}, l_\phi=0.3\text{m}$. The initial value of $\hat{\Theta}(t)$ is set as $\hat{\Theta}(t)=0$.

Fig. 4 shows the responses at the specified location of $l_\psi=0.3\text{m}, l_\phi=0.3\text{m}$. Fig. 4 (a) is the vertical acceleration, (b) is the pitching angular acceleration, and (c) is the rolling angular acceleration. Dotted lines show the responses of the passive robot and thick solid lines are responses of the controlled mobile robot. The responses of the combined ideal model are shown by using thin lines. However since thin lines and thick solid lines are almost same, the thin lines disappeared.

6. CONCLUSION

We propose an adaptive oscillation controller for wheeled mobile robots. Carrying out numerical simulations, it has been shown that for any parameter uncertainties, the oscillation attenuation performance can be achieved.

Abstract: Online customer reviews have been variously employed for text mining and information retrieval in general. However, the result of those analyses has to be well visualized for prospective innovations of firms and enterprises that cannot afford a dedicated expert. In this study, we collected thousands of online customer reviews of hotels and restaurants, and divided them into a couple of groups according to customers' conditions to use those hotels and restaurants. We then made keygraphs of common keywords for each group and compared them visually. This method enables service providers with little knowledge of text mining to grasp different preferences of customers, and thus to improve their services in a more personified way.

***Keywords*: cultural influence, online customer review, distance-biased mi score, chance discovery**

I. INTRODUCTION

In order to sustainably enhance and advance tourism industries, it is important not only to maintain and improve existing resources and services but also to continuously increase tourism resources, which should be either invented or re-discovered. In so doing, it is necessary to investigate both the evaluations of those resources and services on the part of tourists with different preferences and those on the part of tourism industries, which are too often mismatched. For customization of services and information to be provided, there have been a number of studies[1-3], in particular those of collaborative filtering, and the ultimate personification is the ideal there. When a new product or service is devised, however, the ultimate personification is usually too minute to pursue. Based on the consideration above, this study proposes a method of chance discovery for future tourism resources by comparatively investigating various data obtained automatically on the Web. In particular, we focus on cultural preferences or backgrounds that are a basis of personal preferences.

This paper, as a first step of our study, tries to extract cultural biases in online customer reviews. For this purpose, we analyzed online customer reviews on the same targets written in different languages. We devised a distance-biased *mi*-scoring, and based on the scores, we visualized the results and investigated possible interpretations of the results.

II. EFFECTS OF CULTRUAL PREFERENCES

When we go somewhere, the destination as well as those during the path has a different culture and custom. Tourists always have some assumptions / expectations to the destination and the way they will be treated: some of their assumptions/expectations are confirmed while others turn out to be false Among them, some are happy surprises while others lead to dissatisfaction Their assumptions / expectations are affected by many factors: sex, personal backgrounds, personal preferences, and their cultural backgrounds / preferences. Cultural differences among peoples have long been investigated[4], and some computational studies have focused on their extraction [5]. The goal of our study is to propose a finer-grained way to computationally extract these relations, but, in this paper, we investigated the possibility to interpret our results from some stereotypical viewpoints on races/nationalities. Stereotypes on races/nationalities are expressed in various occasions, and some of them are invented by others and others by themselves. The formation of stereotypes is a difficult issue to discuss intensively and extensively, but, in this paper, we manually interpreted our results and checked their validity by making a simple questionnaire survey.

III. DATA

In order to capture cultural differences, it is useful to employ multiple sets of data that contain reviews and opinions that are written by people belonging to each culture. However, it is not a trivial matter to find such sets of data. In this study, we employed online customer reviews on *TripAdvisor.com*.[6] TripAdvisor is a website based on the idea that travelers rely on other travelers' reviews to plan their trips, or at least can be satisfactorily helped in their decisions by them. As of August 2011, TripAdvisor contains 50 million travel reviews and opinions and written by 20 million registered members and counts 50 million of unique visitors per month.[7]

There are some merits to employ online customer reviews on TripAdvisor.com for this study. First, TripAdvisor.com provides scores of, or even hundreds of, customer reviews of a hotel or of a restaurant. Second, it provides not only textual customer reviews but also the following features: overall rating, item-based ratings of price, room, location, cleanness, bed, and service, the date when the reviewer used the reviewed hotel or restaurant, and the purpose, together with reviewer's attributes, as shown in Table 1. So we can analyze them from various viewpoints. Third, and most importantly, it provides reviews written in different languages. Reviews in English or in Spanish can be written not only by their native speakers but also by those who can use them, but reviews in some language, in particular, Chinese, Japanese, and Korean, are highly likely to be written by their native speakers.

As a preliminary study, we gathered more than 5,000 online customer reviews on hotels written in Chinese and Japanese, as shown in Table 2. We then segmented textual data into words with morphological analyzers, MeCab[8] for Japanese and the Stanford Chinese Segmenter and Part-of-Speech Tagger[9].

Table 2 Data

	Japanese	Chinese
Reviews	2,512	2,504
Words	210,418	134,891

IV. METHOD FOR ANALYSIS

In this paper, we focused on relations between nouns and adjectives, since most of the evaluative expressions are combinations of nouns and adjectives. In order to

Table 1 Attributes in Reviews on TripAdvisor.com

	Attribute	Value
Review	Overall Rating	1-5
	Price	1-5

	Evaluation by other users	Numerical
	Rating	Top Contributor, Advanced Contributor, Contributor
	Others	Photo and Self-Introduction

compare Japanese and Chinese data, we picked up the top two hundred nouns and the top fifty adjectives that appeared in Japanese and Chinese data, and we manually translated those words into English.

The strength of co-occurrence of two words can be expressed in various ways, including *mi*-score and dice score. In order to capture the effect of the distance of two words, we calculated the strength of co-occurrence of a noun and an adjective as follows:

$$db\text{-}mi(A_i,\ N_j) = \log_2 \frac{(\Sigma P_k(A_i,\ N_j)/k\ ) \times S}{P(A_i) \times P(N_j)} \quad (1)$$

where k is the distance of A_i and N_j, ($0<k<6$)
S is the sum of the words in the data,
A_i is an adjective,
N_j is a noun

The expression above is to calculate the *mi*-score that is sensitive to the distance between the two words, and we call this score a distance-biased *mi*-score, *db-mi*. We admit that *db-mi* is a very simple concept that reflects the distance between two words with *mi*-score, and a more intelligent way to measure the strength of co-occurrence is to be devised. However, as the interpretation below indicates, *db-mi* can offer an interpretable result. Note also that it is a small problem that we do not count negation. When we pursue a sentiment analysis, negation is a big issue, but in our analysis, the co-occurrence of a noun and an adjective indicates that the noun can be positively or negatively evaluated from the viewpoint of the meaning of the adjective.

We then plotted the results according to *db-mi*-scores by expressing the value with line weight, and by expressing the similarity of meaning between two words of ○ or ● with nearness. A sample of this visualization is shown in Fig.1, where ○ is a noun and ● is an adjective.

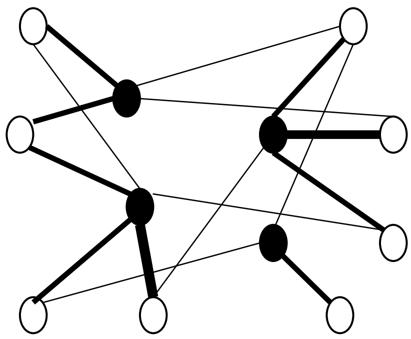

Fig.1 A sample visualization

V. INTERPRETATION

Based on the above method, we prototypically analyzed our data, and here we show some interpretations.

As related to "good evaluation", Japanese frequently use "good atmosphere" while Chinese frequently use "gorgeous," which is already well known, but Japanese's "good atmosphere" turns out to be well related to clerk's behavior, coloring of the room, ambient lighting. That means that Japanese are sensitive to those that are subtle, often invisible. At the same time, these target nouns are well related to "cozy."

On the other hand, Chinese's "gorgeous" is well related to bed, furniture, room bar, etc. That means that Chinese are more sensitive to those remarkably visible things, and these target nouns are also related to "great."

These tendencies are unanimously seen even when we focus on a particular segment of the corresponding Chinese and Japanese groups according to the purpose of the trip, reviewer's age, etc.

Another interesting tendency is that only Japanese are highly sensitive to cleanness. In fact, many Japanese reviewers put cleanness critically higher than other evaluative attributes while most Chinese reviewers do not.

We obtained eight tendencies including the above two that are seemingly culturally bound. Based on our interpretation, we made a simple questionnaire survey that asks if one thinks that the Chinese or the Japanese have a strong preference on X, where X is a tendency among the eight. Then we asked five Chinese, five Japanese, five Westerners including those who are British, Dutch, and French. Almost all of them, regardless of their nationality, answered affirmative to our interpretations, which, though quite intuitive, indicates that the tendencies we obtained are in fact culturally bound.

VI. CONCLUSION

We tried to extract cultural biases in online customer reviews. For this purpose, we employed online customer reviews on hotels on TripAdvisor.com that were written in Chinese and in Japanese. We devised a distance-biased *mi*-score, *db-mi*, to measure the degree of co-occurrence between nouns and adjectives, and visualized the results. We interpreted the visualization and obtained eight tendencies that are seemingly culturally bound, which is confirmed by a simple questionnaire survey. This study is quite a primitive one, but it shows that it is possible to extract culturally-bound characteristics from online customer reviews.

This method, though it should be extensively refined, can offer a seemingly valuable information on cultural differences behind various types of potential customers, and such a knowledge should be utilized for improvements and innovations of tourism industries as well as other industries.

Abstract: When we want to go somewhere, we usually prepare maps, route and route descriptions. In that situation, we need these data to understand easy the map data and route descriptions, to contain appropriate information to reach to destinations from starting points, such as landmarks information and action points,, and not to contain ambiguous information. In this paper, we investigate difference between human route descriptions and those made automatically by Google Maps API in order to obtain the guidelines for good route descriptions.

Keywords: Automatic map construction, Landmark information, Route description.

1 INTRODUCTION

When we go somewhere, we usually proceed two tasks simultaneously. One is, as everyone knows, that we follow the dedicated route description or the map someone else made, and most of us think that we are just following them, but it is not the case. Actually, we reconstruct our own route description adding conspicuous landmarks in order to remember the route. In this sense, the navigation is an action to reach the destination by constructing and using our own route description [1]. The spatial knowledge acquired this way is called a cognitive map by Tolman [2]. From this viewpoint, the trouble with a given route description is caused by mismatches between it and what we expect to be included as landmarks. It is thus necessary to make the gap smaller in order to make a good, sufficient route description.

The aim of our study is to devise a better mechanism to improve route descriptions written by humans and to make route descriptions automatically from the relevant maps. For this purpose, an intense investigation is necessary to compare route descriptions written by humans and those automatically made with online maps. As a first approximation, we employ maps provided by Google Maps API, which we consider to have room to improve. With this investigation, the purpose of this paper is to make clear the guidelines for good route descriptions that is easy for us to understand.

The organization of this paper is as follows: Section 2 defines some important terms. Then section 3 describes our system that automatically generates a route description based on the information provided by Google Maps API and added some extra landmarks from our database of landmarks. Section 4 explains our evaluative experiment and discusses the result. Section 5 is the conclusion.

2 ACTION POINT AND LANDMARK IN ROUTE DESCRIPTIONS

Wherever we go, the route to the destination is not just straightforward. We have to cross a road or a river, turn right or left at a certain point, and so on. In other words, we are repeatedly forced to do actions at certain points, or *action points*. So it is quite important to recognize where the correct action point is for a certain action. Sometimes they are obvious enough to recognize it, but in many cases they are not so obvious and we need some extra key spots with which the action point is easily recognized and remembered. It is often difficult to distinguish between obvious action points and extra key spots for action points because they can be used interchangeably in different route descriptions. So Let us call obvious action points and extra key spots for action points *landmarks*.

Different types of spots can be landmarks. Some are natural and others are artifacts; some are small such as bulletin boards while others are big such as large buildings and rivers. As Lynch pointed out, even when an action point has its internal structure like buildings, it has little to do with its role of a landmark [3]. Whether a landmark is an action point or a key spot between action points that makes the next action point easier to detect, it should be conspicuous enough. Though different people have different preferences and viewpoints, and thus different people may regard different spots as their own landmarks, it is generally considered that there are still many potential landmarks that most people commonly regard as landmarks.

3 OUR ROUTING SYSTEM

In order to construct a more easily accessible navigation system, the current method to make a route description based on maps seems to have problems in adding and selecting the appropriate landmark information, though at the same time the mere addition of extra landmark information may not work. In order to the validity of landmark addition to route descriptions automatically made based on maps, we constructed an experimental routing system. The procedure is as follows:

1. Input of the source and the destination by a human

2. The system obtains the exact location of the source and destination using the prepared database.
3. The system obtains the route with necessary information and its route description from Google Maps API.
4. The system revises the obtained route description and the corresponding map by adding appropriate extra landmarks in the prepared landmark list.
5. The system shows the revised map and route description to the user.

We prepared tree different databases in advance for this sytem, which are described in 3.1.

3.1 Construction of Databases

The system we made has three databases: landmark's list, the list of the source locations like train stations, and the list of the destination locations that consists of restaurants' this time. All sources and destinations are located, for an experimental reason, in a small area, downtowns in Osaka, Japan. All databases are implemented with MySQL.

3.1.1 *The list of destination locations*

The list of destination locations is constructed as follows. First, we chose 1,200 restaurants in the targeted area from *Tabelog*, a famous online restaurant guide site with customer reviews. Second, we extracted the following information of each restaurants:

- Name
- Address
- Route description
- URL of the page of the restaurant in *Tabelog*

Third, the addresses above are modified in order to make them compatible to Google Maps API, using the following regular expression:

```
/(大阪府|京都府|北海道|東京都|[一-
龠]+[県]){1}([一-龠あ-
ケ]+[市区郡町村]){1}([一-龠あ-ケー]+([0-
9]+(\-|－|丁目|丁))*([0-9]+(\-
|－|番地|番))*([0-9]*[号]*))/
```

Fourth, we made queries to Google Geocoder API to obtain the exact location consisting of the latitude and longitude.

The prepared list of destination locations thus has eight fields shown in Table 1.

Table 1 Fields in the database of destination locations

field	description
id	unique id of the record
link	URL
name	the name of the restaurant
full_address	the address obtained from *Tabelog*
short_address	the address modified
lat	the latitude
lng	the longitude
description	the textual description of the restaurant

Lastly, we manually checked the information obtained and corrected errors and wrong data.

3.1.2 *The lists of the sources and landmarks*

As for the lists of the sources and landmarks, we first analyzed the route descriptions given by *Tabelog*, and manually selected the sources and landmarks frequently used in them. Then we obtained *name*, *lat*, and *lng* in the same way above, and the relevant map.

Red markers are landmarks and their information are appended to the route description in the right window. There are two *Green markers*, A is an original point, and B is a destination.
Blue line is a route calculated by our system.

Fig. 1. A screen shot of our system.

3.2 Method

Google Maps API provides maps and routes. The route is available in 3 types of travel modes, which is bicycling, driving, walking. Our purpose is to provide a better navigation for walkers and we chose walking, and add two types of modification to them.

3.2.1 Add Landmark Information

First, we insert pins on the map which means landmark. Landmark's information used for this method are registered in advance in the landmark's list described in section 3.2. The distance between a landmark and an action point is calculated, and if it is within 20m, then the landmark is inserted.

3.2.2 Clarify Directions

Route descriptions obtained from Google Maps API often lack the exact direction to be chosen at action points: e.g., to go straight or to turn left or right when crossing a road. So we manually added the exact direction for these cases.

4 EXPERIMENTS

We conducted two experiments to evaluate the accuracy and usability of the route that Google Maps API provides, and the usefulness of our system.

In the first experiment, in order to confirm that human route descriptions contain enough of information to arrive destinations from stating points and route on the map created by Google Maps API accord or not with human route descriptions, we compared them.

Next, we call it experiment 2, we compare the route's descriptions created by Google Maps API and the human route descriptions and discussed whether are according points and whether are difference in order to reveal what attributes are important for route descriptions to guide readers to destinations correctly.

4.1 Experimental data

We used the data of restaurants extracted from the web site "*tabelog*". Each restaurant data consists of maps, addresses of shops, route descriptions, starting points and destinations information. It turned out that many restaurants used the route description given by Google Maps API, and we extracted 41 data that contain route descriptions that are different from the corresponding route description obtained by Google Maps API and are seemingly described by a human with more than 60 characters.

4.2 Experiment 1: Comparison of route and route descriptions

In Experiment 1, we compared route descriptions by Google Maps API and by humans.

We assume two standard criteria of accordance with constructed routes and route descriptions as follows.

(1) *All actions on the action points of routes are consistent with human route descriptions.*

(2) *All landmarks are actually found from each action-point if the route descriptions contain some landmark information.*

We used Google Street View to confirm whether the criterion (2) is fulfilled or not.

As a result of this experiment 1, the correct route was constructed with 27 data and 14 wrong routes are created with the other data. There are three main reasons for wrong routes.

(i) Discrepancy between the shortest route and the com prehensible route

Route descriptions are supposedly used by a person who is going to the palce for the first time, and thus the most important feature of the route descprtion is comprehensibility. However, Google Maps API has a tendency to provide the shortest route, which is sometimes different from a comprehensible route. Eight of 14 route descriptions have different route between the two.

(ii) Multilayer type

If the starting point is above the subway station, Google Maps API would misunderstand that user is in the station. This type of error is shown only 1 of 14 data.

(iii) Double-sided type

Each destination, which is supposedly a building or a part of a building, is considerably large in size compared to a human, and there is no guarantee that the exact location of the *entrance* to the restaurant is obtained from Google Maps API. It might seem to be trivial, but it is not. Many restaurants face more than one street, and the choice of the correct street among them affects the decision of the total route.

4.3 Experiment 2: Comparison of modified route descriptions and human route descriptions

In this section, we compare human route descriptions with route descriptions obtained from Googe Maps API and modified by our proposed method. And we will show differences between these two types of route descriptions.

We investigated whether modified route descriptions accorded with human route descriptions at three points:

(1) whether all the same action points are contained

(2) whether the direction to chosse at each action point is described or not

(3) whether all the landmarks inserted are the same or not

Table.1 shows results of experiment 2. Experimental data is 27 data that accorded with their route descriptions and human route description in experiment 1.

Table 1. Results of experiment 2

Rate of landmark	Rates of action point	
	GMA⊃H	GMA⊂H
93.2%	60.3%	49.4%

In table 1, the rate of landmark shows the rate of the cases in which the same landmarks are used in both route descriptions. The rates of action point shows the rate of the cases in which the action points used in the route description obtained from one are used in the other. Average of action points of H was 3.4 times in one description, and average of action points of GMA was 5.5 times in them, so GMA is more redundant.

First, some of the landmarks were not contained in the route descriptions obtained from Google Maps API. The landmark information is found in only 1 data. Our proposed method considered landmarks information beside routes and it did not consider about landmarks in front of the routes. We will improve our method to search not only beside areas but also forward areas of routes.

Second, the proposed method cannot add streets and/or rivers as landmarks. Because these are inherently lines, not points, though they can be regarded as a point to be crossed in a route. In other words, if we add the information of relevant roads or rivers as landmarks, we need another method to specify the exact point that is to be regarded as a landmark in each case. 20 out of 27 wrong data contain this type of error, and we are devising some improvements else where.

Thirdly, 10 descriptions have a sentence like "*turn the left at the n-th corner*". The proposed method do not count the number of corners or signals from a particular action point, because it is a relative information to be computed separately.

Many description contained descriptions like "*cross over the ~ river*". Generally, names of rivers are more famous than bridges. Therefore there is not any description of "*cross over on ~ bridge*". Therefore sometimes we cannot obtain which road or bridge to be crossed. We suppose that action-points before rivers are important factors for correct information and we have to describe these information more clearly.

The proposed methods added information about walking time from the previous action point to the current one to route descriptions constructed by Google Maps API's. Human descriptors tend not to write these information, but it often concern people particularly in the case that two action points are rather remote.

Moreover, we also found the descriptions that show directions with compass points. However, we do not always have some devices to know directions like a compass. Because of it, we suppose that we should show direction by words "*right*" and "*left*" in route descriptions.

As the result shows, the rate in which the same landmarks are used in both description is rather high. Though we manually made the landmark list this time, but if the list can be constructed automatically, then we can apply our method to any locations, which is to be pursued else where. The result also shows the tendency that human descriptions contain fewer action points than descriptions obtained from Google Maps API, and the appropriate number of action points for human walkers should be investigated.

5 CONCLUSION

In this paper, we proposed a method to modify the maps, routes, and route descriptions obtained from Google Maps API, and discuss differences between map data by Google Maps API and human route descriptions. We obtained the results that they are often different, particularly in the usage of landmarks, and we proposed a method to add extra landmarks to route descriptions obtained from Google Maps API. The result is not still satisfactory and more refinements are needed, but the result indicates that this kind of improvements are necessary for a more comprehensible route description to be automatically constrcuted.

Abstract: The one-way information provision can not impress the listeners well. As an efficient way, Question & Answer can help information provider understand the response of listeners. However, it is not easy for everyone to set a suitable question. In this paper, we propose an automatic quiz generation system using tourism blogs. The system can generate the quiz by extracting feature words of the topic keyword from the blogs. Our purpose is to help the tourism information providers to advertise their tourism events in an interactive way, in order to impress the tourists. By comparing with other method of quiz generation, we demonstrate that our method is more suitable for information provision.

Keywords: Quiz Generation, Tourism Blog, Feature Word, Information Provision.

1 INTRODUCTION

The traditional method of information provision is a one-way method from information providers to information recipients. There is no interaction between providers and recipients, so it is an inefficient method to provide information. You can image that when you are attending a philosophy class and listening to the virtually unintelligible theories, you may feel nothing but lethargic. But when the teacher says, “Who can answer this question?”, you may feel fresh instantly. Because you may want to know what the question is, and whether you will be asked to answer the question. If you are the one to answer the question unfortunately, you will be impressed by the question. Therefore, as an efficient way, Question & Answer (Q&A) can help information to provider understand the response of listeners. That is because Q&A changes the one-way into two-ways method. On the one hand, listeners not only just listen but also comprehend the content of information. On the other hand, the provider can also know how much the listeners have understood. As a typical form of Q&A, multiple choice questions require a short response time and with the possibility of covering a broad set of topics.

However, in order to set a question, user must quite understand the knowledge of the topic. Meanwhile, user has to read up a lot of literature to ensure the correction of answers. For helping user to set a multiple choice question easily, we propose a novel method to generate multiple choice questions automatically. In this paper, we mainly consider the automatic generation of quiz related to tourism event. Our purpose is to help the tourism information providers such as travel sites, tour guides and some other tour organizations to advertise their tourism events in an interactive way, in order to impress the tourists. The authors of this paper have been doing many researches on data mining of tourism data [1] [2]. In this paper we adopt tourism blogs as the experiment data. That is because the role of blogs became increasingly main stream in recent years. We collect the official blogs of Kyushu Tourism Promotion Organization[1] to generate quiz. Also, we develop a Automatic Quiz Generation System (AQGS) for realize the automatic generation of tourism quiz by using blogs.

2 RELATED WORKS

There is a large body of related work on automatic generation of multiple choice questions.

Tonoike et al [3] proposed an approach of answer validation based on the strengths of lexical association between the keywords extracted from a question sentence and each answer candidate. Tsumori and Kaijiri [4] generated the questions adapted to students' understanding based on the similarity of each word. Mitkov et al [5] distinguished the kind of problem sentences, and analyzed the structures (SVO, SVC, etc.) of the sentences. Moreover, the words that have the similar meaning with the correct answer in Wordnet are chosen as the distracters. Hoshino and Nakakawa [6] made a machine learn based on Naive Bayes and K-Nearest Neibors by using a collection of TOEIC question as training data. The blank in question was determined from the training result. The answers were random and chose from the same sentence.

However, all of these researches paid more attention to the difficulty of the questions. That is because these questions were generated for aims of education. In this

[1]http://www.welcomekyushu.jp/

paper, we focus on the interest of questions instead. Our purpose is make the listeners remember the information easily, not try to test the level of intelligence of listeners.

3 AUTOMATIC GENERATION OF QUIZ

3.1 Creation of Index

Before developing quiz generation system, we need to create an index. Index is design to optimize speed and performance in finding relevant documents for a search query. In this paper, we will not only build an index of full-text but also an index of each sentence.

For building a sentence index, we need to create a sentence-based frequency file. First of all, we divide every article into sentences. Next, we use "ChaSen" [7], which is a morphological parser for the Japanese language, to analyze morpheme of every word. After creating the frequency file, we use "GETA" [8], which is a generic engine for transposable association, to build an index of each sentence.

3.2 Extraction of Feature words

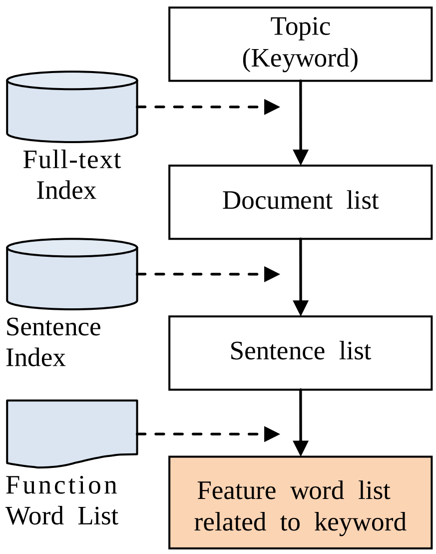

Fig. 1. Extraction of feature words

Typically, a multiple choice quiz contains two parts: a question and a group of suggested answers. In this paper, we generate the answers from a feature word list related to the user's keyword. A feature word is a word that appears in the same sentences with the user's keyword. In this section, we will introduce the extraction of feature words.

Fig. 1 shows the outline of the process for extracting the feature words. Firstly, the user must enter a topic (a keyword) of quiz. When user enters a keyword, the system searches all of the documents by using the full-text index, and generates a list of documents in which the keyword appears. Then, the system finds out all the sentences containing the keyword from the document list by using the sentence index. Finally, system extracts feature word list from the sentence list.

Table 1. Function words in Japanese

Category	Description and Examples
Pronoun	A pronoun is a pro-form that substitutes for a noun (or noun phrase) e.g. 私(I), 彼(he),これ(This), ここ(here)
Conjunction	A conjunction is a word that connects words, phrases, clauses, and sentences. e.g. しかし(but), また(or), そして(and)
Joshi	In Japanese grammar, particles are called joshi. e.g. に(in), で(at), は, を
Auxiliary verb	An auxiliary verb is a verb that gives further semantic or syntactic information about a main or full verb. e.g. できる(can), ない(not)

However, there are many function words in the feature word list. Function words express grammatical relationships with other words within a sentence. They have little lexical meaning or have ambiguous meaning. It is necessary to get rid of the function words from feature word list. Table 1 shows the category of the function words in Japanese. Fortunately, there are not many function words in Japanese, so we can manually create a function word file in advance. By using this file, we get rid of all the function words from feature word list effectively.

3.3 Generation of answers

The answers of a multiple choice quiz always contain a correct answer and a group of distracters. We consider the user's keyword as the topic of the quiz, so we can choose most relevant feature words as the answers. To some extent these feature words can describe the keyword.

In order to find out the most relevant feature words, we need to rank the feature words. In this paper, we use SMART (System for the Mechanical Analysis and Retrieval of Text) [9] to calculate the similarity between feature word and keyword. In other words, every feature word w_i will have $SMART(k, w_i)$, where $SMART(k, w_i)$ is the similarity between keyword k and w_i. If word w_i have a higher $SMART(k, w_i)$, it means that w_i is more similar with k.

Fortunately, GETA supports the computation of SMART, so we can get $SMART(k, w_i)$ of all the feature words as soon as we get the feature word list. According to $SMART(k, w_i)$, we sort the feature word list. If a word get a higher $SMART(k, w_i)$, it will appear at a higher rank. Finally, we choose the top 1 feature word as the correct answer, top 2 ~ 5 feature words as the distracters.

3.4 Generation of questions

As we mentioned above, before we extract the feature words, we have get all the sentences that contain the keyword. We will generate questions from the sentence list.

Table 2. An example of quiz

Question	(　)は、これを防ぐために、若者達が喊声をあげて、観音堂内の鬼の面箱を封じ直すという勇壮な裸絵巻。 現在では、「童子の舞」が(　)の中心となっていて、童子の舞や所作は一見の価値があります。
Answers	行事、イベント、公園、祭り、神社

Firstly, in order to avoid that the distracters appear in the questions, we need to get rid of the sentences that contain the distracters. And then we randomly choose a sentence from the sentence list as the question. Meanwhile, the correct answer will be replaced by brackets. Table 2 shows an example of quiz, where the red answer is the correct answer.

4 AUTOMATIC QUIZ GENERATION SYSTEM

4.1 Design goal

As we mentioned above, the goal of Automatic Quiz Generation System (AQGS) is to help the tourism information providers such as travel sites, tour guides and some other tour organizations to generate quiz easily. These quizzes can help them to advertise their tourism events in an interactive way, in order to impress and attract the tourists.

4.2 Outline of AQGS

We develop the AQGS based on the proposed method with PERL language. User can open the CGI file of AQGS by using any kind of browser. Fig. 2 shows the interface of AQGS. There is only a "topic textbox" and a "search button". When user enters a topic keyword and clicks the search button, the quiz will be displayed below.

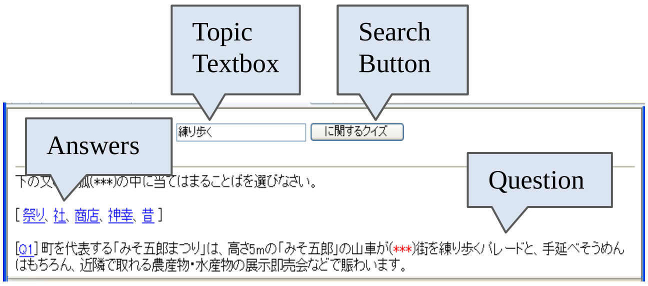

Fig. 2. The interface of AQGS

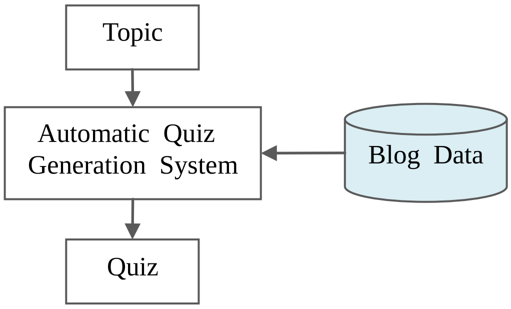

Fig. 3. The outline of AQGS

Fig. 3 shows the outline of AQGS. User only needs to enter a topic keyword. The system will automatically generate quizzes about the topic. It is not necessary for user to understand the topic well.

5 EXPERIMENT AND EVALUATION

5.1 Experiment Data

We collected the official blogs of Kyushu Tourism Promotion Organization to generate quiz. We focused on the events in the region, so we collected 906 events, at the first stage. However, some articles did not contain the date of event. So, we chose 316 articles that contain the date of the events. Some events are performed every year. So, we identified the articles of the same event in different years. As the result, we obtained 312 articles by which we generate quiz.

5.2 Methodology and procedure

To evaluate the usability of AQGS, we introduce a usability experiment. We developed two quiz generation system, one is proposed system by using feature word (F-System), and the other system generates the quiz by using Wordnet [5] (W-System). 5 participants joined in the experiment. Before the experiment, we did not introduce participants the purpose of this experiment. We design the task of usability experiment as follows:

(1) We generate the quizzes by F-System or W-System randomly. And the topic of quiz will also be determined randomly.

(2) We ask participants to answer these quizzes. They do not know whether the quizzes are generated by F-System or W-System.
(3) Participants evaluate each quiz they answered by 4 criterions, every criterion has 4 degrees. Table 3 shows the criterions and their degrees.

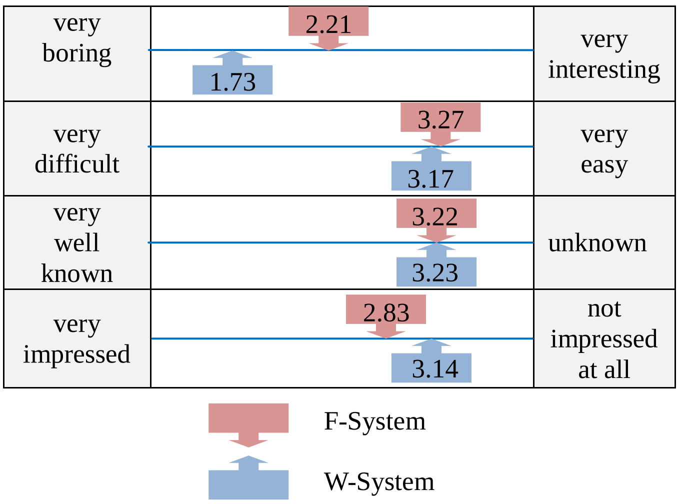
Table 3. Criterions of evaluation

Criterion	Degree
Interest	1 very boring, 2 boring, 3 Interesting, 4 very interesting
Difficulty	1 very difficult, 2 difficult, 3 easy, 4 very easy
Acquaintance	1 very well known, 2 well known, 3 known, 4 unknown
Impression	1 very impressed, 2 impressed, 3 unimpressed, 4 not impressed at all

5.3 Results and Analysis

Finally, we get 200 evaluation data: F-System 100 and W-System 100. We calculate the average degree of each criterion. Table 4 shows the result of evaluation, where the numbers in the arrow present the average degree of each criterion.

Table 4. Result of evaluation



Although "Difficulty" and "Acquaintance" are not the most important criterions, the result shows that quizzes generated by two systems have the same difficulty and acquaintance. It proves that the quizzes are comparable.

The result also shows that the quizzes generated by F-System are considered more interesting than those of W-System. Because the distracters generated by W-System are chosen from similar words of Wordnet, such as ship, boat, vessel and watercraft. Participants consider that it is boring to tell the difference from the words. After all, the quizzes are not generated for intelligence test. Meanwhile, Participants consider the quizzes generated by F-System are more impressed than those of W-System. The result demonstrates that our method is more suitable for information provision instead of intelligence test.

6 CONCLUSION AND FUTURE WORK

In this paper, for providing an interactive way for the tourism information providers, we proposed a novel method to generate the tourism quiz automatically by extracting the feature words of topic keyword. We also developed a Automatic Quiz Generation System. By comparing with other method of quiz generation, we ensure that our method is more suitable for information provision instead of intelligence test. Because the quizzes are interesting, as well as they can impress the users.

In the future, we are planning to build a difficulty and interest model to modulate the quizzes automatically.

Abstract: The investigation activities using a search engine are indispensable to acquisition of new knowledge. When we investigate using a search engine, we leave a memo if needed, seeing the search results to an input keyword. Depending on the case, search refinement and search by a new related keyword are repeated. However, it is difficult to share the knowledge and the experience acquired under investigation activities with the others. On the other hand, SNS which promotes relation with people and a person attracts attention. This paper proposes a community type search platform which combines a search engine and SNS. By seamless use of various activities in search and the mutual comments, users can share a problem or new knowledge.

Keywords: SNS, Search, Community, Knowledge Share.

1 INTRODUCTION

With the development of internet, SNS (Social Network Service) plays a more and more important role on affecting interpersonal relationships. As typical SNS systems, Mixi has the largest number of members in Japan; GREE can support the mobile devices; Facebook is the most popular SNS in the world.

These SNS systems have become community Web sites that can broaden the relationship among person and person. Therefore, the researches on SNS have increased recent years. For instance, the authors of paper [1] take user's friend as a middleman, and proposed a chat system on circle of "user", "user's friend" and "friend of user's friend". The circle of "friends of friend" provides a chance to create new relationships, in order to sharing knowledge among all of friends.

In addition, when we try to investigate something, we always open a search engine, enter some keywords and click the "search" button. There is no doubt that search engine has become an indispensable tool for the current Internet users. Especially, with the increasing of the search engines which provide search service for documents of education and research, new issue or knowledge can be discovered in search activity. Sometimes we need to make a memo to record the discovery or our comment of search results. These memos may contain some important and valuable information. Therefore it is useful to share our memo and read others' memo.

Textbook is not the only way to obtain knowledge. We can also discover new knowledge during our search activity. In order to share the knowledge discovered in search activity, we propose a novel search engine called SNSearch (Social Network Search). It combines the SNS and search engine together. It help user to make memo easily and record user's search history automatically. It makes use of the relationship among persons, which was created through SNS, to share the knowledge to each other.

Our main purpose is to provide a new approach to help users share and obtain new knowledge expediently. In this paper, we consider the researchers as our chief users. The researchers can freely add new friends who may have similar interest. They can use the SNSearch to search papers and make memo. They can also read their friends' memos and search history. Thus the users can easily share and obtain new knowledge among their friends. By doing this research, we expect to affect the future prospects of the current search engines and SNS.

2 RELATED WORK

There are several researches in using access log of Web pages. Nakao et. al. [2] uses access log of a Web pages of each user to calculate the similarity of Web pages. They proposes a recommendation method of Web pages based on the similarity. They considered not only the similarity of Web pages but the similarity between sub-trees. They combined this similarity and the similarity by link structure.

Toda et. al.[3] paid attention to the Web pages visited often by many users to improve the efficiency of Web browsing routines and to discover new information at the same time. They analyzed the time and frequency of users visit to particular pages in their access log, to evaluate the importance of the pages for recommendation. They applied the collaborative filtering for Web page recommendation.

Liao et.al.[4] considered a mentoring system in WBT(Web Based Training) system. They analyzed the learning logs of students and formulated evaluation measures to capture the students feature. They constructed an "evaluation referential graph" to detect abnormal status of students. When such state is found, the system can alarm to keep students learning motivation.

So far qualitative analysis is attached great importance. Recently, the learning logs are attracting many researchers to help communication between users. Totoda et.al. [5] used the activity logs of runners in creating regional and focused communities of runners. Any member can read and comment the training plan of other members. So, participating member of the community can share and learn from others activity logs even if they have few experience.

Watanabe et.al. [6] used collaborative learning logs, where participants form a team to solve the same problem. They evaluated the number of users who made the same annotation in their utterance, and constructed a knowledge graph. They claimed that the graph is useful to point out the key issue for learners.

Anderson et.al. [7] designed and implemented the montage system to improve the experience for routine web browsing that users tend to repeat over and over in similar situations by providing a start page. The start page shows an ensemble of links and content based on a user's browsing history and preferences.

From these studies, we understand that users' logs are useful. However, there is no trial that connects search activity and SNS. The present paper seems to be the first one as far as authors know.

3 WHY SNSEARCH

3.1 Search and knowledge

Why do people search? A simple reason is that they want to know something that they do not know. Today, with the developing of internet, searching is a natural behavior like listening, speaking, reading or writing. There are many reasons for people to use search engine. Sometimes people use search engine to find something they are interested in. Sometime people use search engine to find some methods to solve some problems or do some studies. No matter why they search, people can learn some knowledge by their searching behavior. Different people use different keywords to search different things, and choose different results with different reasons. But, it is possible for different people to have the same characteristics such as interests, research, task, and purpose. In this kind of situation, sharing the experience of search can help people to learn something from other people who have some characteristics.

But, how to share the experience of search and the knowledge learned from search? In order to solve this problem we designed a system named SNSEARCH which combines search engine and a simple SNS system.

3.2 The main idea of SNSEARCH

In this paper, we designed a search engine of papers collected from IEICE technical report. By combining it and SNS communication ability, we provide the SNSEARCH system as a community portal to provide a platform with which people can share his knowledge and learn something from others'. As show in the Figure 1, the main idea of this system is that people can give something and take something by accumulating user's search record, and doing a memo of knowledge found from search behavior and some comments about the search behavior.

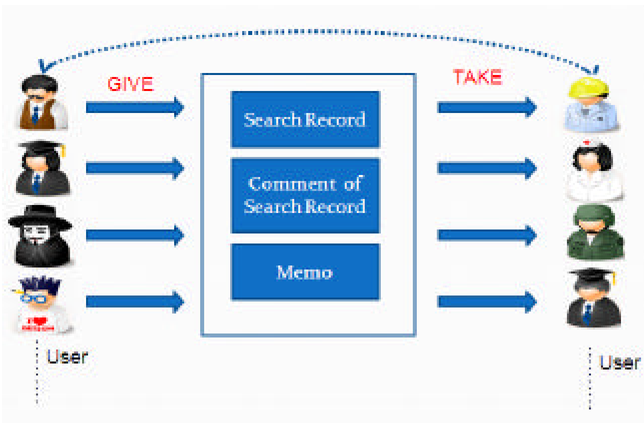

Fig. 1. The main idea of SNSEARCH

4 OUTLINE OF SYSTEM

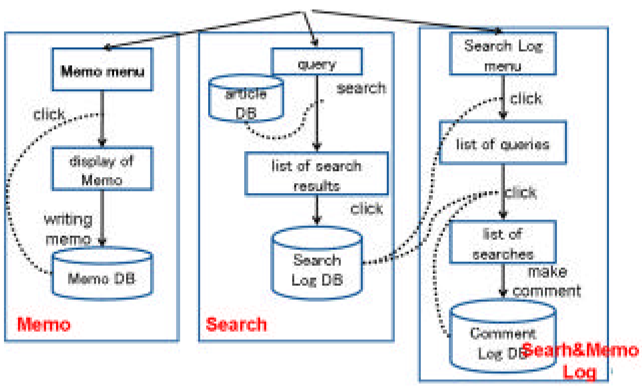

Fig. 2. System

Fig. 2 shows the outline of the system, which consists of three components -- Memo, Search and Comments Log. We used the abstracts of 42,921 articles of IEICE(the Institute of Electronics, Information and Communication Engineering) to create a search engine. The search engine can be substituted with other engine. We call the system as SNSearch, since it combines SNS and Search. The system keeps query logs of users in its database to help sharing the process of search between users. User can see, learn and comment on other search experience and on the search result. The system returns the search results for the query as an ordinary search engine does. When a user chose and clicked a result, the system keeps this behavior as users' preference. The queries and choices of one user can be used as knowledge for other users. Conventional SNS provides a communication environment to participants of the community. In SNSearch, user can give not only their opinion or comment, but also their experience of search. Moreover, they can comment on search process of other members.

5 FUNCTIONS OF SYSTEM

The present version of SNSearch has the following 8 functions.

(1) Writing memo
(2) Displaying the latest 10 memo
(3) Displaying memo of each member
(4) Search engine of articles
(5) Displaying memo according to date and time
(6) Displaying members' queries
(7) Displaying the action for the search result
(8) Making comments on members' search logs

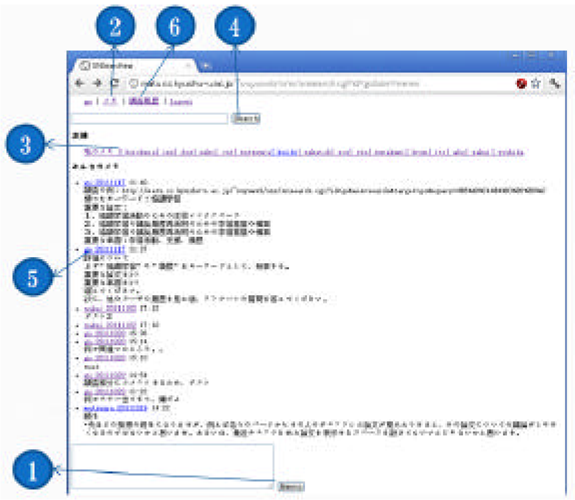

Fig.2 Listing of Memos

When a user logins to the system, he can choose the contents to be displayed from his own memo, the latest memo of all members and the search logs. When memo menu is chosen, the latest memos of all members are shown in order of time (Fig. 3). The list of fiends is always shown in all modes. When the own memo is selected, he can read and write the memo (Fig. 4). If a user wants to check the memo of his friend, he only has to click the name of the friend on the list. A simple click on a query (Fig. 5) can activate the search and re-display the result which his friend checked (Fig. 6).

Fig.3 A user's Memo

Fig.4 Listing of Queries

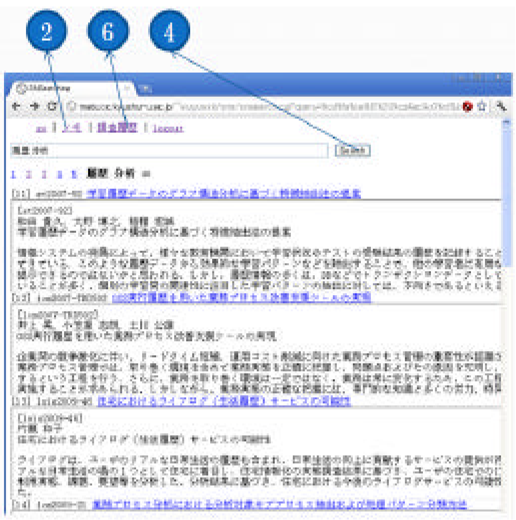

Fig.5 Search Interface

6 EVALUATION PLAN

The key feature of the proposed system is in the combination of a search engine and SNS. The interface of the system, however, influences whether the system is useful and convenient. In the rest of the paper, we analyzed the precedence studies to consider the frame work of evaluation. It turned out that there are two kinds of approaches, i.e., questionnaire by users and comparison of performance as search methods.

Specifically by the previous work, the following evaluations are performed. In [1], the questionnaire survey about an opinion and comment of a system was conducted to 11 users and was used for evaluation. In [2], the browsing logs of 11 users were used to recommend non-visited Web pages. The success ratio of arriving non-visited pages were used as the evaluation score for the method. Toda et. al. [3] used the decrease of users' clicks as the effectiveness of recommendation method for a user to reach the target Web page. In [4], the users are asked to use their system, and then answered the prepared question. Then the questionnaire survey was conducted to obtain the evaluation. In [5], two experiments were performed to compare their system with a conventional community site. In [4], four students were asked to solve three problems of Java programming, where students comprehension was formalized as "knowledge graph".

The authors made a brief hearing of users as preliminary evaluation. The main interests and reaction of users were convenience of an interface, flexibility of a system and whether users can share their knowledge which would be gained when they are actually using our system to explore their problems. We are planning the tasks to be solved by users in our experiment and the questionnaire to analyze these three points.

7 CONCLUSION

In this paper, we designed a search engine of data collected from IEICE technical report, which is different from traditional search engine. The difference is that the result of search if not only links of papers but also can save search log automatically. We combined it with a simple SNS system to provide a community portal, with which people can share their knowledge got from search behavior and learn something from others'. And we gave a detailed account of this system which has three components -- Memo, Search and Comment Log.

This time, we just gave an idea that people can share knowledge with each other by share combining SNS and Search. How to make it more available? How to make it more acceptable? In order to solve this kind of problem, some improvements of this system need to be considered.

As the next step of this study, we are planning to design an Information Recommendation Model to make it easy for people to find something they are intereste d in. By accumulating user's record of using the Infor mation Recommendation Model, we plan to conduct an experiment to evaluate the effectiveness of the system.

Abstract: Online reviews of commercial sites are important sources for customers to obtain information and opinions. However, generally, these reviews contains several mixed information such as purpose and sentiments of reviewers. Therefore users need the method to separate these data and extract appropriate information from the reviews. In this paper, we investigated effectiveness of a method of machine learning *Support Vector Machine (SVM)* whether the method can classify reviews appropriately or not by using reviews of a travel information web site "*TripAdvisor*". We also investigate difference of precisions according to source textual data such as morpheme, bigram and trigram.

Keywords: Online reviews, Sentiment analysis, Support vector machine.

1 INTRODUCTION

The total size of the documents on the Internet has been more and more gigantic. Among them, many researchers and commercial enterprises have been paying more attention to online customer reviews found on various portal and purchase sites like Amazon.com and kakaku.com. These reviews contain a lot of personal opinions and they are considered to be very useful for other customers as well as enterprises. When a person wants to buy something, he can use others' reviews to know the product better from the customers' viewpoints. Enterprises can know better how their products are considered by customers by analysing those reviews. However, what is known with customers' reviews depends on the analytic method to be employed.

There have been many researches to analyze and utilize the reviews. Among them are two typical approaches. One is to search and extract all and only necessary information from the total data. Another approach is to classify reviews into several categories and to know the possible types of customers. For example, in some researches, weblog data are classified into two categories: *positive opinion* or *negative opinion*. In others, newspaper articles are classified into some categories based on various topics found in them.

In this paper, we adopt a different approach that classifies reviews considering not only sentiments and opinions of reviewers but also their personal information. This approach is obviously important because companies often obtain opinions classified based on generations and/or family structures of customers for market research. Therefore, it is very important for a better classification to investigate reviewers themselves together with what they write.

In this paper, we investigate effectiveness of a method to classify documents of reviews of a web site called *TripAdvisor* by experiments. The reviews there contains not only opinions but also other pieces of information such as the situation, the purpose of reviewers and themes for evaluation. For example, a keyword of "*with Friends*" or "*Solo*" are added to some reviews by reviewers. We constructed classifiers of *Support Vector Machine* (*SVM*). We constructed several classifiers by using different training data sets. We then investigate the effectiveness and the differences of each classifier based on different data sets by experimental results of review classification.

In section 2, we explain related works of our research. Next we will explain our data sets. In section 4, we explain techniques for our research, SVM. In section 5, we will show experimental results and discussion. Section 6 is the conclusion.

2 RELATED WORKS

There are two approaches to analyze a large scale document data in order to obtain useful information to human. One is a method to extract opinions, and another is a method to classify opinions.

The former approach considers components of opinions, defines the component and extracts them from text data. Sometimes the relationships of the components are used for the extraction of the opinions. Iida et al. [1] defined that an opinion can be represented as a tuple (Subject, Attribute, Value) and they extracted the pair of Attribute-value from text data.

On the other hand, the latter approach is to classify documents into some classes according to their characteristics. Hashimoto et al. [2] classified newspaper articles according to their topics or other viewpoints. In particular, *sentiment analysis* tries to classify textual data either as positive or as negative. For example, Ikeda et al. [3] classified weblogs into two classes of positive/negative.

Our research belongs to the latter approach and analyzed and classified the reviews that include much subjective information of reviewers such as feelings, reputations, and opinions of themselves. The subjective information depends on personal situations of reviewers. Therefore, in order to obtain the subjective information in the reviews considering personal data of reviewers appropriately, it is very important to classify the reviews firstly into some categories based on features or personal information of reviewers, for example single, married, have a family, and so on.

Therefore, we devised a method to classify reviews considering their personal information.

3 TripAdvisor

"*TripAdvisor*" is a review site that collects useful travel information around the world. This site contains information of hotels and restaurants in the world. And users of these facilities can add reviews to the web pages in the site. This site has more than 50 million reviews written by users in more than 20 different languages. For example, some foreign users of Japanese hotels and/or restaurants can write a review by his native language and add them to the relevant page of "*TripAdvisor*".

When users write reviews, they can add optional keywords called "Tags" that express categories of reviews. The tags show situations or purposes when writers used

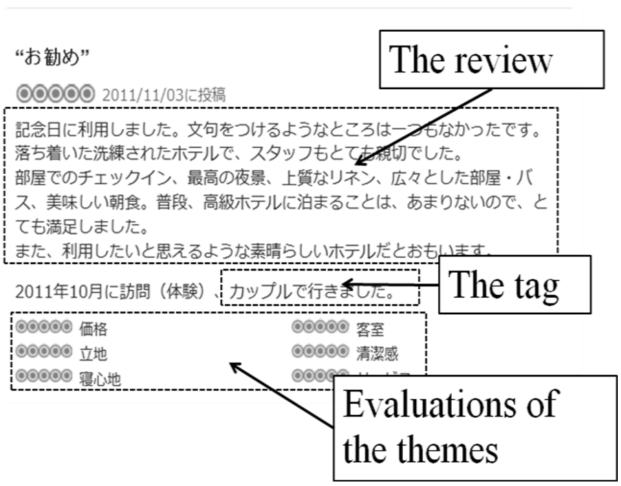

Fig.1. The example of a review in TripAdvisor

these hotels or restaurants. "*TripAdvisor*" provides five kinds of tags: "*Business*", "*Couples*", "*Family*", "*Friends*" and "*Solo*".

Users can also evaluate various themes by five grades. For example of the themes are "*Price*", "*Place*", "*Cleanliness*", "*Services*", and so on.

Fig.1 shows an example of reviews in this site. That shows a review text, tag data, and six themes. In later sections, we use 10,000 reviews automatically extracted from *TripAdvisor* as our data set.

4 PROPOSED TECHNIQUES

There are various methods of machine learning such as decision tree neural network and Support Vector Machine (SVM). In this study, we selected to use SVM because it fit for our purpose. We want to classify two classes: match or not match, and SVM classify data into binary.

4.1 Support Vector Machine

A support vector machine (SVM) is a supervised learning method for binary classification, originally proposed by Vapnik [4]. Fig.2 shows the basic concept of SVM.

The algorithm computes the hyperplane which divides two classes by analyzing the vector data of two classes as teacher data. With the hyperplane, the machine estimates the class of unknown data. Even if vector is high dimensional, the machine can analyze. Since the dimension of vector of documents data is often high, the machine is used for analyzing of natural language.

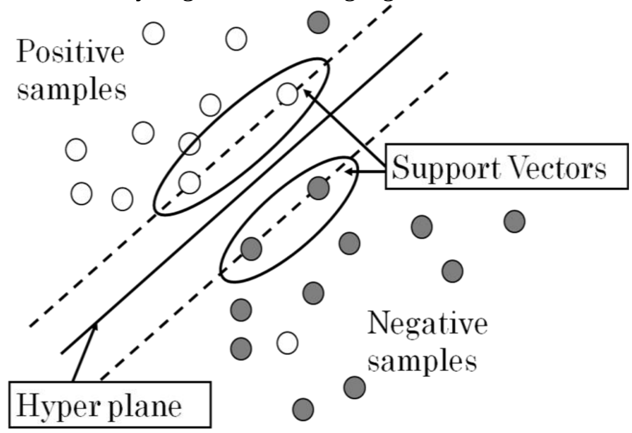

Fig.2 The illustration of SVM

4.2 Vectorization

We used ideas called "bag-of-words". For example, here are two texts S1 and S2:

S1: John likes to watch movies. Mary likes too.

S2: John also likes to watch football games.

Based on these two text documents, a dictionary is constructed as:

dictionary = {1:"John", 2:"likes", 3:"to", 4:"watch", 5: "movies", 6:"also", 7: "football", 8:"games", 9:"Mary", 10:"too"}

This dictionary has 10 distinct words. And using the indexes of the dictionary, each document is represented by a 10-entry vector as follows:

[1, 2, 1, 1, 1, 0, 0, 0, 1, 1]

[1, 1, 1, 1, 0, 1, 1, 1, 0, 0]

In English, there are spaces between each word. However, in Japanese, every words are attached each other. Therefore we need to separate them into pieces of word or other units. We used two major methods to make dictionaries and vectors of documents data.

The methods are as follows:

1. Using words segmented by a morphological analysis
2. Using character *n*-gram

We will explain each approach and their advantage and disadvantage.

4.2.1 Using words segmented by a morphological analysis

The first approach is to use words that are segmented from character strings using a morphological analyzer. We used Mecab[5], a Japanese morphological analyzer.

<u>Advantage</u>

This method can use words in an ordinary sense to make vectors. In addition, it is useful to decrease sizes of indice and dimensions of vectors.

For example, "begin", "began" and "begun" are different forms of the same word, "begin," in English, and using a morphological analyzer, we can easily put these different forms into a single word.

<u>Disadvantage</u>

If some words are not registered in the dictionary of the morphological analyzer employed, these words cannot be analyzed correctly. The information of words are lost.

4.2.2 Using *n*-gram

A character *n*-gram expression is a string of *n* characters. For example, if *n* is set to two, a word "nature" is separated to "na", "at", "tu", "ur", and "re" as 2-gram expressions.

<u>Advantage</u>

We can use this method in any written languages without complex preprocesses.

<u>Disadvantage</u>

An *n*-gram expression may not correpond to a meaningful unit in a usual sense. In addition, the dimension of the vector is very high by this method.

Online customer reviews usually contains expressions that are not registered in a dictionary for morphological analyzers. So if we take the first approach, there is a risk that expressions wrongly segmented badly affects our analysis. On the other hand, if we take the second approach, we need pruning many *n*-gram expressions of lower frequencies to enable a realistic computation. In other words, both approaches have some difficulties. So we compared these two approaces to know which is better for our purpose.

5 EXPERIMENTS AND DISCUSSIONS

5.1 Experiments and results

First, we collected the reviews of the accommodations in Japan from "TripAdvisor". We used only the data which have the tag of "Solo", "Couples", "Family" and "Friends". And we defined two classes that a class with the tag of "Solo" and another with the tags of "Couples", "Family" and "Friends".

We extracted 10,000 data at random from "TripAdvisor". These data are labeled by the two classes. And we divided those data into 5,000 training data and the 5,000 test data.

In the vectorization, vectors are constructed by three data set: morphological analysis, bigram, and trigram that are described in Chapter 4. Moreover we let vectors pass in the filters and made other data sets. The purposes of using filters are to reduce the element of an unnecessary vector and to raise the accuracy of analysis. We thought that heavily used words should have appeared in many reviews. On the other hand, the less frequency words are not special data. Therefore we expected that the accuracy of classification would go up if those words can be removed. We tried to use some simple filters that considered in the

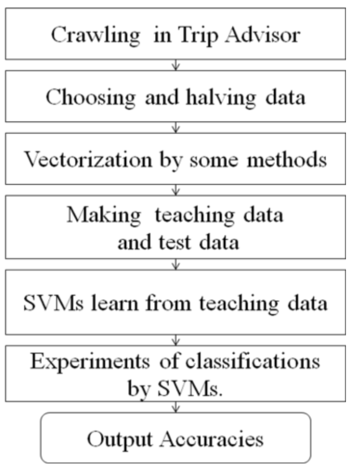

Fig.3. The flowchart of expriments

frequency of words. Seven data sets were made from each method.

- Data containing all the elements
- Data in which deleted the elements that frequency are top 10% , 20% and 30%
- Data in which deleted the elements that frequency are lower 10% , 20% and 30%

We used SVM as the method of machine learning. We used C-SVC of Soft margin classification among the kinds of SVM. Soft margin classification is the technique which allows some errors, loosens restrictions and raises accuracy.

Fig.3 shows the flow of the proposed method.

S1: crawling in Trip Advisor and gathered reviews and their options of tags.

S2: choosing the data of reviews that contain the tags, halving data and making data of teaching data and test data later

S3: making vector from data by the methods.

S4: reduceing elements of vector by the frequency, labeled vector from tag of reviews make teaching data and test data.

S5: SVMs learn from these teaching data.

S6: Experiments of classifications by SVMs using those test data.

Table.1 shows experimental results.

Table 1 Precision Rate of Experimental Results

			word	bigram	trigram
Without pruning			63.8	64.5	65.3
Pruning	top	10%	64.0	64.7	64.5
		20%	64.0	64.1	63.9
		30%	64.2	63.9	64.1
	bottom	10%	56.7	61.6	61.2
		20%	51.9	60.3	60.6
		30%	52.3	59.7	59.7

5.2 Discussions

Most accuracies rates were around 60%. When we use the data in which the top 10%, 20% and 30% of elements are pruned, there is not big difference in precision.

However, when we use the data in which The low 10%, 20% and 30% of elements are pruned, there is a small difference in precision. When we use the data made using word segmented by a morphological analyzer, the accuracy of an experimental result is worse than others. Especially, when the data in which the low 20% are pruned, the result is the worst of all results. It may be because the data whose atomic elements are words segmented by a morphological analyzer contain some important words in their low frequency words. Therefore we must not prune these data and we should give more weights to these data. Moreover, the big difference in accuracy was not observed by *n*-gram.

In this experiment, we cannot confirm the high effectiveness of filtering by the experimental results of the precisions. The precision rates of the data of morphological and bigram increased a little. And, in this experiment, precisions of the data of *n*-gram are not decreased very much. If the data of *n*-gram are used for construction of vectors, filtering technique may be useful for reducing computation times of vectors without decrease of precisions when using the data of *n*-gram.

Considering these experimental results, the experimental results are not of very high quality. We obtained two problems concerning these experiment results. Firstly, we should devise techniques to improve the accuracy rate higher. Next, we devise again techniques to make appropriate filters, especially for the data of morpheme. Filtering is necessary to reduce the computing times of vectors. However, if we apply the filters to the data, the accuracy tends to fall down. Therefore, we must increase the accuracy rate higher before applying the filters.

6 CONCLUSION

We devised a method to classify reviews by using features added by reviewers and we applied the machine learning method SVM to this problem. This work is a preliminary one, and we made a comparison of two data sets whose atomic units are different. Based on this result, we are planning to make an extensive analysis of online customer reviews to construct the best filter set for a certain purpose, and make a better analysis to obtain an intriguing result with online customer reviews.

Abstract: Study on smell sensing and classification has been developed for a long time by many ways. Most of these have been focused on bad smells, when factors of bad smells were known chemically. Many gas sensors have been developed to detect specific chemicals. Our purpose is to make a new measurement system of smell gases and to apply it to classification of many gases. The proposed system has many sensors in a chamber and detects some chemicals at the same time. Smells data are transmitted to an A/D converter in a host PC which can be used to analyze data to classify the smells. The system must classify not only kinds of smells but also densities of them. In this paper, we develop the measurement system for multi-channel sensors made of metal-oxide semiconductors with power supply circuits.

Keywords: metal-oxide gas sensor, smell measurement, multi-channel sensors

1 INTRODUCTION

Study on smell sensing and classification has been developed for a long time by many ways [1]. The olfactory have many receptors in a nose and these receptors can transform the smells to electrical signals. Those signals are transported to our brain to classify the kinds of smells. Much research has been focused on bad smells. Many of these reports on smells were discussed about bad smells when factors of bad smells were known chemically. Many gases sensors were developed to detect these chemicals. These sensors can detect a few chemicals. However, smells consist of many chemicals, and one sensor cannot classify the smells.

Our final goal is to make an artificial olfactory system which is called an electronic nose (e-nose) based on the knowledge of the human olfactory system and a neural network algorithm. To make an efficient e-nose, we must measure a precise smell data. Thus, we develop a high efficient measurement system for smells. For this purpose, it is difficult to realize the high efficient measurement system in which only one smell sensor is attached. In this paper we propose a many sensors array system instead of one smell sensor in a chamber of smell. The system must classify not only kinds of smells but also densities of them.

In this paper, we develop the measurement system for multi-channel sensors made of metal-oxide semiconductors with power supply circuits which satisfy the following conditions:

1. Power supplies for sensors are independently.
2. Power supplies for a sense and a heater are independently.
3. It must be connected with variable register loads as outputs of smell sensors.

Independence of power supply for sensors is to make the sensitivity of the each sensor variable and to change various sensors.

Many gas sensors have heaters in the sensor units. For stable detection, these sensors should be heated a few hour or days. However, only for the heating, the measurement circuit for a sensor is not use and the power of sensor circuit can be switched off. Furthermore, when temperature of a gas is changed, sensed data should be revised. This power system can change the heater power independently, and the revise is to be little.

Because sensors of characters are different, the measurement data should be normalized. However, an activity level of sensor is different. To apply high sensitivity level of sensors, it is necessary to adjust sensor output signal levels.

The proposed system has these features, and they are effective to realize an e-nose system. In this paper, we will consider the multi-channel system, and then the problems to realize it. Next, we will try to tune sensitivity of a sensor for the system, and we will show an evaluation system.

2 PROPOSED SYSTEM

2.1 Over view

Figure 1 shows our proposed system over view, and Figure2 shows a block diagram of the system. The system has 12 metal-oxide gas sensors. They have a 4 contacts for sensor power in, sensor out, heater power in, and GND, and are connected to power supply circuit each. A pair of the contacts is for a heater, and the other pair is for a sensor. Requirement of electric powers for the sensors are different, and there powers are supplied independently. Furthermore, the sensors heater voltage should be stable[2], the power system contribute the require. In our proposed system, a sensor have a 2 power supply system. One is for a heater, and the other is for a sensor circuit. Our evaluation system have 12 sensors. Hence, our system have 24 power supply circuits. In experiments section, we will show the way of tuning for these power supplies for setting sensitivity of a sensor.

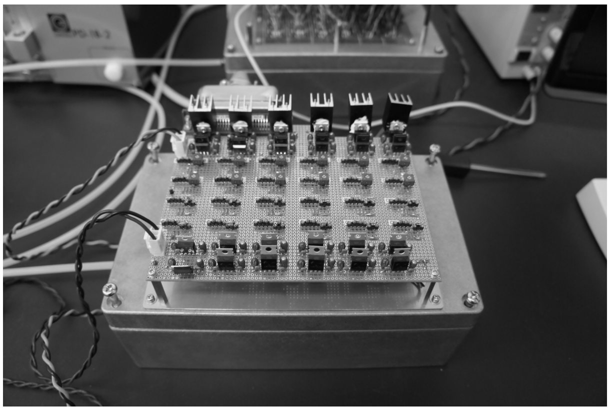

Fig. 1. evaluation system over view

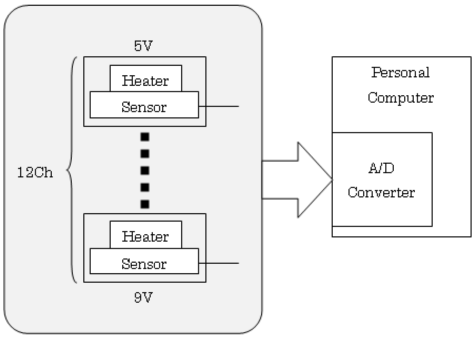

Fig. 2. system block diagram

3 EXPERIMENTS AND CONSIDERS

In this experiments, we evaluate the system using TGS 816 (Figaro Engineering) which is one of sensors in our system. TGS 816 is made for methane, propane and butane, and it can detect a ethanol [3]. An ethanol in a cup (3cm in diameter) and the sensor are in a chamber. Output signal of the sensor is observed by oscilloscope. Figure 3 shows a experiment circuit.

3.1 A transition of gas sens by heater voltage (Experiment 1)

At the first, we evaluate a transition by heater voltage changing. In this experiment, a voltage for VC is fixed, and a voltage for VH is changing. Figure 4 shows an output signal (VH=3V, VC=5V). We evaluate the experiment, we separate the waveform with a first section and a second section.

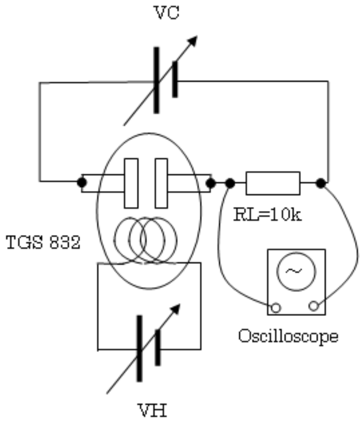

Fig. 3. Experiment circuit

The first section is started at about 38 second and finished at about 60 second in fig.4. The second section is started at about 60second and continue. Table 1 shows a calculation result from waveform. Rising rates of each sections are calculated by

$R = voltage/time$

By changing the heater voltage, the sensibility can be changed. The sensor output signals is different by changing VH. Furthermore, there are peaks of 1st section and 2nd section at different voltage. The result shows an ability to control a sensitivity of sensors. For example, we require a first response, we can select a VC at the peak on 1st section. When we require an result priority to an correct density, we can select a VC at the peak on 2nd section. The signal response in 1st section is too sensitive, and stable response appear in 2nd section. The sensitivity at the 1st section is shown on our next experiment result.

3.2 A transition of gas sens by circuit voltage (Experiment 2)

Next experiments, we evaluate a transition by circuit voltage changing. In this experiment, a voltage for VH is fixed, and a voltage for VC is changing. Table 2 and Fig. 6 shows a experiment results. The result shows a fluctuation of 1st section response is large by changing VC. Moreover, we can see the 2nd section response is stable.

By comparing Table 1 and Table 2, the 2nd section rate is higher than experiment1. When we require the quick response on 2nd section, we set VC voltage to be high.

3.3 Evaluation system

Figure 7 shows sensors in our proposed system, and Table 3 is a list of the sensors. Power supply voltages of each sensors on the system were setting manually with check and try. Some sensors sense some gases. For example, methane will be sensed by TGS 816 and TGS 2611. Thus, the system detect balances of gases, and it is effective to realize a olfactory emulation. These sensors are connected through connectors, and any sensors could be changed other sensors. A chamber of the system is made by aluminum, and has a chemical durability. Signals of sensors are connected to A/D converter in a host PC, the signal voltage is matched by resisters on the system. The system has 2 power input inlets, one is for 5V power line and the other is for power line above 5V. The power line can be changed easily for experiments.

Figure 8 shows a graph of sampling data with 12Ch. This graph is illustrated by Microsoft excel from A/D converter sampling data. These 12 lines are 12 sensors output. They are detected data for ethanol. The result is shown that the sensors reaction are differed and could use an analyzing of gases.

4 CONCLUSION

In this paper, we have shown circuit design method for olfactory emulation system with multi-channel metal-oxide gas sensor. To use gas sensors whose electrical characters are different at the same time, it is necessary to tune the characters. We have realized a way to tune for sensitivity, and shown it. Furthermore, we have shown a evaluation system with 12Ch sensors.

The future research, to realize a automatic tuning, and to develop the system with intelligent signal processing.

In this paper, a reliable electronic nose (EN) system designed from the combination of various metal oxide gas sensors (MOGS) is applied to detect the early stage of fire from various sources. The time series signals of the same source of fire in every repetition data are highly correlated and each source of fire has a unique pattern of time series data. Therefore, the error back propagation (BP) method can classify the tested smell with 99.6% of correct classification by using only a single training data from each source of fire. The results of the k-means algorithms can be achieved 98.3% of correct classification which also show the high ability of the EN to detect the early stage of fire from various sources accurately.

1. Introduction

Every year the damage from the household fire disaster brings about not only severe loss to property assets, but also physical and psychological injuries of the people. Although most of the residences have installed the fire detectors system such as smoke detectors, those devices cannot detect the early stage of fire since their warning signals are triggered by the high smoke density or the high air temperature. In this paper, the reliability of a new electronic nose (EN) system developed from various metal oxide gas sensors (MOGSs) to specify the smell from various sources of fire is presented.

Jame A. Milke [1] has proved that two kinds of MOGSs have the ability to classify several sources of fire more precisely than conventional smoke detector. However, his results can be achieved only 85% of correct classification. In this paper, a new EN that has been successfully applied to classify not only the same smell from different brands, but also the same smell at different concentration levels [2] is applied to measure smells from various sources of fire such as household burning materials, cooking smells, the leakage from the liquid petroleum gas (LPG). The time series signals of the MOGSs from the beginning to the time until the MOGSs are fully absorbed the smell from each source of fire are recorded and analyzed by the error back propagation (BP) neural networks and the k-means algorithms. The average classification rate of 99.6% can be achieved by using the BP method with only a single training data from each source of fire. The results from the k-means algorithm can be achieved 98.3% of correct classification that also confirms the reliability of this new device to be able to detect various sources of fire in the early stage much better than the results of Jame A. Mike [1].

2. Metal Oxide Gas Sensors for EN

A commercial MOGS has been developed widely for more than thirty years.

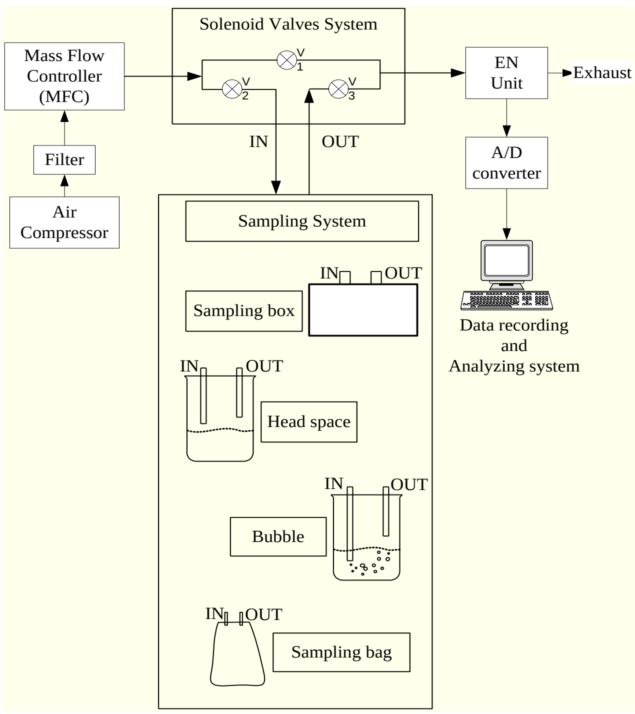

Fig. 1 Schematic diagram of the electronic nose system.

Generally, it is designed to detect some specific smell in electrical appliances such as an air purifier, a breath alcohol checker, and so on. Each type of MOGS has its own characteristics to response to different gases. When combining many MOGSs together, the ability to detect the smell is increased. An EN system shown in Fig. 1 has been developed based on the concept of human olfactory system by using the combination of MOGSs from FIS Inc. listed in Table I as the olfactory receptors in the human nose. The MOGSs unit is combined with the air flow system to flow the air and the tested smell into the MOGSs unit. The data logger converts the analog signals to digital signals and stores them in the data recording system before being analyzed by multivariate analytical methods, such as the BP method and the k-means algorithms.

The main part of the MOGS is the metal oxide element on the surface of the sensor. When this element is heated at a certain high temperature, the oxygen is absorbed on the crystal surface with the negative charge. The reaction between the negative charge of the metal oxide surface and deoxidizing gas makes the resistance of the sensor vary as the partial pressure of oxygen changes [3]. Based on this characteristic, we can measure the total voltage changes during the sensors absorbing the tested odor.

Table I List of MOGSs from the FIS Inc.

Sensor Model	Main Detection Gas
SP-53	Ammonia, Ethanol
SP-MW0	Alcohol, Hydrogen
SP-32	Alcohol
SP-42A	Freon
SP-31	Hydrocarbon
SP-19	Hydrogen
SP-11	Methane, Hydrocarbon
SP-MW1	Cooking vapor

Since the MOGS is sensitive to the temperature and the humidity, the MOGSs unit is put in a small chamber that has a heating system to increase the air temperature during winter season. The heating unit can also decrease the air humidity in the chamber. The clean water is manually sprayed into the chamber when the humidity drops lower than the control level. In this experiment the temperature in the chamber is kept between 20-30°C and the humidity is kept between 30-40%RH. The tested smell is sucked to mix with the fresh air before passing to the MOGSs unit. The distance from the tested smell to the MOGSs unit is approximately 1.5 m.

3. Experimental Data Collection

The smell from twelve sources of fire listed in Table II are measured by the EN system explained in previous section. Each source of fire has been tested with forty repetition data measured in different days in order to check the repeatability response of the MOGSs to the same smell.

For each data, the voltage signal of the normal air is measured every second for one minute and its average value, $\bar{v}_{air}$, is used as an air reference point. After that, the voltage signals of the sensors when absorbing tested smell, $v_{smell,t}$, are collected every two minutes for each smell sample. Finally, the total change in signals at each period, $V_{smell,t}$, is calculated by

$$V_{smell,t} = v_{smell,t} - \bar{v}_{air}$$

where t is the time from 1 to 120s.

After testing one smell the MOGSs need to be cleaned by removing the tested smell and supplying only the fresh air until the MOGSs return to stable point before testing the new sample. This process is just like the human nose which need to breath the fresh air before able to recognize the new smell accurately. Some time series data from the experiment in Fig.2 show that all smells approach the saturation stages within the measuring periods. The signals from the same source of fire in every repetition data are similar in most data sources. The results using the BP method and the k-means algorithm to analyze the time series data from each source of fire every two seconds and the average signals during the saturation stages(time 100-120s) are discussed in Section V.

Table II List of Burning Materials in the Experiment

Sources of fire	Abbreviation
Steam from boiling water	Steam
Burning joss stick	Joss
Burning mosquito coil	Mos
Aroma oil	Aroma
Aroma candle	Candle
Flame from liquid petroleum gas(LPG)	Flame
Leakage of LPG	LPG
Steam from Japanese soup called "oden"	Oden
Boiling vegetable oil	Oil
Toasted bread	Toast
Burning paper	Paper
Burning wood	Wood

4 Correlation of the Experimental Data

Before classifying each source of data, the correlation of each data source is investigated by using the similarity index (SI) and the principal components analysis (PCA).

4.1. similarity index

In the statistical application, the correlation value developed mainly by Karl Pearson is widely used to find the relationship between two random variables. In this paper, we call the correlation value as a similarity index

(SI). The SI value varies from -1 to 1. Two random variables with a SI of either 1 or 1 are highly correlated because knowledge of one provides precise knowledge of the other. However, the SI provides information only about linear relationships between random variables. Random variables could have a nonlinear relationship but still have a SI close to 0 [4]. Therefore, we make an assumption on this application that each data pattern has nearly linear relationship to the other data patterns. The SI value between two data is calculated by

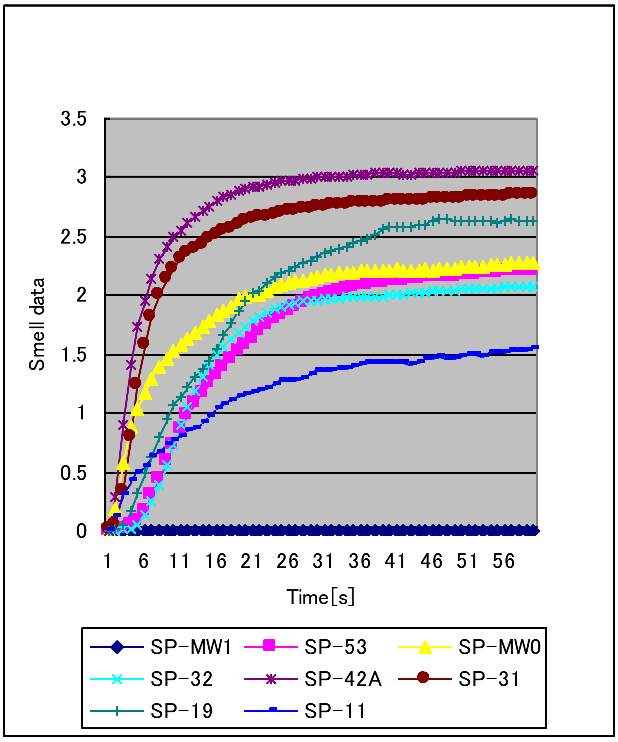

Fig.2 Time series data from some sources of fire in the experiment.

$$r_{xy} = \frac{\sum_{i=1}^{n} x_i y_i - n\bar{x}\bar{y}}{\sqrt{(\sum_{i=1}^{n} x_i^2 - \bar{x}^2)(\sum_{i=1}^{n} y_i^2 - \bar{y}^2)}}$$

where r_{xy} is the SI value, x and y are the comparing data, $\bar{x} = \frac{1}{n}\sum_{i=1}^{n} x_i$, $\bar{y} = \frac{1}{n}\sum_{i=1}^{n} y_i$, and n is the size of each data which equals 480 (60 periodsx8 sensors).

By using the SI to find the relationship between the repetition data of each data source, we found that all data sources except the paper and the wood have high average SI values above 0.99. During the experiment, the paper and the wood have inconsistent burning rates, therefore the signals from the repetition data of these sources are more fluctuated than the other sources that have better consistent burning rate.

4.2 principal components analysis

In this paper, the well known PCA is applied to analyze two cases of the experimental data. The full time series data case uses the data signals every two seconds, but the saturation stage data case uses only the average data from time 100 to 120s for analyzing.

The plots of two main components are shown in Fig.3. The distribution of the paper and the wood burning smell are more scattered than the other kinds of smells especially in the case of saturation stage data. Most of the tested data are separated into their own clusters with some overlap zones between different data source.

5. Experimental Results and Discussion

5.1 experimental result

Two case of data are analyzed by the BP method and k-means algorithm. The full time series data (TSD) case uses the data from all MOGSs every two seconds as the input data. The saturation stage data (SSD) case uses only the average value from time 100 to120s of all sensors as the input data.

The BP structure contains three layers. The input layer of the TSD case, and the SSD case consists of four hundred eighty nodes (8 sensors x 60 periods), and eight nodes(average signal from 8 sensors), respectively. For the hidden layer, we have tried with several values and the size that gives a good accuracy and a reasonable training time for both data cases is forty nodes. The output layer contains twelve nodes, each node represents one data source. The learning rate, the momentum rate, and the minimum mean square error (MSE) during the training period are set by trial and error method to 0.1, 0.001, and 0.0003, respectively.

Based on the information during investigating the correlation of the data, most data sources are highly correlated to their repetition data with high SI values. Therefore, only one data that has the highest average SI value to the other repetition data from each sources of fire are used as the training data for the BP and the rest of the data are used as the test data. We assume that a pattern is classified correctly if (output $\leq$ 0.7 and target=1) or (output $\leq$ 0.3 and target =0). For the k-means algorithm, the training data of the BP method are used as the initialize data and then assigns the data patterns to the nearest cluster center by calculating the Euclidean distance. After that, the new cluster center is recalculated. The process continues until the position of the cluster center is not changed. The final results of this experiment are shown in Table III.

The results using the TSD from both the BP method and the k-means algorithm are sufficiently effective. The data signals from the MOGSs are affected by many factors, such as the sampling condition, the inconsistency burning rate, the fluctuation from the standard air, and so on. Therefore, the saturation stages of the data are varied by those factors. By including the signal before approaching the saturation stage, the accuracy to classify all smell is increased.

5.2 Discussion

Although the distribution of PCA shown in Fig. 3 cannot clearly separate similar smell such as the aroma oil and the aroma candle, the BP method and the k-means algorithms are able to classify them perfectly as shown in Table III. The results of TSD using the BP method have only two incorrect classified data. These two data are not misclassified as the other smells. Only the output values of their paper node are not high enough to classify them as the paper. The output values of these two data on the paper node are only 0.4951, and 0.4799, respectively and the output of the others output nodes are nearly 0. The results are much better than the results from [1] which used two kinds of MOGSs to classify several sources of fire into three fire condition levels, flaming, smoldering, and nuisance, with only 85% of correct classification. The smoke density of the tested data is not high enough to trigger the alarm of the smoke detector. In case of unusual burning smells in the residences such as the wood burning, flaming from the LPG, or the leakage LPG, it is necessary to have a proper device to detect these sources before unable to stop the fire. We can conclude that the new EN system shown in this paper is a proper device for this application.

6. Conclusions

We have proposed a new EN system designed from various kinds of MOGSs. The EN has the ability to identify various sources of fire in the early stage with more than 99% of accuracy by using only a single training data in the BP case. The results from the k-means algorithm are also able to predict the sources of fire with more than 98% of accuracy. It can be concluded that the EN is suitable for detecting the early stage of fire.

Abstract: Human olfactory is examined for a long time and many ways. Olfactory is studied based on gas chromatography technology. These studies have used gas sensors made of metal-oxide semiconductors. The semiconductor-sensors can detect gases as difference of resistance by oxidation or reduction of surface on the sensor. Human olfactory is organized by about 2,000 receptors of smell, and many sensors are used to emulate by electric sensors. We consider to apply multi-channel QCM for these sensors, and build an evaluation system.

Keywords: Olfactory, Multi-Channel-QCM, Oscillator

1 INTRODUCTION

Human senses are examined for long term and many ways and the olfactory of human senses has been examined. Olfactory is like a sense of gas and air, and is studied based on gas chromatography technology. These studies used sensors to detect gases by semiconductors. The semiconductor-sensor detects a gas as difference of resistance by oxidation or reduction of the surface on a sensor. Human olfactory is organized by about 2,000 receptors of smell, and many sensors are used to make an electric sensor[1]. We consider to apply QCM(Quartz Crystal Microbalance) sensors as these sensors.

QCM gas sensors are able to detect a small alternate of a mass on the crystal. By change a gas of air, the mass will change and it can be detected of difference of a frequency by the crystal oscillator. In usual, QCM is applied for measuring absolute alternation of the mass. However for the QCM sensor, we measure relative and differences of the mass. Usually, one QCM composes an instrument to measure the smell absolutely and correctly. In our system, 24 QCM sensors are attached in an instrument to detect differences of some gas in an air simultaneously. These QCM sensors consists of crystals which are coated in different chemical characteristics.

We realize the system to evaluate our proposal method. However, there are a lot of problem to build a stable system. When oscillators are built in a small area, they interfere each other. The interference disturbs oscillation frequencies and makes jams. QCM sensor needs a fine oscillation to detect a difference of an oscillation signal. However, the jams affects the precise measurement of oscillation signals. To realize our propose system, we take measures to the anti-jammers. These measures are as follows:

1. Measures to power supply and power line
2. Measures to signal lines from oscillator to voltage converter
3. Measures to signal lines from voltage converter to FPGA
4. FPGA logics for anti-jammers.

In this paper, we express these measures to realize an olfactory emulation system with QCM.

2 PROPOSED SYSTEM

2.1 Over view

Figures 1 and 2 are shown the block diagram and the proposed evaluation system.

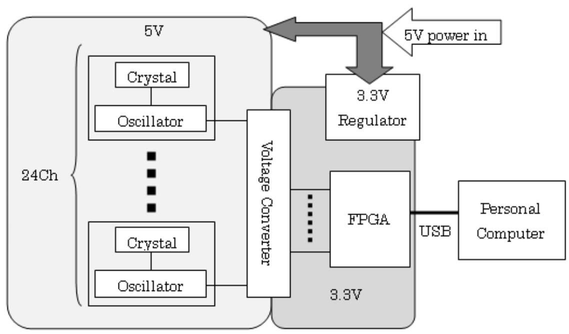

Fig. 1. Proposed system diagram

In Fig.1, the crystal oscillators are sensors of gas. These are connected to an oscillator circuit, and generate stable each pulses. Generated pulses are converted from 3.3V-level to 5V level in a level converter unit, and connected to the FPGA. In the FPGA, these pulses are used as clock signals for counters. These counters have 32bit length registers and count the number of the pulses for one second. The signal for one second is generated in an FPGA from 48MHz clock signal on the FPGA unit. The numbers of pulses are trans-

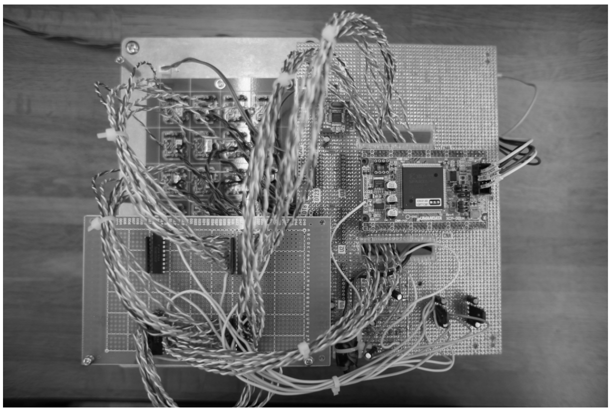

Fig. 2. Evaluation system

mitted to a host personal computer by the FPGA through USB(Universal Serial Bus), and are analyzed on it.

We consider to build a stable measurement system, and the crystals are not processed on their surface of QCM sensors on the evaluation system. Thus, we can get the pulses accurately. Figure 3 shows the crystals for an evaluation of the system.

The crystals are attached to each oscillation circuits which are built with a single inverter as like 74HCU04, CMOS inverter. An oscillator circuit schematic is in Fig. 4.

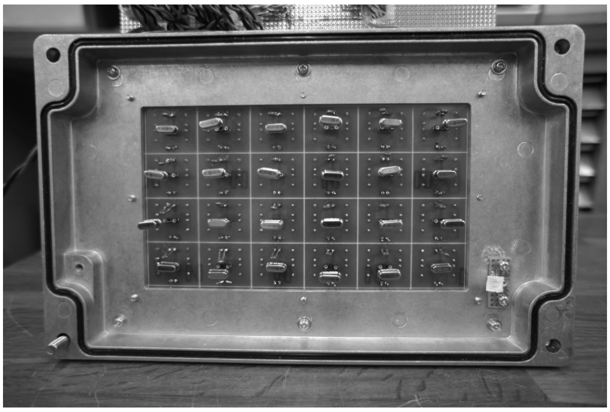

Fig. 3. Crystals for evaluating sensor system

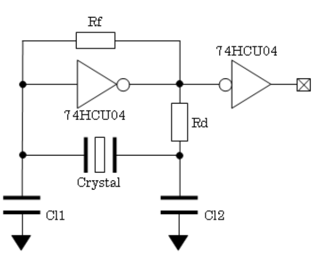

Fig. 4. An oscillator circuit for QCM sensor

2.2 Measure to power supply and power line

In our system, there are 4 power lines which are 5V, 3.3V, 1.2V. The system requires only 5V power. The voltages of 3.3V and 1.2V are generated by regulator circuits in the system. 3.3V power is supplied to the FPGA unit and voltage converter unit. 5V power is supplied to the oscillator circuit. In a conventional digital system, 5V power is generated from AC (100V) line by switching regulator circuit. However, this power is too noisy for the system, our system has direct current stabilized power supplies with series regulator.

3.3V power is delivered to voltage converter and the FPGA unit. In the FPGA, there are counter logics and communication logics. These logics are operated by 48MHz clock signal and there is jamming noise by them on power line. Voltage converter circuit is driven the same power line, convert 24 signals are 20MHz pulse signals from 5Vp-p to 3.3Vp-p. For cutting off the noises each, 3.3V power line is separated to the FPGA line and the voltage converter line. These power lines have 3.3V regulators circuit of each. In this way, a noise which is generated by FPGA logic can be reduced of effect to an oscillator circuit. Furthermore, the power line system can increase signal channels.

2.3 Measures to signal lines from oscillator to voltage converter

The oscillation circuit output is 5Vp-p signal and FPGA input should be lower than 3.3Vp-p, so it is necessary to change the voltage levels. To change the levels, TC74VHC9541[2] is used. This device has following characters.

1. 5V tolerant input (with 3.3V power)
2. Schmitt trigger input
3. Fast speed
4. Power-down protection

5V tolerance input is necessary function for this system. Usual CMOS IC device can not endure higher voltage signal input than VCC, and the device will break down. Schmitt trigger input has dual threshold and hysteresis, and realizes improvement of immunity against cross-talk. On this system, crystals for sensors have natural frequency as about 20MHz, and the device throughput is important. Power-down protection is able to do power control independently in each oscillator circuit and voltage converter circuit.

Signal lines between oscillator circuit to voltage converter are should be treated for emission and immunity of reciprocal action between each lines. These signal lines are connected line with side by side, and these lines have influences on each. By cross-talk which is one of influence, the pulse-signals are transmitted to other lines and it makes jamming to accuracy measurement. Furthermore these signal emissions influence signal lines between voltage converter to FPGA. The emission is to be large when over-shoot or under-shoot of the lines are large. A transmission-line impedance to be low, the emission by the signal can be reduced. For that, the signal lines are terminated at voltage converter input by capacitors and resisters. Next, for build a robust signal lines for immunity, we considered connection ways for the signal lines. The signal lines are 24 channels, and these are connected independently and need large space when using fat lines. To realize a small system, we should use a thin and robust line. An coaxial line is too fat and too hard for bending as small curve. Thin sealed line as like for microphone are weak to emission and immunity. And we selected a twisted-pair line for computer network(Ethernet:100Bast-T). This network line has 4 pairs. We disassembled the line and used a each pair of lines. They are thin and soft, and match the our requirement. Furthermore we can select the line length easily and change the distance the sensor unit and voltage converter unit. We are considering to apply our system for detection dog, the separation of these unit are advantage for the apply.

2.4 Measures to signal lines from voltage converter to FPGA

Converted signals to 3.3Vp-p are transmitted to FPGA input from voltage converter. These signal lines have same problems with signal lines from oscillator to voltage converter. Moreover the lines are weaker than lines from oscillator to voltage converter because of low voltage compared with them. These lines should be treated for immunity from other lines. The lines are connected by twist-pair cable, and are pulled down as 330ohm each. By keeping lower impedance than other lines, the lines immunity is robustly. However to connect the lines to ground line by capacitor, the signal is damped severely, and it makes more transmit error.

2.5 FPGA logics for anti-jammer

FPGA counts the signal pulse from oscillator for one second. the one second signal is generated from 48MHz clock on the FPGA unit. Oscillator signals are connected the FPGA as counters clock signal. These counters are reset by one second signal. Oscillator frequency fluctuation is appeared as counter number fluctuation. The number is transmitted to host PC through USB. When extreme noise influences to signals from oscillator to FPGA, the number will change on a grand scale. Usually in this system the number will be changed among about 1 to 10 for one second. The noise can be detected and canceled by a digital filter of the host PC.

3 EXPERIMENTS AND CONSIDERS

We build the system to evaluate these characters, and do the experiment using the system. In the experiment section, we show results for measured signal lines. Then we compared noise levels and jitters by wires and terminators, and evaluate differences of them. Figure 5 shows a circuit for the experiment. In this figure, 74HCU04 is a part of oscillator circuit for QCM. Other oscillators are oscillation units which are TOYOCOM TCO711A and TCO711A compatible MC0-1510A. Measurements are about each combinations of sealed wires and twisted pair wires. Measurement result is shown in table 1. In this table, QCM is a 74HCU04 output, and it is an equivalence of QCM sensor output. OSC1 and OSC2 are other oscillation unit's status of wirings and outputs. Fluctuation is a voltage at stable voltage region. Jitter is a voltage at voltage transition region.

Figure 6 is shown the measurement by an oscilloscope of condition No.1. In the experiments, this wave is a reference wave of best condition. Condition of No.4 is a changed line of QCM from sealed line to twisted pair line. However, other conditions are the same as No.1. In the conditions of No.1 and No.4, there are no differences of measurements. When other oscillator is no power, we can see there are not noise and jitters.

In conditions No.2 and 3, QCM, OSC1, and OSC2 are connected to 74VHC9541(Level converter) with sealed lines. Figure 7 showed a waveform in condition NO.3. There are

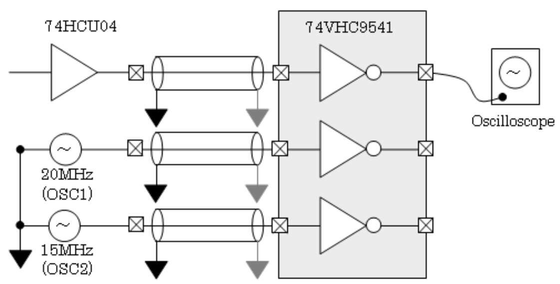

Fig. 5. Experiment circuit

2	S.L.	no	S.L.	680	2.0	
3	S.L.	S.L.	S.L.	720	2.0	fig.7
4	T.P.	no	no	200	0.5	
5	T.P.	S.L.	S.L.	680	2.6	
6	T.P.	T.P.	T.P.	680	1.4	Fig.8

S.L.: sealed line T.P.: twisted pair no: no signal

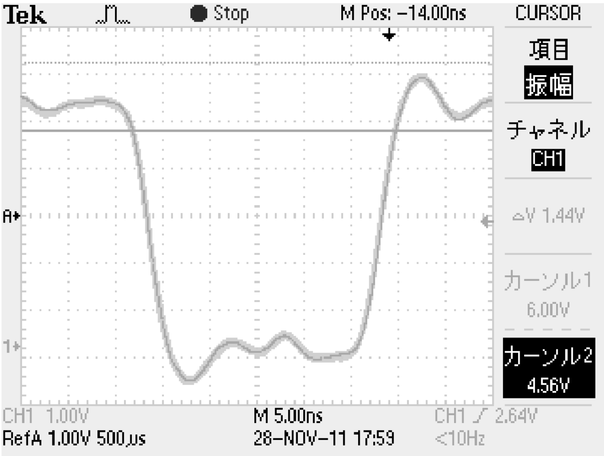

Fig. 6. Wave form of condition No.1

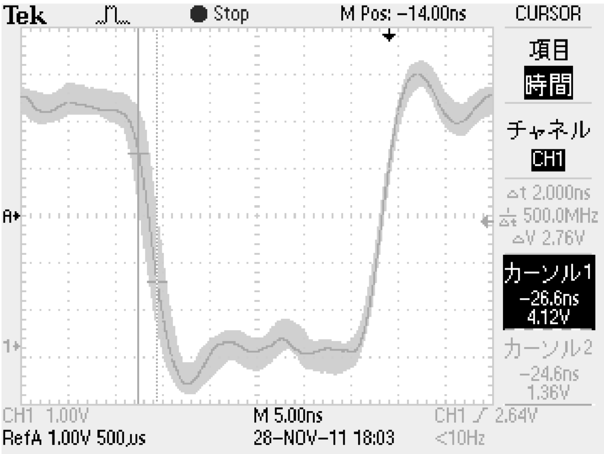

Fig. 7. Wave form of condition No.3

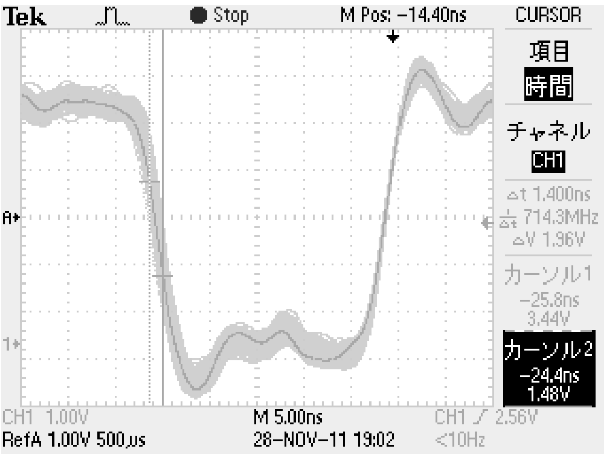

Fig. 8. Wave form of condition No.6

larger noises and jitters than No.1 results. Furthermore, there is no difference of jitters in condition No.2 and 3. The result shows an emission by OSC1 and OSC2 are strong in this condition.

In condition No.5, only QCM is connected by twisted pair wire. OSC1 and OSC2 are connected by sealed line wires. In this result, jitters are large and, fluctuations are the same as No.2 and 3. This result shows that strength of immunity by twisted pair line for QCM is not enough for emissions by OSC1 and OSC2.

Figure 8 is shown a result of condition No.6. In this condition, QCM, OSC1 and OSC2 are connected to 74VHC945 by twisted pair wires. This wave form shows that jitters are smaller than conditions No.2 or No.3. The result shows that an emission of OSC1 and OSC2 are reduced by the wires, and the twisted pair wires are effective for it.

From these experiments, by applying a twisted pare wire for the system, jitters become low. Ratio of jitter for the QCM output frequency is as follows:

$$(2.0 - 1.4)/50 = 0.012$$

$$QCMclock : 20MHz = 50nsec$$

The experiments show that the ratio is improved by 1.2%.

4 CONSOLUSION

In this paper, we show a building method for multi-channel QCM system. The multi-channel QCM can be realized by a small olfactory emulation system. Multi-channel QCM system requires a number of signal lines as channel numbers, and the system should use a thin wire to realize a compact system. Furthermore, jitters for these signals should be low for accuracy measurement. We considered wires to fit these requirements, and showed measured data with the wires. We will make a more flexible olfactory system by changing a number of channels and a stand-alone olfactory system without host PC.

Abstract: Compared with metal oxide semiconductor gas sensors, quarts crystal microbalance (QCM) sensors are sensitive for odors. Using an array of QCM sensors, we measure mixed odors and classify them into an original odor class before mixing based on neural networks. For simplicity, we consider the case where two kinds of odor are mixed since more than two become too complex to analize the classification results. We have used eight sensors and four kinds of odor are used as the original ones. The neural network used here is a conventional layered neural network. The classification is acceptable although the perfect classification could not been achieved.

Keywords: neural networks, separation of mixed gasses, odor classification

1 INTRODUCTION

Over the last decade, odor sensing systems (so-called electronic nose (EN) systems) have undergone important development from a technical and commercial point of view. The EN refers to the capability of reproducing human sense of smell using sensor arrays and pattern recognition systems [1].

We have presented a type of EN system to classify the various odors under the various densities of odors based on a competitive neural network by using the learning vector quantization (LVQ) method in [6]. The odor data were measured by an odor sensor array made of metal oxide gas (MOG) sensors. We used fourteen MOG sensors of Figaro Engineering Inc. [3] in Japan. We considered two types of data for classification in the experiment. The first type was a set of four kinds of teas and the second one was a set of five kinds of coffees of similar properties. The classification results of teas and coffees were about 96% and about 89%, respectively, which was much better than the results in [5].

In this paper, we will consider the classification of mixed odors based on the sensing data by using quarts crystal microbalance (QCM) sensors. QCM sensors are sensitive to odors and we can measure the odor data precisely. Using many QCM sensors, we will try to separate the odors being mixed with two kinds of odor into the original odors based on the neural network classifier.

2 PRINCIPLE OF QCM SENSORS

The QCM has been well-known to provide a very sensitive mass-measuring device in nanogram levels, since the resonance frequency will change sensitively upon the deposition of a given mass on the electrodes. Synthetic polymer-coated QCMs have been studied as sensors for various gasses since QCM coated with a sensing membrane works as a chemical sensor. The QCM sensors are made by covering the surface with several kinds of very thin membrane with about 1 μm as shown in Fig. 1.

Since the QCM oscillates with a specific frequency depending on the cross section corresponding to three axis of the crystal, the frequency will change according to the deviation of the weight due to the adsorbed odor molecular (odorant). The membrane coated on QCM has selective adsorption rate for a molecule and the frequency deviation show the existence of odorants and their densities. Odorants and membrane are in tight relation while it is not so clear whose materials could be adsorbed so much.

In this paper we have used the following materials as shown in Table **??**. The reason why fluorine compounds are used here is that the compounds repel water such that pure odorant molecules could be adsorbed on the surface of the membrane. To increase the amount of odorants to be adsorbed it is important to iron the thickness of the membrane. In Table **??**, we have tried to control the density of the solute in the organic solvent. The basic approach used here is a sol-gel method. The sol-gel process is a wet-chemical technique used for the fabrication of both glassy and ceramic materials. In this process, the sol (or solution) evolves gradually towards the formation of a gel-like network containing both a liquid phase and a solid phase. Typical precursors are metal alkoxides and metal chlorides, which undergo hydrolysis and polycondensation reactions to form a colloid. The basic structure or morphology of the solid phase can range anywhere from discrete colloidal particles to continuous chain-like polymer networks.

3 ODOR SENSING SYSTEM

Generally, it is designed to detect some specific odor in electrical appliances such as an air purifier, a breath alcohol checker, and so on. Each of QCM membranes has its own characteristics in the response to different odors. When combining many QCM sensors together, the ability to detect the odor is increased. An EN system shown in Fig. 2 has been developed, based on the concept of human olfactory system. The combination of QCM sensors, listed in Table **??**, are used as the olfactory receptors in the human nose.

The odors used here are shown in Table 2. Note that the chemical properties of these odors are very similar and it has been difficult to separate them based on the measurement data by using MOGS sensors.

4 CLASSIFICATION METHOD OF ODOR DATA

In order to classify the odors we adopt a three-layered neural network based on the error back-propergation method as shown in Fig. 3.

The error back-propagation algorithm which is based on the gradient method is given by the following steps.

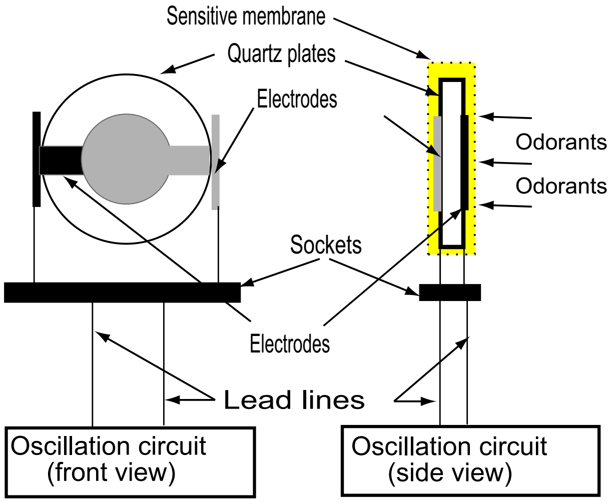

Fig. 1. Principle of QCM. The odorants attached on snsitive mambrane will make the weight of quartz plane. Thus, the original frequency of the crystal occilation will become smaller according to the density of odorants.

Step 1. Set the initial values of $w_{ji}, w_{kj}, \theta_j, \theta_k$,and $\eta (> 0)$.
Step 2. Specify the desired values of the output $d_k, k = 1, 2, \dots, K$ correspondint to the input data $x_i, i = 1, 2, \dots, I$ in the input layer.
Step 3. Calculate the outputs of the neurons in the hidden layer and output layer by

$$\begin{aligned} \text{net}_j &= \sum_{i=1}^{I} w_{ji} x_i - \theta_j, O_j = f(\text{net}_j), f(x) = \frac{1}{1+e^{-x}} \\ \text{net}_k &= \sum_{j=1}^{J} w_{kj} O_j - \theta_k, O_k = f(\text{net}_k). \end{aligned}$$

Step 4. Calculate the error e_n and generalised errors by

$$\begin{aligned} e_k &= d_k - O_k, \delta_k = e_k O_k (1 - O_k) \\ \delta_j &= \sum_{k=1}^{K} \delta_k w_{kj} O_j (1 - O_j). \end{aligned}$$

Step 5. If e_k is sufficiently small for all k, END and otherwise

$$\begin{aligned} \Delta w_{kj} &= \eta O_j \delta_k, w_{kj} \Leftarrow w_{kj} + \Delta w_{kj} \\ \Delta w_{ji} &= \eta O_i \delta_j, w_{ji} \Leftarrow w_{ji} + \Delta w_{ji}. \end{aligned}$$

Step 6. Go to *Step* 3.

Using the above recursive procedure, we can train the odor data. The measurement data is an eight-dimensional vector which are obtained with eight sensors stated in Table **??**.

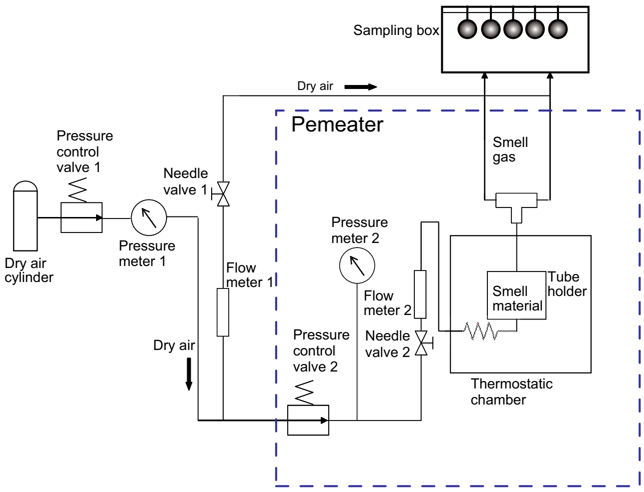

Fig. 2. Odor sensing systems. The air will be emitted from the dry air cylinder. Air flow is controlled by pressure control valves 1 and 2. By using the needle valve 2, more precise folow rate of the dry aircan be achieved and the thermostatic chamber in the pemeater can control the temperature of the dry air. Finally, the air is pull in the sampling box where the QCM sensors are attached on the ceiling of the box.

5 MEASUREMENT OF ODOR DATA

We have measured four types of odors as shown in Table 2. The sampling frequency is 1[Hz], the temperatures of odor gases are 24∼26 [$°C$], and the humidities of gases are 6∼8 [%]. To control the density of gases, we use the deffusion tubes. Odor data are measured for 600 [s]. They may include impulsive noises due to the typical phenomena of QCM sensors. To remove these impulsive noises we adopt a medean filter which replaces a value at a specific time by a median value among neighboring data around the specific time. In Fig. 4 we show the measurement data for the symbol A(ethanol) where the horizontal axis is the measurement time and the vertical axis is the frequency deviation from the standard value(9M[Hz]) after passing through a five-point medean filter.

6 TRAINING FOR CLASSIFICATION OF ODORS

In order to classify the feature vector, we allocate the desired output for the input feature vector where it is nine-dimensional vector as shown in Table 3since we have added the coefficient of variation to the usual feature vector to reduce the variations for odors. The training has been performed until the total error becomes less than or equal to .5 $\times 10^{-2}$ where η=.3.

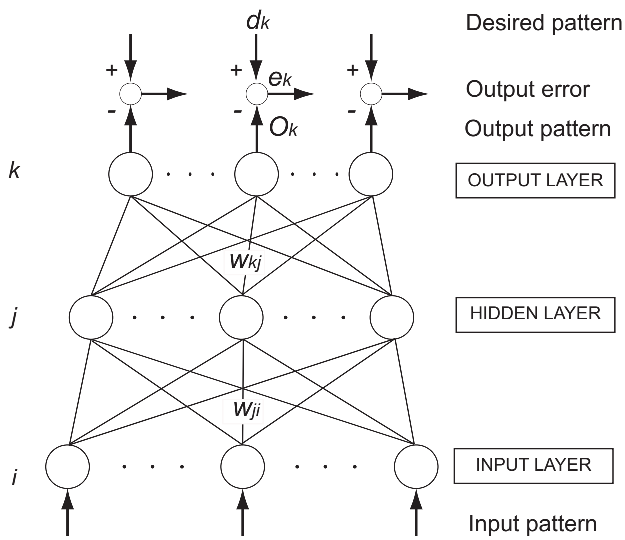

Fig. 3. Three layered neural network with the error back-propagation. The neural network consists of three layers, that is, an input layer i, a hidden layer j, and an output layer k. When the input data $x_i, i = 1, 2, \ldots, I$ are applied in the input layer, we can obtain the output O_k in the output layerwhich is compared with the desired value d_k which is assigned in advance. If the error $e_k = d_k - O_k$ occurs, then the weighting coefficients w_{ji}, w_{kj} are corrected such that the error becomes smaller based on the error back-propagation algorithm.

Table 3. Training data set for ethanol (A), water (B), methyl-salicylate (C), and triethylamine (D).

Symbols	Output A	Output B	Output C	Output D
A	1	0	0	0
B	0	1	0	0
C	0	0	1	0
D	0	0	0	1

7 TESTING FOR CLASSIFICATION OF ODORS

After training the data we have tested the other data sets such that two kinds of odors are mixed with the same rate. Then the classification results are shown in Table 4 where the underlined numerals dente the top case ahrere the maximum output values are achieved. The maximum values show one of the mixed odors. But some of them does not show the correct classification for the remaining odor. Thus, we have modefied the input features such that

$$z = x - 0.9y$$

where x is the feature, y denotes the top value of each row in Table 4, and z is new feature. Using the new feature vec-

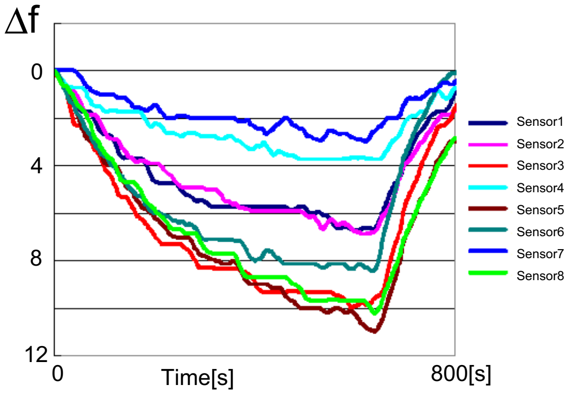

Fig. 4. Measurement data. Here, eight sensors are used and for six handred [s] the data were measured. The maximum value for each sensor among eight sensors is selected as a feature value for the sensor. Therefore, we have eight sensor values for an odor and they will be used for classification.

Table 4. Testing the mixed odors where the top and the second from the top are the classification results.

Symbols	Output A	Output B	Output C	Output D
A and B	.673	.322	.002	.001
B and C	.083	.696	.174	.001
C and D	.001	.004	.016	.992
D and A	.003	.003	.002	.995
A and C	.992	.006	.002	.000
B and D	.003	.003	.003	.995

tor, we have obtained the classification results as shown in Table 5. By changing the features according to the above rlation, better classification results have been obtained. But the coefficient .9 used the abouve equation is not considered so much. The value might be replaced by the partial correlation coefficient in multi-variate analysis.

8 CONCLUSIONS

We have presented the reliability of a new EN system designed from various kinds of QCM sensors. It has been sgown that after training the neural network for each odor, we can classify the original odor from the mixed odors in case of two odor case. More than two mixing case is open for the future research.

Table 5. Testing the mixed odors where except for the largest value the top is selected as the second odor among the mixed odors.

Abstract: Recently, the Estimation of distribution algorithm (EDA) has been studied as a measure to solve the problem that the Genetic algorithm (GA) destroys effective building blocks. The Bayesian optimization algorithm (BOA) that is one of EDAs evolves a population of candidate solutions by building and sampling Bayesian networks. However, the BOA has some problems, for example the processing time is too longer. In this paper, we use the Sudoku puzzle that is one of the real problems, focusing on the problem of processing time and convergence to local solution. We propose the method defined chromosome combined nine candidate regions would make it possible to compress the search spaces. We evaluate this method by using two types of Sudoku puzzles and comparing result of the method that defines a one-dimensional chromosome that has a total length of at most 324 binary numbers and converts binary numbers into integer numbers to the result of our proposal method. In the result, our proposal method reduces processing time and amount of generations than the original program and performs as precision as the original program.

Keywords: Estimation of Distribution Algorithm, Bayesian Optimization Algorithm, Sudoku, Search domain reduction

1 INTRODUCTION

There is research into the solving several problems using GA, for example combinatorial optimization problems, NP-hard problems and so on. However, the GA operations are at risk for breaking building blocks. The Estimation of Distribution Algorithm (EDA) is a one of the way to mitigate risk. The EDAs are a statistical method using the probability distributions. In this research, we focus attention on small examples that typical the EDA, the Bayesian Optimization Algorithm (BOA) [1], is applied to the real problems because of the processing time of the BOA to generate networks using probabilistic models is too long, and study the method that solves the problems of the BOA applying the real problems. The Sudoku is a one of large scale combinatorial optimization problems, and is solved effectively by methods such as back-tracking and meta-heuristics approach, and GA with local search. As it stands now, it is difficult for the BOA that to solve effectively than back-tracking and GA. However, in this paper, we aim for getting a toehold in solving Sudoku with the BOA, and try new approach using candidate regions.

2 SUDOKU PUZZLE

General Sudoku puzzles consist of a 9 x 9 matrix of square cells, some of which already contain a numeral from 1 to 9. The arrangement of given numerals when the puzzle is presented is called the starting point. A Sudoku puzzle is completed by filling in all of the empty cells with numerals 1 to 9, but no row or column and no 3 x 3 sub-block may contain more than one of any numeral. For these basic puzzles, methods such as back-tracking and meta-heuristics approach are effective. Fig.1. shows an example of a Sudoku puzzle. In Sudoku puzzle, tandem 9 cells are called row, horizontal 9 cells are called column and 3 x 3 sub-block is called region.

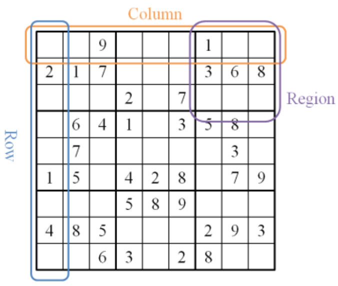

Fig.1. An example of Sudoku puzzle

3 SUDOKU SOLUTION DERIVED USING THE BOA

3.1 The original method using the BOA

3.1.1 The definition of the BOA chromosome

We must convert decimals to binary for the BOA is able to deal with a Sudoku puzzle in order to solve the Sudoku puzzles by using the BOA.Fig.2 and Fig.3 show the original method. Because of numerals 1 to 9 are used in a Sudoku puzzle, 4-bit binary is assigned to a cell. Therefore, to convert a Sudoku puzzle to binary needs at most 324-bit binary codes. When individuals are evaluated, there is a general way that converts binary to decimals to evaluate the individuals.

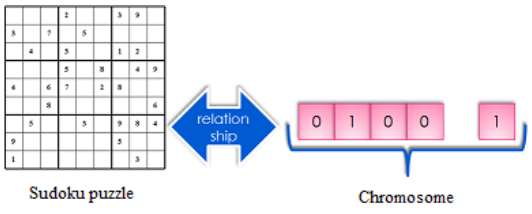

Fig. 2. Relationship between Sudoku puzzle and BOA Chromosome

Fig. 3. Conversion code

3.1.2 The evaluation of the BOA chromosome

We use the function to evaluate the BOA chromosome by

$$f(x) = \sum_{i=1}^{9}(r_i + c_i) \qquad (1)$$

where r_i is a number of different numbers in a row; and c_i is a number of different numbers in a column.

3.2 Problem and countermeasures

Because of a problem that length of chromosome is too long, it takes time to generate and extract the network. In addition, we consider a problem about an initial convergence. An important factor to minimize an initial convergence is the BOA parameter adjustment. Specifically, there are three parameters to minimize an initial convergence, to adjust a large population, to adjust at high rate of parents and to adjust rate of offspring. It creates population of diversity and reduces an initial convergence. However, ensuring population of diversity makes processing time of the BOA slowly. We propose the solution these problems below.

3.3 Proposed method using candidate region

In this paper, we propose definition of chromosome with candidate regions with the dual aims of reducing the processing time and accuracy improvement. Candidate regions compose of all types of regions. Each region has a 19-bit binary code and is referred to by code. We define the BOA chromosome as combination nine codes and enable to express a Sudoku puzzle in at most 171-bit binary codes. In this method, no region may contain more than one of any numeral. Thus, in evaluation term, the BOA doesn't have to evaluate all regions. As a result, we can compress the search space.

3.3.1 Candidate region

Fig.4 shows how to generate the candidate region. Candidate regions compose of all types of regions. Each region has a 19-bit binary code and is referred to by code in evaluation term.

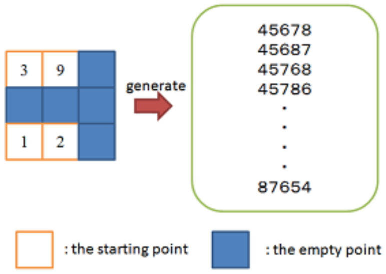

Fig. 4. Generate candidate region

3.3.2 Relationship of chromosome and candidate region

Fig.5 shows relationship of chromosome and the candidate region. There are 9! regions in candidate regions. A region code must express 2^{19} things in a binary code for relating candidate region to it. In other words, the length of region code is at most 19-bit. We define the BOA chromosome as combination nine codes and enable to express a Sudoku puzzle in at most 171-bit binary codes.

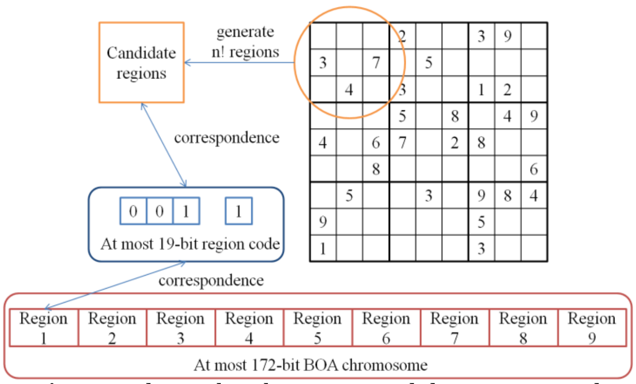

Fig. 5. Relationship between candidate region and chromosome

4 EXPERIMENT

4.1 Experimental methodology

In this research, we use two types of Sudoku puzzles. First one is 38 starting points and second one is 34 starting points. Fig.6 shows the Sudoku puzzle we use [2]. Original program (Original) and proposed method (Proposed) solve two Sudoku puzzles. We evaluate our method by parameter type.

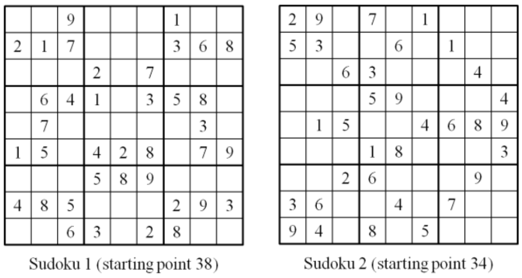

Fig. 6. Sudoku puzzles used in this experiment

4.2 BOA parameters

In this research, we use three types of parameters. Table.1 shows parameters in this research. Parameter group A has difference of population size. Parameter group B has difference of parents size. And parameter C has difference of offspring percentage. We evaluate proposed method by comparing accuracy and processing time with the original program. Additionally, maximal number of generations to perform is 100 generations.

Table. 1. BOA parameters

	Population size	Pearents size	Offspring percentage
Base	2500	50	50
A-1	1250	50	50
A-2	5000	50	50
B-1	2500	40	50
B-2	2500	60	50
C-1	2500	50	40
C-2	2500	50	60

4.3 Experimental result

4.3.1 Accuracy comparison in base parameter

Table.2 shows comparison result. Proposed surpass Original in accuracy rate. When it comes to Sudoku2, the result is that accuracy rate of Original is 12% and accuracy rate of Proposed is 56%. Also Proposed drastically lower Generation performed than Original. And average time required for Original to solve Sudoku1 is about 190 seconds and Sudoku2 is about 309 seconds. On the other hand, average time required for Proposed to solve Sudoku1 is about 9 seconds and Sudoku2 is about 19 seconds

.

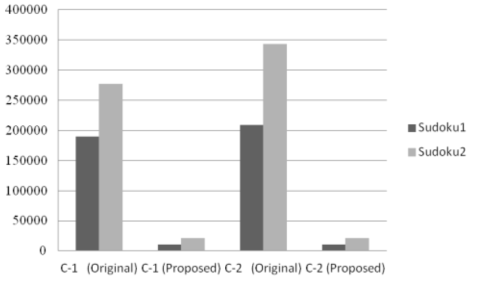

Fig.10. Processing time in parameter group C

5 DISCUSSION

From an examination of section 4, our proposal method surpasses Original in accuracy rate in most parameters. From these results, this is attributed to the fact that search domain reduction by using the candidate regions is effectively. However, Accuracy rate of Original becomes stricter and stricter with increasing population size. But we make sure of either improvement or not in Proposed by increasing population size. Thus, we surmise that when we ignore the processing time, Original surpasses Proposed in accuracy rate. Also generation performed, Proposed is few generations performed than Original. This is attributed to the BOA with candidate regions need not learn regions. Proposed has a large increase in speed of solving a Sudoku puzzles with the BOA. This is attributed to the fact that two factor involve this improve. One is the improving generation performed; the other is search domain reduction by using the candidate regions. In weak point of Proposed, we observe the case that Proposed converge a local solution. This is attributed to the BOA converge local solution once; the BOA is hard to get rid of local solution. We think one of the countermeasures is to add the local search to our approach.

6 CONCLUSIONS

To solve a Sudoku puzzle with the BOA, we propose a new approach with the candidate region. We evaluate our approach with two types of Sudoku puzzles. As a result, generation performed of the proposed method is more improved than generation performed of the original program. Also processing time of proposed method is more improved than processing time of the original program. And the proposed method surpasses the original program in accuracy rate. We showed new capability to solve a Sudoku puzzles with the BOA.

Abstract: Previously, we proposed genetic operations that consider effective building blocks for using genetic algorithms (GA) to solve Sudoku puzzles, and proposed also a stronger local search function. In this paper, we propose performance enhancement by parallelization of genetic operations takes building-block linkage into account. In other words, parallelize sub-blocks (regions) of Sudoku puzzles. Valid parallelization of genetic operations becomes a strong method of speed-up in conjunction with parallelization of individuals, since parallelization of genetic operations is not competing with parallelization of individuals. We show using multi-core processors and OpenMp that parallelization of genetic operations have positive effect of for speeding up.

Keywords: Genetic Algorithms, Linkage, Parallelization, Sudoku.

1 INTRODUCTION

Sudoku puzzle that belong to constraint satisfaction problem is one of famous pencil puzzles. There are several conventional researches which applied GA to Sudoku, and it is demonstrated that be able to solve a Sudoku with GA. However, the execution time and number of steps leading to the optimum solution, particularly the difficult problem has become enormously large [1]. The presumed cause is that there are many local solutions, and the crossover that is the main operation of GA is more likely to destroy some of the valid solutions (building blocks) insofar as Sudoku puzzles. Therefore, in many cases conventional research have addressed the issue in conjunction with Grammatical Evolution [2] or Cultural Algorithm [3] to GA. Previously, we proposed a genetic operations considering the linkage of loci, and tried to improve the accuracy of the program. As a result, the conventional example of the difficulty in solving problems was able to derive a solution with half the number of runs [4]. However, in terms of Sudoku solving algorithms, and another algorithm that like a backtracking algorithm can be done faster than solving the proposed method. Parallel research using multi-core processors and GPU as a means to speed up the GA, many have been in recent years. Began to be popular in the general PC with multi-core processors and GPU, it became available relatively cheaply, was considered one of the reasons many examples of research.

2 THE RULES OF SUDOKU

The Sudoku rules are explained in Fig.1. General Sudoku puzzles consist of a 9 x 9 matrix of square cells, some of which already contain a numeral from 1 to 9. The arrangement of given numerals when the puzzle is presented is called the starting point. The degree of difficulty varies with the number of given numerals. In general, it will be difficult by increasing the number. A Sudoku puzzle is completed by filling in all of the empty cells with numerals 1 to 9, but no row or column and no 3 x 3 region (:the sub-blocks are bound by heavy lines in Fig.1) may contain more than one of any numeral.

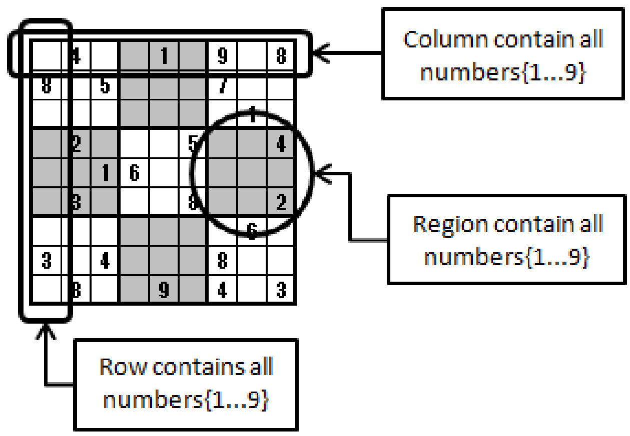

Fig.1 An example of Sudoku puzzles.

3 METHOD OF ACCURACY IMPROVEMENT OF SUDOKU SOLVING BY GA

GA is generally found to be useful for problems with a wide search range of solutions. However, the conventional example is applied to Sudoku to GA, has become a huge number of generations it takes to solve a problem with low number of initial placement [1]. The presumed cause is that the crossover that is the main operation of GA is more likely to destroy building blocks insofar as Sudoku puzzles, GA has a low performance of local search, and there are prone to local solution. In previous research, we have proposed genetic operations considering the linkage in order to improve these problems. Describe the proposed genetic operations below.

3.1 Genetic operation that consider linkage of genetic locus

3.1.1 Initial value setting

The initial value is determined by random numbers to fill in the blank mass other than initial placement. At that time, numbers do not overlap each region. Thereby, there meet conditions of Sudoku rules from the start that "No duplicate numbers in all regions". By performing the operations in each region, and continue meeting the above criteria, there are hardly disrupted the building blocks in the region.

3.1.2 Evaluation

As shown in Equation (1), evaluation value is sum of all evaluation value of row and column that is number of elements, with condition of "No duplicate number in each row and column". In addition, equation (2) and (3) as indicated, the numbers entering each row and column is limited to 1-9.

$$f(x) = \sum_{i=1}^{9} g_i(x) + \sum_{j=1}^{9} g_j(x) \tag{1}$$

$$g_i(x) = |x_i| \tag{2}$$

$$g_j(x) = |x_j| \tag{3}$$

3.1.3 Mutation

Mutation is performed for each region. As shown in Fig.2, randomly select two numbers in a region other than the initial placement, to replace the position for avoid duplicate numbers in the region.

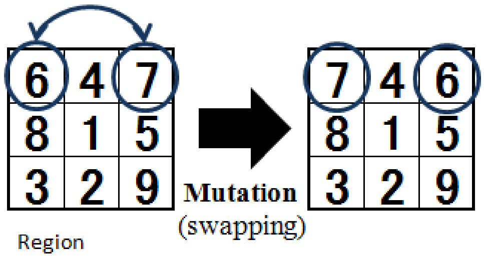

Fig.2 An example of mutation

3.1.4 Crossover

In the crossover, to generate two child individuals from two parent individuals. One is compares the evaluation value of each three rows, and child individuals inherit a higher parent individual. The other is compares of columns in a similar way with rows. Thus, compares have been six times by each three times with row-wise and column-wise comparison. Fig.3 shows the crossover.

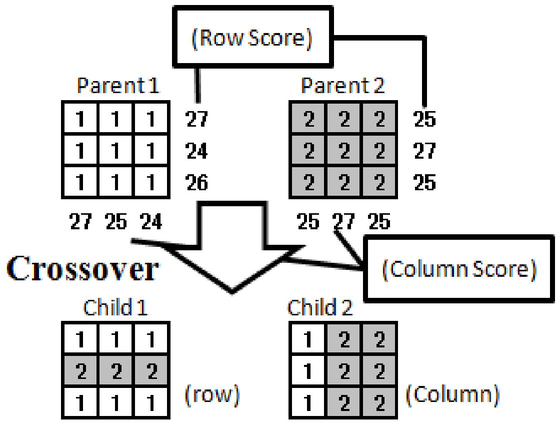

Fig.3 An example of crossover

3.2. Proposed method of improved local search

In general, local search is low performance than global search. Therefore, to improve the performance of local search, by means of population produces twice the number of child individuals produced by mutation, a wider range of child individuals is generated by selecting individuals from the high-evaluation-value.

4 PROPOSED METHOD OF PERFORMANCE INCREASE WITH PARALLELIZATION

There are various methods of the parallelization of the GA, in generally, most often do parallel by individuals, and has been successful in speed-up about solving Sudoku by GA [5]. In this paper, parallel operations by considering the linkage of genetic loci, aims to accelerate further, and we used the OpenMP about the implementation of parallelism.

4.1 Parallelization of genetic operation

4.1.1 Parallel mutation

In mutation, randomly select two numbers in a region other than the initial placement, to replace the position. Therefore, the number of times to replace by one individual is about nine times same by the number of the region. As Fig.4 shows, in parallelization, the parallel becomes 9-parallel by single thread to perform operations in one region.

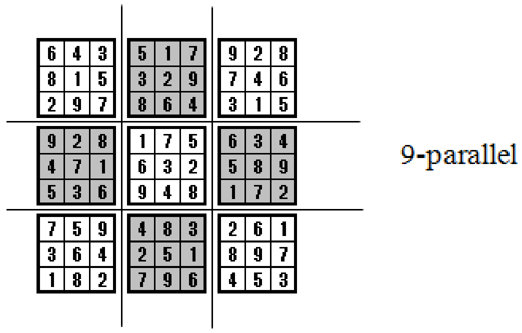

Fig.4 Parallelization of mutation

4.1.2 Parallel crossover

In the crossover, comparisons and inherited are six times as described in Section 3.1.4. As Fig.5 shows, in parallelization, the parallel becomes 3-parallel by performing the same thread with processing with row-wise and column-wise. Parallelized in one block has that calculation of evaluation value, comparison, and inherited to the child individuals.

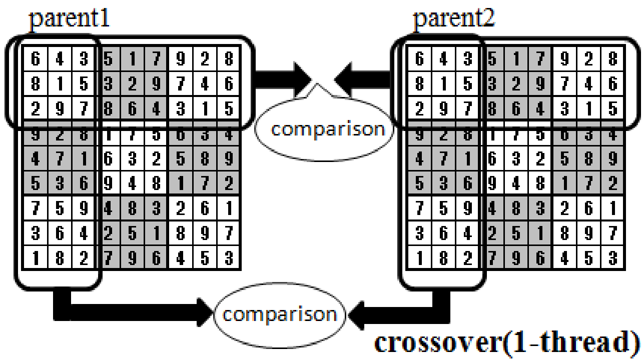

Fig.5 Parallelization of crossover

4.1.3 Parallel evaluation calculation

Evaluation calculation is performed in the same thread 1 by 1 evaluation calculations. As Fig.6 shows, Sudoku puzzles used in the experiment because it is a matrix with 9 rows 9 columns, the parallelization is 9-parallel.

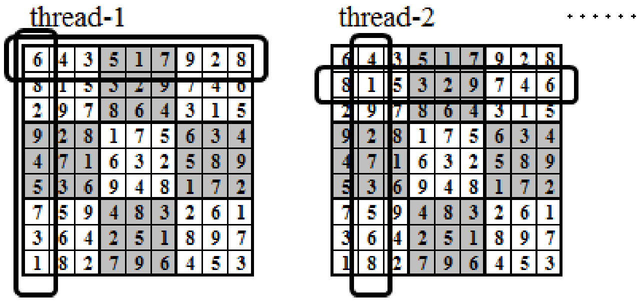

Fig.6 Parallelization of Evaluation Calculation

5 EVALUATION EXPERIMENTS

5.1 Experimental method

In this paper, the selection is used tournament selection. We used the Sudoku of workbook [6], and selected the 6 problems from the beginner, intermediate, and advanced problem each 2 problems.

5.2 Experiments about accuracy improvement

Fig.7 shows a graph of experimental results. If a solution was not obtained before 20,000 generations, the result was displayed as 20,000 generations. The tests were run 100 times and the averages of the results were compared. In Fig.7, direction x is the number of initial placement, and direction y is the number of generation.

In this paper, the method of described in Section 3.1 called Genetic Operation that consider Linkage (GOL). Random search, GOL, and proposed method compare, each method is proven to be effective.

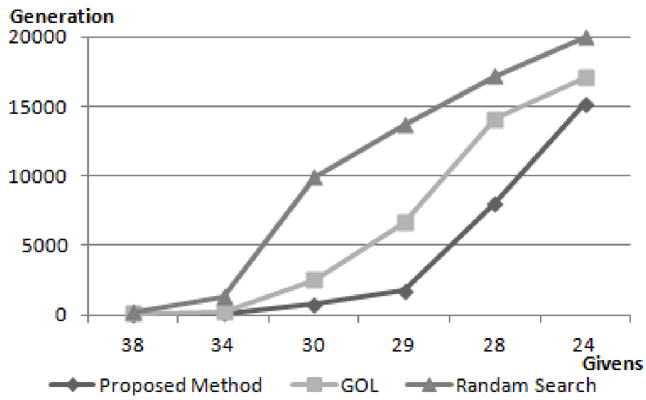

Fig.7 Relationship between givens and the average of generation

5.3 Experiments about performance increase

5.3.1 Basic specifications of a computer

Table.1 show the specifications of PC used in these experiments.

Table.1 Basic specifications of a computer

OS	Microsoft Windows 7 Enterprise
Processor	Intel Core i5 M520 @ 2.40GHz
Core	2/4 (logical / physical)
Memory	4.00GB

5.3.2 Result of experimentation

Table.2 and Fig.8 shows the experimental results. execution time is average of 50 times, and this is result of run of 10,000 generations. In Fig.8, direction x is the number of initial placement, and direction y is the execution time.

Parallelization of crossover is slower than no-parallelization. Parallelization of evaluation calculation and mutation succeeded in a speed-up. In the parallelization of mutation, many number of initial placement is more effective than less number of it.

Table.2 execution time

Gives	38	34	30	29	28	24
No-Parallel	32.11	31.57	28.93	31.21	28.48	28.43

P-Evaluation(E)	31.05	30.33	27.80	29.61	26.79	26.10
P-Mutation(M)	28.67	27.86	26.10	27.19	26.51	26.69
P-E & M	24.61	24.70	23.46	24.05	23.13	23.22

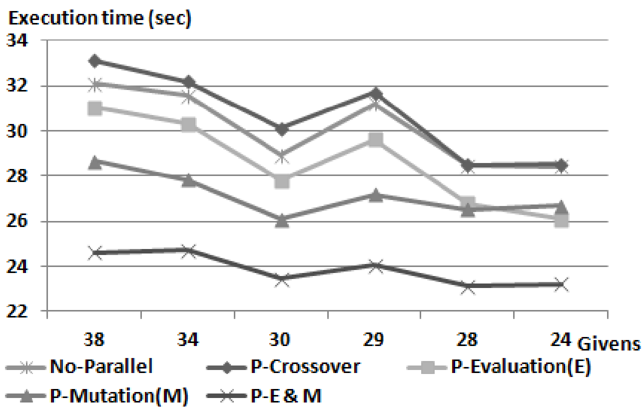

Fig.8 Relationship between givens and the execution time

5.4 Consideration

In the experiments about accuracy improvement, the proposed method finds optimum solution more than half within 20,000 generations. The proposed method has significantly improved accuracy compared with the conventional method [1] that is about 5% rate of solving within 100,000 generations. However, there is the high initial value dependence, and great variation in the number of generations to derive the optimum solution, and needs to consider, including how to escape from local solutions. In experiments about performance increase, together with parallelization of the evaluation calculation and the mutation, the effect of speed-up was obtained from 20 to 30%. And so the proposed method is parallelization of genetic operation, and we can use it in conjunction with parallelization of individuals. In consequence, the effect of each parallelization has been expected to be multiplied by the effect of both. The high-speed parallelization is less effective. This is attributed to that the small rate of each operation in the overall program, and creating threads and communication between threads is cost too much. And the future, reduced the cost of creating threads and communication, and we need a comparison with experiments using different ways such as a GPU.

6 CONCLUSION

In this paper, we propose speed-up of parallelization of genetic operations based on method of genetic operations that consider effective building blocks that previously we proposed. As a result, we succeeded in constant speedup and were able to improve performance. A proposed method which is parallelization of genetic operations becomes a strong method of speed-up in conjunction with parallelization of individuals, since parallelization of genetic operations is not competing with parallelization of individuals.

Abstract: Small nucleolar RNAs (snoRNAs) are known that they will participate with RNA modification. However, details of snoRNA's functions have not been clear still yet. In order to make clear functions of snoRNA, finding snoRNAs and studying their works in cells are required. In this paper, we propose a method to detect snoRNA genes using extended-weights-updating Self-organizing Map (eSOM). An input vector to eSOM consists of a feature vector and a target vector. A winner node for an input vector is decided by the feature vector, and all the weights around the winner node are updated to be close to the input vector. We employ base appearance probability and the complementary base pair ratio for feature vector only, and a flag for target vector. Experimental results showed our method achieved 91% and 93% detection ratio for boxC/D and boxH/ACA type snoRNA gene, respectively.

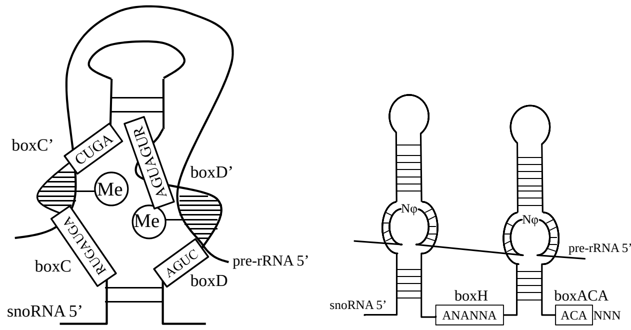
Keywords: Self-organizing Map (SOM), snoRNA, extended-weight-updating, eSOM

1 INTRODUCTION

Genome consists of two regions; one is the coding region which encodes information into protein, and the other is non-coding region. Non-coding regions have not been paid attention very much, but now we know non-coding regions include non-coding RNA (ncRNA) genes which play important roles such as gene expressions regulation or RNA modification, etc. Small nucleolar RNA (snoRNA) is a kind of ncRNA, and it will participate in RNA modifications such as methylation [1]. There are two types of snoRNAs; boxC/D type and boxH/ACA type. The functions of snoRNAs in detail have not been known still yet. In order to make clear functions of snoRNA, finding more snoRNAs and studying their works in cells are required.

As conventional snoRNA gene detecting method, Sakakibara *et al.* [2] has proposed to use support vector machine (SVM) with "stem kernel". It detects snoRNA gene based on characteristic structure of snoRNA called "stem". The SVM with stem kernel shows good performance for detecting boxC/D type snoRNA gene. However, detection accuracy for boxH/ACA type snoRNA gene is not enough still yet.

In this paper, we propose a method to decide whether a DNA sequence include a snoRNA gene or not using extended-weights-updating Self-organizing Map (eSOM) [3]. The eSOM is an extension of Kohonen's self-organizing map [4]. In the eSOM, an input vector is extended to consist of two parts; one is the conventional feature vector, the other is target vector. The dimension of a weight vector is the same of the input vector. A winner node for an input vector is decided by the feature vector part of the input vector, and all the weights in the winner node are updated to be close to the input vector. It means that the eSOM is self-organized based on the feature vector, and competitive nodes simultaneously obtain appropriate weight according to the target vector.



(a) Secondly structure of boxC/D type snoRNA.

(b) Secondly structure of boxH/ACA type snoRNA.

Fig. 1. Secondly structure of snoRNAs.

2 THE SNORNA

SnoRNA is a kind of ncRNA in nucleolus of cells. As shown Figure 1, there are two types snoRNAs based on their characteristic base sequences and secondary structure. BoxC/D type snoRNAs and boxH/ACA type snoRNAs con-

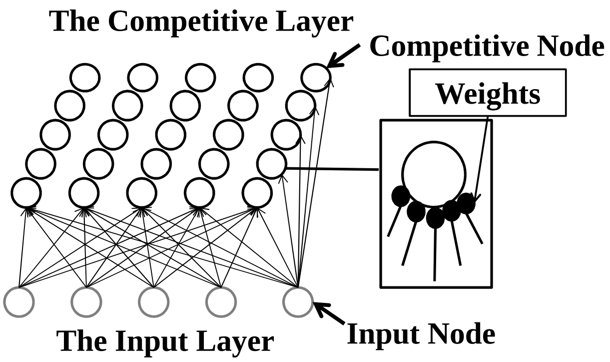


Fig. 2. Structure of SOM.

sist of 60-100 bases and 120-250 bases, respectively. The most of boxC/D type snoRNA genes have characteristic sequences called as "box C" and "box D", and they sometimes have other characteristic sequences called as "box C′" and "box D′". BoxH/ACA type snoRNA genes have characteristic sequences called as "box H" and "box ACA". Both types of snoRNAs also have characteristic secondary structure called as stem composed by complementary base pairs.

3 EXTENDED-WEIGHTS-UPDATING SELF-ORGANIZING MAP

3.1 Structure and learning algorithm of eSOM

Figure 2 illustrates the typical structure of SOM composed an input layer and a competitive layer. Competitive nodes are arranged as $N \times N$ mesh, and each of them has weights. The eSOM has the same structure of SOM.

Figure 3 shows the learning procedure of eSOM. When an input vector which consists of k-dimensional feature vector and 1-dimensional target vector is presented at the time $t (t = 1, 2, \cdots, T)$, the eSOM calculates distance $d^{ij}(t)$ between the input vector $\boldsymbol{x}(t) \in \Re^{k+1}$ and the weight vector $\boldsymbol{w}^{ij}(t) \in \Re^{k+1}$ of node $(i, j)(i, j = 1, 2, \cdots, N)$ according to Equation (1),

$$d^{ij}(t) = \sum_{m=1}^{k} \sqrt{(x_m(t) - w_m^{ij}(t))^2}. \quad (1)$$

Then, we decide the node with the smallest distance $d^{ij}(t)$ as a winner node C. After the winner node is decided, the neighboring nodes around the winner node update their all weights to be close to the input vector by Equation (2),

$$\boldsymbol{w}^{ij}(t+1) = \boldsymbol{w}^{ij}(t) + h_{cij}(t)[\boldsymbol{x}(t) - \boldsymbol{w}^{ij}(t)], \quad (2)$$

where $h_{cij}(t)$ is a neighborhood function defined by Equation (3),

$$h_{cij}(t) = \begin{cases} \alpha(t) & i, j \in N_c(t), \\ 0 & \text{otherwise}, \end{cases} \quad (3)$$

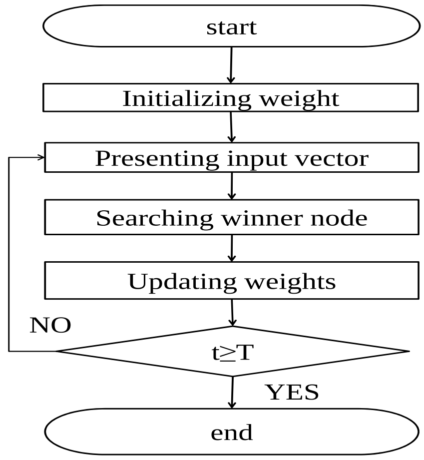

Fig. 3. Flow chart of eSOM.

where $\alpha(t)$ is a learning rate and $N_c(t)$ is a size of neighboring region around the winner node defined by Equation (4) and Equation (5), respectively. Both $\alpha(t)$ and $N_c(t)$ are gradually decreased as increasing of the t.

$$\alpha(t) = \alpha(0)\left(1 - \frac{t}{T}\right)\left(\frac{1}{d_c + 1}\right), \quad (4)$$

$$N_c(t) = N_c(0)\left(1 - \frac{t}{T}\right), \quad (5)$$

where d_c is the euclidian distance between the winner node (i_c, j_c) and the neighboring node (i_n, j_n).

In this paper, we give the information about base sequences to the elements of feature vector, and a real number flag that shows whether a snoRNA gene is included or not to the target vector. Thus, the eSOM is self-organized based on the similarity of the information about base sequences, and each competitive node simultaneously obtains appropriate flag value as a weight according to the similarity of feature vector.

3.2 Preparation of input vectors

We obtain the sequences including a snoRNA gene from the database "snOPY" [5]. They are used as positive samples. The negative samples without snoRNA gene are random base sequences whose length are the same as the positive samples. From these sequences, two kinds of information are extracted; the one is the base(s) appearance probabilities, and the other is complementary base pair ratio.

We employ the following three kinds of the base appearance probabilities;

- single-base appearance probabilities (eg. A, G, T, C),
- pair-base appearance probabilities (eg. AA, AG, $\cdots$, CC),
- triplet-base appearance probabilities (eg. AAA, AAG, $\cdots$, CCC).

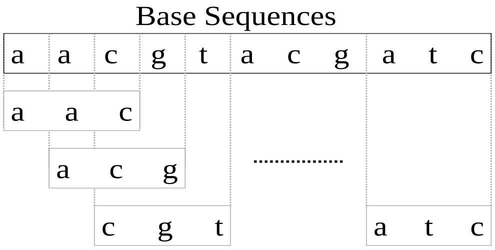

Fig. 4. An example for calculating triplet-base appearance probability.

Figure 4 shows how to count the triplet-base appearance frequencies. Each triplet-base appearance frequencies is divided by the sum of appearance frequencies. Since the number of combinations for single-base, pair-base and triplet-base is 4, 16 and 64 respectively, a part of the feature vector for the base(s) appearance probability has the same dimension of these combinations.

The complementary base pair ratio expresses the probability that the sequence forms the stem structure. We use CentroidFold [6] to calculate the complementary base pair ratio. This complementary base pair ratio is described as a scalar number. The concatenation of the base(s) appearance probability and the complementary base pair ratio becomes a feature vector of an input vector.

Finally we append the flag 1.0 to the input vector for positive samples, and 0.0 to that for negative samples. For the above three kinds of base(s) appearance probabilities, the total dimension of an input vector becomes 6, 18 and 66 respectively.

4 EXPERIMENTS AND DISCUSSIONS

4.1 Experimental conditions

We obtain 1,082 and 871 positive samples for boxC/D type snoRNA and boxH/ACA type snoRNA, respectively. As described in Section 3.2, the same number of negative samples are generated. These samples are divided into five groups, and we use four groups for learning and one group for validation as changing the combination of groups.

We use torus SOM to avoid discontinue on the edge of mesh. Experimental conditions are as follows:

- Competitive layer size : 100×100 nodes
- Initial neighboring region $N_c(0)$: 60×60 nodes
- Initial learning ratio $\alpha(0)$: 0.7
- Max learning iterations T : 100
- Numbers of positive (negative) samples for learning :

  boxC/D : 866 (866)

  boxH/ACA : 693 (693)

- Numbers of positive (negative) samples for validation :

  boxC/D : 216 (216)

  boxH/ACA : 174 (174)

- Number of trials : 10
- Initial weight range : 0.0∼1.0

We evaluate proposed method by the three indexes. The index "Accuracy" is a ratio of the correctly classified positive and negative samples to the total samples. The index "Sensitivity" is a ratio of the actual positive samples to the samples classified as positive samples. The index "Specificity" is a ratio of the actual negative samples to the samples classified as negative samples. If these are 1.0, perfect classification will be achieved.

4.2 Results and Discussions

We make eSOM learn on the condition described in Section 4.1. After learning, we present the validation samples to the learned eSOM, and decide winner node by Equation (1). If the weight of winner node corresponding to the target vector for a validation sample is more than 0.5, we decide this sample includes a snoRNA gene.

(a) Map of single-base appearance probability. (b) Map of pair-base appearance probability. (c) Map of triplet-base appearance probability.

Fig. 6. Map for boxH/ACA type snoRNA gene.

Table 1. Experimental results for boxC/D type snoRNA gene detection.

Data	Accuracy	Sensitivity	Specificity
single-base	0.780	0.772	0.788
pair-base	0.893	0.901	0.885
triplet-base	0.918	0.931	0.905

Table 2. Experimental results for boxH/ACA type snoRNA gene detection.

Data	Accuracy	Sensitivity	Specificity
single-base	0.789	0.770	0.806
pair-base	0.934	0.930	0.937
triplet-base	0.931	0.917	0.944

Figure 5 and Figure 6 show self organized map. The brightness of both figures denotes the value of weights corresponding to the target vector, it becomes more bright when the node has larger weight.

Fig. 5 and Fig. 6 said that increasing of the dimensions in the feature vector give us clear boundary between dark area and bright area. Especially, Fig. 5(c) is clearly divided between the dark areas and bright areas. We fill negative samples with randomly generated bases, so the base(s) appearance probabilities for the negative samples are almost the same. Meanwhile positive samples have characteristic sequences that compose Boxes or stems. Since eSOM can utilize this fluctuation among base(s) appearance probabilities and complementary base pair ratio, it clearly classifies positive samples and negative samples into two areas.

In Fig. 5(c) and Fig. 6(c), the bright nodes compose a cluster. It means that feature vectors of positive samples are similar each other. We try to utilize this similarity of feature vectors to detect snoRNA genes.

Table 1 and Table 2 show the average accuracy, sensitivity and specificity when we try to detect boxC/D type snoRNA genes and boxH/ACA type snoRNA genes, respectively.

Table 1 shows the experimental results for boxC/D type snoRNA gene detection. The best accuracy is 0.918 when we employ triplet-base appearance probability. Table 2 show the experimental results for boxH/ACA type snoRNA gene detection. The best accuracy is 0.934 when we employ pair-base appearance probability.

It is more desirable that the sensitivity is larger than the specificity to detect snoRNA genes. However, specificities for boxH/ACA type snoRNA gene detection are always better than sensitivities in our method. We guess it is no problem for practical use because sensitivities are high enough.

Sakakibara *et al.*[2] has reported that the accuracies to detect boxC/D type snoRNA genes and boxH/ACA type snoRNA genes by stem kernel method were 0.640 and 0.660, respectively. In comparison with these results, our method achieved much higher performance by using eSOM.

5 CONCLUSIONS

We proposed a new method to decide whether a DNA sequences include a snoRNA gene or not using eSOM. An input vector is compose of a feature vector and a target vector. A feature vector has information about base sequences, and a target vector has information about presence of absence of snoRNA gene. Our method organizes competitive nodes on eSOM based on the similarity of feature vectors, and each competitive node obtain an appropriate snoRNA existence probability as a weight.

We present the validation samples to the learned eSOM, and decide winner node. If the weight of winner node corresponding to the target vector for a validation sample is more than 0.5, we decide this sample includes a snoRNA gene. We discuss on detecting results and Maps.

Experimental results showed that the best accuracy for boxC/D type snoRNA gene detection was 91% when the triplet-base appearance probability was used, and it for boxH/ACA type snoRNA gene was 93% when the pair-base appearance probability was used. It was much superior than those of previous works. Those remain future works to make negative samples from real DNA sequences and to investigate the difference of sensitivity between pair-base and triplet-base for boxH/ACA type snoRNA gene detection.

Abstract: In recent researches of molecular cell biology and bioinformatics, it is one of the most important tasks to find and analyze functional RNAs, called as non-coding RNAs (ncRNAs) those do not carry any information to synthesize protein, but participate in post-translational modification. In this paper, we propose a method to detect intronic genes of small nucleolar RNA (snoRNA), it is a kind of functional RNA. SnoRNAs exist in the nucleolus, and contribute to the ribosomal RNA (rRNA) modification process. From their structure, snoRNAs can be classified into two types; the Box C/D type and the Box H/ACA type. Since each of them has some characteristic base sequences, we aim to detect snoRNA genes based on thes e characteristic base sequences and secondary structures. We evaluate proposed method by comparative experiments with other kernel function methods.

Keywords: snoRNA, box existence probability, stem appearance probability, secondary structure, functional RNA

1 INTRODUCTION

In recent researches of molecular cell biology and bioinformatics, it is one of the most important tasks to find and analyze functional RNAs, called as non-coding RNAs (ncRNAs) those do not carry any information to synthesize protein [1]. Many kinds of functional RNAs take part in various life phenomena such as basic metabolism, ontogeny and cell differentiation, etc. Researchers have reported that the defective functional RNA causes some kinds of diseases, so the progress of research on ncRNAs will give us significant advance in the field of drug discovery and regenerative medicine, etc.

In this paper, we propose a method to detect intronic genes of small nucleolar RNA (snoRNA) which is a kind of functional RNA. SnoRNAs exist in the nucleolus, and contribute to the ribosomal RNA (rRNA) modification process. From their structure, snoRNAs can be classified into two types; the Box C/D type snoRNA and the Box H/ACA type snoRNA. As shown in Figure 1, each of them has some characteristic base sequences and secondary structures. The Box C/D type snoRNAs have the Box C (AUGAUGA), the Box D (CUGA), the Box C' (UGAUGA) and the Box D' (CUGA). The Box H/ACA type snoRNAs have the Box H (ANANNA, N is an arbitrary base) and the Box ACA (ACA). Both types also have characteristic secondary structure called as stem. A stem consists of some complementary base pairs (A-U and C-G). We aim to detect snoRNA genes based on these characteristic base sequences and secondary structures.

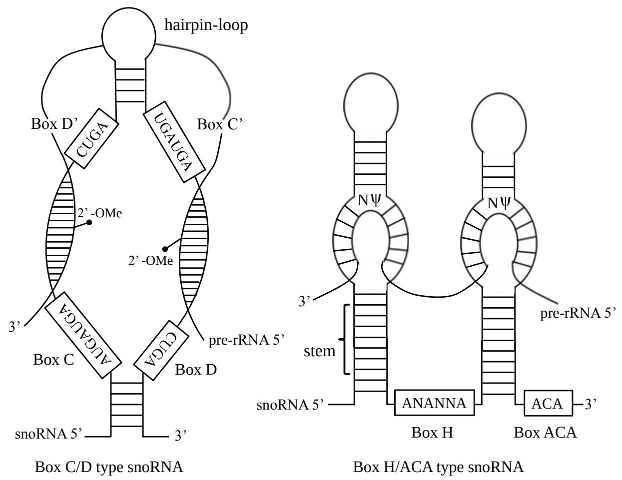

Fig. 1. Structure of the Box C/D type snoRNA and the Box H/ACA type snoRNA.

2 INTRONIC snoRNA GENE DETECTION

2.1 Small nucleolar RNA (snoRNA)

SnoRNAs exist in the nucleolus, and their length are about 60-250nt. SnoRNAs mainly work in biosynthesis process of ribosome, and they participate in modification of rRNA precursor. Until now, 236 and 75 kinds of snoRNAs are found in humans and in yeast, respectively. SnoRNAs are classified into the Box C/D type and the Box H/ACA type by their structural characteristic.

The length of Box C/D type snoRNAs is 60-100nt in general, a stem structure is composed by the complementary bases at the 3'end and the 5'end. The Box C/D type snoRNAs also have characteristic sequence AUGAUGA (Box C) and CUGA (Box D) adjacent the stem. Moreover, it sometimes has another similar sequences (Box C' and Box D') near the loop. Another stem is also found before the hairpin loop. Fig. 1 also says that the Box C/D type snoRNA has complementary sequences (9-20nt) to the targeted rRNA, the rRNA methylation occurs at the fifth nucleotide of the complementary domain as shown as the "2'-OMe" in Fig.1.

On the one hand, the length of the Box H/ACA type snoRNAs is 120-250nt, they consist of two hairpin loops as shown in Fig. 1. The Box H exists between stems, and the Box ACA exists in three nucleotides before from the 3' end. In the middle of stems, they have complementary sequences (6-20nt) to the targeted rRNAs. The rRNA is modified at the pseudouridine pocket in this domain.

Our proposed method utilizes these features to detect snoRNA genes.

2.2 Previous works

In this paper, we compare the performance of our method with the following two methods, the String Subsequence Kernel [2] and the Stem Kernel [3,4,5].

String subsequence kernel is a kernel for character strings, and it uses the appearance frequency of the string consisting of n characters as the coordinate of feature space. It counts the frequencies of the continuous or discontinuous strings in the sequence, and then these frequencies are weighted by λ^m where m is the length of partial string including gaps.

Stem kernel is a kernel for RNA sequences, and the feature space of this kernel considers the secondary structure of RNAs. The feature vector of this kernel consists of the appearance frequencies of arbitrary length continuous or discontinuous candidates for stem structures.

2.3 Proposed method

2.3.1 Flow of proposed method

Our method decides whether a peace of base sequence includes a snoRNA gene or not by the box existence probability and the stem appearance probability.

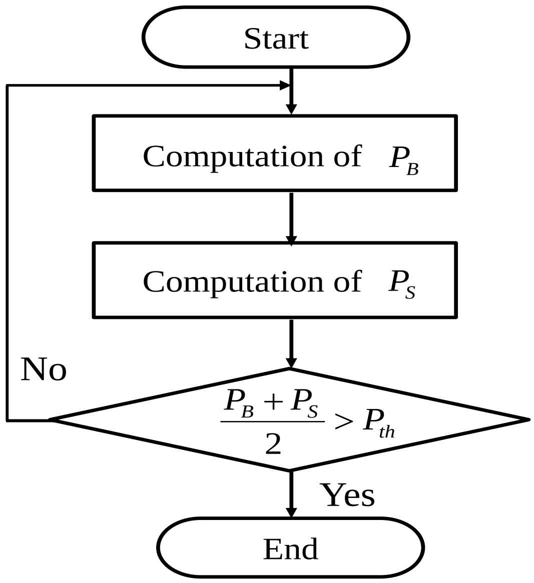

Fig. 2. Procedure of proposed method.

For this objective, we compare the target sequences with the box sequences and derive the similarity between these sequences. This similarity is denoted as box existence probability (P_B). Next, we also decide the target sequences have complementary base pairs that can organize stem structure. This is also denoted as Stem Appearance Probability (P_S). As shown in Figure 2, the average of the P_B and the P_S is more than the threshold value P_{th} , we decide the peace of base sequence include a snoRNA gene.

2.3.2 Box existence probability

Here explains how to calculate box existence probability in detail using an example case. Suppose we decide the sequence X [ACCUGAUGUAG] includes the Box D (CUGA) or not. As shown in Figure 3, the Box D consists of four bases, the first four bases [ACCU] of the X are compared with the Box D. In this case, no base is consistent with the Box D, so it gives us 0% as the box existence probability. Then the next four bases [CCUG] of the X are also compared with the Box D. In this case, only the first locus has the same base, so the box existence

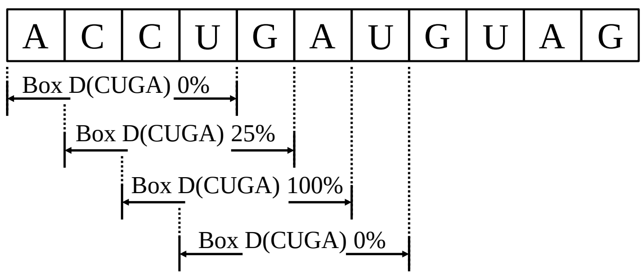

Fig. 3. A comparison of sequence X with the Box D, and calculation of the box existence probability.

probability becomes 1/4=25%. Hereafter, the same process is repeated until the end of the sequence X. The maximum probability is employed for the Box D existence probability for the sequence X. If the box existence probability will be less than 50%, we decide the sequence X does not have the Box D. The same process is repeated for the other Boxes.

2.3.3 Stem appearance probability

It is commonly known that the specific secondary structures in the cell are important features for modeling and detecting RNA sequences. The folding of an RNA sequence into a functional molecule is largely governed by the formation of the standard Watson-Crick base pairs A-U and C-G as well as the wobble pair G-U. Such base pairs constitute "biological palindrome" in the genome as shown in Figure 4. The secondary structures of RNAs are generally composed of stems, hairpins, bulges, interior loops, and multi-branches. A stem is a double stranded region of base-pair stacks. A hairpin loop occurs when RNA folds back on itself as shown in Fig. 4.

Here explains how to calculate the stem appearance probability between the Boxes. For this purpose, we calculate the appearance probability of the complementary base pairs (A-U and C-G). Suppose the sequence Y consists of eight bases [GUACGUAG]. Since the number of complementary pairs is three (U(A(CG)U)A) in the sequence Y as shown in Figure 5, the stem appearance probability becomes 6/8, 75%.

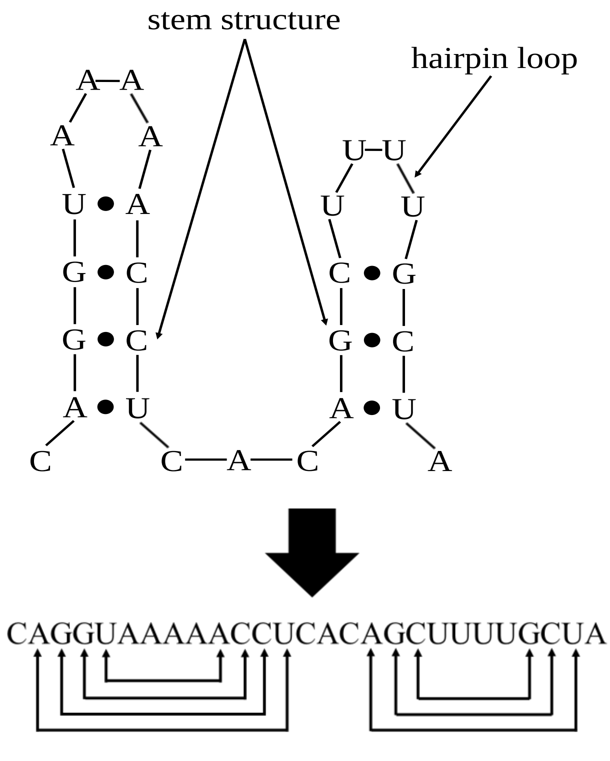

Fig. 4. Stem structure of an RNA sequence and its biological palindrome.

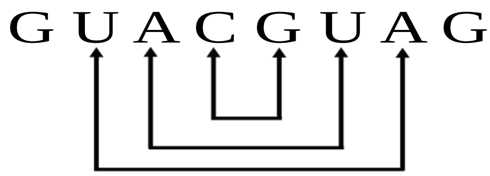

Fig. 5. Three complementary base pairs (U-A, A-U, C-G) are contained in the sequence Y.

3 EXPERIMENTS AND DISCUSSIONS

3.1 Data and conditions

We evaluate our method by actual snoRNA sequence data. All the positive examples that include a gene of a snoRNA are taken from the database "snOPY" [6]. We obtain 1,000 positive samples for Box C/D type snoRNAs and Box H/ACA type snoRNAs, respectively. For negative samples, we randomly shuffle the bases consisting of positive samples.

We use the following four indexes to evaluate proposed method. The sensitivity S_n is the ratio of the number of samples those are decided as including snoRNA gene to the positive samples. The specificity S_p is the ratio of the number of samples those are decided as not including snoRNA gene to the negative samples. The accuracy Acc is defined as the average of S_n and S_p in this paper. Figure 6 illustrates an example of ROC curve, where the x-axis is $1-S_p$ and the y-axis is S_n when the P_{th} is changed. The area under the ROC curve (AUC) means detection accuracy, $AUC=1.0$ denotes that all the positive and the negative samples are correctly identified.

3.2 Experimental results

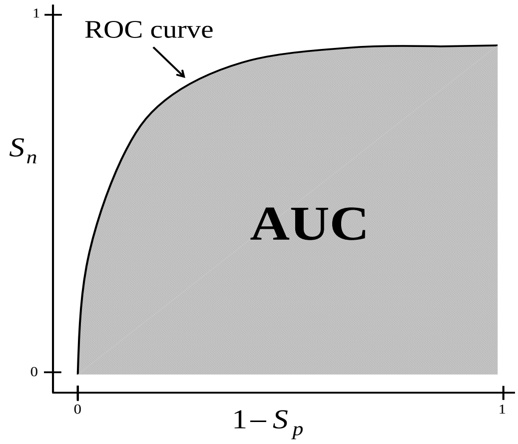

Fig. 6. Area under the ROC curve.

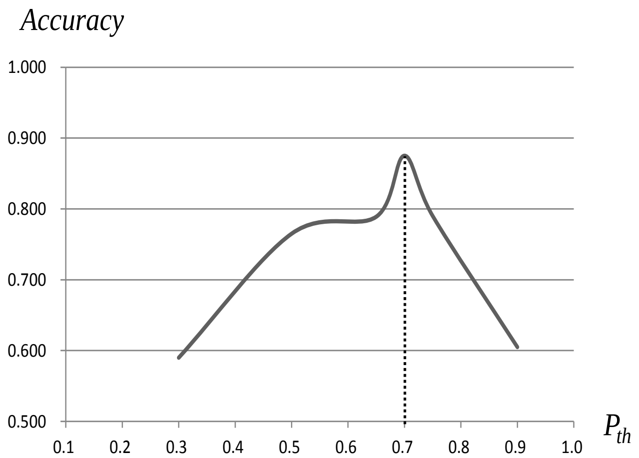

Fig. 7. The average accuracy in proportional to the P_{th}.

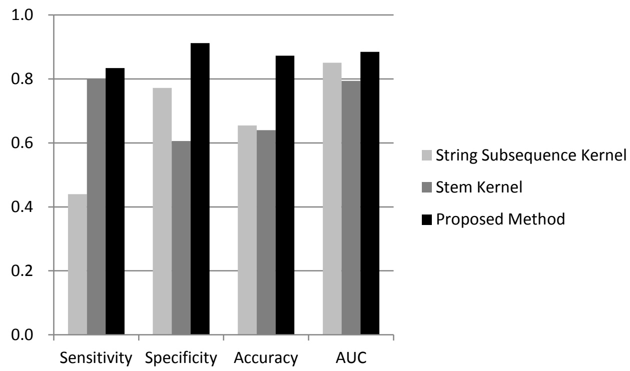

Fig. 8. Experimental results comparison with String Subsequence Kernel, Stem Kernel and proposed method.

We decide the sequence includes a snoRNA gene if the average of Box existence probabilities and stem appearance probability is more than P_{th}. It means that detection accuracy depends on the P_{th}, so we find appropriate P_{th} through preliminary experiments. Firstly we divide positive and negative samples into ten groups which have 100 positive and negative samples. Secondly we calculate accuracy described in Section 3.1 for each group as changing P_{th}, then derive the average accuracy among ten groups. Finally, we employ the P_{th} which shows the highest average accuracy. Figure 7 shows the average accuracy in proportional to the P_{th}. Fig.7 teaches us the highest accuracy is obtained when $P_{th} = 0.7$.

Here we compare proposed method with the string subsequence kernel method and the stem kernel method. As the same as the preliminary experiments, we execute cross-fold validation tests using above ten groups, and derive the average S_n, S_p, Acc and AUC. Experimental results showed that our method achieved the $S_n = 0.834$ and the $S_p = 0.912$ with 2,000 positive and negative samples when $P_{th} = 0.7$ as shown in Figure 8.

Fig.8 also said that our proposed method achieved more accurate snoRNA detection than that of the string subsequence kernel method and the stem kernel method. In Fig.8, the string subsequence kernel method showed poor S_n in comparison with the other methods. It means that the information about stems play an important role to detect the Box C/D type snoRNA genes. The stem kernel method showed inferior S_p than that of the other methods in Fig.8. It means that the using only information about stems cause miss classification of positive samples. To append the information about the Boxes contributed to improve specificity greatly. Since proposed method utilizes both the information about Boxes and Stems, it achieved the highest Accuracy.

4 CONCLUSIONS

In this paper, we proposed a method which is combined of the box existence probabilities with the stem appearance probability to detect the snoRNA genes, and it was evaluated by actual snoRNA base sequences. The detection accuracy for Box C/D type snoRNA was $Acc = 0.873$, however it for Box H/ACA type snoRNA was only $Acc = 0.547$. It is because the primary characteristic base sequence of the Box H/ACA type snoRNAs are uncertainty, detection accuracy stayed in low. Improvement of the detection accuracy for the Box H/ACA type snoRNA gene remains as a future work.

Abstract: An experimental and analytical investigations are performed for OneMax problem using Wright-Fisher model. This study investigates the distribution of the first order schema frequency in the evolution process of Genetic Algorithm (GA). Effects of mutation in GA is analyzed for the standard mutation and asymmetric mutation models. If a population is in linkage equilibrium, it can be shown that OneMax problem is equivalent to the asymmetric mutation model. Thus we can apply theoretical results obtained in the asymmetric mutation model to OneMax problem, and investigate the convergence time within the framework of Wright-Fisher model.

Keywords: Genetic Algorithms, first order schema , asymmetric mutation , OneMax problem, Wrihgt-Fisher model

1 INTRODUCTION

Over the last decades, significant progress has been made in the theory, design and application of genetic and evolutionary algorithms. A decomposition design theory was proposed and several competent GAs have been developed [1]. Genetic algorithms are stochastic optimization techniques that apply three basic genetic operators; selection, crossover and mutation. Applying these genetic operators to a population of chromosomes, or individuals that represents possible solutions of the problem, forms new generations of the population [2]. Mutation plays an important role in computation of GAs. Doerr, B. et al. considered an asymmetric mutation operator for the Eulerian cycle problem and examine the effect of the asymmetric mutation on the runtime of the algorithms [3]. They showed that such an asymmetry of the mutation operator can speed up computations.

In this work, we study effects of mutation in the GA on OneMax problem. The analysis is made for standard mutation and asymmetric mutation models. The OneMax problem is a bit-counting problem where the fitness value of each binary string (individual) is equal to the number of bit 1's in it. The goal of OneMax problem is to maximize the number of 1's in the bit string.

We focus on the frequencies of the first order schemata, and calculate their changes in time by using the Wright-Fisher model of Markov chain. Furutani et al. calculated their changes in time by using the Wright-Fisher model [4]. We apply their stochastic approaches to the present problem, and consider the evolution of first order schema in the GA on OneMax problem with the finite population size.

2 MATHEMATICAL MODEL

As an evolution model, we use Simple Genetic Algorithm (SGA) proposed by Goldberg. For the case of OneMax problem, we derive the relation between standard mutation model and asymmetric mutation model. Individuals are represented by binary strings of fixed length ℓ, and there are $n = 2^\ell$ genotypes. The ith genotype is given by the binary representation of an integer i,

$$< i(\ell), \cdots, i(1) >, \quad (0 \le i \le n-1),$$

where $i(k)$ is a binary value of i at position k. We use the frequency $N_i(t)$ and relative frequency $x_i(t)$ of the ith genotype at generation t. The population size N is assumed to be time-independent, and

$$N = \sum_{i=0}^{n-1} N_i(t).$$

The relative frequency $x_i(t)$ is

$$x_i(t) = \frac{N_i(t)}{N}.$$

Fitness function f_i of OneMax problem for the ith genotype is defined as

$$f_i = \sum_{k=1}^{\ell} i(k).$$

The fitness is maximum when all bits are 1.

The linkage is an important notion to represent the status of population in genetics [5]. It also has a great influence on calculations of GA. Crossover and mutation make the linkage weak, and work to lead a population to linkage equilibrium [6]. If population is in linkage equilibrium, the distribution of individuals depends only on the frequencies of the first order schemata. We have the evolution equation for the first order schema [6]

$$h_1(t+1) \,=\, a h_1(t) + b, \tag{1}$$

where h_1 is the relative frequency for the first order schema of bit 1. The coefficients a and b are given by

$$a \,=\, (1-\frac{1}{\ell})\,(1-2p_m), \quad b \,=\, \frac{1}{\ell}(1-2p_m)+p_m.$$

In GA with asymmetric mutation, we assume mutation rate p_α for the mutation $1 \to 0$, and p_β for $0 \to 1$, respectively. We assume that all fitness values are $f_i = 1$. The deterministic evolution equation is given by

$$h_1(t+1) \,=\, (1-p_\alpha-p_\beta)h_1(t)+p_\beta. \tag{2}$$

Comparing this equation with equation (1), we have the following relations

$$p_\alpha \,=\, p_m, \quad p_\beta \,=\, p_m + \frac{1}{\ell}(1-2p_m). \tag{3}$$

3 WRIGHT-FISHER MODEL

Wright and Fisher put forward their evolution equation by considering the finite individuals [5]. The Wright-Fisher model treats chromosomes having one locus and two alleles, corresponding to the GA of $\ell = 1$ with genotypes $k \in \{0,1\}$ [7]. The number of the first genotype 1 takes the values of

$$N_1 \,=\, 0,1,\ldots,N,$$

and that of the genotype 0 is given by $N_0 = N - N_1$.

We analyze evolution processes by taking into account the effect of random sampling, and consider the fitness proportionate selection. If there are $N_1 = i$ copies of the genotype 1 at the current generation t, the probability $P(j|i)$ of N_1 taking the value of j at the next generation $t+1$ is given by the binomial distribution

$$P_{i,j} = P(j|i) = \binom{N}{j}\, p_i^j\,(1-p_i)^{N-j} \tag{4}$$

$$p_i \,=\, ay+b \,=\, a(\frac{i}{N})+b,$$

where i is the number of genotype 1 at the current generation t, and j is the number of genotype 1 at the next generation $t+1$.

The probability $P(j|i)$ specifies the process of random sampling, and the future behavior of the process only depends on its current frequencies [7]. Thus this process is a Markov chain. Let $\mu_i(t)$ be the probability that the population is in the state of $N_1 = i$ at generation t.

In the following, we use the vector notation

$$\mu^T \,=\, (\mu_0,\,\mu_1,\ldots,\mu_N),$$

with the normalization condition

$$\sum_{i=0}^{N} \mu_i(t) \,=\, 1. \tag{5}$$

Then the evolution process is described by

$$\mu_j(t+1) = \sum_{i=0}^{N} \mu_i(t)\,P_{i,j}. \tag{6}$$

The evolution equation is given in the vector form

$$\mu(t+1)^T \,=\, \mu(t)^T\,P, \tag{7}$$

where P is a matrix of the size $(N+1)\times(N+1)$. We know the eigenvalues of this matrix [8],

$$\lambda_0 \,=\, 1, \quad \lambda_1 \,=\, a, \quad \lambda_2 \,=\, a^2\,(1-1/N),\ldots. \tag{8}$$

It should be noted that the second largest eigenvalue λ_1 does not depend on the population size N. We denote the left and right eigenvectors

$$\mathbf{u}_i^T\,P \,=\, \lambda_i\,\mathbf{u}_i^T, \quad P\,\mathbf{v}_i \,=\, \lambda_i\,\mathbf{v}_i, \quad (0 \le i \le N).$$

These eigenvectors satisfy the orthogonality condition

$$\mathbf{u}_i^T \cdot \mathbf{v}_j \,=\, 0 \quad (i \ne j). \tag{9}$$

The explicit form of the right eigenvector $\mathbf{v}_0$ is given by

$$\mathbf{v}_0 \,=\, (1,1,\ldots,1)^T, \tag{10}$$

and all elements of the left eigenvector $\mathbf{u}_0$ are positive. We adopt the normalization conditions

$$\sum_{i=0}^{N} |u_i| \,=\, 1, \quad \mathbf{u}_i^T \cdot \mathbf{v}_i \,=\, 1.$$

We consider the GA under positive mutation rate $p_m > 0$. In this case, all elements of the transition matrix P are positive, and the Markov chain of schema evolution is irreducible and aperiodic. The Markov chain theory states that an irreducible and aperiodic Markov chain converges to the stationary distribution π

$$\lim_{t\to\infty} \mu(t) \,=\, \pi, \tag{11}$$

and all elements π_i are positive [8].

The initial distribution of the first order schema can be expanded in terms of the left eigenvectors

$$\mu(t=0)^T \,=\, \sum_{i=0}^{N} C_i\,\mathbf{u}_i^T. \tag{12}$$

Since $\mathbf{u}_i$ is eigenvector, and from equation (7), we have

$$\mu(t)^T \,=\, \sum_{i=0}^{N} \lambda_i^t\,C_i\,\mathbf{u}_i^T. \tag{13}$$

Multiplying the right eigenvector $\mathbf{v}_0$ from right side

$$\mu(t)^T \cdot \mathbf{v}_0 = \sum_{i=0}^{N} \lambda_i^t \, C_i \, \mathbf{u}_i^T \cdot \mathbf{v}_0 = \lambda_0^t \, C_0 = C_0,$$

and from equations(5) and (10), we have $C_0 = 1$. At large t, $\mu(t)$ is approximately given by

$$\mu(t) \approx \mathbf{u}_0 + a^t \, C_1 \, \mathbf{u}_1, \tag{14}$$

and $\mathbf{u}_0$ is the stationary distribution π.

In this study, we treat the convergence time T_c of Markov chain. To this end, the convergence time of the average fitness is defined as

$$T_c(\text{fitness}) \;=\; \min_t \{ \frac{\bar{f}(\infty) - \bar{f}(t)}{\bar{f}(\infty) - \bar{f}(0)} < 0.05 \}, \tag{15}$$

where $\bar{f}(t)$ is the average fitness at t, and $\bar{f}(\infty)$ is the average fitness in the stationary state. The theoretical estimation of the convergence time is given by

$$T_c(\text{eigenvalue}) \;=\; \min_t \{ a^t < 0.05 \}, \tag{16}$$

where a is the second largest eigenvalue of the transition matrix P.

4 NUMERICAL EXPERIMENTS

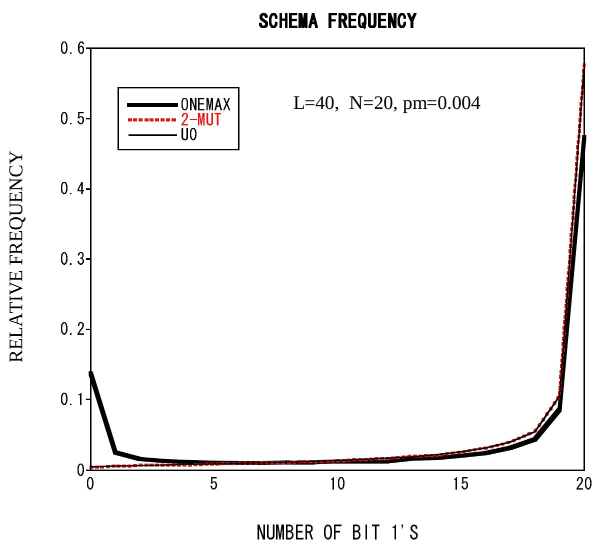

Fig. 1. The distribution of the number of bit 1's with $N = 20$ and $p_m = 0.004$. The thick solid line shows the result of OneMax GA calculation. The dotted line for asymmetric mutation model and the thin solid line for the left eigenvector $\mathbf{u}_0$, respectively.

Numerical experiments are performed in GA by standard mutation model on OneMax problem and asymmetric mutation model. They are compared with the theoretical results obtained by Wright-Fisher model. We carry out GA

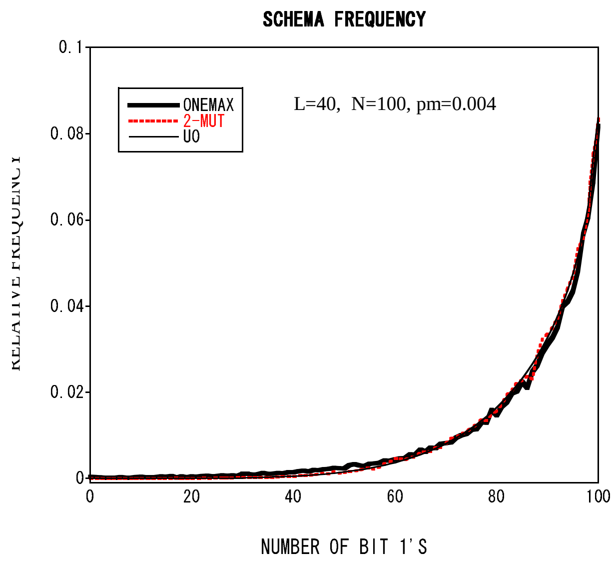

Fig. 2. The distribution of the number of bit 1's with $N = 100$ and $p_m = 0.004$.

with the fitness proportionate selection, and apply the uniform crossover with crossover rate $p_c = 1$. The string length is $\ell = 40$. The results are obtained by averaging 1000 repeated runs.

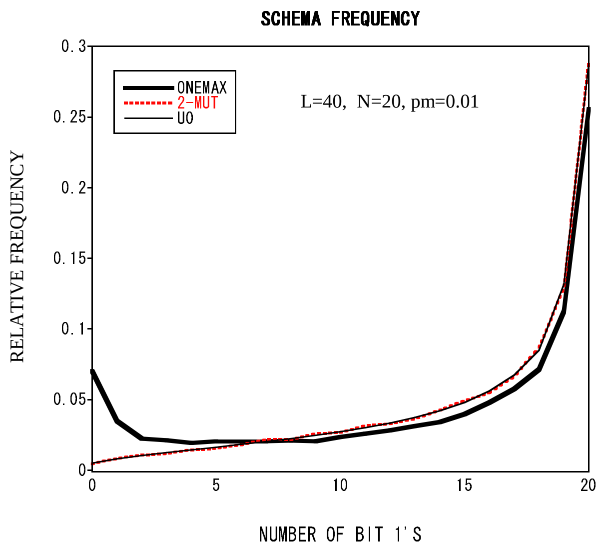

Fig. 3. The distribution of the number of bit 1's with $N = 20$ and $p_m = 0.01$.

Figure 1 shows the probability distribution of the first order schema with $N = 20$ and $p_m = 0.004$. The horizontal axis represents number of bit ones. The vertical axis represents the probability of the first order schema. The eigenvector $\mathbf{u}_0$ of Wright-Fisher model can reproduce the first order schema of the asymmetric mutation model almost com-

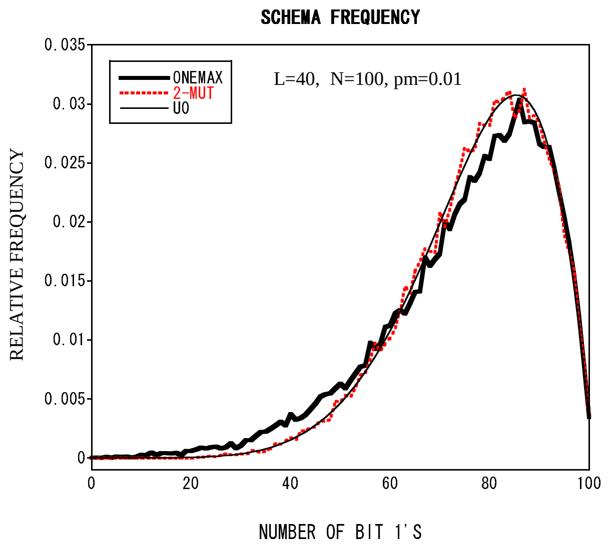

Fig. 4. The distribution of the number of bit 1's with $N = 100$ and $p_m = 0.01$.

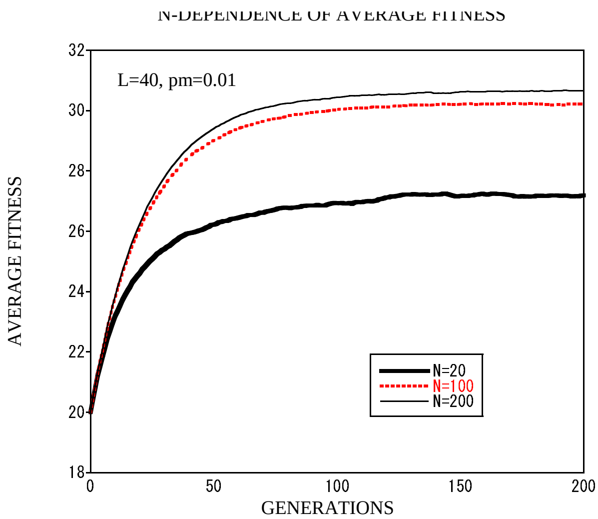

Fig. 5. Dependence of the average fitness on N. $pm = 0.01$. The horizontal axis represents generation.

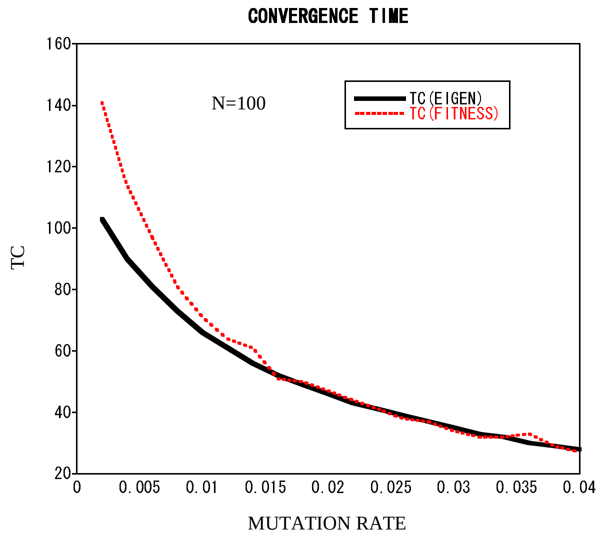

Fig. 6. The mutation rate dependence of the convergence times $T_c(\text{fitness})$ and $T_c(\text{eigenvalue})$ with $N = 100$.

pletely. However there are some discrepancies in the region of small i for OneMax GA calculation.

Figure 2 shows the probability distribution of the first order schema with $N = 100$ and $p_m = 0.004$. We used the same parameter as Fig.1 except for N. We notice that the difference between OneMax GA and asymmetric mutation model is small. The theory of Wright-Fisher model can reproduce both GA experiments.

Figure 3 and Figure 4 are the results with $N = 20$ and 100, respectively. For investigating the effects of mutation, we used the different mutation rate of $p_m = 0.01$ to compare $p_m = 0.004$ used in Figures 3 and 4. The form of schema distribution shows large difference in the comparison between Fig.2 and Fig.4.

Figure 5 shows the dependence of average fitness on N with $p_c = 1$ and $p_m = 0.01$ as function of generation t. We performed GA with $N = 20, 100, 200$. The dependence of average fitness $\bar{f}(t)$ on N is weak for large N, and $\bar{f}(t)$ shows almost the same behavior for large population size $N = 100$ and 200.

Figure 6 demonstrates the convergence times $T_c(\text{fitness})$ and $T_c(\text{eigenvalue})$ defined by equations (15) and (16), respectively. This figure gives the mutation rate p_m dependence of T_c. Theoretical estimation $T_c(\text{eigenvalue})$ well reproduces the the convergence time $T_c(\text{fitness})$ of GA calculation except for small p_m.

Figure 7 gives the population size N dependence of $T_c(\text{fitness})$. Since the second largest eigenvalue $\lambda_1 = a$ has no N dependence, it is concluded that the N dependence of $T_c(\text{fitness})$ is very weak. The figure supports this prediction.

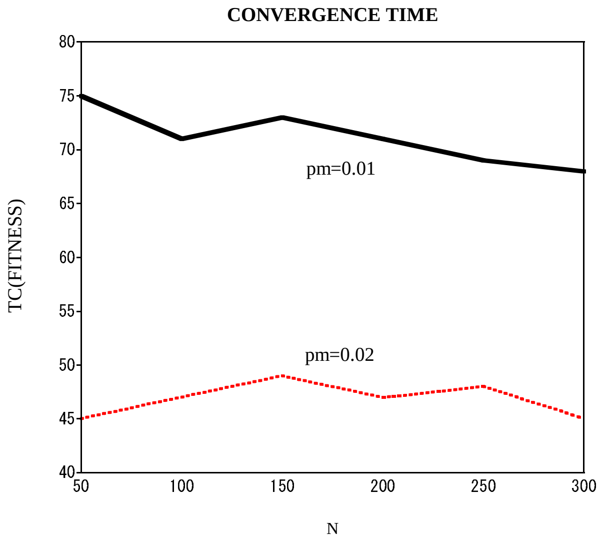

Fig. 7. The population size dependence of the convergence time $T_c(\mathrm{fitness})$ with $p_m = 0.01$ and 0.02.

5 SUMMARY

We report some results of probabilistic analysis of One-max problem in GA. The study of GA on OneMax problem demonstrates the effects of mutation on the performance of GA calculations. If the population is in linkage equilibrium, OneMax problem is equivalent to the asymmetric mutation model. We treat the distribution of the first order schema in the frame work of Markov chain, and Wright-Fisher model can give the distributions of the first order schema of One-Max problem and the asymmetric mutation model. The theoretical estimation of the convergence time is also given by using Wright-Fisher model, and can reproduce the convergence time of GA calculation.

There are many theoretical reports on asymmetric mutation model, and thus we can apply these findings to OneMax problem. Another interesting property of asymmetric mutation model is that this model leads to a considerable speed-up of GA calculation[3]. Further works have to be done for the application of the asymmetric mutation model.

Abstract: Waveform distortion is one of serious problems in electronic packaging design in GHz-era because conventional impedance matching techniques for waveform improvement do not work anymore. In order to overcome this difficulty and to ensure the signal and power integrities (SI and PI), we have proposed a new techniques called segmental transmission line (STL) already. The STL does not adopt the impedance matching but impedance mismatching between the adjacent segments. We have applied the STL to some transmission systems and have showed its effectiveness in prototype measurements. In this paper, we apply the STL to another transmission system and show it effectiveness. Furthermore, we demonstrate the STL's high waveform learning capability changing the input signal.

Keywords: bus, genetic algorithms, memory module, signal integrity, transmission line

1 INTRODUCTION

One of tough problems in the electronic packaging in GHz-era is waveform distortion in digital signals on PCB traces. This is because the digital signals behave as "waves" and reflection occurs at every impedance mismatching point resulting serious waveform distortions. Furthermore, conventional impedance matching techniques cannot work in the GHz-era anymore.

In order to overcome this difficulty and to ensure the signal integrity (SI) and power integrity (PI), we have proposed a novel transmission line called "Segmental Transmission Line (STL)" already, which is designed based on the genetic algorithms (GAs) [1]. Furthermore, we have also shown its effectiveness using some prototypes already [2][3].Following the successful results in [2][3], in this paper, we demonstrate other experimental results that show high "waveform learning capability" in the STL.

2 SEGMENTAL TRANSMISSION LINE

No waveform distortion occurs in the PCB traces if nothing is connected to them. However, if some devices (e.g., VLSIs or Memory Modules), are connected to the traces (Fig. 1), their inputs, which can be regarded as load capacitances, cause characteristic impedance mismatching and dramatically distort the signals as shown in the lower figure in Fig. 1.

In the STL, a transmission line is divided into multiple (N) segments of individual characteristic impedance Z_i and length L_i as shown in Fig. 2. And each Z_i and L_i are adjusted to achieve an ideal digital waveform at target points such as input-points to the VLSIs on the line by superposing reflection waves generated at the interfaces between adjacent segments Z_i and Z_{i+1}. The adjustment of all Z_is however, results in a combinatorial-explosion-problem because the search-space expands to n^m, where n is the number of impedance and segment-length range candidates and m is the number of segments and it comes to 100^{10}-order usually. We have proposed to apply the genetic algorithms (GAs) to solve this problem and have already shown its effectiveness [1][2][3].

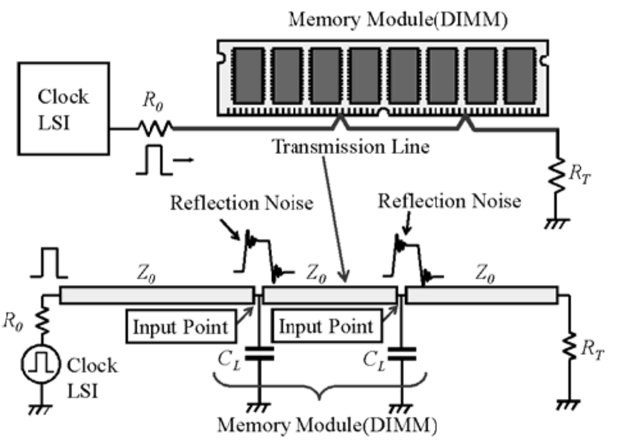

Fig. 1. Waveform distortion in bus-system

Figure 3 shows a bird-eye view and a cross-sectional view of STL in a PCB. Characteristic impedance Z is a function of trace width W, trace thickness T, and insulator thickness D. In the STL, Z is thus controlled easily by adjusting *W*.

The STL structure can be easily and well mapped onto the chromosome of one-dimensional array of genes as shown in the upper figure in Fig. 4. This chromosome is called "Simple Chromosome". In the STL, each segment-length L_i can be also used as a parameter, which expands the search-space more widely to include better solutions. The chromosome composed of both characteristic impedance Z_i and segment-length L_i is called "Hybrid Chromosome". In this variable-length-segment approach, however, we have to be careful not to produce fatal genes under the constraint that the total length is fixed.

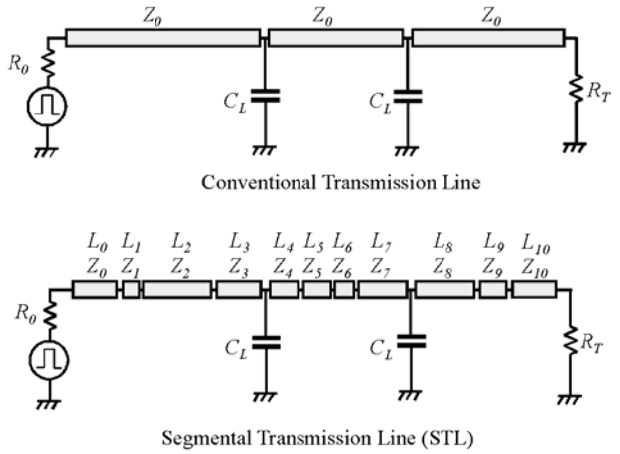

Fig. 2. Conventional transmission line and segmental transmission line (STL) for bus-system

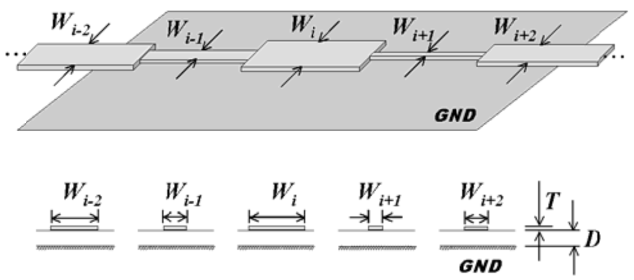

$$Z = f(W, T, D) = \frac{87}{\sqrt{\varepsilon_r + 1.41}} \ln \frac{5.98D}{0.8W + T}$$

Fig. 3. STL applied for PCBs

We have already developed an STL design system called STL Designer. Figure 5 shows outline of the STL Designer that is composed a GA-loop mainly. In the fitness evaluation, the STL Designer outputs the SPICE net list in which the genes, or characteristic impedances and segment lengths are embedded, and the circuit simulator SPICE is started up to simulate the net list. The resultant waveform is then fed back to the STL Designer and evaluated based on the area-difference between the calculated waveform (current waveform) and an ideal waveform as shown in Fig. 6: the difference area *Diff* between the ideal waveform *I*(t) and the current waveform *R*(t) is used for the fitness. The fitness is defined as the reciprocal of this difference area *Diff*.

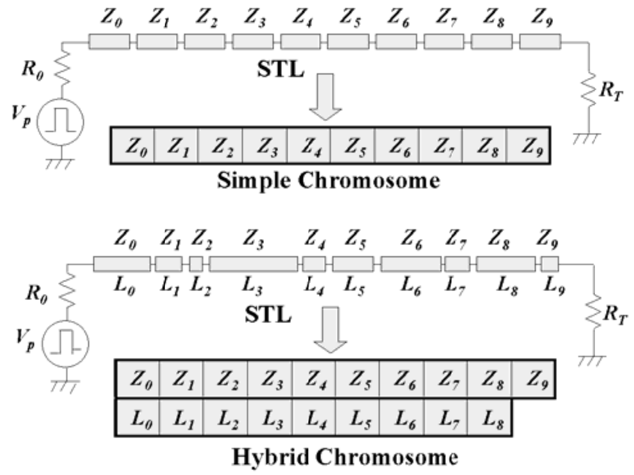

Fig. 4. STLs and their mapping onto chromosomes

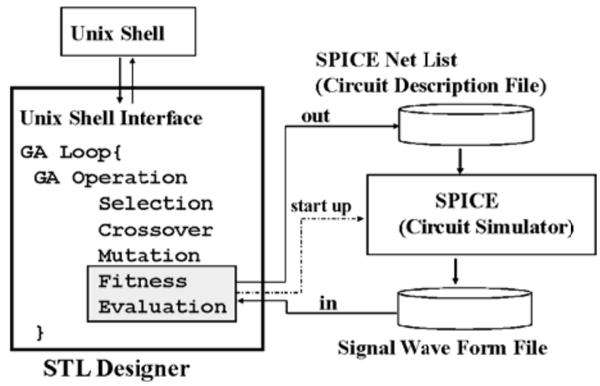

Fig. 5. Configuration of STL Designer

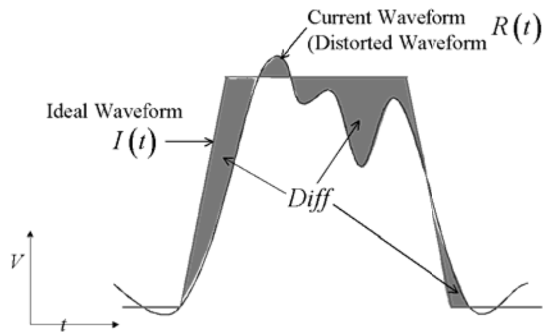

$$Diff = \int_{-\frac{T}{2}}^{\frac{T}{2}} |I(t) - R(t)| dt \qquad fitness = \frac{1}{Diff}$$

Fig. 6. Evaluation of waveforms (fitness used in the STL Designer for bus-system)

3 PROTOTYPE OF STL

3.1 Design Target

A design target for prototype is shown in Fig. 7, where a memory module (DIMM: Dual in-line Memory Module) of two inputs is connected to a 1GHz clock driver LSI through the STL (PCB trace) of 15cm long. Each input is equivalent to a load capacitance of 4pF, which causes the characteristic-impedance mismatch resulting in serious waveform distortion.

The 250MHz STL scale-up prototype is designed based on the 1GH DIMM (Fig. 7): The transmission line length L and the load capacitance C_L are designed to 60cm and 15pF, respectively from the scale-up ratio of 4, i.e., 250MHz to 1GHz. And the transmission line of 60cm is divided into 15 segments (T1 to T15), totally. P_O in the figure is the first input from the clock-driver-LSI to the DIMM and it is the waveform-observation-point in this paper.

3.2 STL Prototype and Its Evaluation

Table 1 shows the design result of characteristic impedance Z and length L of each segment (T1 to T15). We used a set of characteristic impedances from 30Ω to 120Ω at 5Ω intervals. As shown in the table, the lowest characteristic impedance of 30Ω to the highest of 115Ω are assigned in the design. This means many reflection waves are generated in each boundary between adjacent segments, and they are used to improve the distorted wave.

We have fabricated a 250MHz STL scale-up prototype based on the design result shown in Tab. 1. The lower photograph in Fig. 8 is the STL prototype while the upper one is the conventional-transmission-line of Z =50Ω uniformly.

The STL and the conventional-transmission-line both run in each board of 31cm long in U-turn way, where the line-space is designed widely enough to avoid cross-talk noises. Two chip-capacitors (C_L) of 15pF each are connected to the line, which represent the input-capacitances of the memory module (DIMM). In the waveform observation, we used a digital-storage oscilloscope of 2GHz bandwidth and 10GS/s sampling-rate (WR204Xi, LeCroy Ltd.).

Figure 9 shows waveforms observed at P_O in the conventional-transmission-line: the upper ones show simulation results of the input and observed (distorted) waveforms and the lower one shows the observed waveform in the prototype. The waveform in the prototype is dramatically distorted in its shape and amplitude: each pulse loses its sharpness in its rise and fall curves and has small jagged reflections on it. In addition, its amplitude is reduced to 1.06V from 1.8V of original input clock signal. As a result, the clock-signal in the conventional transmission line can be hardly used in the DIMM clock-signals.

Figure 10 shows waveforms observed at P_O in the STL: the upper ones show simulation results of the input and observed (distorted) waveforms and the lower one shows the observed waveform in the prototype. The distorted waveform in the conventional transmission line is well improved in the STL successfully: the reduced amplitude is restored to 1.6V, and jagged reflection noises disappear. The waveform is almost like a trapezoidal wave in its shape, which is close to the original clock-signal. The signal in the STL is thus enough for the clock-signal in its shape.

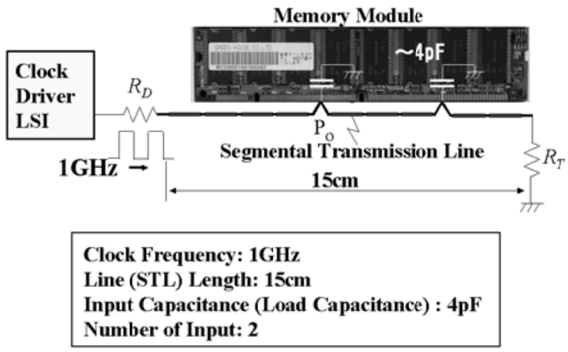

Fig. 7. Design target (1GHz memory-bus system for DIMM)

Table 1. Design result of STL

Seg.	T1	T2	T3	T4	T5	T6	T7	T8

L(mm)	40	39.5	38.5	42	32	32.5	35.5

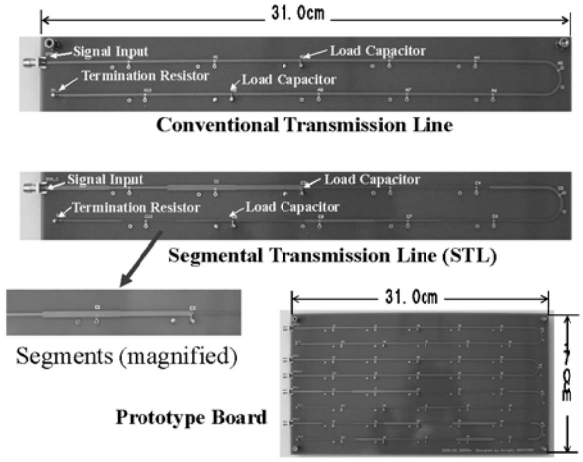

Fig. 8. Photograph of prototype

3.3 Waveform learning capability

In the design for Fig. 10, the input signal waveform outputted from the pulse generator, shown as "Input Signal", is used, and the STL learns it successfully. We have tried another STL design using an idealized trapezoid signal written in SPICE script as the input shown as "Input Signal (Ideal Waveform) in Fig. 11.

Figure 11 shows the STL waveforms designed for the idealized trapezoid signal and observed in the other prototype fabricated in this design, and Tab. 2 shows the STL design result of characteristic impedance and segment length, which can be compared with Tab. 1.

As shown in the results, the STL learns the idealized waveform successfully, and it is demonstrated in the prototype that the observed waveform is changed from the one in Fig. 10 and transforms into a trapezoid waveform closer to the ideal one. This result clearly shows the high waveform learning capability in the STL that can be applied widely to ensure the SI and PI.

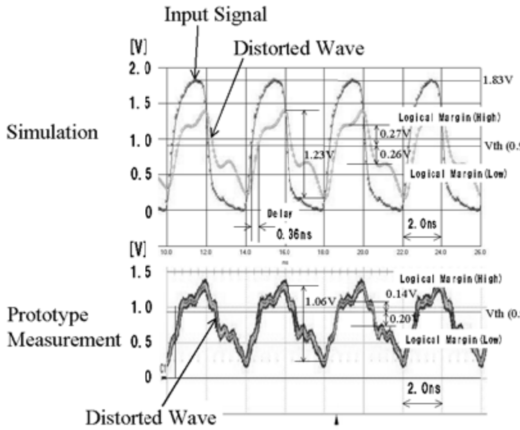

Fig. 9. Waveforms in conventional transmission line

5 CONCLUSIONS

The segmental transmission line (STL) for a 1GHz memory bus connected with DIMM (Dual In-line Memory Module) was designed and its prototype was fabricated. The observation results showed that the distorted waveform in the conventional transmission line was restored almost completely in the STL prototype. The observed waveform in the prototype was also well matched the design result, or the simulation result. Effectiveness of the STL to restore the distorted waveform and to ensure the SI and PI was thus well demonstrated experimentally using the prototype. The STL for another input waveform was also designed, and the STL was able to learn the other waveform successfully, which showed the high waveform learning capability of the STL.

Abstract: Generally, it is difficult to make a food menu composed from many limitations. In this paper, we define the problem to make a menu of the one-week meal as a multi-objective constraint satisfaction problem with the upper and the lower limitations. We considered the nutritional composition and a composition of meals. Thereby, the composition of a menu which structured at one composition ought to compete with the nutritional composition. Additionally, we propose a method to apply Genetic Algorithm solving this making menu problem, thus we evaluate menus by applying multiple functions with GA. In conclusion, the results means that the composition of meals don't compete with the nutritive composition, moreover these are not correlation.

Keywords: Genetic Algorithm, Food Menu, Pareto optimal solution

1 INTRODUCTION

Generally, it is difficult to think about making a food menu. At first, a dietitian counsels a patient, next, the dietitian makes menu after defines the table of nutritional composition and the dietary composition list, at the last, examines the menu. Making menu, there are limitations which consist of the healthy situation, the salary dietary standard, the everyday nutrition situation, age, gender, taste, dietary habits and the activity level. According to food group selected for the menu, the dietitian makes the dietary composition list which determined the consumption to meet the table of nutritive composition. The dietitian makes a menu which considered the made dietary composition list, a season, colors and a pattern based on the set consisting of staple food, master greens, vice-greens, soup and dessert. In addition, the dietitian checks the menu. Because it is very serious that the dietitian makes a menu in this process and that the dietitian adjusts a menu fine, the menu is desirable to be made automatically. Furthermore, it is desirable for the best multiple solutions to be generated as the menu, because the only one menu should not be generated uniquely. Therefore, in this paper, we propose a menu making method using Genetic Algorithm; GA, thereby we discuss the method.

2 PROBLEMS IN MAKING MENU

In the menu making, at first, it becomes the problem whether the patient can take necessary nutritive value without over value. The index for nutritive values is determined with "Japanese nutrition standard" [1] in Japan. There are nutrients which are not applied the tolerable upper intake level, whereas a large quantity of intake is not recommended. Therefore, we determine a standard of intake in reference to recommended dietary allow or adequate intake. In addition, a combination of staple food, the main greens, vice-greens and soup is necessary to make menu. We suggest an application method of GA for the purpose of various menu making at next section.

3 Proposal of the GA application method

3.1. Structure of chromosome for various menu

At first, we define the individual. Fig. 1 illustrates an individual's chromosome of the menu. This chromosome has 21 lists. These lists have various number array from 1 to 5 length. The numbers mean a dish.

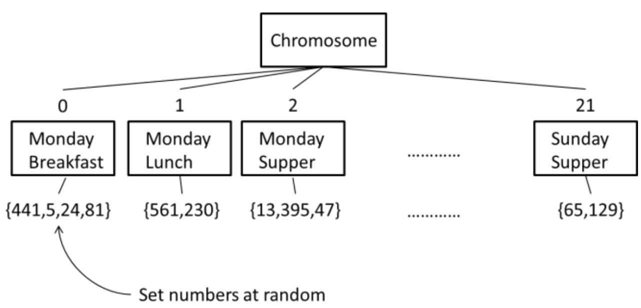

Fig. 1. The structure of a food menu's chromosome

3.2. Crossover method

We crossover the elements in 21 lists. The lists mean one meal, for example, breakfast, lunch, or supper. The number of dishes in the meal is various numbers. In addition, there is not numbers in the lists. Therefor, we crossover elements in the lists between same index of lists at random. If there is no number to crossover in the list, the number is changed to null.

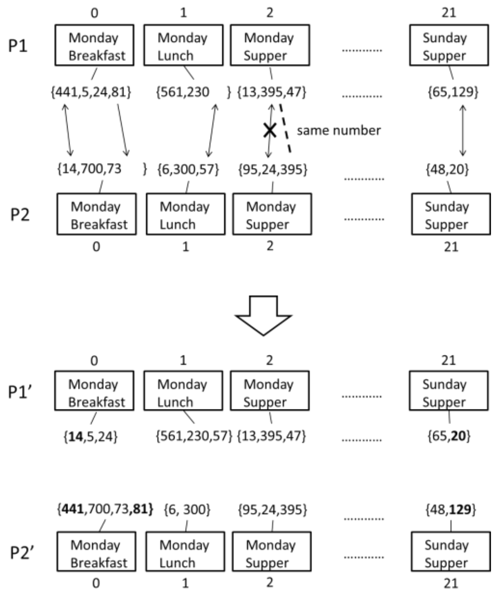

Fig.2. Crossover method for various length of gene

3.3. Method to evaluate the individual

3.3.1 Method to evaluate nutrient composition

We propose the method to evaluate balance of nutritive values. For example, when we evaluate value of total fat, we refer to “Japanese Nutrition Standard”[1]. Table. 1 shows the standard of fat intake. Additionally, We refer to “Nation health nourishment investigation”[2]. Table. 2 shows the distribution of fat intake. Therefore, we show an expression (1) using normal distribution. Fig.3 shows expression (1).

$$f(x) = N(\mu, \sigma^2)\cdot\sqrt{2\pi}\sigma = e^{-\frac{(x-\mu)^2}{2\sigma^2}} \qquad (1)$$

Consequently, the evaluation function of the lipid intake everyday is next expression (2) like Fig. 4.

$$f_{fat}(x) = \begin{cases} 1 & if\ \ 20 \le x < 30 \\ \frac{1}{2}\left(1 + erf\,\frac{x-20}{\sqrt{2}\sigma}\right) & if\ \ 0 \le x < 20 \\ \frac{1}{2}\left(1 - erf\,\frac{x-50}{\sqrt{2}\sigma}\right) & if\ \ x \ge 30 \end{cases} \qquad (2)$$

Table.1. The table of the fat intake standard

Age	Fat	
	Man	Woman
	DG(FPE*:%)	DG(FPE:%)
1~2 3~5 6~7 8~9 10~11 12~14 15~17 18~29	less than 30 more than 20	less than 30 more than 20
30~49 50~69 Over 70	less than 25 more than 20	less than 25 more than 20

* $FPE = Total\ Fat(g)\cdot 9(kcal/g)/Total\ Energy(kcal)\cdot 100$

Table.2. Distributions of fat intake

	people	μ	σ
The whole country	8,762	25.3	7.5

Percentile								
1	5	10	25	50	75	90	95	99
8.2	13.3	15.8	20.3	25.3	30.2	34.9	37.5	43.3

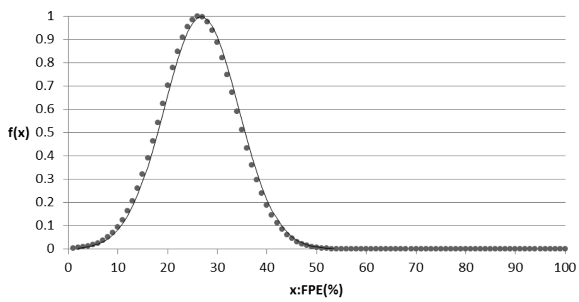

Fig.3. Normal distribution of fat intake

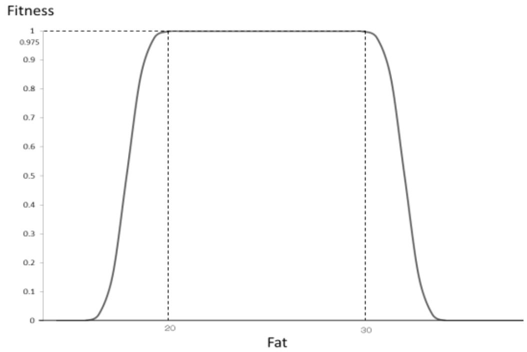

Fig.4. Fitness of fat intake

As a result, we show the function (3) which evaluates the nutritive intake every day. The number of nutrients is N.

$$f_{Nutritive} = \frac{1}{N}\sum_{k=1}^{N} f_k \tag{3}$$

3.3.2 Method to evaluate composition of dishes

The Japanese general menu structured with the mod el; soup, three side dishes and rice." The three dishes consisted of two vegetable dishes and one meat or fish dish. We make the menu which applied this model.

We classify dishes in A: Staple food, in B: Meat or fish dish, in C: Vegetable dish, in D: Soup, in E: Others; likes a fruit. Additionally, we give a point to the dishes (4).

$$\begin{aligned} W &= \{\lambda_A, \lambda_B, \lambda_C, \lambda_D, \lambda_E\} \\ &= \{0.2, 0.2, 0.1, 0.2, 0.2\} \end{aligned} \tag{4}$$

For example, if the menu is consisted of dish1: curry and rice, dish2: salad, and dish3: soup, we express three equations (5), (6), (7). The dish1 includes A, B, and C. The dish2 is C. The dish3 is D. Therefore, these three dishes can be expressed with byte code like follow equations. Consequently, this menu can be expressed with an equation (8).

$$dish\ 1 = \{1, 1, 1, 0, 0\} \tag{5}$$

$$dish\ 2 = \{0, 0, 1, 0, 0\} \tag{6}$$

$$dish\ 3 = \{0, 0, 0, 1, 0\} \tag{7}$$

$$\begin{aligned} table &= dish\ 1 + dish\ 2 + dish\ 3 \\ &= \{1, 1, 2, 1, 0\} \end{aligned} \tag{8}$$

Consequently, we define the function (9) which evaluates composition of dishes applying equation (4) to the array of a menu like the equation (8).

$$f_{table} = 1 - \left| 1 - table\, W^t \right| \tag{9}$$

In the case of the equation (8), a fitness value is 0.8. Therefore, from an expression (9), we define a purpose function for the composition of the menu every day the next expression (10).

$$f_{Composition} = \frac{1}{3}\sum_{k=1}^{3} f_{table_k} \tag{10}$$

If we evaluate the composition of the example menu consisting of soup, three side dishes and rice, that menu's evaluate level is maximum 1.

3.3.3 Method to evaluate a food menu

Thereby we express equation (3) is f_0, and equation (10) is f_1, we define purpose function which evaluates composition of menu everyday (11).

$$f_{Day} = \lambda_0 \cdot f_0 + \lambda_1 \cdot f_1 \tag{11}$$

$$\text{subject to} \quad \lambda_0 + \lambda_1 = 1 \quad (\lambda_0 \geq 0,\ \lambda_1 \geq 0) \tag{12}$$

Consequently, we define the evaluation function of the one-week menu which is 1 individual applying the equation (11) with the next equation (13).

$$f_{week} = \frac{1}{7}\sum_{k=1}^{7} f_{Day_k} \tag{13}$$

4 EXPERIMENT

4.1. Experimental method

4.1.1 Input and output

We prepared 700 samples of the dish, and we used each nutritive value, and the sample referred to the thing of the recipe site [4].

About nutrients, we consider energy, protein, total lipid, cholesterol, carbohydrates, a dietary fiber, vitamin B_1, vitamin B_2, niacin, vitamin B_6, folic acid, vitamin B_{12}, pantothenic acid, vitamin C, vitamin A, vitamin E, vitamin D, vitamin K, magnesium, calcium, phosphorus, ferrum, manganese, copper, zincum, sodium, potassium.

We set 25 years old, life activity level with 2 at a man who is menu user. The program prints the last population and an elite individual.

4.1.2 Setting GA parameters

We use the roulette selection and uniform crossover, population size with 100, generation size with 1000, mutation rate with 0.02, crossover rate with 0.25, the number of the elite preservation with 1. We change weights of functions in equation (12) by 0.1.

4.2. Experimental Results

The results appear in Fig. 5, Fig. 6. The graph in Fig.5 illustrates the evaluation level of functions (3), (10), (13). The scatter diagram in Fig. 6 shows fitness values of the composition of dishes and of the nutritive values.

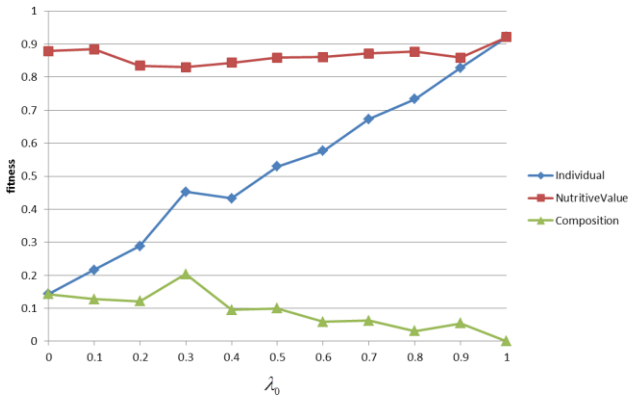

Fig.5. Diferrence of fitness about three functions

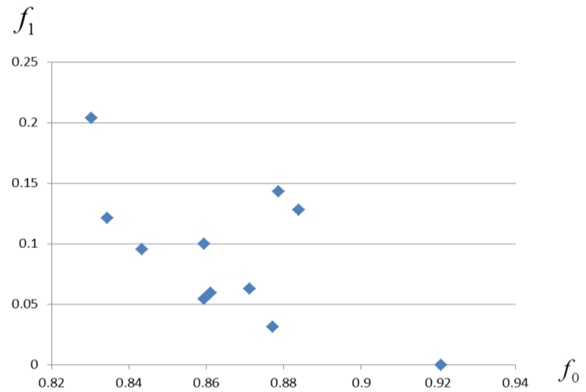

Fig.6. Scatter diagram with two functions

5 DISCUSSION

The nutritive values and the composition of dishes are seem not to have competetivity, moreover these are not correlation.in Fig.1 and Fig.2. It is easy to balance the nutritive values of the food menu, however, it is difficult to balance the composition of the dishes. When the composition of dishes decided strictly, the fitness of individual is very low. Therefore, the purpose function of the composition of dishes is necessary to be considered as important function. As the reason why an evaluation of the constitution of the dishes is low, the classification method of dishes is variable by a culture. For example, we classify the scone which is rich in carbohydrates as others this experiment and classify potato dishes as vice-greens. However, if we classify these meals as staple foods, the fitness value of individuals may be up. We change the classification of the dishes and the weight of the functions in the next research.

6 CONCLUSION

In this paper, we proposed an application method using GA for the menu making problem. The menu ought to be satisfying balance of the intake nutritive value and the composition of the meal consisting of soup, three side dishes and rice.

Abstract: Recently, soccer game algorithm has become shorter life cycle, due to complex game environment. We proposed hybrid classifier system for soccer video game simulation in recent paper and it indicated that hybrid classifier system is effective for online soccer strategy learning system. In this paper, we propose an individually role assignment for soccer game agent to reduce learning time and to achieve higher winning rate. We investigated individually role assignment by referring using real world soccer role assignment. Forwards agent's reward of shot should be high, and midfielder agent's should be separated into center and outer. We evaluated learning efficiency of our algorithm. As a result, it was found that winning rate of our algorithm with individually role assignment achieved greater than our former algorithm without individually role assignment.

Keywords: Classifier system, Reinforcement learning, Soccer game strategy

1 INTRODUCTION

Recently, it is common in the production of video games for human designers to explicitly specify the decision-making algorithms to be used by game agents. Meanwhile, video game environment has been changing offline to online in recent years. As a result, there are two problems in producing decision making algorithms. First, a single algorithm cannot possible satisfy all users, and as the number of users increase, differences in strategies is needed. Second, the appearance of users with advanced techniques has generated a need for decision-making algorithms under even more complicated environments. In additionally, as the Internet makes it easy for new users to appear one after another, it must be possible to provide and maintain bug-free programs that support such complex decision-making algorithms in a time frame much shorter than that in the past. As a means for addressing the above problem, taking a soccer game as an example of a video game. We have already proposed a hybrid learning classifier system [1] and we have also shown that we can automate the setting of reward values using genetic algorithms [2].

In this paper, we propose individually reward value allotment to soccer agents. Section 2 presents an overview of the conventional soccer game on which this study is based. In Section 3 we present soccer agent with individually role assignment. In Section 4 we present an evaluation method and the results of our tests, and we finally conclude with a summary.

2 CONVENTIONAL SOCCER VIDEO GAME AND ASSOCIATED PROBLEMS

The team of our soccer video game has 11 players each team. Two teams battle for the most points. Figure 1 shows a typical game scene targeting the area around the current position of the ball.

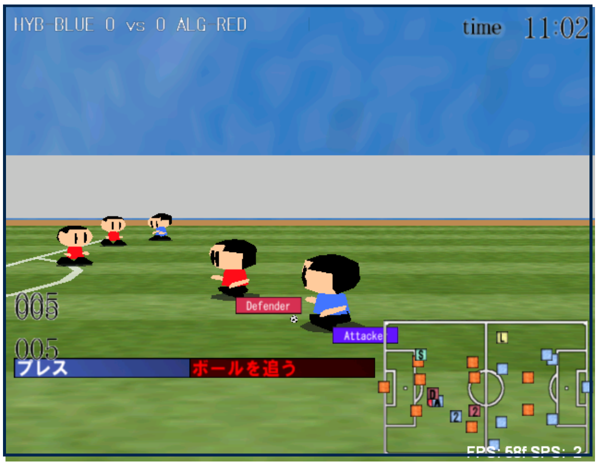

Fig. 1. Example of a typical game scene

We have studied the equipping of game programs with machine learning functions as an approach to solving the above problems. A number of techniques can be considered for implementing machine learning functions such as Q-learning [4] and genetic algorithms. We have decided on incorporating functions for acquiring rules based on classifier systems. We came to this decision considering the many examples of applying evolutionary computation to the acquisition of robot decision-making algorithms [5-8], learning classifier systems takes advantage of Gas and reinforcement learning to build adaptive rule-based systems that learn gradually via online experiences [4].

IF-THEN from learning methods is suitable for problem of selecting action under a situation such as game algorithm. As a result, IF-THEN learning methods can decreases bugs and increase mentenability.

Classifier system has rule set consist of condition part and consequents part. Rule held in IF-THEN form. Classifier system feedbacks selected action rules from rule set. It detects situation from environment by detector. Figure 2 is an overview of our hybrid classifier system. To improve learning efficiency, we proposed hybrid classifier system. Hybrid classifier system keeps privileged rules and learned rules from game. We succeeded learning time shorter by using hybrid classifier system. Figure 3

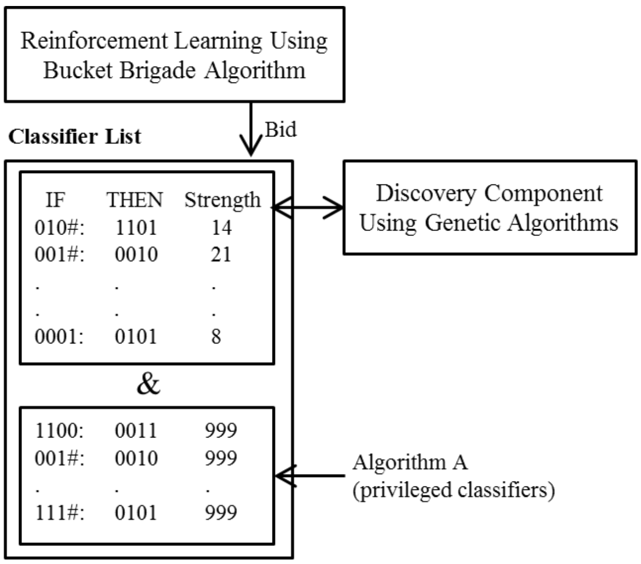

Fig.2. Overview of hybrid classifier system

Classifier system uses bucket brigade algorithm. System can learn continuous stream of action considering time series. In our previous study [3], we used 4-4-3 formation and FW, MF, DF. However, in real soccer game, FW can separated into side FW and center FW, DF can separated into center back and full back and required role is different. Separating position only FW, MF, DF can cause contradiction of role. For example, side MF should be more aggressive than center MF. Therefore, we can expect improve learning efficiency by defining player role more precisely.

3 INIDIVIDUALLY ROLE ALLOTMENT

We propose individually role allotment agent to solve these problems, and increase learning efficient, and set reward value based on real soccer game. Figure 3 shows overview of individually role allotment.

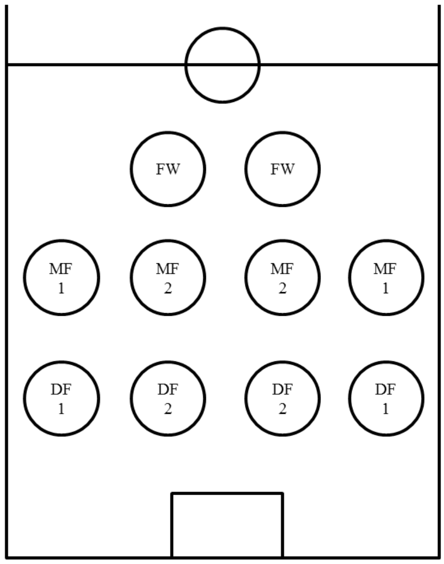

Fig.3. Individually role allotment agent

(I) FW

To get goal is priority role. Therefore we set get goal reward value high.

(II) MF (Center)

To pass ball to FW from DF is priority role. We expect pass route like DF2 to MF2 and forward from figure 3. Therefore we set dribble reward value and pass reward value high.

(III) MF (Side)

This position is relatively aggressive than (II). We expect pass route like DF1 to MF1 and forward from figure 3 this role also get goals if chance happen. We set dribble, pass, and get goal reward value high.

(IV) DF (Center)

To defend from opponent team is priority role. Therefore we set get ball reward value high.

(V) DF (Side)

This position is relatively required ability of pass than (IV), for example, we expect pass route like DF1 to MF1 or MF2, so we set dribble, pass, and get ball reward value high.

4 EXPERIMENT

4.1 Experimental method

Experiment conducts using 2 teams includes 22 agents. Conducts match with team using hybrid learning system and tem using only algorithm without learning system.

We define 200 matches as one learning and 30 learning is one set, and obtain winning rate. We use 4 reward settings such as Base, Position, Attack and Balance and conduct a match with algorithm A, B and C then investigate efficiency of individually role allotment.

There are three opponent algorithms with decision-making system A, B, and C. Algorithm A is a balanced team which attack and defense ability is balanced. Algorithm B is offensive team which attack ability is better than offence ability. Algorithm C is defensive team which defense ability is better than attack ability.

Table1 shows a Base reward. Base is designed to compare with a team which reward value is set by position. Therefore base team's reward value is set uniformly.

Table.1. Reward value of Base

Base	FW	MF	MF2	DF	DF2
GETGOAL	60	60	60	60	60
PASS	16	16	16	16	16
DRIBBLE	4	4	4	4	4
GETBALL	25	25	25	25	25
LOSTBALL	−50	−50	−50	−50	−50

Table2 shows a Position reward. Position is designed to compare with a team which reward value is set by individually. Therefore position team's reward value is set by position and do not separate reward value by MF1, MF2.

Table.2. Reward value of Position

Position	FW	MF	MF2	DF	DF2
GETGOAL	80	50	50	35	35
PASS	8	16	16	16	16
DRIBBLE	2	4	4	4	4
GETBALL	15	35	35	50	50
LOSTBALL	−50	−50	−50	−50	−50

Table3 shows a Balance reward. Balance's reward value is set by individually and this is our proposal. We set reward value individually like FW, MF1, MF2, DF1, DF2.

Table.3. Reward value of Balance

Balance	FW	MF	MF2	DF	DF2
GETGOAL	80	50	65	35	50
PASS	8	16	8	16	8
DRIBBLE	2	4	2	4	2
GETBALL	15	35	30	50	55
LOSTBALL	−50	−50	−50	−50	−50

Table4 is an Attack reward. Attack's reward value is set by individually like Balance, and we set relatively offensive than Balance team. We investigate winning rate with Balance team and Attack team, to find difference between two team.

Table.4. Reward value of Attack

Attack	FW	MF	MF2	DF	DF2
GETGOAL	80	50	60	35	45
PASS	8	16	12	16	12
DRIBBLE	2	4	3	4	3
GETBALL	15	35	30	50	45
LOSTBALL	−50	−50	−50	−50	−50

We use under formula (1) to calculate winning rate.

$$R_w = N_w / (N_t - N_c) \qquad (1)$$

Nt is a number of total match, *Nd* is a number of draw, *Nw* is a number of win. We define one set is 30 learning and one learning is 200 match.

4.2 Experimental result

4.2.1 Experimental result with algorithm A

Figure 4 is an experimental result of match with Base, Position, Attack and Balance to Algorithm A. Attack's winning rate is higher than Position from 3rd match and winning rate is 77% at 100th match. Balance's winning rate is higher than Position from 2nd match and winning rate is 78 % at 100th match.

4.2.2 Experimental result with algorithm B

Figure 5 is an experimental result of match with Base, Position, Attack and Balance to Algorithm B. Balance's winning rate is 82% at 9th match and 84% at 100th match.

Balance's winning rate is 82% at 9th match while Position's winning rate is 69%.

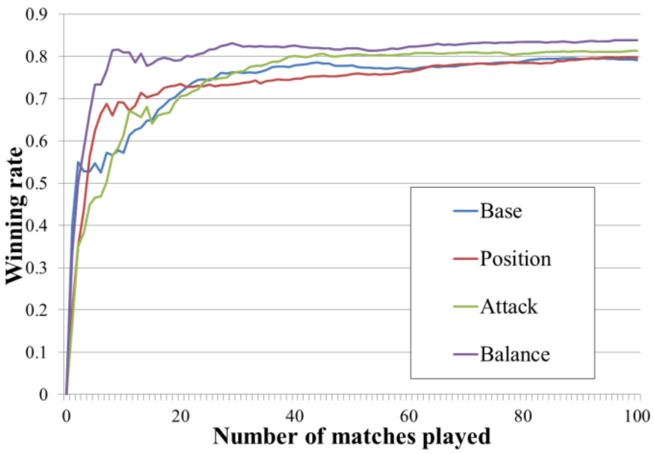

Fig.5. Winning rate with algorithm B

4.2.3 Experimental result with algorithm C

Figure 6 is an experimental result of match with Base, Position, Attack and Balance to Algorithm C. Balance's winning rate is 73% at 100th match while Position's winning rate is 69% at 100th match.

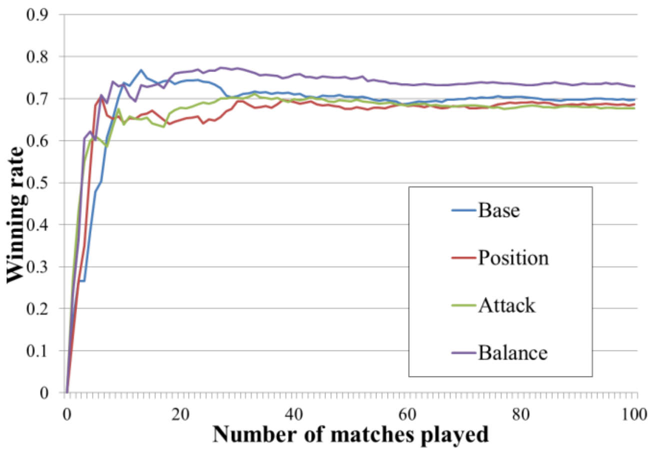

Fig.6. Winning rate with algorithm C

5.4 DISCUSSION

Compare individually role allotment agent with position agent, individually role allotment agent's winning rate average is higher than position agent with algorithm A at 2%, algorithm B at 7%, algorithm C at 7%. Balance team's winning rate is higher than Attack team's winning rate. Especially, this result is same with algorithm C which is defensive team. From this result, only raising offensive reward cannot cause raise of winning rate.

One reason of individually role allotment agent' winning rate is higher than position agent and offensive reward table does not always raise winning rate is we guess contradiction of rule set of classifier system decreased, because individually role allotment is more specific reward allotment than position role allotment. Second reason is the possibility of number of communication between players increased, so offensive reward table may interrupt communications between players and balanced reward table may assist increase of communications between players.

6 CONCLUSION

We proposed individually role allotment agent. From experimental result, individually role allotment agent obtained higher winning rate than position role allotment agent' winning rate, and offensive reward table do not always cause raise winning rate. Communications between players may one factor of winning rate. We continue to research about what factor is relate with winning rate.

Abstract

A CAM system for an articulated-type industrial robot RV1A is described from the viewpoint of robotic servo controller. It is defined here that the CAM system includes an important function that allows the industrial robot to move along cutter location data (CL data) consisting of position and orientation components. Another important point is that the proposed CAM system has a high applicability to other industrial robots whose servo systems are technically opened to end-user engineers. Our CAM system works as a straightforward interface without using any robot languages between CAD/CAM and industrial robots. Here, in order to raise the relationship between a conventional CAD/CAM and an industrial robot, a design and an implementation of CAM system are shown.

1 Introduction

Up to now, many studies focusing on the teaching of industrial robots have been conducted. Several promising teaching systems for industrial robots have been already developed according to each task. However, it seems that CAM system from the viewpoint of robotic servo system has not been sufficiently discussed yet.

In this paper, it is defined that CAM system includes an important function that enables an industrial robot to be accurately controlled along CL data consisting position and orientation components. Another important point is that the proposed CAM system has a high applicability to other industrial robots whose servo systems are technically opened to engineering users. At the present stage, the relationship between CAD/CAM and industrial robots is not deep, compared to NC machine tools widely spread in manufacturing industries. It seems that the CAM/CAM technology generating NC codes is technically matured for various NC machine tools. On the other hand, however, the CAM system for industrial robots has not been sufficiently considered and standardized yet, so that there still exist many kinds of robot languages. That is the reason why when an industrial robot is applied to a task, the required position and orientation data are acquired by on-line and/or off-line teaching system in almost all cases.

In this paper, a CAM system for an articulated-type industrial robot RV1A shown in **Fig. 1** is described from the viewpoint of robotic servo controller.

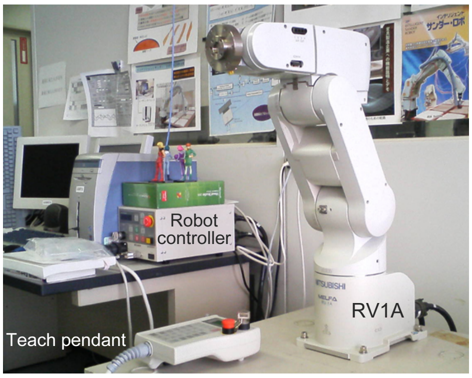

Figure 1: Desktop-size industrial robot RV1A.

The RV1A is one of the industrial robots provided by Mitsubishi Electric Corporation. In order to raise the relationship between a CAD/CAM and the industrial robot, a simple and straightforward CAM system is proposed. A basic design of the CAM system and experimental results are shown.

2 Desired Trajectory

2.1 Main-processor of CAM

Various kinds of CAD/CAM such as Catia, Unigraphics, Pro/Engineer, etc. are widely used in manufacturing industries. The main-processor of each CAM can generate CL data consisting of position and orientation components along a 3D model. In this section, how to calculate desired position and orientation for robotic servo system is described in detail.

For example, robotic sanding task needs a desired trajectory so that the sanding tool attached to the tip of the robot arm can follow the object's surface, keeping contact with the surface from the normal direction. If the object is fortunately designed by a CAD/CAM and manufactured by an NC machine tool, then CL data can be referred to as the desired trajectory consisting of position and orientation elements. It is important to show a guideline for raising the relationship between main-processor of CAD/CAM and industrial robot, which is the role of the CAM system proposed after this section.

2.2 Position and orientation for discrete-time control system

In order to realize non-taught operation, we have already proposed a generalized trajectory generator [1]

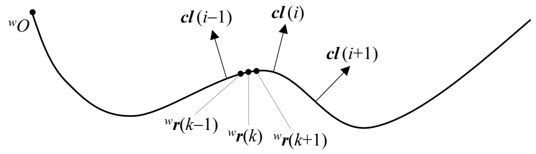

Figure 2: Relation between CL data $\boldsymbol{cl}(i)$ and desired trajectory ${}^w\boldsymbol{r}(k)$, in which ${}^wO$ is the origin of work coordinate system.

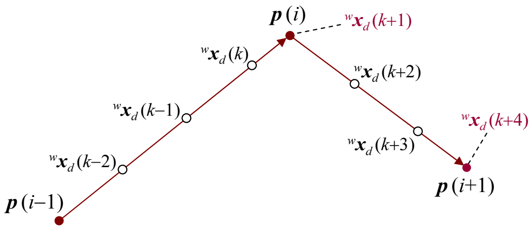

Figure 3: Relation between position component $\boldsymbol{p}(i)$ in CL data and desired position ${}^w\boldsymbol{x}_d(k)$, in which $\boldsymbol{p}(i) - {}^w\boldsymbol{x}_d(k)$ and $\boldsymbol{p}(i+1) - {}^w\boldsymbol{x}_d(k+3)$ are called the fraction vectors.

using CL data, that yields desired trajectory ${}^w\boldsymbol{r}(k)$ at the discrete time k given by

$$ {}^w\boldsymbol{r}(k) = \left[{}^w\boldsymbol{x}_d^T(k)\ {}^w\boldsymbol{o}_d^T(k)\right]^T \tag{1}$$

where the superscript w denotes the work coordinate system, ${}^w\boldsymbol{x}_d(k) = [{}^wx_d(k)\ {}^wy_d(k)\ {}^wz_d(k)]^T$ and ${}^w\boldsymbol{o}_d(k) = [{}^wo_{dx}(k)\ {}^wo_{dy}(k)\ {}^wo_{dz}(k)]^T$ are the position and orientation components, respectively. ${}^w\boldsymbol{o}_d(k)$ is the normal vector at the position ${}^w\boldsymbol{x}_d(k)$. In the following, we explain in detail how to make ${}^w\boldsymbol{r}(k)$ using the CL data.

A target workpiece with curved surface is generally designed by a 3D CAD/CAM, so that CL data can be calculated by the main-processor. The CL data consist of sequential points along the model surface given by a zigzag path or a whirl path. In this approach, the desired trajectory ${}^w\boldsymbol{r}(k)$ is generated along the CL data. The CL data are usually calculated with a linear approximation along the model surface. The i-th step is written by

$$\boldsymbol{cl}(i) = [p_x(i)\ p_y(i)\ p_z(i)\ n_x(i)\ n_y(i)\ n_z(i)]^T \tag{2}$$
$$\{n_x(i)\}^2 + \{n_y(i)\}^2 + \{n_z(i)\}^2 = 1 \tag{3}$$

where $\boldsymbol{p}(i) = [p_x(i)\ p_y(i)\ p_z(i)]^T$ and $\boldsymbol{n}(i) = [n_x(i)\ n_y(i)\ n_z(i)]^T$ are position and orientation vectors based on the origin ${}^wO$, respectively. ${}^w\boldsymbol{r}(k)$ is obtained by using both linear equations and a tangential velocity scalar v_t called feed rate.

A relation between $\boldsymbol{cl}(i)$ and ${}^w\boldsymbol{r}(k)$ is shown in **Fig. 2**. In this case, assuming ${}^w\boldsymbol{r}(k) \in [\boldsymbol{cl}(i-1), \boldsymbol{cl}(i)]$ we obtain ${}^w\boldsymbol{r}(k)$ through the following procedure. First, a direction vector $\boldsymbol{t}(i) = [t_x(i)\ t_y(i)\ t_z(i)]^T$ is given by

$$\boldsymbol{t}(i) = \boldsymbol{p}(i) - \boldsymbol{p}(i-1) \tag{4}$$

so that v_t is decomposed into x-, y- and z-components

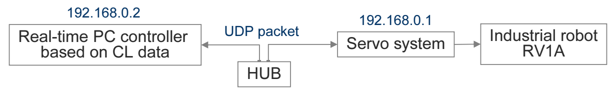

Figure 4: Block diagram of communication system by using UDP packet.

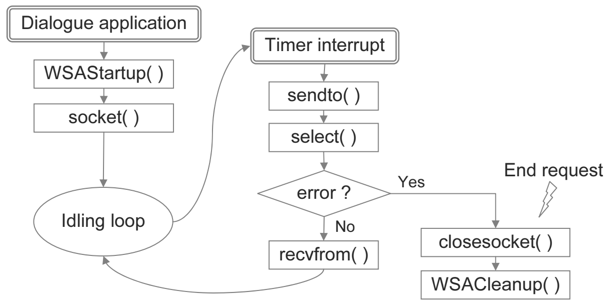

Figure 5: Communication scheme by using UDP packet between PC and Industrial robot RV1A, in which the sampling period Δt is set to 10 ms.

in work coordinate system as written by

$$v_{tj} = v_t \frac{t_j(i)}{\|\boldsymbol{t}(i)\|} \quad (j = x, y, z) \tag{5}$$

Using a sampling width Δt, each component of the desired position ${}^w\boldsymbol{x}_d(k)$ is represented by

$${}^wx_d(k) = {}^wx_d(k-1) + v_{tx}\Delta t \tag{6}$$
$${}^wy_d(k) = {}^wy_d(k-1) + v_{ty}\Delta t \tag{7}$$
$${}^wz_d(k) = {}^wz_d(k-1) + v_{tz}\Delta t \tag{8}$$

Next, how to calculate the desired orientation $\boldsymbol{o}_d(k)$ is considered. By using the orientation components of two adjacent steps in CL data, a rotational direction vector $\boldsymbol{t}_r(i) = [t_{rx}(i)\ t_{ry}(i)\ t_{rz}(i)]^T$ is defined as

$$\boldsymbol{t}_r(i) = \boldsymbol{n}(i) - \boldsymbol{n}(i-1) \tag{9}$$

Each component of desired orientation can be linearly calculated with $\boldsymbol{t}_r(i)$ as

$${}^wo_{dj}(k) = n_j(i-1) + t_{rj}(i)\frac{\|\boldsymbol{x}_d(k) - \boldsymbol{p}(i-1)\|}{\|\boldsymbol{t}(i)\|} \quad (j = x, y, z) \tag{10}$$

${}^w\boldsymbol{x}_d(k)$ and ${}^w\boldsymbol{o}_d(k)$ shown above are directly obtained from the CL data without either any conventional complicated teaching process or recently proposed off-line teaching methods. The desired position and orientation in the discrete time domain are very important to control the tip of an industrial robot in real time, i.e., to design a feedback control system.

If the linear approximation is applied when CL data are generated by the main-processor of CAD/CAM, CL data forming a curved line are composed of continuous minute lines such as $\|\boldsymbol{p}(i) - \boldsymbol{p}(i-1)\|$ and $\|\boldsymbol{p}(i+1) - \boldsymbol{p}(i)\|$ shown in **Fig. 3**. In this case, it should be noted that each position vector in CL data such as $\boldsymbol{p}(i)$ and $\boldsymbol{p}(i+1)$ shown in **Fig. 3** have to be carefully dealt with in order to be accurately followed along the CL data. For example, ${}^{w}\boldsymbol{x}_d(k+1)$ and ${}^{w}\boldsymbol{x}_d(k+4)$ are not calculated by using Eqs. (6), (7) and (8) but have to be directly set with $\boldsymbol{p}(i)$ and $\boldsymbol{p}(i+1)$, respectively, just before the feed direction changes. $\|\boldsymbol{p}(i) - {}^{w}\boldsymbol{x}_d(k)\|$ and $\|\boldsymbol{p}(i+1) - {}^{w}\boldsymbol{x}_d(k+3)\|$ are called the fraction.

3 Implementation to RV1A

3.1 Communication with robot controller

A Windows PC as a controller and the RV1A are connected with Ethernet as shown in **Fig. 4**. The servo system in Cartesian coordinate system of the RV1A is technically opened to users, so that absolute coordinate vectors of position and orientation can be given to the reference of the servo system. The servo rate of the robot is fixed to 7.1 ms. **Figure 5** illustrates the communication scheme by using UDP packet, in which sampling period is set to 10 ms. The data size in a UDP pachet is 196 bytes. The packet transmitted by 'sendto( )' includes values of desired position $\boldsymbol{X}_d(k) = [X_d(k)\ Y_d(k)\ Z_d(k)]^T$ [mm] and desired orientation $\boldsymbol{O}_d(k) = [\phi_d(k)\ \theta_d(k)\ \psi_d(k)]^T$ [rad] in robot absolute coordinate system. $\phi_d(k)$, $\theta_d(k)$, $\psi_d(k)$ are the rotational angles about x-, y- and z-axes, respectively, which are called X-Y-Z fixed angles or roll, pitch and yaw angles. The desired position and the desired orientation are set in a UDP packet as the reference of arm tip in the Cartesian servo system. Also, the packet received by 'recvfrom( )' includes values of current position $\boldsymbol{X}(k) = [X(k)\ Y(k)\ Z(k)]^T$ [mm] and current orientation $\boldsymbol{O}(k) = [\phi(k)\ \theta(k)\ \psi(k)]^T$ [rad] in robot absolute coordinate system, which can be used for feedback quantity.

3.2 Desired position and orientation

How to make $\boldsymbol{X}_d(k)$ and $\boldsymbol{O}_d(k)$ = based on the position and the orientation given by Eq. (1) is discussed in detail by using an example shown in **Fig. 2**, in which the tip of robot arm follows the trajectory keeping the orientation along normal direction to the surface. Each components of $\boldsymbol{X}_d(k)$ is represented with the initial position $\boldsymbol{X}_d(0)$ as

$$X_d(k) = X_d(0) + {}^{w}x_d(k) \tag{11}$$
$$Y_d(k) = Y_d(0) + {}^{w}y_d(k) \tag{12}$$
$$Z_d(k) = Z_d(0) + {}^{w}z_d(k) \tag{13}$$

where $\boldsymbol{X}_d(0)$ means the values of ${}^{w}O$ in robot absolute coordinate system.

Next, we consider the rotational components. Generally, rotational matrices R_X, R_Y and R_Z around x-, y- and z-axes are respectively given by

$$R_X = \begin{pmatrix} 1 & 0 & 0 \\ 0 & \cos\phi(k) & -\sin\phi(k) \\ 0 & \sin\phi(k) & \cos\phi(k) \end{pmatrix} \tag{14}$$

$$R_Y = \begin{pmatrix} \cos\theta(k) & 0 & \sin\theta(k) \\ 0 & 1 & 0 \\ -\sin\theta(k) & 0 & \cos\theta(k) \end{pmatrix} \tag{15}$$

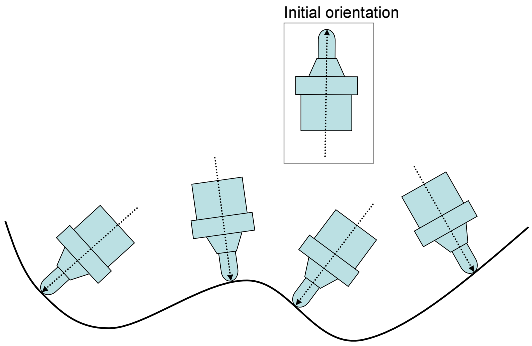

Figure 6: Orientation control of arm tip based on CL data shown in **Fig. 2**, in which the initial orientation is given with $[\phi(k)\ \theta(k)\ \psi(k)]^T = [0\ 0\ 0]^T$.

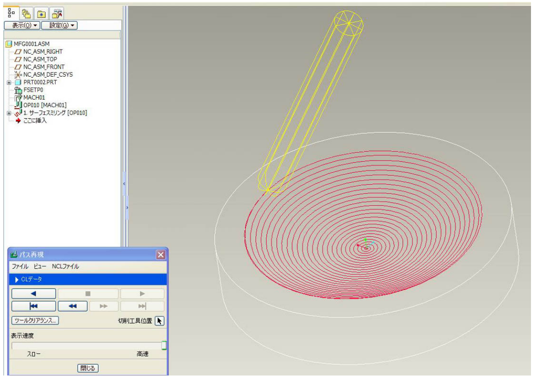

Figure 7: CL data $\boldsymbol{cl}(i) = [\boldsymbol{p}^T(i)\ \boldsymbol{n}^T(i)]^T$ consisting of position and orientation components, which is used for desired trajectory of the tip of robot arm.

$$R_Z = \begin{pmatrix} \cos\psi(k) & -\sin\psi(k) & 0 \\ \sin\psi(k) & \cos\psi(k) & 0 \\ 0 & 0 & 1 \end{pmatrix} \tag{16}$$

Accordingly, the rotational matrix $R_Z R_Y R_X$ with a roll angle $\phi(k)$, a pitch angle $\theta(k)$, and a yaw angle $\psi(k)$ is given by

$$\begin{pmatrix} C_\theta C_\psi & S_\phi S_\theta C_\psi - C_\phi S_\psi & C_\phi S_\theta C_\psi + S_\phi S_\psi \\ C_\theta S_\psi & S_\phi S_\theta S_\psi + C_\phi C_\psi & C_\phi S_\theta S_\psi - S_\phi C_\psi \\ -S_\theta & S_\phi C_\theta & C_\phi C_\theta \end{pmatrix} \tag{17}$$

where, for example, S_θ and C_θ means $\sin\theta(k)$ and $\cos\theta(k)$, respectively. **Figure 6** illustrates the trajectory following control along CL data shown in **Fig. 2**. As can be seen, the direction of ${}^{w}\boldsymbol{o}_d(k)$ is just inverse to the one of the arm tip. When referring the orientation components in CL data, the arm tip can be determined only with the roll angle and the pitch angle except for the yaw angle. That means $\psi(k)$ can be always fixed to 0 [rad]. Thus, the roll angle $\phi(k)$ and the pitch angle $\theta(k)$ at the discrete time k are obtained by solving

$$\begin{pmatrix} -{}^{w}o_{dx}(k) \\ -{}^{w}o_{dy}(k) \\ -{}^{w}o_{dz}(k) \end{pmatrix} = \begin{pmatrix} C_\theta & S_\phi S_\theta & C_\phi S_\theta \\ 0 & C_\phi & -S_\phi \\ -S_\theta & S_\phi C_\theta & C_\phi C_\theta \end{pmatrix} \begin{pmatrix} 0 \\ 0 \\ 1 \end{pmatrix} \tag{18}$$

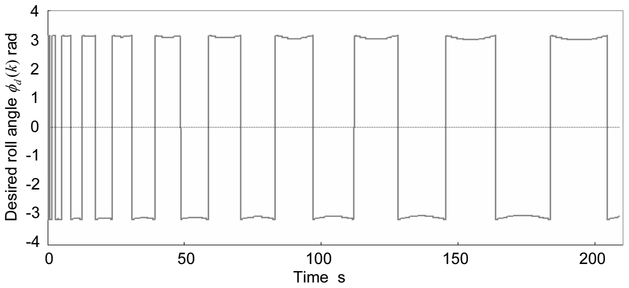

Figure 8: Initial part of desired roll angle $\phi_d(k)$ calculated from the desired trajectory shown in **Fig. 7**.

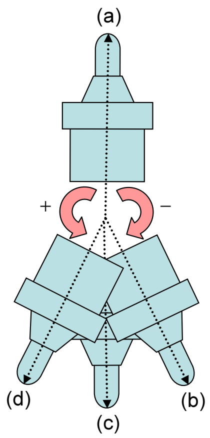

Figure 9: Roll angles around x-axis, in which (a) is the initial angle represented by $\phi(k) = 0$, (b) is the case of $-\pi \leq \phi(k) < 0$, (c) is the case of $\phi(k) = \pm\,\pi$, and (d) is the case of $0 < \phi(k) \leq\ \pi$.

where $[0\ 0\ 1]^T$ is the initial orientation vector in robot absolute coordinate system as shown in **Fig. 6**. Finally, $\phi(k)$ and $\theta(k)$ are calculated by using inverse trigonometric functions as

$$\phi(k) = \text{atan2}\{-{}^{w}o_{dx}(k),\ -{}^{w}o_{dz}(k)\} \quad (19)$$
$$\theta(k) = \text{asin}\{{}^{w}o_{dy}(k)\} \quad (20)$$

If the yaw angle is fixed to 0, then $\phi_d(k)$ and $\theta_d(k)$ can be calculated with Eqs. (19) and (20), respectively.

4 Experiment

In this section, an experiment of trajectory following control is conducted to evaluate the effectiveness of the proposed CAM system. **Figure 7** shows the desired trajectory generated by using the main-processor of 3D CAD/CAM Pro/Engineer, which consists of position and orientation components written by multi-lined "GOTO/" statements. It is tried that the arm tip is controlled so as to follow the position and orientation. The value of feed rate, i.e., tangent velocity, is set to 1 mm/s; the desired values composed of $\boldsymbol{X}_d(k)$ and $\boldsymbol{O}_d(k)$ are given to the references of the servo controller of RV1A every sampling period through UDP packets.

When the desired position $\boldsymbol{X}_d(k)$ and orientation $\boldsymbol{O}_d(k)$ is transmitted to the robotic servo system, the roll angle $\phi_d(k)$ has to be given within the range from $-\pi$ to π. **Figure 9** shows four examples of roll angle around x-axis, in which (a) is the initial angle represented by $\phi(k) = 0$, (b) is the case of $-\pi \leq \phi(k) < 0$, (c) is the case of $\phi(k) = \pm\,\pi$, and (d) is the case of $0 < \phi(k) \leq\ \pi$. It should be noted how to calculate the desired roll angle $\phi_d(k)$ as an manipulated value if the orientation changes as (b)→(c)→(d) or (d)→(c)→(b), i.e., in passing through the situation (c). In such cases, the sign of $\phi_d(k)$ has to be suddenly changed as shown in **Fig. 8**. In order to smoothly control the orientation of the arm tip , the following control rules were applied for the correction of roll angle.

if $\phi_d(k) > 0$ and $\phi(k) < 0$

$$\Delta\phi(k) = K_p\,\{\phi_d(k) - \phi(k) - 2\pi\} \quad (21)$$

else if $\phi_d(k) < 0$ and $\phi(k) > 0$

$$\Delta\phi(k) = K_p\,\{\phi_d(k) - \phi(k) + 2\pi\} \quad (22)$$

else if $\text{sgn}\{\phi_d(k)\} = \text{sgn}\{\phi(k)\}$

$$\Delta\phi(k) = K_p\,\{\phi_d(k) - \phi(k)\} \quad (23)$$

where $\phi_d(k)$ and $\phi(k)$ are the desired roll angle transmitted to the robotic servo controller and actual roll angle transmitted from the robotic servo controller, respectively. $\Delta\phi(k)$ is the output of proportional control action with a gain K_p. In fact, the desired roll angle $\phi_d(k+1)$ is generated as

$$\phi_d(k+1) = \phi(k) + \Delta\phi(k) \quad (24)$$

It was confirmed from the experiment that desirable control results of position and orientation could be obtained. The arm tip could gradually move up from the bottom center along the spiral path shown in **Fig. 7**. In this case, the orientation of the arm tip was simultaneously controlled so as to be normal direction to the surface. It was successfully demonstrated that the proposed CAM system allows the tip of the robot arm to desirably follow the desired trajectory given by multi-axis CL data without any complicated teaching tasks.

5 Conclusions

A CAM system for an articulated-type industrial robot RV1A has been proposed in order to raise the relationship between a design tool such as CAD/CAM and industrial robots spread to industrial manufacturing fields. The CAM system required for the industrial robot RV1A was realized as an integrated system including not only conventional main-processor of CAM but also robotic servo system and kinematics.

Abstract: Central Pattern Generators (CPGs) as neural oscillators can determine a periodic motion state just like a walk. There exists a simple CPG for realizing the walk of an insect. It has been confirmed that a successive jump was able to be realized by applying such a simple structure. Furthermore, it was proved that different jumping appearances were generated according to the jumping-out posture, even if similar jumping generators were used. In this paper, for a CPG of a successive jumping six-legged robot, it is checked that parameters related to the CPG should be changed and optimized, depending on the jumping-out posture. A simple genetic algorithm is used as an optimization method. The simulation results that were obtained from a successive jumping simulation conducted by a dynamic simulator OpenHRP3, are used to evaluate the individuals in the GA.

1 INTRODUCTION

Many wheels, crawlers, and legs are used as a locomotion mechanism of robots that move on the ground. Among them, since the locomotion using a leg can move on the rugged ground surface, it has some advantageous features[1]. Using such features, various legged robots are developed for explorations and work on irregular background. Now, the locomotion of legged robots is mainly based on a static walking. This is a natural selection in movement on the rugged ground surface for the legged robot whose mass becomes large comparatively to suppress an unexpected affection due to the changes of a ground surface, or to cope with such changes. However, a legged robot may move on the flat ground surface. In movement on the flat ground surface, the locomotion using wheels or crawlers has an advantage in speed.

Therefore, a dynamic walking is adopted for improving the locomotion speed of a legged mobile robot. The dynamic walking is a walk to which the time when a leg does not contact a ground surface exists in a walking cycle. A kind of dynamic walking has a jump. The successive jump can aim at improving a locomotion speed as a dynamic walking[2], [3]. Moreover, taking a jumping-out angle and an initial rate appropriately, a jump may be able to avoid a bigger obstacle than one that a static walking can do. This can extend the range of robot activities.

We have already set a jump mechanism in the leg-tip of a six-legged (or hexa-) robot, and have proposed how to generate the rhythm of a successive jump (hopping) using Central Pattern Generator (CPG)[4], [5]. Furthermore, it was confirmed that different jumping appearances were generated according to the jumping-out posture, even if similar jumping generators were used[6]. In this paper, for a CPG of a successive jumping six-legged robot, it is proved that parameters related to the CPG should be changed and optimized, depending on the jumping-out posture. A simple genetic algorithm (GA) is used as an optimization method. The simulation results that were obtained from a successive jumping simulation conducted by a dynamic simulator OpenHRP3, are used to evaluate the individuals in the GA.

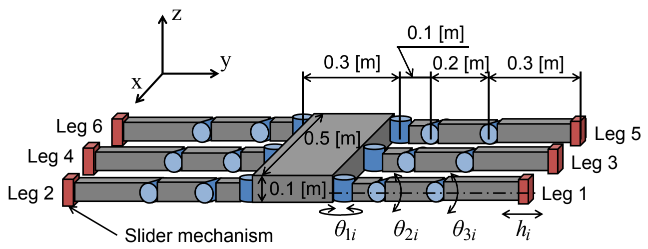

Fig. 1. Jumping six-legged robot

2 JUMPING SIX-LEGGED ROBOT

Although there are several legged robots that have different number of legs, in this paper, a six-legged robot is adopted because it is known that static stability nature is fully guaranteed during a walk. There are three joints in each leg of the robot to keep the posture and achieve walk movement. In addition, it has a prismatic mechanism at each leg-tip as a jump mechanism, which can slide to the leg-tip direction. Therefore, the six-legged jumping robot under study has 24 degrees of freedom in total because it has four degrees of freedom per each leg. The model for the six-legged jump-

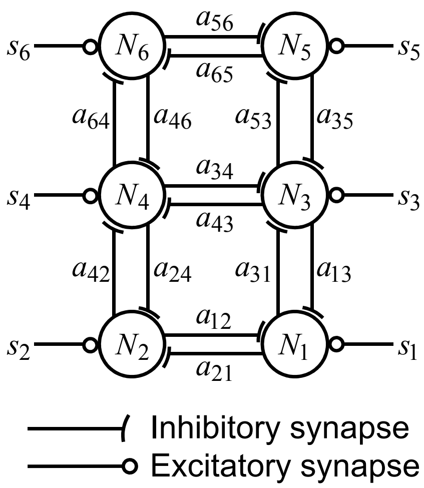

Fig. 2. Network for CPG

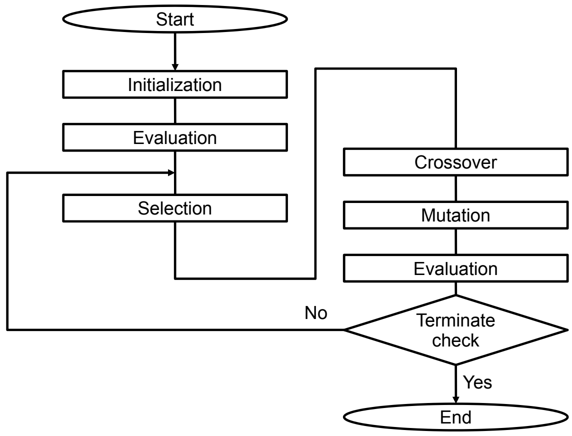

Fig. 3. GA flow chart

ing robot, the associated each link length and the leg number which were used in the dynamics simulator are shown in Fig. 1. The line extended above the robot in Fig. 1 denotes the perpendicular axis, which is regarded as z-axis, and the line extended to the front of the robot is viewed as x-axis. Furthermore, assume that y-axis makes a right-hand system, together with x- and z- axes. Let the field visible in front of Fig. 1 be a front face of the robot. When seeing the robot by him, odd numbers were assigned to the left legs and even numbers were assigned to the right legs, where the front leg of the left was set to Leg 1.

The total mass of the robot is 12.6 kg. For each leg, let joint angle be θ_{1i}, θ_{2i}, θ_{3i}, and h_i starting from the body, where i denotes the leg number. The length of each leg extending from each joint was 0.1 m, 0.2 m, and 0.3 m. The sliding mechanism for a jump can slide in $+0.05$ m and -0.05 m on the basis of the leg-tip. The other legs have the same mechanisms as stated above. In addition to the potentiometer to measure the joint displacement, the robot has a 3-axis accelerometer attached to the center of the fuselage. In the 3D model for the simulator, to overcome the contact calculations between parts of the robot, assume that a contact with the other leg and own body was not considered for the joint angle configuration. In the simulation, four cases will be prepared for the initial posture. The same controller will be used for all cases, and we examine how the jump behavior is changed due to each posture.

3 JUMPING RHYTHM GENERATOR

CPG is a kind of a neuron model and generates the periodic signal considered to be deeply related to the periodical activity of a living thing. When two or more CPG neurons exist, it is known that a phenomenon called an attraction is generated in the output periodic signal of each neuron with progress of time by suitably defining the coupling coefficients between neurons. Although there were some mathematical models proposed so far in CPG, in this paper, the Matsuoka oscillator with a comparatively simple relationship among parameters was used[7]. The Matsuoka model is formulated by

$$T_r \frac{\mathrm{d}u_i}{\mathrm{d}t} + u_i = -\sum_{j=1}^{n} a_{ij} y_j + s_i - b f_i \tag{1}$$

$$y_i = g(u_i) \quad (g(u_i) \triangleq \max(0, u_i)) \tag{2}$$

$$T_a \frac{\mathrm{d}f_i}{\mathrm{d}t} + f_i = y_i \tag{3}$$

where t is the time variable, i, j denote the neuron number. T_r is a rise time constant, u_i is the membrane potential of neuron body, a_{ij} (≥ 0 for $i \neq j$ and $= 0$ for $i = j$) is a weight of inhibitory synaptic connection from j-th neuron to the i-th neuron. y_i is a firing rate or an output of the neuron, s is an impulse rate of input. b is the parameter that determines the steady-state firing rate for a constant input. f is a fatigue state (or an adaptation variable), T_a is an adaptation time constant.

The composition of the CPG network by inhibited connections of six neurons used in this paper is shown in Fig. 2. The output value y from each neuron of the constituted CPG network is used as a next desired value of the sliding mechanism for a jump of the leg number i as shown by

$$h_{oi} = -y_i \tag{4}$$

However, it is assumed that if the accelerations in x- and y-directions of the robot center of gravity are less than a value and also z-directional acceleration approaches the gravitational acceleration enough, then the robot vibration is sufficiently settled down. Then, a CPG output is used as a desired value, as long as the robot vibration is fully settled down. The output of the sliding mechanism for a jump is calculated

Table 1. Joint angles of each leg for Case 1

i	θ_{1i}	θ_{2i}	θ_{3i}

by using the desired value acquired from the CPG such that

$$T_i = P(h_{oi} - h_i) + D(v_{oi} - \dot{h}_i) \qquad (5)$$

where i denotes the leg number, h_i is the displacement of the slide joint, v_{oi} is an objective velocity (now, $v_{oi} = 0$). P is the proportional gain and D is the differential gain. Thus, the force for a jump is generated periodically.

4 GENETIC ALGORITHM

GA is an algorithm that imitates the evolution of a living thing, which was proposed by Holland and others late in the 1960s. The GA models the evolutionary mechanism of a living thing and is the algorithm in which an individual with the highest fitness against the environment is determined as the optimal solution to the objective function. The optimal solution in GA is searched by repeatedly applying the genetic operation of Selection, Crossover, and Mutation to the population. The fundamental flow of GA is shown in Fig. 3. A simple GA in which an individual is expressed by a binary number is adopted in this research, and parameters related to a CPG are explored optimally.

5 SIMULATION

5.1 Simulation Condition

Joint angles θ_{1i}, θ_{2i} and θ_{3i} of each leg prepared for the initial posture of the robot are shown in Table 1 to Table 2. The appearance when the robot actually becomes each initial posture by the dynamics simulation is shown in Fig. 4 to Fig. 5.

The total number of parameters is 35, which involve the CPG parameters. Each parameter is described by a binary number in 32 bits and put them in order to make one individual. A simulation is performed by using the parameters related to a certain individual, and the maximum jump height of the robot in each trial and continuous simulation time is used as a fitness of the individual. The design parameters related to this GA are as follows: the population size is 20 and the end of generation is 30; the individual length is 1120 bites because there are 35 parameters one of which is described by 32 bits; the Selection is a tournament selection by three individuals; the Crossover is one point crossover with the probability of 0.6; and the Mutation is produced with the rate of 1/1120.

PD gains are set to be constant in simulations. P and D gains at each joint are given in an order from the joint near the body; the 1st joint has P_{1i} = 50 and D_{1i} = 1; the 2nd joint has P_{2i} = 50 and D_{2i} = 0.8; and the 3rd joint has P_{3i} = 30 and D_{3i} = 1.

Each gain of a jump mechanism is set to P_{4i} = 10 and D_{4i} = 10. Note however that each leg is assumed to use the same gain. Furthermore, it is assumed that each gain is set by 100 times the above ones to generate a bigger power, when the

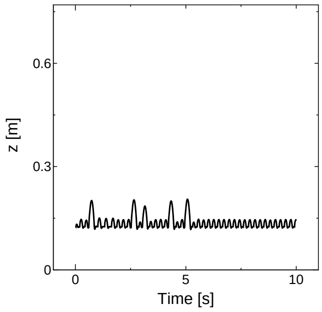

Fig. 6. Time history of the jump height for Case 1

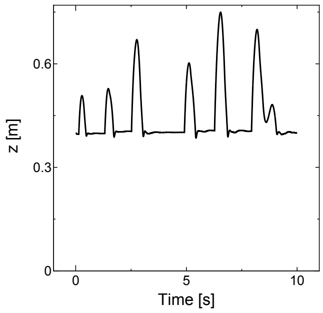

Fig. 7. Time history of the jump height for Case 2

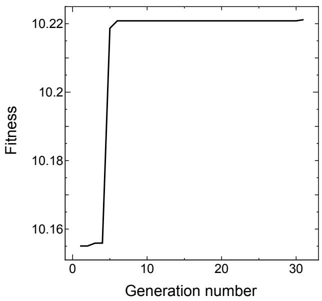

Fig. 8. Fitness history by generation for Case 1

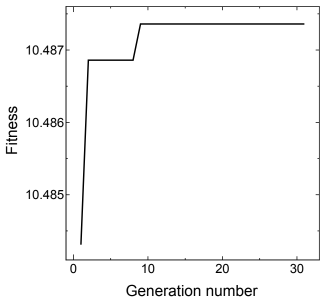

Fig. 9. Fitness history by generation for Case 2

robot jumps.

5.2 Simulation Result

By applying the CPG parameters decided by manual tuning in advance, the simulation results for cases 1 and 2 are shown in Fig. 6 and Fig. 7. These results prove that successive jumps have been realized using the outputs of CPG.

Furthermore, the simulation results of cases 1 and 2 optimized by GA are presented in Fig. 8 to Fig. 11. The best fitness values verses generations are shown in Fig. 8 and Fig. 9. It is found that the higher jump is gradually obtained as the GA search progresses.

Fig. 10 and Fig. 11 show the jump situations with the optimized parameters. Although the maximum jump height is not enough, compared to that tuned by any manual method, it seems that the robot can succeed a successive jump and there are less changes in jump.

6 CONCLUSION

In this paper, we have searched for the optimal CPG parameters to make a successive jump for a six-legged robot. In the simulation using the parameters optimized by GA, the six-legged robot was shown to realize a successive jump, whose amplitude change is less, compared to that tuned by any manual method. Thus, it is revealed a relationship between the initial jumping posture and the resultant jumping motion.

Abstract

Recently, many studies on educational system are being conducted. In this manuscript, a unique education system is proposed for mechanical engineers to be able to efficiently learn basic mechatronics techniques. The system is composed of three subsystems. The first system is used to learn input/output port operations, periodically LED lights ON/OFF and a stepping motor control. The second system is effective to learn AD transformation for several sensor information, DA transformation for DC motor control and a PID control method. Further, the third system is multiple mobile robots system to learn the subsumption architecture for schooling behavior. The effectiveness of the proposed systems was confirmed through experimental instructions in Tokyo University of Science, Yamaguchi.

1 Introduction

Recently, many studies on educational system are being conducted. In this manuscript, a unique educational system is proposed for mechanical engineers to be able to efficiently learn basic techniques of mechatronics. Here, C++ of Microsoft Visual Studio is recommended as a software development environment, because which is one of the professional technical skills required from industrial fields. The system is composed of three subsystems. The first subsystem is used for second year students to learn input/output port operations with hexadecimal number, periodically LED lights ON/OFF by using Windows Timer, e.g., with a sampling period of 10 ms , and stepping motor controls built in a position control module and a mobile robot with two wheels. The second system is also used for third year students to learn AD transformation for several sensor information, DA transformation for DC motor control and PID control method. Further, the third system is multiple mobile robot system for the graduation study of fourth year students to learn the subsumption architecture for swarm intelligence. The effectiveness of the proposed systems is evaluated through experimental instructions in Tokyo University of Science, Yamaguchi.

2 Mechatronics System I

Figure 1 shows the first mechatronics system consisting of an LED display board, a position control device and a mobile robot with two wheels. The system is used in the experimental lecture of "Experiments on Mechanical Engineering I" for the second year students. Figure 2 shows the block diagram of the LED display experiment. Sixteen LEDs are arrayed with two rows as shown in Fig. 3 and each row is related to output port B and C, respectively. In Fig. 3, hexadecimal number 0x55 and 0xAA are set to port B and port C, respectively. Lighting pattern can be designed by giving the hexadecimal number, also lighting period

can be changed by using Windows timer interrupt of 10 ms.

Figure 4 shows the position control device driven by a stepping motor. A photo interrupter is attached to the head to detect the position of the slit,i.e., black or transparent. The stepping motor is driven by pulse signals. One pulse signal rotates the stepping motor with 1.8 degrees, and this moves the head 6.25 μm. The pulse signal is generated by the lower four bits of output port B. Relation between binary number given to the port B and motion is as follows:

Figure 5 illustrates the mobile robot with two wheels and two photo reflectors. wheel 1 and 2 are driven by stepping motor 1 and 2, respectively. The stepping motor 1 and 2 are excited by the lower four bits of output port B and C, respectively. In. Fig. 5, v and ω are the translational velocity and the rotational velocity of the robot in robot coordinate system; $2L$ is the distance between the two wheels and R is the radius of each wheel. The robot can perform forward/backward motion or rotational motion. When forward/backward motion is applied, then the velocity of each wheel, v_1, v_2, are given by

$$v = v_1 = \omega_1 R = v_2 = -\omega_2 R \tag{1}$$

Also, when the rotational motion is conducted, the rotational velocity w is given by

$$\omega = \frac{\omega_1 R}{L} = \frac{\omega_2 R}{L} \tag{2}$$

where ω_1 and ω_2 are the rotational velocities of two wheels, respectively.

3 Mechatronics System II

Figure 6 shows the second mechatronics system consisting of three sensors for measuring temperature, dis-

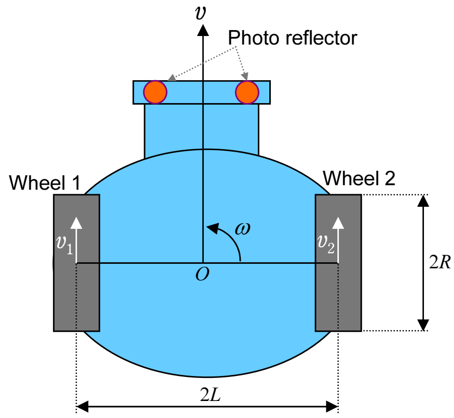

Figure 5: Top view of two-wheeled mobile robot with two photo reflectors.

tance and brightness, AD/DA transformation interfaces, an LCD display panel and a DC motor with a sensor of photo interrupter, which is provided by C-TASK Co., Ltd. The system is used in the experimental lecture of "Mechanical Engineering Experiment II" for the third year students.

Here, the basic software developed for velocity control of the DC motor is explained. A ladder type DA converter is connected to the output port 1, so that the voltage within the range from 0 to 3.3 V can be outputted with the resolution of 256 steps. The velocity control of the DC motor can be performed by changing the voltage. The velocity of the motor is controlled by a PI-action in the discrete time k given by

$$\tau(k+1) = \tau(k) + \Delta\tau(k) \tag{3}$$

$$\Delta\tau(k) = K_p\{v_d - v_s(k)\} + K_i \sum_{n=1}^{k} \{v_d - v_s(n)\} \quad (4)$$

where $\tau(k)$ is the output torque to the DC motor at the discrete time k; K_p and K_i are the P-gain and I-gain, respectively; v_d is the reference value of rotational velocity and $v_s(k)$ is the rotational velocity measured by using a photo interrupter shown in Fig. 7. A rotational wheel with a small hole is fixed to the DC motor. The pass of the hole can be counted by detecting the change of signal form the photo interrupter, i.e., from HIGH level to LOW level. The rotational velocity is defined as counted number of the hole per a constant time period.

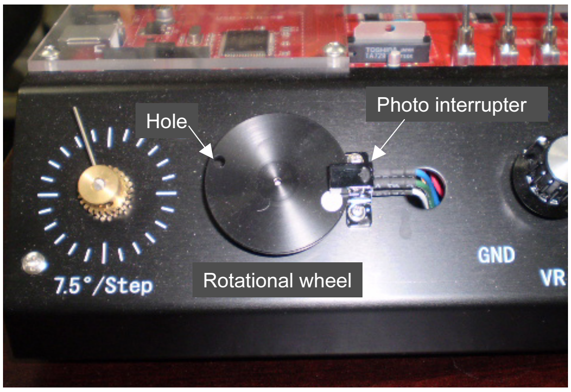

Figure 7: Rotational wheel fixed to a DC motor with a sensor of photo interrupter.

4 Basic Dialogues for Students' Experiment

In this section, basic dialogues developed for mechatronics experiments I and II are introduced. Students can effectively design a control program by using the dialogue and learn basic peripheral techniques concerning mechatronics.

4.1 Dialogue for Mechatronics Experiment I

Mechatronics Experiment I is considered for second year students in department of mechanical engineering, which is composed of three subjects, i.e., an LED lights ON/OFF experiment, a positioning experiment of a position control module and a line trace experiment of the two-wheeled mobile robot. As an example, Fig. 8 shows the windows dialogue designed for the line trace experiment using a mobile robot in mechatronics experiment I. At first, the students learn how to program important basic functions such as moving forward/backward, turning left/right and sensing two photo-reflectors through the dialogue developed by using Microsoft Visual C$^{\#}$. Then, students can make a program for a line trace by making use of the basic functions. Fifteen hours (five hours, three days) are allotted to Mechatronics Experiment I.

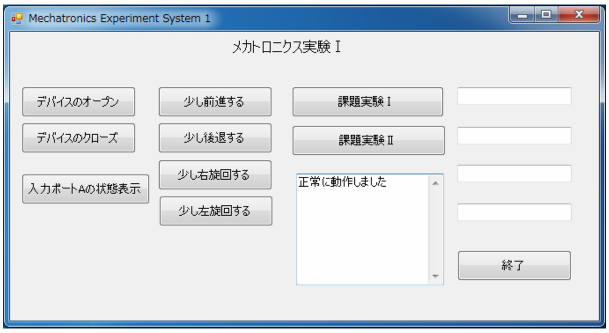

Figure 8: Windows dialogue designed for Mechatronics Experiment I.

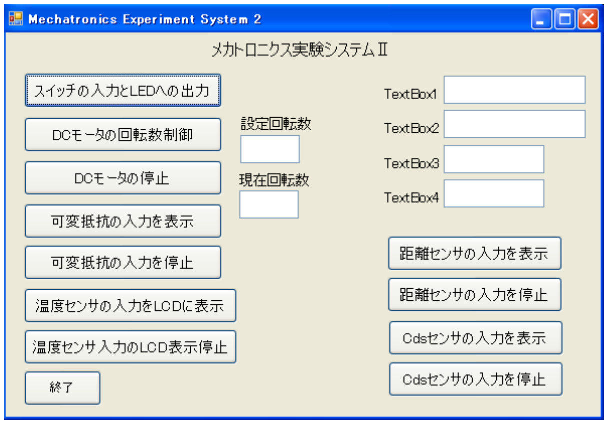

Figure 9: Windows dialogue designed for Mechatronics Experiment II.

4.2 Dialogue for Mechatronics Experiment II

Mechatronics Experiment II is considered for third year students, which is mainly composed of three subjects, i.e., AD transformation of several sensor signals such as distance, temperature and brightness, and DA transformation for velocity control of a DC motor. Students try to design a discrete-time PID controller for the velocity control of the DC motor. Figure 9 shows the windows dialogue designed for the Mechatronics Experiment II. Ten hours (five hours, two days) are allotted to Mechatronics Experiment II.

5 Multiple Mobile Robots System for Graduation Study

Students, who have gone through the experimental lectures Mechatronics I and II, can smoothly cope with the graduation study at fourth year. Finally, one of the student's graduation studies is introduced, in which multiple mobile robots with six sensuous sensors as shown in Fog. 10 are constructed for schooling behavior.

The third subsystem is designed with multiple mobile robots with three wheels and six PSD sensors [1], which is applied to the graduation study of fourth year students, e.g., to learn the subsumption architecture for schooling behavior. The subsumption architecture

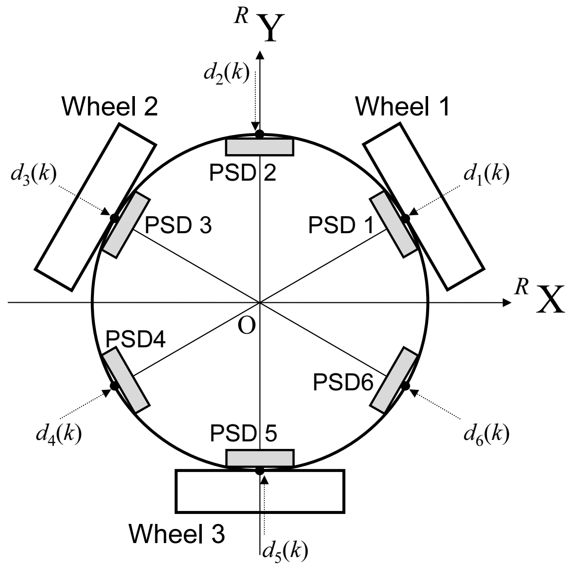

Figure 10: Positions of six PSD sensors fixed around a mobile robot.

is called Behavior-Based Artificial Intelligence, which was first proposed by Brooks [2]. Students can practically know the concept of subsumption architecture which provides a method for structuring reactive systems from lower level to higher level using layered sets of rules, i.e., reactive behaviors according to the change of environment.

Figure 11 shows an example of the controller based on the subsumtion atchitecture and Fig. 12 shows the experimental scene. If the schooling mode is set to all mobile robots, they try to regularly move along the inner of a circular fence keeping the distance to both the fence and other mobile robots. This mode allows the robots to behave like carps in a Japanese artificial circular pond. For example, when a robot moves counterclockwise along a circular fence, the following control law is basically applied by the task of "Move forward".

$$\dot{\boldsymbol{x}}_r = v\frac{\dot{\boldsymbol{x}}_{r2}}{\|\dot{\boldsymbol{x}}_{r2}\|} \tag{5}$$

where $\dot{\boldsymbol{x}}_r = [\dot{x}_r \ \dot{y}_r]^T$ is the translational velocity in robot coordinate system, $\dot{\boldsymbol{x}}_{r2} = [0 \ 1]^T$ is the normalized velocity for moving to PSD sensor 2. v is the scalar signifying the magnitude of the velocity. Also, the orientation is controlled by the task of "Turn to left or right" as

$$\dot{\phi}_r = K_\phi\{d_6(k) - d_1(k)\} \tag{6}$$

where $d_1(k)$ and $d_6(k)$ are the values measured by PSD sensors 1 and 6, respectively. K_ϕ is the gain which can control the orientation of the robot to be parallel to the inner of the circular fence. Further, the highest priority task "Avoid objects" actuates three wheels in order to avoid collisions to other robots.

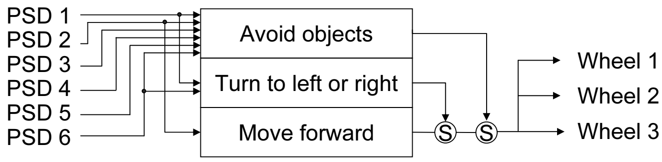

Figure 11: Controller designed based on subsumption architecture for schooling behavior.

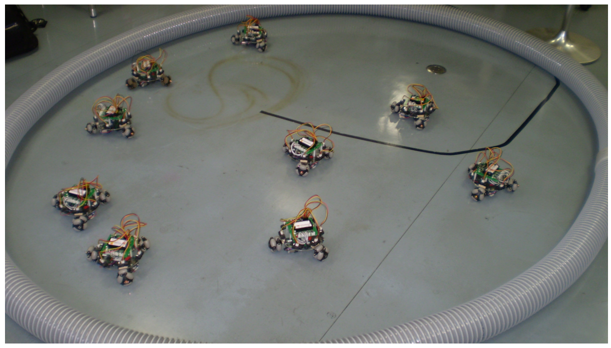

Figure 12: Experiment of schooling behavior based on subsumption architecture.

6 Conclusions

In this manuscript, a unique education system has been proposed for mechanical engineers to practically learn basic mechatronics techniques. The system is composed of three subsystems. The first system is used for second year students to mainly learn input/output port operations, periodically LED lights ON/OFF and a stepping motor control. The second system is effective for third year students to learn AD transformation for several sensor information, DA transformation for DC motor control and a design of a PID controller. Further, the third system is multiple mobile robots system as one of graduation studies so that the fourth year students can learn the subsumption architecture for schooling behavior. The effectiveness of the proposed mechatronics education system is evaluated through experimental instructions in Tokyo University of Science, Yamaguchi.

Abstract: In this paper, stabilization of a class of second-order nonholonomic systems for an underactuated X4-AUV is investigated. We present a model of the underactuated X4-AUV with six degrees-of-freedom (DOF) and four control inputs. Then the system is written in a control-affine form by applying a partial linearization technique and a dynamic controller based on Astolfi's discontinuous control is derived to stabilize all states of the system to the desired equilibrium point exponentially. A simulation is conducted to demostrate the effectiveness of the proposed controller.

Keywords: Discontinuous control, underactuated X4-AUV

I. INTRODUCTION

In the past few years, the problem of controlling nonholonomic systems has attracted much attention. These studies were primarily limited to first-order nonholonomic systems which undergo non-integrable kinematic constraints. However, there is still another type of nonholonomic systems called second-order nonholonomic systems, satisfying nonintegral relations involving not only generalized coordinates and velocities but also the generalized accelerations. Second-order and high-order nonholonomic systems arise in underactuated systems [1][2], where the numbers of available control inputs are less than the number of degrees of freedom. The lack of actuators introduces a set of nonholonomic constraints in the dynamic equations. These constraints are inherently at the acceleration level and generally not integral to velocity constraints, and hence are second-order nonholonomic. The studies of control issue of underactuated system with second-order nonholonomic constrains allow the design of fault-tolerant robots and the use of the energy resources more rationally while precisely controlling the system. Different from the first-order nonholonomic systems such as wheeled vehicles and free-floating space robot which have velocity constraints geometrically limiting the direction of mobility, second-order nonholonomic constraints, on the other hand, are the constraints that limit the generalized accelerations and cannot be integrated to first-order nonholonomic or holonomic constraints. These constraints make it difficult to directly apply the techniques so far developed for the first-order nonholonomic systems. It is known that certain mechanical systems can be converted to a second-order chained form, and more generally, a class of underactuated mechanical systems can be converted to a second-order chained form by constructing coordinate and input transformations. By converting the system to a second-order chained form, the dynamics are considerably simplified, and thus easy for controller design. The control problem of a second-order nonholonomic chained form has been studied by some researchers. Laiou and Astolfi [2] solved the stabilization problem for nonlinear systems in a generalized high-order chained form by means of discontinuous state feedback control law, yielding exponential converge of the states to the origin. Xu and Ma [3] converted a class of second-order nonholonomic systems to the second-order nonholonomic chained form, and proposed a discontinuous control law to stabilize states to the desired equilibrium point exponentially.

It has been proven that several classes of second-order nonholonomic systems are transformable into the following chained form by smooth state and input transformations

$$\begin{cases} \ddot{y}_1 &= u_1 \\ \ddot{y}_2 &= u_2 \\ \ddot{y}_3 &= y_2 u_1 \end{cases} \tag{1}$$

This paper is organized as follows: In section 2 the coordinate system of AUV is presented. The equations of motion of the system are presented in section 3. The discontinuous control law based on Astolfi's discontinuous control for an X4-AUV is constructed in section 4. The last section presents concluding remarks.

II. COORDINATE SYSTEMS OF AUV

Fig. 1 shows the coordinate systems of AUV, which consist of a right-hand inertial frame {E} in which the downward vertical direction is to be positive and a right-hand body frame {B}.

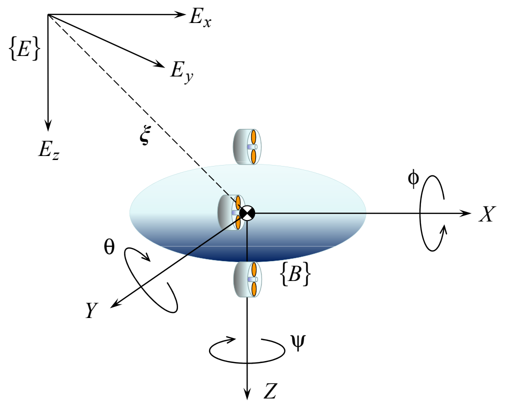

Fig. 1. Coordinate systems of AUV

Letting $\boldsymbol{\xi} = [x \quad y \quad z]$ denote the mass center of the body in the inertial frame, defining the rotational angles of X-, Y- and Z-axis as $\boldsymbol{\eta} = [\phi \quad \theta \quad \psi]^T$, the rotational matrix R from the body frame {B} to the inertial frame {E} can be reduced to:

$$R = \begin{bmatrix} c\theta c\psi & s\phi s\theta c\psi - c\phi s\psi & c\phi s\theta c\psi + s\phi s\psi \\ c\theta s\psi & s\phi s\theta s\psi + c\phi c\psi & c\phi s\theta s\psi - s\phi c\psi \\ -s\theta & s\phi c\theta & c\phi c\theta \end{bmatrix} \tag{2}$$

where $c\alpha$ denotes $\cos\,\alpha$ and $s\alpha$ is $\sin\,\alpha$.

III. DYNAMICAL MODEL

Defining $\boldsymbol{q} = [\boldsymbol{\xi}^T \quad \boldsymbol{\eta}^T]$, the dynamical model of an X4-AUV is described in the following matrix form [4]:

$$M(\mathbf{q})\ddot{\mathbf{q}} + V_m(\mathbf{q},\dot{\mathbf{q}})\dot{\mathbf{q}} + G(\mathbf{q}) = B(\mathbf{q})\boldsymbol{\tau} \tag{3}$$

where $M(\mathbf{q}) \in \Re^{6\times6}$ is the symmetric, positive definite inertia matrix, $V_m(\mathbf{q},\dot{\mathbf{q}}) \in \Re^{6\times6}$ is the centrifugal and Coriolis matrix, $G(\mathbf{q}) \in \Re^{6}$ is the gravitational vector, $B(\mathbf{q}) \in \Re^{6\times4}$ is the input transformation matrix, and $\boldsymbol{\tau} \in \Re^{4}$ is a generalized force vector consisting of force or torque components.

Note also that each matrix in the dynamical model can be reduced to

$$M(\mathbf{q}) = \begin{bmatrix} m_1 & 0 & 0 & 0 & 0 & 0 \\ 0 & m_2 & 0 & 0 & 0 & 0 \\ 0 & 0 & m_3 & 0 & 0 & 0 \\ 0 & 0 & 0 & I_x & 0 & 0 \\ 0 & 0 & 0 & 0 & I_y & 0 \\ 0 & 0 & 0 & 0 & 0 & I_z \end{bmatrix}$$

$$V_m(\mathbf{q},\dot{\mathbf{q}}) = \begin{bmatrix} 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & I_z\dot{\psi} & -I_y\dot{\theta} \\ 0 & 0 & 0 & -I_z\dot{\psi} & 0 & J_t\Omega + I_x\dot{\phi} \\ 0 & 0 & 0 & I_y\dot{\theta} & -J_t\Omega - I_x\dot{\phi} & 0 \end{bmatrix}$$

$$B(\mathbf{q}) = \begin{bmatrix} c\theta c\psi & 0 & 0 & 0 \\ c\theta s\psi & 0 & 0 & 0 \\ -s\theta & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & l & 0 \\ 0 & 0 & 0 & l \end{bmatrix}$$

$$\mathrm{diag}(m_1, m_2, m_3) = m_b I + M_f$$
$$\mathrm{diag}(I_x, I_y, I_z) = J_b + J_f$$

Here, I denotes the unit matrix, M_f is an added mass matrix, and J_f is an added moment of inertia matrix. Assuming that the fluid density is ρ and the present AUV form is ellipsoid, it is found that suitable M_f and J_f are obtained [5]. Furthermore assume that the X4-AUV is in the state of neutral buoyancy to neglect the potential energy, so that $G(\mathbf{q}) = 0$.

From the rotational matrix (2), the kinematic equation for X4-AUV

$$\dot{\mathbf{q}} = S(\mathbf{q})v \tag{4}$$

can be reduce to

$$\begin{bmatrix} \dot{x} \\ \dot{y} \\ \dot{z} \\ \dot{\phi} \\ \dot{\theta} \\ \dot{\psi} \end{bmatrix} = \begin{bmatrix} c\theta c\psi & 0 & 0 & 0 \\ c\theta s\psi & 0 & 0 & 0 \\ -s\theta & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix} \begin{bmatrix} \dot{x}_b \\ \dot{\phi} \\ \dot{\theta} \\ \dot{\psi} \end{bmatrix} \tag{5}$$

because the lateral type X4-AUV has only the total thrust in the X-direction, where v= $[\dot{x}_b \ \dot{\phi} \ \dot{\theta} \ \dot{\psi}]^T$, where $\dot{x}_b$ denotes the X-directional translational velocity and $[\dot{\phi} \ \dot{\theta} \ \dot{\psi}]^T$ is the rotational angular velocity vector in the body frame.

Applying a partial linearizing technique, it gives

$$\begin{aligned} \ddot{x} &= v_1 \\ \ddot{\phi} &= v_2 \\ \ddot{\theta} &= v_3 \\ \ddot{\psi} &= v_4 \\ \ddot{y} &= (m_1/m_2)\tan\psi v_1 \\ \ddot{z} &= (-m_1/m_3)\tan\theta\sec\psi v_1 \end{aligned} \tag{6}$$

where

$$\begin{aligned} v_1 &= \cos\theta\cos\psi\tau_1/m_1 \\ v_2 &= [\tau_2 - I_z\dot{\psi}\dot{\theta} + I_y\dot{\theta}\dot{\psi}]/I_x \\ v_3 &= [l\tau_3 + I_z\dot{\psi}\dot{\phi} - (J_t\Omega + I_x\dot{\phi})\dot{\psi}]/I_y \\ v_4 &= [l\tau_4 - I_y\dot{\theta}\dot{\phi} + (J_t\Omega + I_x\dot{\phi})\dot{\theta}]/I_z \end{aligned}$$

In the matrix form, Eq. (6) is described by

$$\begin{bmatrix} \ddot{x} \\ \ddot{y} \\ \ddot{z} \\ \ddot{\phi} \\ \ddot{\theta} \\ \ddot{\psi} \end{bmatrix} = \begin{bmatrix} 1 & 0 & 0 & 0 \\ \frac{m_1}{m_2}\tan\psi & 0 & 0 & 0 \\ -\frac{m_1}{m_3}\frac{\tan\theta}{\cos\psi} & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix} \begin{bmatrix} v_1 \\ v_2 \\ v_3 \\ v_4 \end{bmatrix} \tag{7}$$

and

$$\begin{bmatrix} \tau_1 \\ \tau_2 \\ \tau_3 \\ \tau_4 \end{bmatrix} = \begin{bmatrix} \frac{m_1}{\cos\theta\cos\psi} & 0 & 0 & 0 \\ 0 & I_x & 0 & 0 \\ 0 & 0 & \frac{I_y}{l} & 0 \\ 0 & 0 & 0 & \frac{I_z}{l} \end{bmatrix} \begin{bmatrix} v_1 \\ v_2 \\ v_3 \\ v_4 \end{bmatrix}$$

$$+ \begin{bmatrix} 0 \\ -\dot{\theta}\dot{\psi}(I_y - I_z) \\ -\dot{\phi}\dot{\psi}\frac{I_z - I_x}{l} + J_t\dot{\psi}\Omega \\ -\dot{\phi}\dot{\theta}\frac{I_x - I_y}{l} - J_t\dot{\theta}\Omega \end{bmatrix} \tag{8}$$

IV. DISCONTINUOUS CONTROL

To facilitate the derivation of the stabilizing control law for the second-order form Eq. (6), the following proposition and lemma are needed[3].

Proposition 1. *For the nonlinear system*

$$\dot{x}_1 = x_2, \quad \dot{x}_2 = -s_1 s_2 x_1 - (s_1 + s_2)x_2,$$

if $s_2 > s_1 > 0$, *and the initial states* $(x_1(0), x_2(0))$ *satisfy* $x_1(0)(s_2 x_1(0) + x_2(0)) > 0$, *then*

$$x_1(t) \neq 0 \quad (\forall t \in (0, \infty)),$$

$$\lim_{t\to\infty} (\frac{x_2(t)}{x_1(t)} + s_1) = 0, \tag{9}$$

$$\int_0^\infty \left| \frac{x_2(t)}{x_1(t)} + s_1 \right| dt < \infty.$$

Lemma 1. *For the linear time-varying system*

$$\dot{x} = (A_1 + A_2(t))x, \tag{10}$$

where A_1 *is a constant Hurwitz matrix, and* $A_2(t)$ *a time-varying matrix. If* $A_2(t)$ *satisfies*

$$\lim_{t\to\infty} A_2(t) = 0, \quad \int_0^\infty \|A_2(t)\| \, dt < \infty, \tag{11}$$

then $\dot{x} = (A_1 + A_2(t))$ *is exponentially stable.*

In what follows, a discontinuous control law will be derived to stabilize the system to the origin exponentially based on the discontinuous coordinate transformation. Let $y_1 = x$, $y_2 = \dot{x}$, $y_3 = \phi$, $y_4 = \dot{\phi}$, $y_5 = \theta$, $y_6 = \dot{\theta}$, $y_7 = \psi$, $y_8 = \dot{\psi}$, $y_9 = y$, $y_{10} = \dot{y}$, $y_{11} = z$, and $y_{12} = \dot{z}$, the second-order form in Eq. (6) can be written as

$$\begin{aligned} \dot{y_1} &= y_2 \\ \dot{y_2} &= v_1 \\ \dot{y_3} &= y_4 \\ \dot{y_4} &= v_2 \\ \dot{y_5} &= y_6 \\ \dot{y_6} &= v_3 \\ \dot{y_7} &= y_8 \\ \dot{y_8} &= v_4 \\ \dot{y_9} &= y_{10} \\ \dot{y_{10}} &= (m_1/m_2)\tan y_7 v_1 \\ \dot{y_{11}} &= y_{12} \\ \dot{y_{12}} &= (-m_1/m_3)\tan y_5 \sec y_7 v_1 \end{aligned} \tag{12}$$

Designing control input

$$v_1 = -(k_1 + k_2)y_2 - k_1 k_2 y_1 \tag{13}$$

where $k_2 > k_1 > 0$ are constants, then $y_1 \neq 0$ $(\forall t \in (0, \infty))$ is guaranteed by Proposition 2 given in [3], and so the coordinate transformation

$$\begin{aligned} z_i &= y_i \quad (i = 1, \cdots, 8), \\ z_j &= \frac{y_j}{y_1} \quad (j = 9, \cdots, 12) \end{aligned} \tag{14}$$

is well defined. In the new coordinates z_i $(i = 1, \cdots, 12)$, Eq. (12) becomes

$$\begin{aligned} \dot{z_1} &= z_2 \\ \dot{z_2} &= -(k_1 + k_2)z_2 - k_1 k_2 z_1 \\ \dot{z_3} &= z_4 \\ \dot{z_4} &= v_2 \\ \dot{z_5} &= z_6 \\ \dot{z_6} &= v_3 \\ \dot{z_7} &= z_8 \\ \dot{z_8} &= v_4 \\ \dot{z_9} &= z_{10} + k_1 z_9 - (\frac{z_2}{z_1} + k_1)z_9 \\ \dot{z_{10}} &= (m_1/m_2){k_1}^2 z_7 + k_1 z_{10} \\ &\quad - (\frac{z_2}{z_1} + k_1)[\frac{m_1}{m_2}(k_1 + k_2)z_7 + z_{10}] \\ \dot{z_{11}} &= z_{12} + k_1 z_{11} - (\frac{z_2}{z_1} + k_1)z_{11} \\ \dot{z_{12}} &= -(m_1/m_3){k_1}^2 z_5 + k_1 z_{12} \\ &\quad + (\frac{z_2}{z_1} + k_1)[\frac{m_1}{m_3}(k_1 + k_2)z_5 - z_{12}] \end{aligned} \tag{15}$$

if $y_5 \simeq 0$ and $y_7 \simeq 0$.

The above Eq. (15) can be reorganized compactly as

$$\begin{aligned} \dot{z_1} &= z_2 \\ \dot{z_2} &= -(k_1 + k_2)z_2 - k_1 k_2 z_1 \\ \dot{Z}_{3-12} &= (A_1 + A_2(t))Z_{3-12} + B\mathbf{v} \end{aligned} \tag{16}$$

where $Z_{3-12} = [z_3 \quad z_4 \quad \cdots \quad z_{12}]^T$, $\mathbf{v} = [v_2 \quad v_3 \quad v_4]^T$ and

$$A_1 = \begin{bmatrix} 0 & 1 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 1 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 1 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & k_1 & 1 & 0 & 0 \\ 0 & 0 & 0 & 0 & \frac{m_1}{m_2}k_1^2 & 0 & 0 & k_1 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & k_1 & 1 \\ 0 & 0 & -\frac{m_1}{m_3}k_1^2 & 0 & 0 & 0 & 0 & 0 & 0 & 1 \end{bmatrix},$$

$$A_2(t) = (\frac{z_2}{z_1} + k_1) \begin{bmatrix} 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & -1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & a & 0 & 0 & -1 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & -1 & 0 \\ 0 & 0 & b & 0 & 0 & 0 & 0 & 0 & 0 & -1 \end{bmatrix}$$

where $a = -\frac{m_1}{m_2}(k_1 + k_2)$ and $b = \frac{m_1}{m_3}(k_1 + k_2)$.

$$B = \begin{bmatrix} 0 & 0 & 0 \\ 1 & 0 & 0 \\ 0 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & 1 \\ 0 & 0 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & 0 \end{bmatrix}$$

By Proposition 2 given in [3], we know

$$\lim_{t\to\infty}(\frac{z_2}{z_1} + k_1) = 0, \qquad \int_0^\infty \left|\frac{z_2}{z_1} + k_1\right| dt < \infty.$$

It follows that

$$\lim_{t\to\infty} A_2(t) = 0, \qquad \int_0^\infty \|A_2(t)\|\, dt < \infty.$$

Now let us check the controllability of $[A_1, B]$. Its controllability matrix can be calculated as $[B, A_1B, A_1^2B, A_1^3B, A_1^4B, A_1^5B, A_1^6B, A_1^7B, A_1^8B, A_1^9B]$, which is nonsingular because $k_1 > 0$. Therefore, $[A_1, B]$ is controllable and we can choose feedback gain matrix L as

$$L = \begin{bmatrix} l_1 & l_2 & l_3 & l_4 & l_5 & l_6 & l_7 & l_8 & l_9 & l_{10} \\ l_{11} & l_{12} & l_{13} & l_{14} & l_{15} & l_{16} & l_{17} & l_{18} & l_{19} & l_{20} \\ l_{21} & l_{22} & l_{23} & l_{24} & l_{25} & l_{26} & l_{27} & l_{28} & l_{29} & l_{30} \end{bmatrix},$$

so that the matrix $A_1 + BL$ is a Hurwitz matrix, i.e., control input

$$\mathbf{v} = LZ_{3-12}$$

can exponentially stabilize the linear system

$$\dot{Z}_{3-12} = A_1 Z_{3-12} + B\mathbf{v}$$

From Lemma 1, we can conclude that system

$$\dot{Z}_{3-12} = (A_1 + BL + A_2(t))Z_{3-12}$$

is exponentially stable, i.e., system

$$\dot{Z}_{3-12} = (A_1 + A_2(t))Z_{3-12} + B\mathbf{v}$$

can be exponentially stabilized to the origin by feedback control

$$\mathbf{v} = LZ_{3-12}$$

Since states z_1, z_2 are exponentially convergent to zeros, the whole states z_i (i=1, 2, $\cdots$, 12) converge to zeros exponentially. From $y_i = z_i$ (i = 1, $\cdots$, 8); $y_j = z_j z_1$ (j = 9, $\cdots$, 12), we can conclude that y_i (i = 1, 2, $\cdots$, 12) converge to zeros exponentially, and so do $(y, \dot{y})$. The above results are summarized in the following theorem.

Theorem 1. *If the initial states $(y_1(0), y_2(0))$ satisfy $y_1(0)(k_2 y_1(0) + y_2(0)) > 0$, $y_5 = y_7 \simeq 0$ and L is chosen such that $A_1 + BL$ is a Hurwitz matrix, then the second-order form in (6) can be exponentially stabilized to the origin by the following control law*:

$$\begin{aligned} v_1 &= -(k_1 + k_2)y_2 - k_1 k_2 y_1 \\ v_2 &= l_1 y_3 + l_2 y_4 + l_3 y_5 + l_4 y_6 + l_5 y_7 \\ &\quad + l_6 y_8 + l_7 \frac{y_9}{y_1} + l_8 \frac{y_{10}}{y_1} + l_9 \frac{y_{11}}{y_1} + l_{10} \frac{y_{12}}{y_1} \qquad (17) \\ v_3 &= l_{11} y_3 + l_{12} y_4 + l_{13} y_5 + l_{14} y_6 + l_{15} y_7 \\ &\quad + l_{16} y_8 + l_{17} \frac{y_9}{y_1} + l_{18} \frac{y_{10}}{y_1} + l_{19} \frac{y_{11}}{y_1} + l_{20} \frac{y_{12}}{y_1} \\ v_4 &= l_{21} y_3 + l_{22} y_4 + l_{23} y_5 + l_{24} y_6 + l_{25} y_7 \\ &\quad + l_{26} y_8 + l_{27} \frac{y_9}{y_1} + l_{28} \frac{y_{10}}{y_1} + l_{29} \frac{y_{11}}{y_1} + l_{30} \frac{y_{12}}{y_1} \end{aligned}$$

where $k_2 > k_1 > 0$ are two constants.

V. CONCLUSION

In this paper, we have converted the model of second-order nonholonomic systems of an underactuated X4-AUV to a certain second-order form by applying a partial linearization technique. A discontinuous time-invariant state feedback control law was derived to stabilize such a second-order form. It has been proved that the proposed control law was able to stabilize the second-order form exponentially, when the initial state is in or has been driven into certain regions of state space, and pitch and yaw angles are very small.

Abstract: Visual servoing methods for hand-eye configuration are vulnerable for hand's dynamical oscillation, since nonlinear dynamical effects of whole manipulator stand against the stable tracking ability (trackability). Our proposal to solve this problem is that the controller for visual servoing of the hand and the one for eye-vergence should be separated independently based on decoupling each other, where the trackablity is verified by Lyapunov analysis. Then the effectiveness of the decoupled hand & eye-vergence visual servoing method is evaluated through simulations incorporated with actual dynamics of 7-DoF robot with additional 3-DoF for eye-vergence mechanism by amplitude and phase frequency analysis.

Keywords: Visual servoing, Eye-vergence, trackability

1 INTRODUCTION

Recently much research attention has turned to focus on full DoF pose control of the robot end-effector toward a target object [1]. Full 3D Visual servoing requires simultaneously full 3D pose measurement and 3D motion control also. But researches so far seem to have tended to deal with these two problems separately as isolated issues. Different kinds of visual servoing – position-based, image-based or $2\frac{1}{2}$-D visual servoing [2] – usually discuss their methodologies based on an assumption that pose measurement is known or could be easily received from some other devices.

Eye-vergence function bears two fundamental fruits as kinematical merit and dynamical one. Firstly kinematical merit is described. Observing ability of a fixed-hand-eye configuration may be deteriorated by relative geometry of the camera and the target, as the robot cannot observe the object well when it is near the cameras (Fig. 1 (a)), small intersection of the possible sight space of the two cameras (Fig. 1 (b)), and the image of the object cannot appear in the center of both cameras, so we could not get clear image information of target reflected at its periphery, reducing the pose measurement accuracy (Fig. 1 (c)). To solve these problems, eye-vergence functions to rotate eye cameras orientation to see target object at center of the cameras' view, as shown in Fig. 2(a)-(c), enhancing the measurement accuracy in trigonometric calculation and avoiding aberration, i.e. peripheral distortion of camera lens. Moreover, recent researches on visual servoing are limited generally in a swath of tracking an object while keeping a certain constant distance, which are the researches based on different task scenarios from the approaching visual servoing discussed here.

The second merit is concerning dynamical effects to keep tracking a moving target in the camera's view. Needless to say in visual servoing application, keeping closed loop of visual feedback is vital from a view point of stability in control

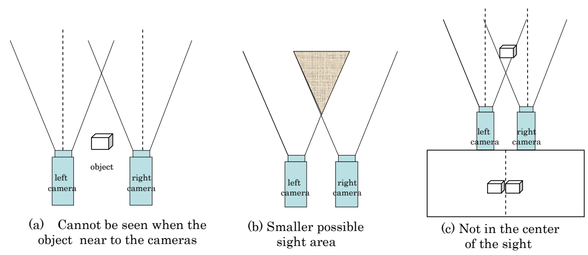

Fig. 1. Disadvantage of fix camera system

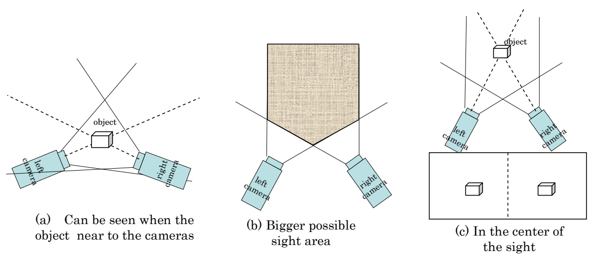

Fig. 2. Advantage of Eye-vergence system

theory. Cameras fixed at the hand of manipulator are keeping staring at the object at first, but when the target moves so fast that the manipulator cannot catch up the speed of the target because of whole manipulator's dynamics, resulting in the visual feedback cut , loosing feedback. To improve this pose tracking difficulty of fixed hand eye system, the eye-vergence function seems dynamically effective, because of small mass and inertia moment of the eye ball comparing those of full manipulator's structure. Therefore tracking ability of eye-vergence can be better than fixed, like animals tracks target with eye motion before rotate their heads to the target.

In this report, we propose a new control method of hand and eye-vergence dual visual servoing system with a stability analysis of Lyapunov method, guaranteeing that both the tracking pose errors of hand and eye-vergence orientation error converge to zero, providing target object stopping in work space. Further to evaluate the trackability through frequency response experiment we need a new measure to rate the eye's

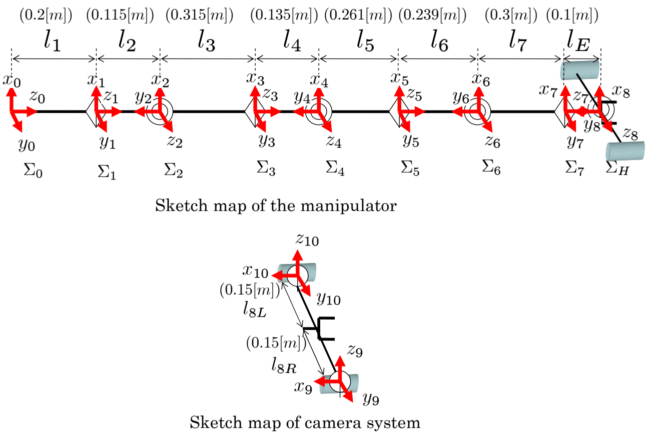

Fig. 3. Frame structure of manipulator

trackability to the target object oscillating with designated amplitude and angular velocity. We also come up with a yardstick to measure the eye's trackability.

2 SIMULATOR AND ROBOT DYNAMICS

The dynamics equation of the system is

$$\boldsymbol{M}(\boldsymbol{q})\ddot{\boldsymbol{q}} + \boldsymbol{h}(\boldsymbol{q}, \dot{\boldsymbol{q}}) + \boldsymbol{g}(\boldsymbol{q}) = \boldsymbol{\tau} \tag{1}$$

here $\boldsymbol{q}$ is a vector express the angle of each joint where $\boldsymbol{q}$ can be divided into $\boldsymbol{q} = [\boldsymbol{q}_E^T, \boldsymbol{q}_C^T]^T$, $\boldsymbol{\tau} = [\tau_1, \cdots, \tau_n]^T$ is the input torque, and $\boldsymbol{M}(\boldsymbol{q})$ is the inertia matrix, $\boldsymbol{h}(\boldsymbol{q}, \dot{\boldsymbol{q}})$is the vector representing the centrifugal and coriolis forces, $\boldsymbol{g}(\boldsymbol{q})$ is the vector representing the gravity load.

Our simulator is model PA-10 by using the actual physical parameters of the PA-10. Here, we install two cameras conclude 3 free degrees on the end-effector of PA-10.The structure of the system is shown in Fig. 3. The Homogeneous Transformation from coordinate static to the end-effector Σ_8 to the end-effector coordinate Σ_E is expressed by a constant matrix ${}^8\boldsymbol{T}_E$. In this paper we use $\boldsymbol{T}$ to express Homogeneous Transformation matrix. Σ_9 and Σ_{10} express the coordinate of the right and left camera separately, they will be written as Σ_R and Σ_L. While the two cameras are both installed on the end-effector, both the cameras share a same tilt angle, but each of them has an own pan angle, angular velocity $\boldsymbol{\omega}_i$, angular acceleration $\dot{\boldsymbol{\omega}}_i$, link acceleration $\ddot{\boldsymbol{p}}_i$ and the acceleration of the center of gravity $\ddot{\boldsymbol{s}}_i$ can be calculated by the method written in [3].

3 HAND & EYE VISUAL SERVOING

3.1 Desired-trajectory Generation

As shown in Fig. 4, the world coordinate frame is denoted by Σ_W, the target coordinate frame is denoted by Σ_M, and the desired and actual end-effector coordinate frame is denoted by Σ_{Ed}, Σ_E respectively. The desired relative relation between the target and the end-effector is given by Homogeneous Transformation as ${}^{Ed}\boldsymbol{T}_M$, the relation between the

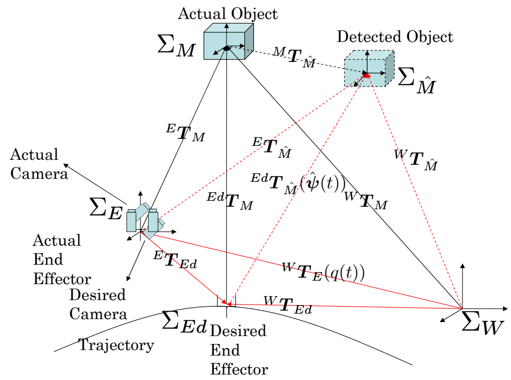

Fig. 4. Motion of the end-effector and object

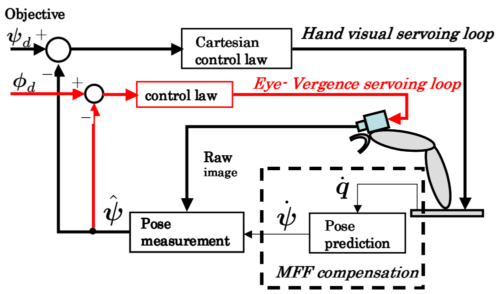

Fig. 5. Hand & Eye Visual servo system

target and the actual end-effector is given by ${}^E\boldsymbol{T}_M$, then the difference between the desired end-effector pose Σ_{Ed} and the actual end-effector pose Σ_E is denoted as ${}^E\boldsymbol{T}_{Ed}$, and calculated by:

$${}^E\boldsymbol{T}_{Ed}(t) = {}^E\boldsymbol{T}_M(t)\,{}^{Ed}\boldsymbol{T}_M^{-1}(t) \tag{2}$$

(2) is a general deduction that satisfies arbitrary object motion ${}^W\boldsymbol{T}_M(t)$ and arbitrary visual servoing objective ${}^{Ed}\boldsymbol{T}_M(t)$. However, the relation ${}^E\boldsymbol{T}_M(t)$ is only observed by cameras using the on-line model-based recognition method and 1-step GA [4]. Let $\Sigma_{\hat{M}}$ denote the detected object, there always exist an error between the actual object Σ_M and the detected one $\Sigma_{\hat{M}}$. However, in visual servoing we use different methods to decrease this error. for example, we can limit the error inside 5[mm] in [4]. So in visual servoing, (2) will be rewritten based on $\Sigma_{\hat{M}}$ that includes the error ${}^M\boldsymbol{T}_{\hat{M}}$, as

$${}^E\boldsymbol{T}_{Ed}(t) = {}^E\boldsymbol{T}_{\hat{M}}(t)\,{}^{Ed}\boldsymbol{T}_{\hat{M}}^{-1}(t), \tag{3}$$

where ${}^E\boldsymbol{T}_{\hat{M}} = {}^E\boldsymbol{T}_M$ determined by the given visual servoing objective. Differentiating Eq. (3) with respect by time twice,

$$\begin{aligned}{}^E\ddot{\boldsymbol{T}}_{Ed}(t) = {}^E\ddot{\boldsymbol{T}}_{\hat{M}}(t)\,{}^{\hat{M}}\boldsymbol{T}_{Ed}(t) + 2\,{}^E\dot{\boldsymbol{T}}_{\hat{M}}(t)\,{}^{\hat{M}}\dot{\boldsymbol{T}}_{Ed}(t) + \\ {}^E\boldsymbol{T}_{\hat{M}}(t)\,{}^{\hat{M}}\ddot{\boldsymbol{T}}_{Ed}(t),\end{aligned} \tag{4}$$

where ${}^{\hat{M}}\boldsymbol{T}_{Ed}$, ${}^{\hat{M}}\dot{\boldsymbol{T}}_{Ed}$, ${}^{\hat{M}}\ddot{\boldsymbol{T}}_{Ed}$ are given as the desired visual servoing objective. ${}^E\boldsymbol{T}_{\hat{M}}$, ${}^E\dot{\boldsymbol{T}}_{\hat{M}}$, ${}^E\ddot{\boldsymbol{T}}_{\hat{M}}$ can be observed by cameras. From these preparations, we can calculate the variables in the controllers of the system in the next subsection, such as $\Delta \boldsymbol{p}_E$ and so on, leaving detail explanation for next subsection. As shown in Fig. 4, there are two errors that we should decrease to the value as small as possible in the visual servoing process. First one is the error between the actual object and the detected one, ${}^M\boldsymbol{T}_{\hat{M}}$, and the other is the error between the desired end-effector and the actual one, ${}^E\boldsymbol{T}_{Ed}$. In our research, the error of ${}^M\boldsymbol{T}_{\hat{M}}$ is decreased by on-line recognition method of 1-step GA, MFF compensation method and the eye-vergence camera system, and the error of ${}^E\boldsymbol{T}_{Ed}$ can be decreased by the hand visual servoing controller.

3.2 Hand Desired Acceleration

The block diagram of our proposed hand & eye-vergence visual servoing controller is shown in Fig. 5. The hand-visual servoing is the outer loop. The controller used for hand-visual servoing is proposed by B.Siciliano [5]. First we will introduce the variables defined in the system:

$$\Delta \boldsymbol{p}_E = \boldsymbol{p}_d - \boldsymbol{p}_E \tag{5}$$

here d and E in the bottom right corner of the $\boldsymbol{p}$ means the desired position and actual position of the end-effector. There is no letter in the top left corner, it means the vector or the matrix is expressed in the world frame.

A special type of angle/axis representation of the orientation error is obtained with the quaternion, i.e

$$\begin{aligned} {}^E\eta &= cos\frac{\theta_{Ed}}{2} & (6)\\ \Delta {}^E\boldsymbol{\epsilon} &= sin\frac{\theta_{Ed}}{2}\ {}^E\boldsymbol{k}_{Ed} & (7)\end{aligned}$$

Here θ and $\boldsymbol{k}$ are the rotation angle and the rotation axis of the object. The letter in the top left corner express the coordinate where the vector or the rotation matrix is expressed in. While the angle velocity error between the desired and the actual angle velocity is defined as

$$\Delta \boldsymbol{\omega}_E = \boldsymbol{\omega}_d - \boldsymbol{\omega}_E \tag{8}$$

With the variables defined above, we just show main equations of the hand visual servoing controller that are used to calculate input torque $\boldsymbol{\tau}$.

$$\boldsymbol{a}_{pE} = \ddot{\boldsymbol{p}}_d + \boldsymbol{K}_{D_p}\Delta\dot{\boldsymbol{p}}_E + \boldsymbol{K}_{P_p}\Delta \boldsymbol{p}_E \tag{9}$$

$$\boldsymbol{a}_{oE} = \dot{\boldsymbol{\omega}}_d + \boldsymbol{K}_{D_o}\Delta\boldsymbol{\omega}_E + \boldsymbol{K}_{P_o}\boldsymbol{R}_E{}^E\Delta\boldsymbol{\epsilon} \tag{10}$$

$$\boldsymbol{s}_E = \boldsymbol{J}_E^+(\boldsymbol{q}_E)\{\boldsymbol{a}_E - \dot{\boldsymbol{J}}_E(\boldsymbol{q}_E, \dot{\boldsymbol{q}}_E)\dot{\boldsymbol{q}}_E)\} + \{\boldsymbol{I} - \boldsymbol{J}_E^+(\boldsymbol{q}_E)\boldsymbol{J}_E(\boldsymbol{q}_E)\}\{\boldsymbol{E}_p(\boldsymbol{q}_{Ed} - \boldsymbol{q}_E) + \boldsymbol{E}_d(\dot{\boldsymbol{q}}_{Ed} - \dot{\boldsymbol{q}}_E)\} \tag{11}$$

Here, $\ddot{\boldsymbol{q}}_E$ is a 7×1 vector representing the angular accelerations of the 7 links of the PA-10 manipulator. $\boldsymbol{a}$ can be written short for $[\boldsymbol{a}_p^T, \boldsymbol{a}_o^T]^T$. The quaternion error from the actual orientation to the desired orientation of the end effector ${}^E\Delta\boldsymbol{\epsilon}$ can be extracted from the transformation ${}^E\boldsymbol{T}_{Ed}$, and the other error variables in (9), (10) are described in Σ_W, which can be calculated by the transformation ${}^E\boldsymbol{T}_{Ed}$, ${}^E\dot{\boldsymbol{T}}_{Ed}$, ${}^E\ddot{\boldsymbol{T}}_{Ed}$ in (3), (4), using the rotational matrix ${}^W\boldsymbol{R}_E(\boldsymbol{q})$ through coordinate transformation.

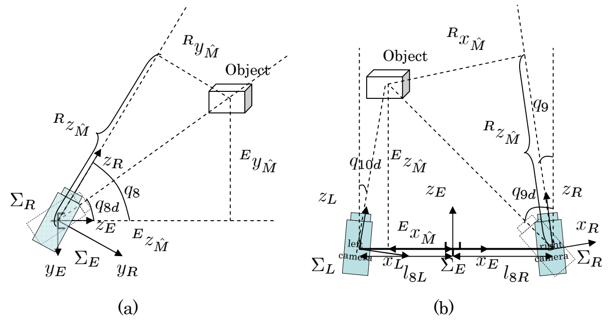

Fig. 6. Pan and Tilt Camera Angles Defined Based on Relation between Target object and Cameras

And $\boldsymbol{J}_E(\boldsymbol{q}_E)$ is the Jacobian matrix from the world coordinate to the end effector, which means that $\boldsymbol{\omega}_E = \boldsymbol{J}_E(\boldsymbol{q}_E)\dot{\boldsymbol{q}}_E$, and $\boldsymbol{J}_E^+(\boldsymbol{q}_E)$ in (11) is the pseudo-inverse of $\boldsymbol{J}_E(\boldsymbol{q}_E)$ given by $\boldsymbol{J}_E^+(\boldsymbol{q}_E) = \boldsymbol{J}_E^T(\boldsymbol{J}_E\boldsymbol{J}_E^T)^{-1}$. $\boldsymbol{K}_{D_p}$, $\boldsymbol{K}_{P_p}$, $\boldsymbol{K}_{D_o}$, $\boldsymbol{K}_{P_o}$ are positive control gains.

3.3 Eye-vergence Desired Acceleration

The eye-vergence visual servoing is the inner loop of the visual servoing system shown in Fig. 5. In this paper, we use two pan-tilt cameras for eye-vergence visual servoing. Here, the positions of cameras are supposed to be fixed on the end-effector. For camera system, q_8 is tilt angle, q_9 and q_{10} are pan angles, and q_8 is common for both cameras. As it is shown in Fig. 6, ${}^Ex_{\hat{M}}$, ${}^Ey_{\hat{M}}$, ${}^Ez_{\hat{M}}$ express position of the detected object in the end-effector coordinate. The desired angle of the camera joints $\boldsymbol{q}_{cd}^T = [q_{8d}, q_{9d}, q_{10d}]^T$ can be calculated by:

$$\begin{aligned} q_{8d} &= atan2({}^Ey_{\hat{M}}, {}^Ez_{\hat{M}}) & (12)\\ q_{9d} &= atan2(-l_{8R} + {}^Ex_{\hat{M}}, {}^Ez_{\hat{M}}) & (13)\\ q_{10d} &= atan2(l_{8L} + {}^Ex_{\hat{M}}, {}^Ez_{\hat{M}}), & (14)\end{aligned}$$

where $l_{8L} = l_{8R} = 150[mm]$ is the camera location. We set the center line of a camera as the z axis of each camera coordinate, so the object will be in the center of the sight of the right camera when ${}^Rx_{\hat{M}} = 0$ and ${}^Ry_{\hat{M}} = 0$. Here ${}^Rx_{\hat{M}}$, ${}^Ry_{\hat{M}}$, ${}^Rz_{\hat{M}}$ express the position of the detected object in the right camera coordinate.

$$\Delta \boldsymbol{q}_C = \boldsymbol{q}_{Cd} - \boldsymbol{q}_C \tag{15}$$

$$\boldsymbol{s}_C = \ddot{\boldsymbol{q}}_{Cd} + \boldsymbol{K}_{D_C}\Delta\dot{\boldsymbol{q}}_C + \boldsymbol{K}_{P_C}\Delta \boldsymbol{q}_C \tag{16}$$

here, $\boldsymbol{K}_{D_C}$, $\boldsymbol{K}_{P_C}$ are positive definite diagonal matrix.

3.4 Hand/Eye-vergence Controller

By the desired accelerations from (11) and (16), input $\boldsymbol{\tau}$ is calculated by:

$$\boldsymbol{s} = \begin{bmatrix} \boldsymbol{s}_E \\ \boldsymbol{s}_C \end{bmatrix} \tag{17}$$

$$\boldsymbol{\tau} = \boldsymbol{M}(\boldsymbol{q})\boldsymbol{s} + \boldsymbol{h}(\boldsymbol{q}, \dot{\boldsymbol{q}})\dot{\boldsymbol{q}} + \boldsymbol{g}(\boldsymbol{q}) \tag{18}$$

4 STABILITY OF HAND & EYE-VERGENCE MOTION

4.1 Manipulator Dynamics

First, we discuss about the convergence of our proposed hand visual servoing system. From the input torque of each joint in (18) and the dynamics equation of the system (1)

$$\ddot{\boldsymbol{q}} = \boldsymbol{s} \tag{19}$$

so

$$\ddot{\boldsymbol{q}}_E = \boldsymbol{s}_E. \tag{20}$$

Take (11) (here we do not consider the second item in the right side which is the controller of the redundance) into (20) we have

$$\boldsymbol{a}_E = \boldsymbol{J}_E(\boldsymbol{q}_E)\ddot{\boldsymbol{q}}_E + \dot{\boldsymbol{J}}_E(\boldsymbol{q}_E, \dot{\boldsymbol{q}}_E)\dot{\boldsymbol{q}}_E \tag{21}$$

so

$$\begin{bmatrix} \ddot{\boldsymbol{p}}_E \\ \dot{\boldsymbol{\omega}}_E \end{bmatrix} = \boldsymbol{J}_E(\boldsymbol{q}_E)\ddot{\boldsymbol{q}}_E + \dot{\boldsymbol{J}}_E(\boldsymbol{q}_E, \dot{\boldsymbol{q}}_E)\dot{\boldsymbol{q}}_E \tag{22}$$

which means:

$$\begin{bmatrix} \ddot{\boldsymbol{p}}_E \\ \dot{\boldsymbol{\omega}}_E \end{bmatrix} = \begin{bmatrix} \boldsymbol{a}_{pE} \\ \boldsymbol{a}_{oE} \end{bmatrix}. \tag{23}$$

Submit $\boldsymbol{a}_{pE}$, $\boldsymbol{a}_{oE}$ in (23) into (9) and (10),

$$\Delta\ddot{\boldsymbol{p}}_E + \boldsymbol{K}_{D_p}\Delta\dot{\boldsymbol{p}}_E + \boldsymbol{K}_{P_p}\Delta\boldsymbol{p}_E = \boldsymbol{0} \tag{24}$$

$$\Delta\dot{\boldsymbol{\omega}}_E + \boldsymbol{K}_{D_o}\Delta\boldsymbol{\omega}_E + \boldsymbol{K}_{P_o}\boldsymbol{R}_E\Delta^E\boldsymbol{\epsilon} = \boldsymbol{0} \tag{25}$$

4.2 Camera Dynamics

For the cameras, from (19),

$$\ddot{\boldsymbol{q}}_C = \boldsymbol{s}_C. \tag{26}$$

From (16), The close loop becomes:

$$\Delta\ddot{\boldsymbol{q}}_C + \boldsymbol{K}_{D_C}\Delta\dot{\boldsymbol{q}}_C + \boldsymbol{K}_{P_C}\Delta\boldsymbol{q}_C = \boldsymbol{0} \tag{27}$$

4.3 Stability Analysis

We invoke a Lyapunov argument, the feed back gains are taken as scalar matrices, i.e. $\boldsymbol{K}_{D_p} = K_{D_p}\boldsymbol{I}$, $\boldsymbol{K}_{P_p} = K_{P_p}\boldsymbol{I}$, $\boldsymbol{K}_{D_o} = K_{D_o}\boldsymbol{I}$ and $\boldsymbol{K}_{P_o} = K_{P_o}\boldsymbol{I}$. Here we assume that the feedback gains of the links are the same.

$$\begin{aligned} V &= \Delta\boldsymbol{p}_E^T\boldsymbol{K}_{P_p}\Delta\boldsymbol{p}_E + (\Delta\dot{\boldsymbol{p}}_E)^T\Delta\dot{\boldsymbol{p}}_E \\ &\quad + K_{P_o}\{(\eta-1)^2 + (\Delta\boldsymbol{\epsilon})^T\Delta\boldsymbol{\epsilon}\} + \frac{1}{2}(\Delta\boldsymbol{\omega}_E)^T\Delta\boldsymbol{\omega}_E \\ &\quad + \Delta\boldsymbol{q}_C^T\boldsymbol{K}_{P_C}\Delta\boldsymbol{q}_C + (\Delta\dot{\boldsymbol{q}}_C)^T\Delta\dot{\boldsymbol{q}}_C \\ &\geq 0 \end{aligned} \tag{28}$$

so

$$\begin{aligned} \dot{V} &= 2\Delta\dot{\boldsymbol{p}}_E^T(\Delta\ddot{\boldsymbol{p}}_E + \boldsymbol{K}_{P_p}\Delta\boldsymbol{p}_E) \\ &\quad + 2K_{P_o}\{(\eta-1)\dot{\eta} + \Delta\boldsymbol{\epsilon}^T\Delta\dot{\boldsymbol{\epsilon}}\} + \Delta\boldsymbol{\omega}_E^T\Delta\dot{\boldsymbol{\omega}}_E \\ &\quad + 2\Delta\dot{\boldsymbol{q}}_C^T(\Delta\ddot{\boldsymbol{q}}_C + \boldsymbol{K}_{P_C}\Delta\boldsymbol{q}_C) \end{aligned} \tag{29}$$

from (24) we can know that

$$\Delta\ddot{\boldsymbol{p}}_E + \boldsymbol{K}_{P_p}\Delta\boldsymbol{p}_E = -\boldsymbol{K}_{D_p}\Delta\dot{\boldsymbol{p}}_E \tag{30}$$

from the quaternion definition we can know that

$$\dot{\eta} = -\frac{1}{2}(\Delta\boldsymbol{\epsilon})^T\Delta\boldsymbol{\omega}_E \tag{31}$$

and

$$\Delta\dot{\boldsymbol{\epsilon}} = \frac{1}{2}\boldsymbol{E}(\eta, \Delta\boldsymbol{\epsilon})\Delta\boldsymbol{\omega}_E \tag{32}$$

where $\boldsymbol{E}(\eta, \boldsymbol{\epsilon}) = \eta\boldsymbol{I} - \boldsymbol{S}(\boldsymbol{\epsilon})$. $\boldsymbol{S}(\boldsymbol{a})$ is a antisymmetric matrix that satisfies $\boldsymbol{S}(\boldsymbol{a})\boldsymbol{b} = \boldsymbol{a} \times \boldsymbol{b}$.

From (27) we can get:

$$\Delta\ddot{\boldsymbol{q}}_C + \boldsymbol{K}_{D_C}\Delta\boldsymbol{q}_C = -\boldsymbol{K}_{D_C}\Delta\dot{\boldsymbol{q}}_C \tag{33}$$

Substitute (25), (30), (31), (32) and (33) into (29) we can get:

$$\begin{aligned} \dot{V} &= -2\Delta\dot{\boldsymbol{p}}_E^T\boldsymbol{K}_{D_p}\Delta\dot{\boldsymbol{p}}_E - \Delta\boldsymbol{\omega}_E^T\boldsymbol{K}_{D_o}\Delta\boldsymbol{\omega}_E \\ &\quad - 2\Delta\dot{\boldsymbol{q}}_C^T\boldsymbol{K}_{D_C}\Delta\dot{\boldsymbol{q}}_C \leq 0 \end{aligned} \tag{34}$$

here, because $\boldsymbol{K}_{D_p}$, $\boldsymbol{K}_{D_o}$ and $\boldsymbol{K}_{D_C}$ are positive definate, only if $\Delta\dot{\boldsymbol{p}}_E = \boldsymbol{0}$, $\Delta\boldsymbol{\omega}_E = \boldsymbol{0}$ and $\Delta\boldsymbol{q}_C = \boldsymbol{0}$, $\dot{V} = 0$. $\Delta\dot{\boldsymbol{p}}_E = \boldsymbol{0}$ and $\Delta\ddot{\boldsymbol{p}}_E = \boldsymbol{0}$, from (24),$\Delta\boldsymbol{p}_E = \boldsymbol{0}$. For the same reason, when $\Delta\dot{\boldsymbol{q}}_C = \boldsymbol{0}$, from (27), $\Delta\boldsymbol{q}_C = \boldsymbol{0}$. when $\Delta\boldsymbol{\omega}_E = \boldsymbol{0}$, $\Delta\dot{\boldsymbol{\omega}}_E = \boldsymbol{0}$. and from (25) $\Delta^E\boldsymbol{\epsilon} = \boldsymbol{0}$. The definition domain of θ is $(-\pi, \pi)$, so the manipulator and the cameras asymptotically converge to the invariant sets s.

$$\begin{aligned} s = \{&\Delta\boldsymbol{p}_E = \boldsymbol{0},\ \Delta\dot{\boldsymbol{p}}_E = \boldsymbol{0},{}^E\eta = 1,\ \Delta^E\boldsymbol{\epsilon} = \boldsymbol{0}, \\ &\Delta\boldsymbol{\omega}_E = \boldsymbol{0},\ \Delta\boldsymbol{q}_C = 0,\ \Delta\dot{\boldsymbol{q}}_C = 0\} \end{aligned} \tag{35}$$

so,

$$\lim_{t\to\infty} {}^E\boldsymbol{T}_{Ed} = \boldsymbol{I}, \quad \lim_{t\to\infty} {}^E\dot{\boldsymbol{T}}_{Ed} = \boldsymbol{0} \tag{36}$$

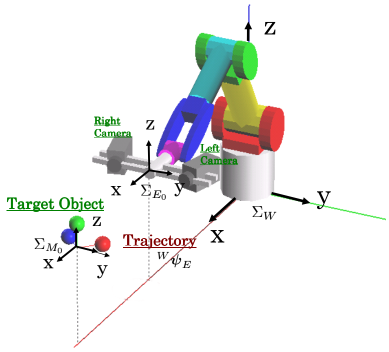

Fig. 7. Object and the visual-servoing system

substitute (36) to (3),

$$\lim_{t\to\infty} {}^E\boldsymbol{T}_{\hat{M}} = \lim_{t\to\infty} {}^{Ed}\boldsymbol{T}_{\hat{M}} \tag{37}$$

and from (12) to (14)

$$\lim_{t\to\infty} {}^R z_{\hat{M}} = 0,\ \lim_{t\to\infty} {}^R y_{\hat{M}} = 0,\ \lim_{t\to\infty} {}^L y_{\hat{M}} = 0 \tag{38}$$

which means the object will become on the center line of the cameras, which means that the object will always keep in the center of the sight of the cameras.

5 SIMULATION OF HAND & EYE-VERGENCE VISUAL SERVOING

To verify the effectiveness of the proposed hand & eye visual servoing system, we conduct the experiment of visual servoing to a 3D marker that is composed of a red ball, a green ball and a blue ball as Fig. 7. The radiuses of these three balls are set as 30[mm].

5.1 Simulation Condition

The recognition error does not affect the dynamic error, so we assume that ${}^M\boldsymbol{T}_{\hat{M}} = \boldsymbol{I}$, The position and orientation of the target object are given to the robot directly in the simulation. The initial hand pose is defined as Σ_{E_0}, while the initial object pose is defined as Σ_{M_0}, and the homogeneous transformation matrix from Σ_W to Σ_{M_0} is:

$${}^W\boldsymbol{T}_{M_0} = \begin{bmatrix} 0 & 0 & -1 & -1410[mm] \\ 1 & 0 & 0 & 0[mm] \\ 0 & -1 & 0 & 355[mm] \\ 0 & 0 & 0 & 1 \end{bmatrix}. \tag{39}$$

The target object move according to the following time function

$$\begin{aligned} {}^{M_0}\boldsymbol{\psi}_M &= [0, {}^{M_0}y_M(t), 0, 0, 0, 0]^T && (40)\\ {}^{M_0}y_M(t) &= 200\sin(\omega t)[mm] && (41) \end{aligned}$$

here, ω is the angular velocity of the motion of the object.

The relation between the object and the desired end-effector is set as:

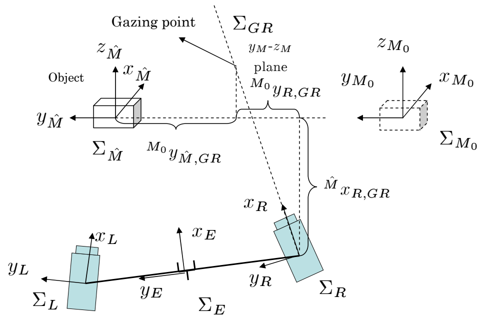

Fig. 8. Cameras' and End Effector's gazing point

$${}^{Ed}\boldsymbol{\psi}_M = [500[mm], 0, 0, 0, 0, 0] \tag{42}$$

The controller gain of the system $\boldsymbol{K}_{D_p}$, $\boldsymbol{K}_{P_p}$, $\boldsymbol{K}_{D_o}$, $\boldsymbol{K}_{P_o}$ are affected by the mass, initial moment, the amplifier output and many other conditions. From the common sense because the camera mass is smaller than the manipulator, $\boldsymbol{K}_{D_C}$ and $\boldsymbol{K}_{P_C}$ can be set bigger than $\boldsymbol{K}_{D_o}$ etc. Here $\boldsymbol{K}_{P_C} = diag\{5,5,5\}, \boldsymbol{K}_{D_C} = diag\{3,3,3\}, \boldsymbol{K}_{P_p} = \boldsymbol{K}_{P_o} = \boldsymbol{K}_{D_p} = \boldsymbol{K}_{D_o} = diag\{1,1,1\}$.

5.2 Definition of Trackability

5.2.1 Camera trackability

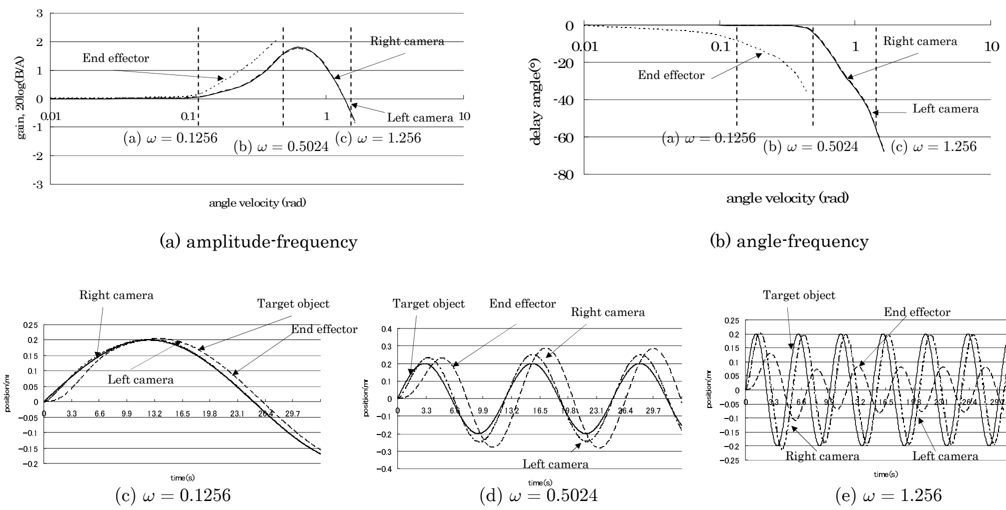
Here, to compare the trackability of the eye-vergence system and fixed camera system, we define a concept of gazing point. As it is shown in Fig. 8 the intersection of the gazing line of right camera and the y_{M_0}-z_{M_0} plane is defined as the gazing point. The relative relation between Σ_{M_0} and Σ_R is given by Homogeneous Transformation as ${}^{M_0}\boldsymbol{T}_R$, ${}^{M_0}\boldsymbol{T}_R$ conclude the rotation matrix ${}^{M_0}\boldsymbol{R}_R$ and the position vector ${}^{M_0}\boldsymbol{p}_R$, and the rotation matrix ${}^{M_0}\boldsymbol{R}_R$ can be written as $[{}^{M_0}\boldsymbol{x}_R, {}^{M_0}\boldsymbol{y}_R, {}^{M_0}\boldsymbol{z}_R]$. The direction of ${}^{M_0}\boldsymbol{l}_R$ in Fig. 8 is same to the direction of x_R, and ${}^{M_0}\boldsymbol{l}_R$ can be expressed as:

$${}^{M_0}\boldsymbol{l}_R = {}^{M_0}\boldsymbol{p}_R + k_R {}^{M_0}\boldsymbol{x}_R \tag{43}$$

here k_R is a scalar variable. The gazing point of the right camera expressed in Σ_{M_0} is ${}^{M_0}\boldsymbol{p}_{GR} = [0, {}^{M_0}y_{GR}, {}^{M_0}z_{GR}]^T$. For ${}^{M_0}\boldsymbol{l}_R = {}^{M_0}\boldsymbol{p}_{GR}$ in x direction, $({}^{M_0}\boldsymbol{p}_R)_x + k_R({}^{M_0}\boldsymbol{x}_R)_x = 0$. And usually $({}^{M_0}\boldsymbol{x}_R)_x \neq 0$, k_R can be calculated by $k_R = -({}^{M_0}\boldsymbol{p}_R)_x/({}^{M_0}\boldsymbol{x}_R)_x$, and the y, z coordinate of the gazing point in Σ_{M_0} can be calcated by:

$$\begin{aligned} {}^{M_0}y_{GR} &= ({}^{M_0}\boldsymbol{p}_R)_y + k_R({}^{M_0}\boldsymbol{x}_R)_y && (44)\\ {}^{M_0}z_{GR} &= ({}^{M_0}\boldsymbol{p}_R)_z + k_R({}^{M_0}\boldsymbol{x}_R)_z && (45) \end{aligned}$$

The target object's motion is given by (40), (41), because the motion of the target object M is parallel to the $\boldsymbol{y}_{M_0}$, we take ${}^{M_0}y_M(t)$ as the input, and the gazing point of the right camera ${}^{M_0}y_{GR}(t)$ as the response. And define the concept of trackability by the frequency response of ${}^{M_0}y_{GR}(t)$, the trackability of the left camera can be defined in the same way.



(a) amplitude-frequency (b) angle-frequency

(c) $\omega = 0.1256$ (d) $\omega = 0.5024$ (e) $\omega = 1.256$

Fig. 9. Comparison of Cameras' and End-effector's Trackabilities by Frequency Response

5.2.2 End-effector trackability

To compare with the trackability of the camera, it is necessary to define the End-effector trackability. Here the gazing line direction of normal static hand eye system is same to the x direction of Σ_E, so the gazing point of the static hand-eye system is same to the gazing point of the end-effector.

5.3 Simulation Results

The original position of the target object ${}^{W}\boldsymbol{T}_{M_0}$ is given by (39), the target object motion function is (40), the desired relation between the end-effector and the target object is given in (42). The ω in (40) changes from 0.01 to 2.00. In Fig. 9, we show the result of our experiment. The amplitude-frequence curve and the delay frequency curve are shown in Fig.9 (a) and Fig.9 (b). Here, for the fixed camera $A = {}^{M_0}y_M(t), B = {}^{M_0}y_{GE}(t)$. For the right camera of Eye-Vergence system $A = {}^{M_0}y_M(t), B = {}^{M_0}y_{GR}(t)$, for the left camera $A = {}^{M_0}y_M(t),\ \ B = {}^{M_0}y_{GL}(t)$. In this two figures the abscissa axes are logarithmic scalar of ω. In (a), (b), we sign the angular velocity when $\omega = 0.1256, 0.5024, 1.256$, and show the position of the gazing point of the cameras in eye-vergence simulation and the position of the gazing point of the end-effector in fixed camera experiment in (c), (d), (e). We can see that both the fixed-camera system and eye-vergence system can track the target object when $\omega = 0.1256$ while the fixed-camera system cannot track the target object when $\omega > 0.5024$ so in (e), and the eye-vergence system can track the target object even when $\omega = 1.256$.

From Fig. 9 (a) we can see the data of the cameras and the end-effector all become bigger as ω increases for the reason of resonance, but the curve of the fixed camera system is always below the curves of the cameras, we can see that the amplitude of the eye-vergence system is more closed to the target object than the fixed camera system, the fixed camera system cannot track the target object when $\omega > 0.5024$, so the point line dispear near $\omega = 0.5024$, while in eye-vergence system the fastest velocity of the target object under which the system can catch up with is 1.6956. From (b) the the curve of the fixed camera system is also below the curves of the cameras, which means that delay of the fixed camera system is bigger than the eye-vergence system, To be understood easily, we show the position of the gazing point of the cameras in eye-vergence experiment and the position of the gazing point of the end-effector in fixed camera experiment in (c), (d), (e). From the figures it is also easy to see that comparing with the fixed camera system, the eye-vergence system can track the target object better.

6 CONCLUSION

In this paper, we propose a concept of trackability to evaluate the observation ability on a moving object of visual servoing system. We get amplitud-frequency and phase-frequency curves of the cameras of the eye-vergence system and the fixed camera system under moving object with different angular velocity in simulation and get the conclusion that the trackability and stability of the eye-vergence system is better than that of the fixed-camera system.

Abstract: A four-wheel steered mobile robot is fit for a higher power or improvement in the movement speed of a robot than a two-independent wheeled one. Since a steered mobile robot that slips very often cannot apply a popular dead-reckoning method by using rotary encoders, it is desirable to use external sensors such as cameras. This paper describes a method to trace a straight line for four-wheel steered mobile robots by using an image-based control method. Its controller is designed as a fuzzy controller and evaluated through some simulations and real robot experiments.

Keywords: Fuzzy control, Image-based control, Steered mobile robot, Trajectory tracking, Visual servo

1 INTRODUCTION

Although most of wheeled robots that are developed recently adopt a two-independent wheeled type which excels in simple mechanism and in turning-performance, steered mobile robots will be able to extend the field of robot applications, because it is fit for a higher power or improvement in the movement speed of a robot. Since a steered mobile robot that slips very often cannot apply a popular dead-reckoning method by using rotary encoders, it is desirable to use external sensors such as cameras.

Control methods using cameras are classified roughly into two methods[1, 2, 3, 4]. One is called "position-based" control method, which controls a robot by using the robot position that is estimated from matching previous knowledge of 3D environmental models with a captured image. The other is called "image-based" control method, which can operate a robot indirectly without using the robot position by controlling only image information on an image plane. This method seems to be similar to the processing that is performed by human, in fact that human behaviors are decided without using its own position. Thus, an image-based control method is studied in this research. As the earlier research of image-based control, Chen et al. [5] designed the fuzzy controller to stabilize an inverted pendulum by referring to images that is captured with a camera in front of the inverted pendulum. Kurashiki et al. [6] designed a controller to trace a curving line for two-wheel independent mobile robots by using a model based control method.

This paper describes a method to trace a straight line for four-wheel steered mobile robots by using an image-based control method. When designing the controller, it is hard to model the relationship between image information and robot states, so that a model-free fuzzy controller [7, 8] is adopted. The designed controller is evaluated through some simulations and real robot experiments.

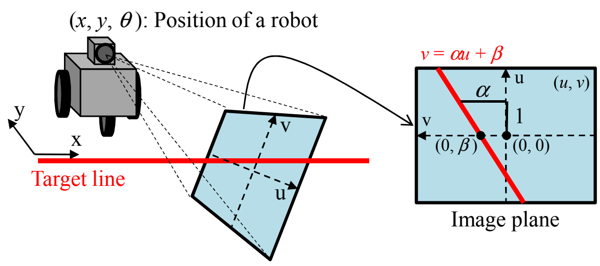

Fig. 1. World coordinate and image coordinate

2 PROBLEM SETTING

The goal of the present control is that a robot equipped with a camera tracks the target line drawn on the floor by image-based control. Fig. 1 shows the environmental overview and the definition of coordinates. Since the world coordinate is defined as x-axis to be along the target line, the function of the target line is $y = 0$. The image coordinate is represented by u-v coordinate with the direction of axes as shown in Fig. 1. On the image coordinate, the function of the target line is denoted as $v = \alpha u + \beta$, where α is the gradient and β is the intercept of the target line. The α and β can be obtained from an image processing.

The controlled object is a four-wheel steered mobile robot

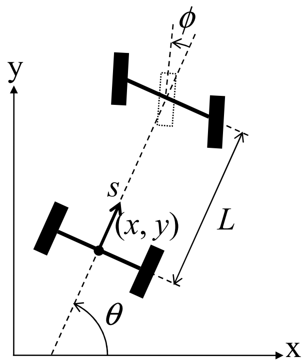

Fig. 2. Model of a mobile robot

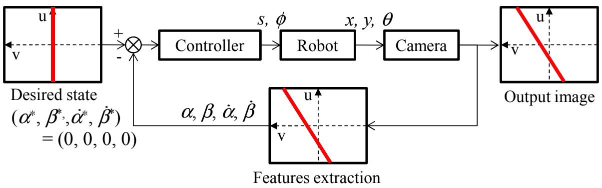

Fig. 3. Block diagram of the image-based control

as shown in Fig. 2. The robot state is denoted by the position and the direction such as (x, y, θ), and the steering angle is ϕ, the advanced speed is s, and the wheel base is L.

To track the target line, it can predict intuitively that α = 0 and β = 0 should be accomplished on the image coordinate instead of performing y = 0 and θ = 0 on the world coordinate. Therefore, the state variables are defined as (α, β, $\dot{\alpha}$, $\dot{\beta}$) and these desired values are (α^*, β^*, $\dot{\alpha}^*$, $\dot{\beta}^*$) = (0, 0, 0, 0). The controller is designed with the definition of control inputs as (s, ϕ). Fig. 3 shows the block diagram of this image-based control. In Fig. 3, the controller determines the control inputs, s and ϕ, from α, β, $\dot{\alpha}$, and $\dot{\beta}$ which are extracted by some image processing of a captured image. This block diagram shows that the robot is controlled without referring to its positions.

3 FUZZY CONTROLLER

The fuzzy controller determines the control inputs through mainly three steps:

1. Fuzzification of state variables
2. Calculation of grade of each rule
3. Defuzzification of input values

These are described below in detail.

3.1 Fuzzification of state variables

Fuzzification is to convert real numbers into fuzzy sets which are linguistic representations with grades which are given by membership functions. Fig. 4 shows the membership function of each state variable. Value of each state variable is fuzzified to linguistic representations (N: Negative, ZO: Zero, P: Positive) with grades which are given these membership functions. The membership functions are prepared from some preliminary experiments by heuristic method and depend on the properties of the camera and the robot.

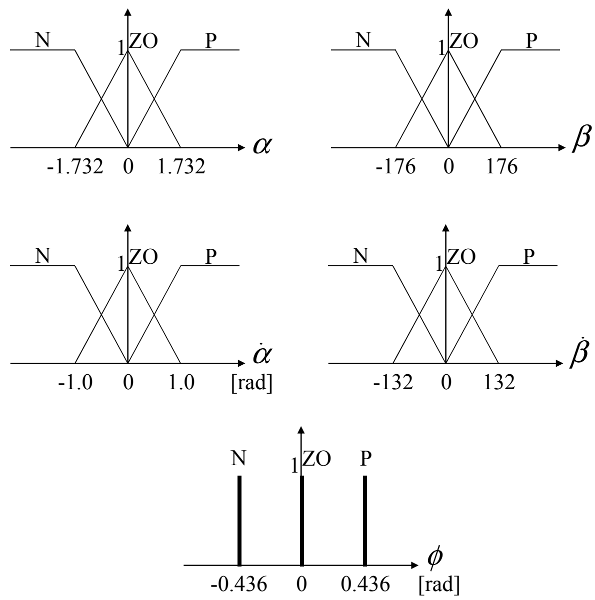

Fig. 4. Membership functions

3.2 Calculation of confidence of each rule

Table 1 shows fuzzy control rules for ϕ which are constructed based on the roughly separated positional relations with the fuzzified state variables, where s is assigned to be a constant. The interpretation of these rules is, for example, such that the rule No. 1 represents

$$\text{if } \alpha = \mathrm{N}, \beta = \mathrm{N} \text{ then } \phi = \mathrm{N} \tag{1}$$

The grade of each control rule is the same as the minimum value among the degrees of truth of the fuzzified state variables related to the rule. Although the degree of truth of each rule is adopted as the degree of truth of the control input, if other rules have the same values, then the maximum value among these degrees of truth is adopted (min-max algorithm).

3.3 Defuzzification of input values

Control inputs which are obtained as fuzzy sets should be defuzzified to provide control input values as real numbers. The defuzzification is the calculation of a weighted mean by a simplified fuzzy reasoning method with singletons as fol-

Table 1. Fuzzy rules for ϕ

No.	α	β	$\dot{\alpha}$	$\dot{\beta}$	ϕ
1	N	N	-	-	N
2	N	ZO	-	-	N
3	N	P	-	-	ZO
4	ZO	N	-	-	N
5	ZO	ZO	N	N	N
6	ZO	ZO	N	ZO	N
7	ZO	ZO	N	P	ZO
8	ZO	ZO	ZO	N	N
9	ZO	ZO	ZO	ZO	ZO
10	ZO	ZO	ZO	P	P
11	ZO	ZO	P	N	ZO
12	ZO	ZO	P	ZO	P
13	ZO	ZO	P	P	P
14	ZO	P	-	-	P
15	P	N	-	-	ZO
16	P	ZO	-	-	P
17	P	P	-	-	P

lows:

$$\phi = \frac{-0.436 \cdot h_{\phi,\mathrm{N}} + 0 \cdot h_{\phi,\mathrm{ZO}} + 0.436 \cdot h_{\phi,\mathrm{P}}}{h_{\phi,\mathrm{N}} + h_{\phi,\mathrm{ZO}} + h_{\phi,\mathrm{P}}} \tag{2}$$

where $h_{\phi,\mathrm{N}}$ denotes the grade of ϕ =N.

4 EXPERIMENTS

Simulations and real robot experiments were conducted to confirm that the designed image-based fuzzy controller can achieve the straight line tracking.

4.1 Simulation experiment

The initial state of the robot was assumed to be (x, y, θ) = (0.0 [m], -0.4 [m], $\pi/4$ [rad]) and the advanced speed of the robot s = 0.5 [m/s]. Maintaining of y = 0 was considered to be an accomplishment of the trajectory tracking. The working volume of steering angle was -0.436 [rad] $< \phi <$ 0.436 [rad] and its rate was -1.75 [rad] $< \dot{\phi} <$ 1.75 [rad]. The wheel base L was 0.26 [m]. The camera was attached on the robot, in which its height was 0.09 [m], the angle was 70 [deg] for forward from vertically downward, the focal length was 0.02 [m], the angle of view was 2.09 [rad], and the frame rate was 30 [fps]. The gradient of the target line on an image plane was represented as $-\infty < \alpha < \infty$ and the interception was to be $-\infty < \beta < \infty$. The time step of this simulation was set to 10 [ms].

Fig. 5 shows the movement trajectory of the robot on this simulation. Although the overshoot arose when the robot reached the target line at the first time, it was able to trace the line y = 0 without oscillations.

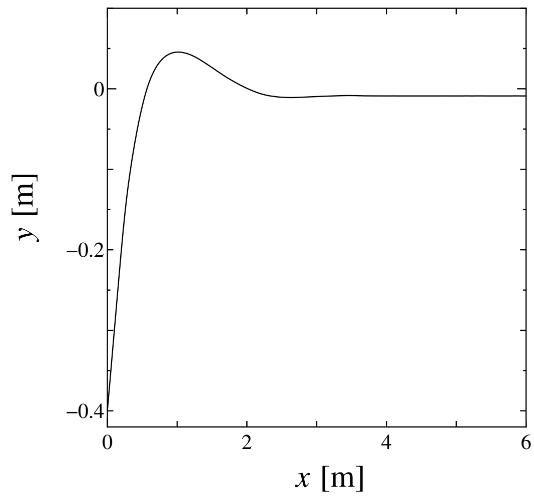

Fig. 5. Result of the simulation experiment

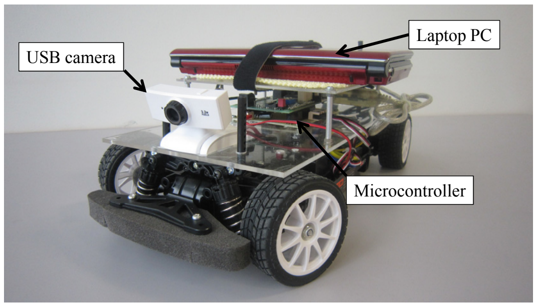

Fig. 6. Real robot for the experiment

4.2 Real robot experiment

The designed controller was tested on the real robot experiment, to check the usability on real environment. Fig. 6 shows the robot which was used for this experiment. This robot was a four-wheel steered mobile robot, which was made by modifying a commercially available radio controlled car to control it by a microcontroller. The USB camera attached on forefront gazes at floor to capture the target line. The laptop PC executes the image processing to extract α and β by using Hough transform from the captured image like as shown in Fig. 7. The rates, $\dot{\alpha}$ and $\dot{\beta}$, are to be the difference between current and previous extracted values. The initial state of the robot was assumed to be (x, y, θ) = (0.0 [m], -0.4 [m], $\pi/4$ [rad]) and the advanced speed was to be about 0.5 [m/s] as the same as the condition of the simulation.

Fig. 8 shows the result of this experiment. Although the robot moved along the target line y = 0 without both overshoots and oscillations, the residual error remained about -0.06 [m] for y-axis.

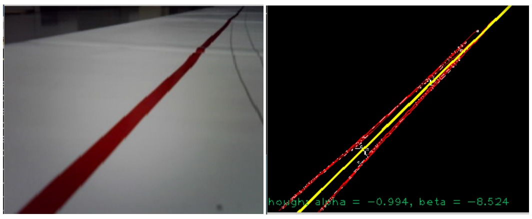

Fig. 7. Image processing

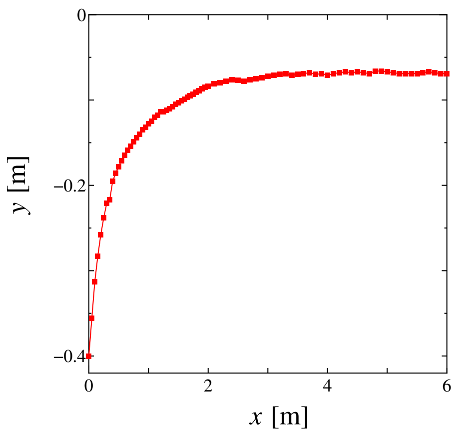

Fig. 8. Result of the real robot experiment

5 CONSIDERATION

The results of both simulations and real robot experiments show the usability of the designed controller. On the real robot experiment, the residual error remained about -0.06 [m] for y-axis. One of error causes is attributed to the fact that there is a robot property which turns right a little when it goes straight due to the difference of wheel diameters or the bias of center of gravity. Additionally, there is a little residual error in the result of the simulation. Thus, the error cause is coming from not only the robot property but also theoretical reasons. Fig. 9 shows a case where a robot exists along a target line with a little error for y-direction. In this case, since the state variables are α = N and β = P, the robot will advance because it believes the wrong situation such as shown in Fig. 10. Although one possible solution is to further refine the membership functions and the control rules in order to separate these similar situations, the tuning of the fuzzy controller will be very complicated. To adopt this solution, any optimization methods are required to automate the tuning process.

6 CONCLUSION

In this paper, an image-based control method which controls robots without referring to positions has been described. The objective was that a robot equipped with a camera was

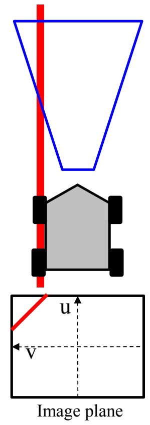

Fig. 9. Robot advancing along the target line

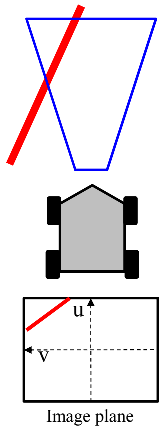

Fig. 10. Robot advancing toward the target line

to track a straight line drawn on a floor by image-based control, and a fuzzy controller was designed. The results of both simulations and real robot experiments showed the usability of the designed controller and it shed light on some problems. In the future, we have to consider a curvilinear trajectory tracking method and a speed control method to utilize characteristics of four-wheel steered mobile robots.

Abstract: In human living environments, it is often the case that the cleaning area is three-dimensional space such as a high-rise building. An autonomous cleaning robot is proposed so as to move on all floors including stairs in a building. The proposed robot has a body frame of a rectangular solid, which is equipped with L-shaped legs on the both sides and drive wheels on the top and bottom sides. The present robot climbs down stairs by rotating the body using L-shaped legs and it moves on smooth surfaces using wheels. In this paper, a mobile mechanism and a control method are described for translational locomotion. The operational check of the translational mechanism was conducted by facing the robot to the edge of stairs using the position sensitive detector (PSD).

Keywords: Cleaning robot, Climbing robot, Mechanism

1 INTRODUCTION

Recently, various robots that support and act for human work have been developed to be utilized in various fields. One of such robots is the autonomous cleaning robot [1]. The automation of cleaning by robots reduces labors and saves energy for a cleaning task, so that there is an increasing need for it in large areas such as stations and airports.

In human living environments, it is often the case that the cleaning area is a three-dimensional space such as a high-rise building. Considering cleaning in a three-dimensional space, the cleaning area includes the steps of stairs which lead from one level of a building to another. However, many of cleaning robots are not considered to move on places between floors. Tajima et al. [2][3] have developed a robotic system in which the cleaning robot cooperated with the elevator to clean floors in a high-rise building. However, this system did not consider the cleaning of stairs. As a result, a cleaning robot itself needs the ability to move on stairs for cleaning in a three-dimensional space. Also, the several types of climbing robot using crawlers, wheels and legs were proposed to move on stairs [4]-[6]. Those robots were developed to move on stairs only for improving transfer performance of them in uneven surfaces and transporting people or objects. Therefore, a cleaning robot for cleaning in a three-dimensional space needs to be able to turn itself and keep posture level on the tread board of stairs, as well as moving on stairs.

The objective of this study is to develop a climbing robot which can move on all floors including stairs in a building for autonomous cleaning in a three-dimensional space. A climbing robot has been already proposed, where its structure was divided into two mechanisms for climbing down stairs and translational movement [7][8]. In this paper, a mobile mechanism and a control method are described for translational locomotion. The operational check of the translational mechanism was conducted by facing the robot to the edge of stairs using the position sensitive detector (PSD).

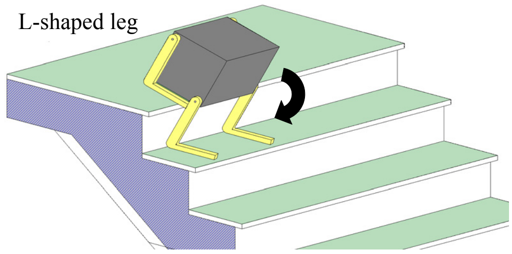

Fig. 1. Outline of a climbing robot for cleaning stairs

2 CONCEPT OF CLIMBING ROBOT

Fig. 1 shows the proposed robot whose structure is divided into two mechanisms for climbing down stairs and translational locomotion. The L-shaped legs which are equipped with on the both sides of a body are used as a climbing mechanism. The proposed robot climbs down stairs by rotating the body so that the top and bottom sides of body may be reversed using L-shaped legs with two degrees-of-

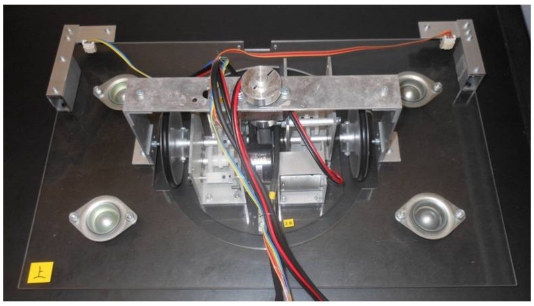

Fig. 2. Overview of translational mechanism

freedom. A translational locomotion mechanism is discussed in section 3.

3 MOBILE MECHANISM FOR TRANSLATIONAL LOCOMOTION

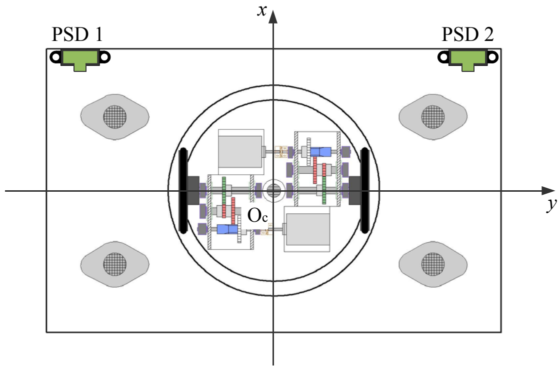
It is assumed that the cleaning robot is used in an indoor environment that is flat such as wooden floor or tile floor. The robot performs translational locomotion using wheels that have high transfer efficiency. However, the robot may be limited in motion by its corners colliding with the wall and the riser of stairs when turning around, because the robot shape is a rectangular solid as shown in previous sections. So omni directional mobility is adopted to move and turn around keeping a posture.

For some of omni directional mobile mechanisms with wheels, there are mechanisms with omni-wheel, mechanum wheels, etc. Since the robot climbs down stairs by rotating the body so that the upper and lower sides of body may be reversed, this mechanism is attached to the top and bottom of the robot. To reduce the robot weight, it is desirable to use the fewest possible actuators. Therefore, the mobile mechanism for translational mobility used an omni directional mobile mechanism of two-wheel-drive system in this study.

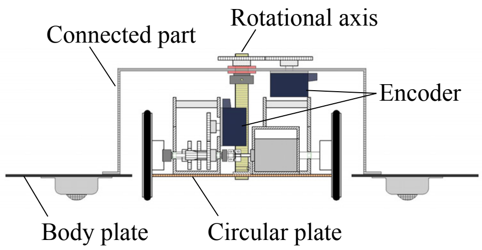
3.1 Mobile mechanism design

Fig. 2 shows the proposed mechanism for translating on stair treads. The size of the mechanism is as follows: the width is 400 mm, the length is 250 mm, and the vehicle height is 20 mm. Its mechanism consists of four ball-casters and two driving wheels that are attached on a circular plate with a joint.

Fig. 3 shows the layout of sensors mounted on a translational locomotion mechanism. The PSD as the range sensor is used for the robot to recognize stairs. Two PSDs are attached on both ends in the front side of mobile mechanism for translational locomotion. If the origin is set at the rotational axis, the positions of PSD 1 and PSD 2 are (x_{psd}, $-y_{\mathrm{psd}}$) and (x_{psd}, y_{psd}) as an x-y coordinate, respectively.



(a) Top view



(b) Lateral view

Fig. 3. Design of a variety of sensors

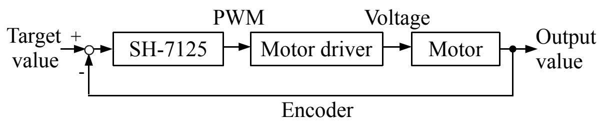


Fig. 4. Block diagram of velocity control

Also, the encoders are used to measure the forward velocity of the robot or the angle of the circular plate.

3.2 Controller design

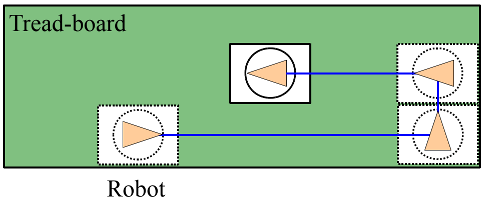
Cleaning robots keep the quality of cleaning constant by velocity control. A velocity of the robot is controlled using a PD controller with encoders to measure the rotation of wheels. Fig. 4 shows the block diagram of velocity control. The motors for wheel can be controlled in normal and reverse rotations, stop and braking by sending the signal from the microcomputer SH7125 through a motor driver.

4 LOCOMOTION ON STAIRS

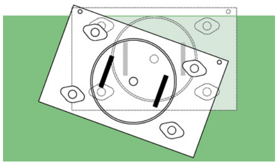
The locomotion of the robot on stairs assumes two motions, i.e., the cleaning motion and the recognition motion.

4.1 Cleaning motion

The locomotion of commonly-marketed cleaning robots is classified into four basic motions, while are parallel, spiral, wall-reflection and wall-following motions. the parallel motion which is a repeated motion combining advance and



(a) Parallel motion to clean stairs



(b) Turning motion to be faced to stairs

Fig. 5. Translational locomotion on stairs

90-degree turns is one of more suitable motions for cleaning stairs, because the shape of step is a rectangular form which makes a path planning easy to make for cleaning evenly. In the cleaning motion based on the parallel motion, the robot repeats straight going and 90-degree turn, keeping the posture as shown in Fig. 5(a).

4.2 Recognition motion

When the robot changes from translational locomotion to climbing down motion, the robot might fall down stairs due to its posture. Whenever stairs are recognized, the robot turns to be faced to the edge of stair as shown in Fig. 5(b)

4.3 Kinematic model of mobile mechanism

The kinematic model of the mechanism for translational locomotion is given by

$$\begin{bmatrix} \dot{x} \\ \dot{y} \\ \dot{\theta}_c \end{bmatrix} = \begin{bmatrix} \frac{r}{2}\sin\theta_c & \frac{r}{2}\sin\theta_c \\ \frac{r}{2}\cos\theta_c & \frac{r}{2}\cos\theta_c \\ \frac{r}{2d} & -\frac{r}{2d} \end{bmatrix} \begin{bmatrix} \dot{\theta}_R \\ \dot{\theta}_L \end{bmatrix} \tag{1}$$

where x and y are the position coordinate of the robot, θ_c is the rotated angle of a circular plate, θ_R and θ_L are the rotational angles for the right and left wheels, r is the wheel radius, and $2d$ is the distance between wheels.

5 STAIR RECOGNITION USING PSD

The robot recognizes stairs by discriminating a difference between the vehicle height and the rise of stairs by using a PSD. The PSD outputs the value that converts a distance to an object into DC voltage. When a PSD value is less than or equal to a threshold for discriminating stair and floor, the robot recognizes it as a stair. On the other hand, the robot recognizes it as a floor.

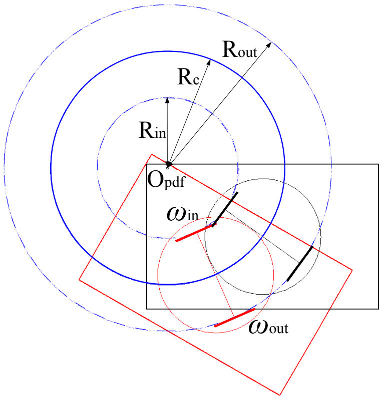


Fig. 6. Kinematic model of turning motion

The robot turns to be faced to the edge of stairs using two PSDs. If anyone of PSDs is recognizes a stair, a circular plate of the robot is rotated so that a reacted PSD is located on the wheel axis. Next the robot turns in direction, so the other PSD recognizes a stair. Finally, the robot stops if both PSDs recognizes stairs.

Also, the robot turns as shown in Fig. 6, if the angular velocities of inner and outer wheels have a relationship in their turning radii such as as follows:

$$\left|\frac{\omega_{\mathrm{in}}}{\omega_{\mathrm{out}}}\right| = \left|\frac{R_{\mathrm{in}}}{R_{\mathrm{out}}}\right| \tag{2}$$

where ω_{in} and ω_{out} are the angular velocities of the inner and outer wheels, and R_{in} and R_{out} are the turning radii of the inner and outer wheels.

5.1 Operational check

We had conducted an operational check to verify the accuracy of recognition motion using PSDs. The evaluation item is the posture of the robot after it was turned to be faced to stairs at a constant velocity of 150 mm/s from initial positions. Initial positions were assumed as 15 degrees, 30 degrees, 45 degrees, 60 degrees and 75 degrees. A threshold for recognizing a stair was decided as 300 in A/D converted value, because a rise is defined as 180 mm in this study. As a result, it is confirmed that the robot turned and stopped using PSDs. Fig. 7 shows the posture of the robot which was faced to the edge of stairs by initial postures. Table 1 shows the average and standard deviation (SD) of posture angles by initial postures.

5.2 Consideration

The error in the posture angle is within plus or minus five degrees through an operational check. This subsection states the error in posture angles.

A relationship between the angular velocity and the turning radius of wheel is $\omega_{\mathrm{in}} = 0.43\omega_{\mathrm{out}}$ defined by Eq. (2) in ideal condition. But in fact a relationship of them was

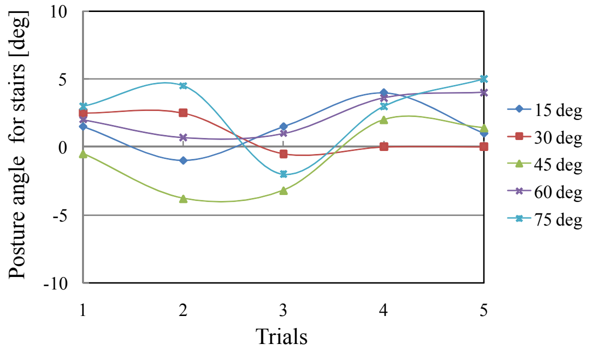

Fig. 7. Posture angle in faced to step

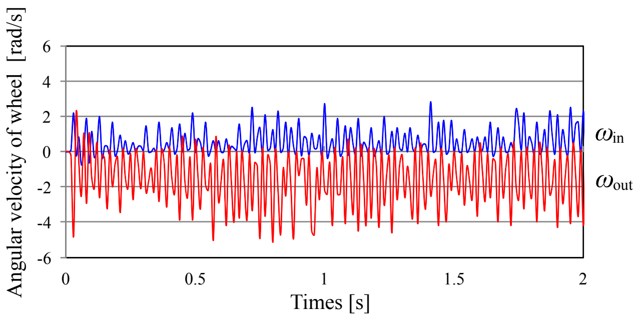

Fig. 8. Wheel velocity based on velosity control

Table 1. Average and SD of posture angles

Angle [deg]	Average [deg]	SD [deg]
15	1.40	1.59
30	0.90	1.32
45	–0.82	2.34
60	2.26	1.34
75	2.70	2.48

$\omega_{\text{in}} \simeq 0.28\omega_{\text{out}}$ as shown in Fig. 8. The inner wheel might stop, because ω_{in} was near zero. For a target of turning velocity of 150 mm/s, the motor was driven at duty cycle of 45 percents for inner wheel and 48 percents for outer wheel by the PWM signal. It is confirmed to be unstable at a low duty cycle by the PWM signal. Also, motors might give unstable behaviors due to the influence of the noise.

This problem will be overcome by reaalizing that the robot attains a velocity equal to a target at a high duty cycle by increasing gears reduction ratio.

6 CONCLUSION

A cleaning robot to climb down stairs has been developed for cleaning a three-dimension space. In particular, mobile mechanisms and a locomotion control method were proposed for the robot to clean and climb down stairs. The operational check of the robot was conducted for recognizing stairs. In the result, it was confirmed that it needs to change the high duty cycle. As future work, a stair cleaning robot will be developed to solve the above problem, together with making a real robot.

The Experiment of the Path Planning to Respect Human Movements Using a Human Frequency Map for a Mobile Robot

Kimiko Motonaka[1], Shoichi Maeyama[1], and Keigo Watanabe[1]

[1] Okayama University, Okayama, Okayama 700-8530 , Japan
(k.motonaka@usm.sys.okayama-u.ac.jp)

Abstract: A robot requires any path planning to respect human movements when the robot works with the person in an environment. Therefore, we use a Human Frequency Map (HFM) generated by using observed human positions. By applying the HFM, the robot can achieve the path planning that cares about the human movements and the pathway width. This paper describes the effectiveness of the HFM through some experiments in the real environment. The experimental results of navigation using a real mobile robot is also discussed.

Keywords: Mobile Robot, Path Planning, Human Observation, Environment Map

1 INTRODUCTION

Nowadays, a mobile robot has been expected to foray into home or office, and there exist many studies about path planning for these mobile robots[1][2]. However, it is often the case that path planning is studied for calculating the shortest distance to a goal[3]. Then, the mobile robot has to not only search the shortest path but also perform the path planning to respect human movement.

There are some approaches that several sensors are distributed in the environmental side for observing human positions and the data are used for path planning[4]. If the human's walking route is used, the robot can obtain the information on a safe route without searching on the whole environment[5][6]. Therefore, when implementing the safe operation of a robot in a real world, the robot should also consider the possibility for encountering human, and whether there is a wide aisle for path each other easily.

In this study, our path planning approach has a unique point so as to focuse the behavioral change of human in each time zone. Observed human positions are used for making a "Human Frequency Map (HFM)" , which is a grid map based on the observed human positions and frequency in each term. The pathway generated by the HFM contains the information on the passage width and the human frequency in the term. This research has a feature that the present path planning can minimize the possibility for encountering human by considering the human frequency of a certain time zone and the current position of human. Additionally, we conducted the experiment of navigation using a real mobile root by the path information generated from the HFM.

2 HUMAN FREQUENCY MAP

In this study, human positions are observed by sensors distributed in the environmental side. Then, the HFM is generated by the observed human positions. The HFM uses the grid map that has only the data of human frequency in each grid on the map (Fig. 1). Each grid keeps the data of human frequency in 4 levels (high, middle, low and zero) and the data can be referred to by an (i, j) element in the map. For more information about HFM, please refer to [7].

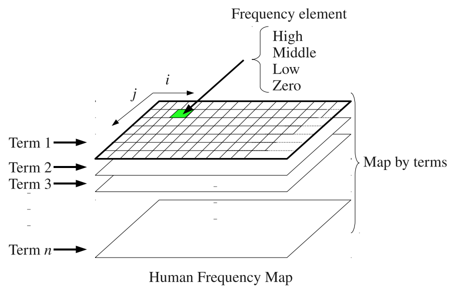

Fig. 1: Data structure of human frequency map

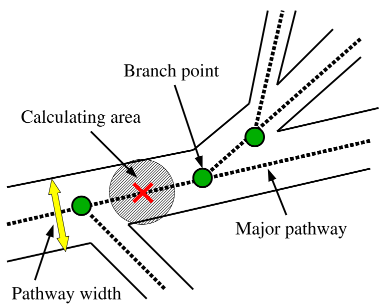

Fig. 2: Topological map of human's pathway

2.1 Generation of Pathway Information

The HFM has the information of human positions, but no information on the routes human which walked. Therefore, the pathway information should be reconstructed from the human positions. The pathway information means a passage

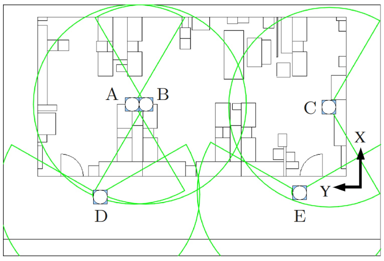

Fig. 3: Experimental environment

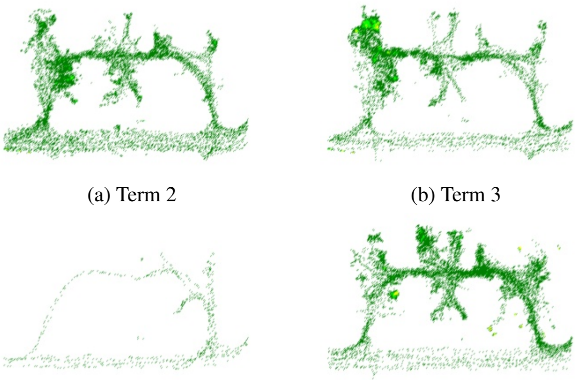


(a) Term 2 (b) Term 3

(c) Term 10 (d) Term 12

Fig. 4: Human frequency map

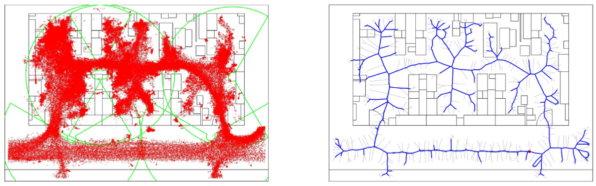
area, the passage width and human frequency(Fig. 2). These information could be calculated from the human positions data stored on HFM.

2.2 An Example of Generated Human Frequency Map

In this experiment, five laser range scanners were used to observe human positions in our office to generate the HFM. The size of the room is 12.6 $\times$ 6.6 [m^2]. Fig. 3 shows the layout chart of the room, the origin, the positions of sensors and the range of observations. Observed time was 24 hours from 18:00 to 18:00 on the next day. We call each observation duration every two hours (18:00–20:00,...,16:00–18:00) term 1 to term 12. The human frequency is the average number of times for the observed humans per grid. If observed more than one time in 5 minutes, it is set as High; if more than one time in 10 minutes, it is set as Middle; if observed only one time in the duration, it is set as Low; and if not observed at all, it is set as Zero. Note here that the door was released in this case.

Fig. 4 and Fig. 5 are the experimental results, in which Fig. 4 shows the HFM obtained in terms 2, 3, 10 and 12, whereas Fig. 5a depicts the human observed area through term 1 to term 12 with the room layout chart and Fig. 5b shows the major pathway generated by the HFM with the room layout chart.

The major pathway generated by the HFM was sufficiently close to the real passage (Fig. 5a). Additionally, the end-point node of the pathway reached the workspace such as doors or desks, so that the obtained pathway can be useful as an environmental map for the path planning of a robot. It was confirmed from the present method that the passage area and the major pathways were able to be calculated from the human positions.



(a) Human observed area (b) Major pathway

Fig. 5: Generation of pathway information

3 PATH PLANNING

3.1 Evaluation of Path Candidates

In this method, a major pathway is stored as a non-directed graph. Here, the node of the graph is the branch point of the major path, and the edge of the graph is the major path. When the start and goal were set, all adjoining nodes are explored and all the pathways which reach the goal are saved as the path candidates.

Then, all candidates are evaluated and the best one is selected. In the evaluation, the pathway width and the traffic are considered. The evaluation function for the path selection V is give by

$$V = \sigma_a(l_p)\rho \tag{1}$$

Here,

$$\sigma_a(x) = \frac{K}{1 + e^{-a(x-b)}}$$

$$\rho = \begin{cases} \rho_m & \text{if } t_h \leq t_r \\ \rho_0 & \text{otherwise} \end{cases} \tag{2}$$

where ρ_m is the human frequency and l_p is the pathway width of the edge.

$\sigma_a(x)$ at $K = 1$ is called a sigmoid function, which is the threshold function and has the property of $(-\infty, \infty) \rightarrow (0, 1)$. In addition, a and b are constant, but note that a is a negative value in our case. t_h and t_r represent the minimum arrival time of human and robot, respectively. If $t_h > t_r$, then the robot doesn't encounter the human, otherwise the robot has possibilities to encounter the human. ρ_0 is sufficiently small compared to ρ_m. This is based on the idea that it is not necessary to care about the traffic if the robot doesn't encounter the human. V is increased when the pathway width is decreased or the human frequency ρ_m is increased. It means that V is more increased, if it is harder to pass the pathway.

3.2 Experimental Example of Path Planning

In this experiment, it is assumed that the robot runs in term 3 (Fig. 4b) and term 12 (Fig. 4d) of the HFM. V is calculated with $K = 1.0$, $a = \;\; 0.0367$, $b = l_r + l_h = 30.0 + 60.0$ [cm], $v_r = 30.0$ [cm/s] and $v_h = 105.0$ [cm/s], where l_r, l_h, v_r and v_h denote the robot width, the human width, the velocity of the robot and the velocity of the human, respectively.

The robot was given an order to start from the corridor and reach to the sink. Fig. 6 shows the room layout, start, goal and human positions.

All the paths from the start to the goal are shown in Fig. 7. The red line ($t_h \quad t_r$) and the blue line ($t_h > t_r$) are the major pathway.

Fig. 8 shows the graph of the evaluation value (V) of path 4 in term 3. The horizontal axis is a distance from the start point and the right endpoint of the graph is the goal point. The path having a minimum value of the sum of V is chosen as the best path in the term. Fig. 9 shows each sum of V of paths 1–4 in term 3 and term 12, and Fig. 10 shows the best path in each term with the room layout chart.

3.2.1 Considerations

It is found from Fig. 8 that V increases at the narrow or crowded passage. By comparing term 3 with term 12 as shown in Fig. 9, there is a difference in the sum of V even if they have the same path because the human frequency is different each other. Any pass is selected so as to have the minimum sum of V, because V increases in the point where it is hard to pass. The path length is also taken into account by using V.

According to this, path 2 is the best candidate for the robot in term 3, whereas path 4 is the best candidate in term 12. Thus, the path to be selected is changed depending on the time zone. It means that the path change can be achieved according to the human frequency every time zone. As seen in Fig. 10, the path is chosen so as to avoid the human crowded area. This is because the position of the current human movement is considered. There is a high possibility that human moves to the high human frequency area in each time zone.

4 EXPERIMENTS USING MOBILE ROBOT

In this section, it is discussed about the navigation for the mobile robot by means of the path generated from HFM. For distant navigation, the only odometry is not enough for localization because of the cumulative error. Therefore, we need the additional information for localization. The system to generate the HFM has the function of the human position detection by the laser range sensors mounted on the environmental side. This system can be extended to estimate the robot position. The part of the robot body can be measured by these environment-side sensors. Then, we propose the localization method by fusion of odometry-based position and the robot position estimated by environment-side sensors. The proposed method makes it possible for the robot to keep own position over long distances.

4.1 Experiments

The experiment on the navigation of a mobile robot along a path generated by HFM is conducted. The objective of this experiment is to verify whether the proposed path can be used for the mobile robot navigation. Therefore, this experiment is done in the almost static environment in this instance. The experiment environment is the same as the environment shown in Fig. 3 and the size of the robot is 550 600 1430 [mm] shown in Fig. 11. In this experiments, 4 kinds of the path is provided to the mobile robot. The robot moves according to the path given by the branch point coordinates.

As the result of this experiment, the robot could reach the goal safely in four different routes. At this time, it confirmed that the robot could run through the narrow passage area like the entrance of the room. Therefore, it is confirmed that the path generated from the HFM is suitable for the navigation for the mobile robot.

Note however that, this experiment was conducted in the almost static environment with only a few human at only the one term. It is necessary to verify at various time zone with the view to usefulness of the HFM. Also, for the case where an unexpected obstacle is encountered, the robot should implement obstacle avoidance function as well.

5 CONCLUSION

In this paper, a path planning method has been proposed for mobile robots to respect human movements by using the HFM. First, the HFM based on the observed human position has been described with the sensors mounted on the environment. By using the HFM, the major pathway in the environment was calculated and the route from a start to the given goal was found. Then, the information of the human frequency and the pathway width were used as the evaluated value to select the best path. Finally, we confirmed that the robot can navigate according to four different paths given by the HFM at one time zone.

Abstract: A holonomic omnidirectional mobile robot is well known for a high mobility and capability in maneuvering. In our approach, the holonomic omnidirectional mobile robot was developed using two active dual-wheel caster assemblies with conventional tires. In this paper, we are focusing on the stability issues in the tipping problem that may occur in the existing of static and dynamic environments. We derive the dynamic model of the omnidirectional mobile robot to estimate the supporting force at each wheel and evaluate it through simulations.

Keywords: Tip-over, Roll-over, Stability, Balancing

1 INTRODUCTION

Tipping stability is an important concern for vehicles, especially for those related to a human driver or passenger. In most cases, the failure in instability monitoring and prevention could cause a catastrophic incident which leads to major injuries to the human and property losses. Most of the mobile robots constructed with more than two wheels configuration were statically stable. However, the mobile robots begin to be unstable when they are starting to operate in a high speed, making a sudden acceleration or deceleration (braking), turning in speed or operating in a slopped terrain. Mobile robots with higher center of gravity (CoG) and heavier mass possess higher possibility to tip-over or roll-over in a dynamic motion environment.

Most of the stability studies in wheeled mobile robotics were related to the two wheeled differential drive mobile robot [1] and four wheeled mobile robot [2]. There is also a few studies related to the omnidirectional mobile robots [3], but the study was mainly discussing on the conventional omnidirectional mechanism which uses some combination of the universal wheels. Most of these wheeled mobile robots also have a fixed wheel arrangements. Therefore, the shape of the support polygon was maintained all the time. In our approach, the supporting polygon will keep changing according to the trajectory path due to the changing of orientation for both active dual-wheel casters.

The existing study of stability focuses on the CoG projection [4, 5], static stability margin [6] and energy stability margin [7]. These stability studies belong to the class of quasi-static stability where in addition to the assumption of slow motion relative to the inertial frame, it was assumed that there were no inertial accelerations except for gravitational acceleration. However, in reality the inertial acceleration exists and it is possible to cause the mobile robot to tip-over. Therefore, in this paper a model of the omnidirectional mobile robot with active dual-wheel caster assemblies (ADWC) is presented to investigate both static and dynamic effects on the tipping stability. The model presented here is an extended one to the previous study of planar dynamics by Yamada et al [8]. Here, we derived the vertical dynamical model for the omnidirectional mobile robot with the existing of human passenger especially for the roll and pitch stability control. In our model, the omnidirectional mobile robot is assumed to be stable in a static condition due to the wide geometric footprint. The dynamics were derived using the Newtonian and D'Alembert principles to compute the instantaneous normal forces acting on the wheels, according to the current state of the caster's configuration.

2 OMNIDIRECTIONAL MOBILE ROBOT

The mobile robot used in this research is a holonomic omnidirectional mobile robot with active dual-wheel caster assemblies as shown in Fig. 1. A couple of active dual-wheel caster assemblies are arranged in a longitudinal direction. Each caster can generate velocity in the forward direction (X_i-axis) and sideway direction (Y_i-axis) of the passive steering axis which is caused by the differences in angular velocity of the right- and left-wheels. The existing of these velocities induces a holonomic motion to the center of the mobile robot, O where the velocity in X-axis, $\dot{x}$, velocity in Y-axis, $\dot{y}$ and the instantaneous rotation at Z-axis, ϕ were produced.

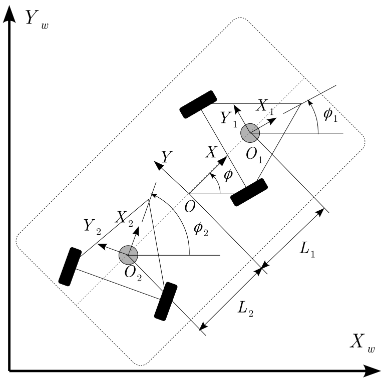

Fig. 1. Omnidirectional mobile robot with active dual-wheel caster assemblies

3 DERIVATION OF DYNAMICAL MODEL

The goal of this section is to derive a relationship between the dynamics of omnidirectional mobile robot and the normal forces acting on each wheel. In order to derive this relationship, we will make the following assumptions: (i) the mobile robot can operate in omnidirectional direction with the holonomic motion of $[\dot{x}\ \dot{y}\ \dot{\phi}]$, (ii) there is no additional motion in any direction; therefore, the mobile robot is kept in a stabilizing condition, i.e., equilibrium of moments.

3.1 Normal Forces Acting on Each Wheel

Let us consider the dynamical model as shown in Fig. 2 and Fig. 3 as our reference. Here, we assumed that the upper part of the vehicle includes the seat, passenger and the mobile platform as a single mass. We first calculate the normal forces at the steering axis of both dual-wheel casters and find its relationship to the supporting forces at each contact point of the wheel with the ground. The nomenclatures are as follows:

M_a	mass of the driver, seat and mobile platform, i.e., the total mass of upper vehicle
m_i	mass of the i-th dual-wheel caster
L_i	distance between i-th steering axis and CoG of the mass M_a
N_i	normal forces acting on steering axis
h_{M_a}	height of CoG of the mass M_a
h_{si}	height of steering axis
h_{mi}	height of CoG of the dual-wheel caster
$\ddot{x}, \ddot{y}$	accelerations at CoG of the mass M_a
$\ddot{x}_{gi}, \ddot{y}_{gi}$	accelerations at CoG of dual-wheel caster
g	gravitational acceleration
f_{xi}, f_{yi}	force acting on steering axis in Σ_w
${}^if_{xi}, {}^if_{yi}$	force acting on steering axis in Σ_i
f_{xri}, f_{xli}	driving forces of the wheel
f_{yri}, f_{yli}	sideway forces of the wheel
f_{zri}, f_{zli}	normal forces of the wheel
I	moment of inertia of the upper part of the vehicle

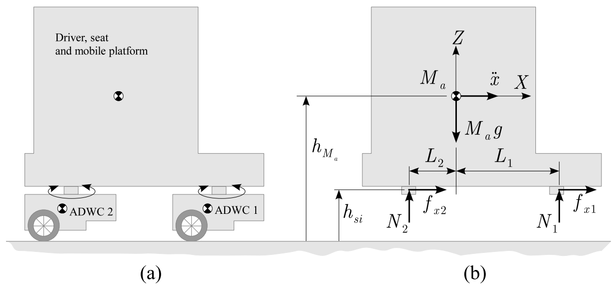

Fig. 2. Dynamical model of the omnidirectional mobile robot: (a) Single mass model, (b) Dynamics of upper part

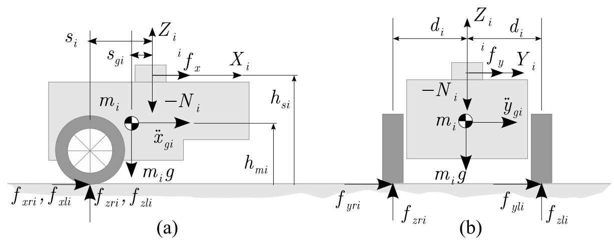

Fig. 3. Dynamical model of ADWC assemblies: (a) Side view (X_iZ_i-frame), (b) Front view (Y_iZ_i-frame)

Using the above mentioned assumptions, we can derive the following relation by applying Newton's motion of law for linear motion in x-, y- and z-direction and equilibrium of moments around x- and y-axis:

$$f_{zri} = \frac{1}{s_{ai}}H_{ai} - \frac{1}{2d_i}H_{bi} + \frac{1}{2s_{ai}}H_{ci} \tag{1}$$

$$f_{zri} = \frac{1}{s_{ai}}H_{ai} + \frac{1}{2d_i}H_{bi} + \frac{1}{2s_{ai}}H_{ci} \tag{2}$$

where,

$$\begin{aligned}
H_{ai} &= {}^if_x h_{ci} + m_i \ddot{x}_{gi} h_{mi} \\
H_{bi} &= {}^if_y h_{si} + m_i \ddot{y}_{gi} h_{mi} \\
H_{ci} &= N_i s_{bi} - m_i g s_{ai} \\
s_{ai} &= s_i - s_{gi} \\
s_{bi} &= s_i + s_{gi} \\
h_{ci} &= 2h_{mi} - h_{si}
\end{aligned}$$

Here, the value of N_i can be calculated from Fig. 2(b) as:

$$N_1 = \frac{1}{L}(M_a g L_2 - M_a \ddot{x} h_a) \tag{3}$$

$$N_2 = \frac{1}{L}(M_a g L_1 + M_a \ddot{x} h_a) \tag{4}$$

where, $L = L_1 + L_2$ and $h_a = h_{M_a} - h_{si}$.

Therefore, defining $\boldsymbol{f}_{zi} = [f_{zri}\ f_{zli}]^T$, ${}^i\boldsymbol{f} = [{}^if_x\ {}^if_y]^T$, ${}^i\ddot{\boldsymbol{x}}_{gi} = [\ddot{x}_{gi}\ \ddot{\phi}_i]^T$ and $\ddot{\boldsymbol{x}} = [\ddot{x}\ \ddot{y}\ \ddot{z}]^T$, the following equation is obtained by combining Eqs. (1)–(4) and replacing $\ddot{y}_{gi}$ with the time derivative of the non-holonomic constraint, $\ddot{y}_{gi} = s_{gi}\ddot{\phi}_i$.

$$\boldsymbol{f}_{zi} = \boldsymbol{A}_i {}^i\boldsymbol{f} + \boldsymbol{B}_i {}^i\ddot{\boldsymbol{x}}_{gi} + \boldsymbol{C}_i \ddot{\boldsymbol{x}} + \boldsymbol{D}_i \tag{5}$$

where,

$$\boldsymbol{A}_i = \begin{bmatrix} \frac{h_{ci}}{s_{ai}} & -\frac{h_{si}}{2d_i} \\ \frac{h_{ci}}{s_{ai}} & \frac{h_{si}}{2d_i} \end{bmatrix}, \boldsymbol{B}_i = m_i h_{mi} \begin{bmatrix} \frac{1}{s_{ai}} & -\frac{s_{gi}}{2d_i} \\ \frac{1}{s_{ai}} & \frac{s_{gi}}{2d_i} \end{bmatrix}$$

$$\boldsymbol{C}_1 = \begin{bmatrix} c_1 & 0 & 0 \\ c_1 & 0 & 0 \end{bmatrix}, \boldsymbol{C}_2 = \begin{bmatrix} -c_2 & 0 & 0 \\ -c_2 & 0 & 0 \end{bmatrix}, c_i = \frac{s_{bi} M_a h_a}{2 s_{ai} L}$$

$$\boldsymbol{D}_1 = \begin{bmatrix} \frac{s_{b1} M_a g L_2}{2 s_{a1} L} + \frac{m_1 g}{2} \\ \frac{s_{b1} M_a g L_2}{2 s_{a1} L} + \frac{m_1 g}{2} \end{bmatrix}, \boldsymbol{D}_2 = \begin{bmatrix} \frac{s_{b2} M_a g L_1}{2 s_{a2} L} + \frac{m_2 g}{2} \\ \frac{s_{b2} M_a g L_1}{2 s_{a1} L} + \frac{m_2 g}{2} \end{bmatrix}$$

Then, introducing the coordinate transformation matrix from Σ_i to Σ_w as ${}^w\boldsymbol{T}_i$, defining the normal force vector $\boldsymbol{f}_z = [\boldsymbol{f}_{z1}^T \ \boldsymbol{f}_{z2}^T]^T$ for the wheel, setting $\boldsymbol{f}_w = [\boldsymbol{f}_{w1}^T \ \boldsymbol{f}_{w2}^T]^T$, and $\ddot{\boldsymbol{x}}_g = [{}^1\ddot{\boldsymbol{x}}_{g1}^T \ {}^2\ddot{\boldsymbol{x}}_{g2}^T]^T$ gives

$$\boldsymbol{f}_z = \boldsymbol{A}\boldsymbol{f} + \boldsymbol{B}\ddot{\boldsymbol{x}}_g + \boldsymbol{C}\ddot{\boldsymbol{x}} + \boldsymbol{D} \tag{6}$$

where,

$$\boldsymbol{A} = \begin{bmatrix} \boldsymbol{A}_1 {}^w\boldsymbol{T}_1^T & \boldsymbol{0}_{2\times2} \\ \boldsymbol{0}_{2\times2} & \boldsymbol{A}_2 {}^w\boldsymbol{T}_2^T \end{bmatrix}, {}^w\boldsymbol{T}_i = \begin{bmatrix} \cos\phi_i & -\sin\phi_i \\ \sin\phi_i & \cos\phi_i \end{bmatrix}$$

$$\boldsymbol{B} = \begin{bmatrix} \boldsymbol{B}_1 & \boldsymbol{0}_{2\times2} \\ \boldsymbol{0}_{2\times2} & \boldsymbol{B}_2 \end{bmatrix}, \boldsymbol{C} = \begin{bmatrix} \boldsymbol{C}_1 \\ \boldsymbol{C}_2 \end{bmatrix}, \boldsymbol{D} = \begin{bmatrix} \boldsymbol{D}_1 \\ \boldsymbol{D}_2 \end{bmatrix}$$

Also the dynamic property for the omnidirectional mobile robot also can be described as:

$$\boldsymbol{M}\ddot{\boldsymbol{x}} = \boldsymbol{E}\boldsymbol{f} \tag{7}$$

where,

$$\boldsymbol{M} = \text{diag}(M_a, M_a, I)$$

$$\boldsymbol{E} = \begin{bmatrix} 1 & 0 & 1 & 0 \\ 0 & 1 & 0 & 1 \\ -L_1\sin\phi & L_1\cos\phi & L_2\sin\phi & -L_2\cos\phi \end{bmatrix}$$

Inserting the inverse equation of Eq. (7) into Eq. (6) yields

$$\boldsymbol{f}_z = \boldsymbol{A}\boldsymbol{E}^*\boldsymbol{M}\ddot{\boldsymbol{x}} + \boldsymbol{B}\ddot{\boldsymbol{x}}_g + \boldsymbol{C}\ddot{\boldsymbol{x}} + \boldsymbol{D} \tag{8}$$

where $\boldsymbol{E}^*$ denotes the pseudoinverse of matrix $\boldsymbol{E}$ as described by

$$\boldsymbol{E}^* = \frac{1}{L}\begin{bmatrix} L_2 + \alpha_{cc}(\phi) & \alpha_{sc}(\phi) & -\sin\phi \\ \alpha_{sc}(\phi) & L_2 + \alpha_{ss}(\phi) & \cos\phi \\ L_1 - \alpha_{cc}(\phi) & -\alpha_{sc}(\phi) & \sin\phi \\ -\alpha_{sc}(\phi) & L_1 - \alpha_{ss}(\phi) & -\cos\phi \end{bmatrix}$$

$$\alpha_{ss}(\phi) = \tfrac{1}{2}(L_1 - L_2)\sin^2\phi$$
$$\alpha_{sc}(\phi) = \tfrac{1}{2}(L_1 - L_2)\sin\phi\cos\phi$$
$$\alpha_{cc}(\phi) = \tfrac{1}{2}(L_1 - L_2)\cos^2\phi$$

Also the relationship between ${}^i\dot{\boldsymbol{x}}_{gi}$ and $\dot{\boldsymbol{x}}_i$ can be written as

$${}^i\dot{\boldsymbol{x}}_{gi} = \boldsymbol{F}_i\dot{\boldsymbol{x}}_i \tag{9}$$

where,

$$\boldsymbol{F}_i = \begin{bmatrix} \cos\phi_i & \sin\phi_i \\ -\frac{1}{s_i}\sin\phi_i & \frac{1}{s_i}\cos\phi_i \end{bmatrix}$$

Letting $\boldsymbol{x}_a = [\boldsymbol{x}_1^T \ \boldsymbol{x}_2^T]^T$ and referring to Eq. (9), the following equation is satisfied:

$$\dot{\boldsymbol{x}}_g = \boldsymbol{F}\dot{\boldsymbol{x}}_a \tag{10}$$

where,

$$\boldsymbol{F} = \begin{bmatrix} \boldsymbol{F}_1 & \boldsymbol{0}_{2\times2} \\ \boldsymbol{0}_{2\times2} & \boldsymbol{F}_2 \end{bmatrix}$$

Meanwhile, from the inverse kinematics equation [8] we obtained:

$$\dot{\boldsymbol{x}}_a = \boldsymbol{G}^*\dot{\boldsymbol{x}} \tag{11}$$

where,

$$\boldsymbol{G}^* = \begin{bmatrix} 1 & 0 & -L_1\sin\phi \\ 0 & 1 & L_1\cos\phi \\ 1 & 0 & L_2\sin\phi \\ 0 & 1 & -L_2\cos\phi \end{bmatrix}$$

Combining Eqs. (10) and (11) gives

$$\dot{\boldsymbol{x}}_g = \boldsymbol{F}\boldsymbol{G}^*\dot{\boldsymbol{x}} \tag{12}$$

Hence differentiating Eq. (12) with respect to time, we obtain

$$\ddot{\boldsymbol{x}}_g = (\dot{\boldsymbol{F}}\boldsymbol{G}^* + \boldsymbol{F}\dot{\boldsymbol{G}}^*)\dot{\boldsymbol{x}} + \boldsymbol{F}\boldsymbol{G}^*\ddot{\boldsymbol{x}} \tag{13}$$

Replacing Eq. (13) into Eq. (8) and rearranging the equation yields

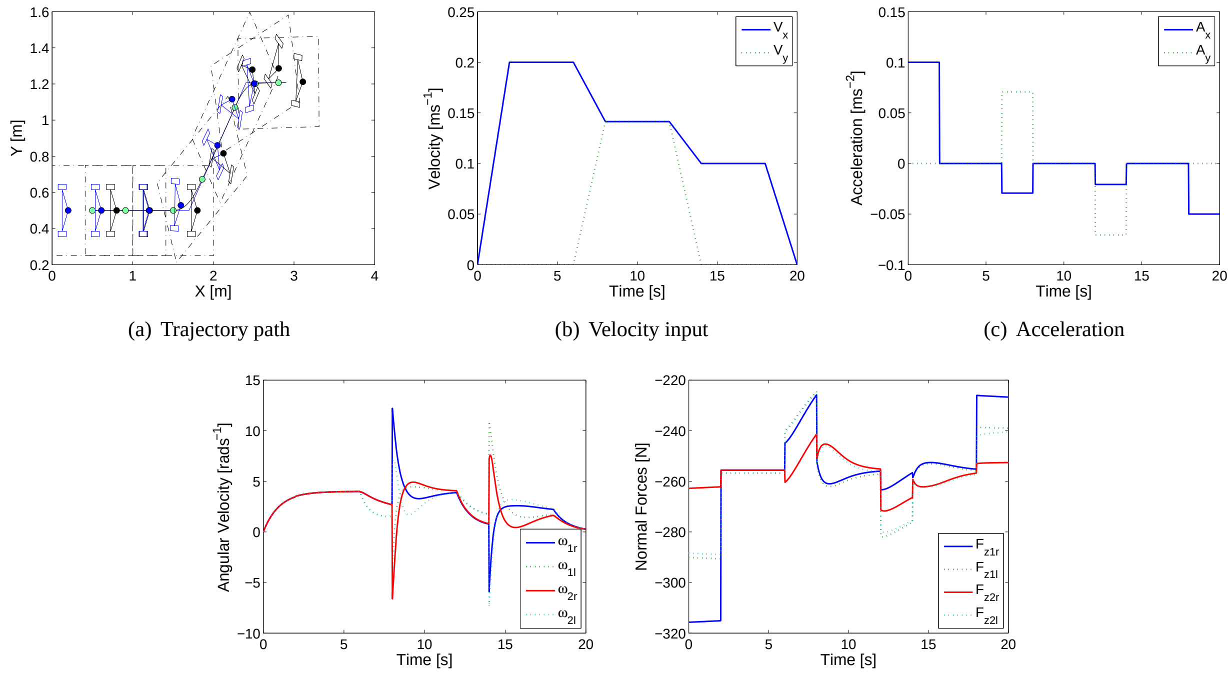
$$\boldsymbol{f}_z = \boldsymbol{K}'\dot{\boldsymbol{x}} + \boldsymbol{K}''\ddot{\boldsymbol{x}} + \boldsymbol{D} \tag{14}$$

where,

$$\boldsymbol{K}' = \boldsymbol{B}(\dot{\boldsymbol{F}}\boldsymbol{G}^* + \boldsymbol{F}\dot{\boldsymbol{G}}^*)$$
$$\boldsymbol{K}'' = \boldsymbol{A}\boldsymbol{E}^*\boldsymbol{M} + \boldsymbol{B}\boldsymbol{F}\boldsymbol{G}^* + \boldsymbol{C}$$

4 SIMULATION RESULTS

The simulation time was 20 s, sampling period 20 ms, the initial pose of the omnidirectional mobile robot was $\boldsymbol{x} = [0 \ 0 \ 0]^T$ and the initial orientation of each dual-wheel caster is set to 0 rad. The reference trajectory was a straight line, whose gradient was 0 rad for the first 8 s, $\pi/4$ rad for 6 s and 0 rad for the rest. This simulation was conducted under the resolved velocity control [9]. The mobile robot is set to move from a stationary position to the velocity of 0.2 ms^{-1}, changing to 0.1 ms^{-1} after 14 s and stop at the time of 20 s. The purpose of this simulation was to estimate the supporting forces according to the given dynamics effect. Physical parameters are listed in Table 1.



(a) Trajectory path (b) Velocity input (c) Acceleration

(d) Angular velocity of the wheel (e) Supporting forces

Fig. 4. Simulation results

Table 1. Physical parameters

d_1, d_2	0.13	[m]	r_1, r_2	0.05	[m]
s_1, s_2	0.075	[m]	s_{g1}, s_{g2}	0.0595	[m]
I_1, I_2	0.103	[kgm^2]	I	12.708	[kgm^2]
M_a	122	[kg]	m_1, m_2	6.5	[kg]
L_1, L_2	0.3	[m]	h_{M_a}	0.7	[m]
h_{s1}, h_{s2}	0.4	[m]	h_{m1}, h_{m2}	0.15	[m]

Presented in Fig. 4 is the result of the conducted simulation for estimating the supporting forces. The negative value of the force shows that the ground is supporting the load from the wheel with the same amount of force. Tipping instability may only occur when the value of the force is approaching zero which also increasing the tendency of the wheel to be lifted from the ground.

5 CONCLUSION AND FUTURE WORKS

In this paper, we have derived the vertical dynamics equation of the holonomic omnidirectional mobile robot with active dual-wheel caster assemblies. These equations have been verified through the MATLAB simulation but need to be compared with the real data. This study is the preliminary study which we would be implemented with higher techniques in the near future.

Abstract: This paper proposes an uscented transformation for a FastSLAM framework. The unscented transformation is used to estimate robot's poses in conjuction of generic particle filter used in standard FastSLAM framework. This method can estimate robot's poses more consistently and accurately than the use of single standard particle filters, especially when involving highly nonlinear models or non-Gaussian noises. In addition, our algorithm avoids the calculation of the Jacobian for motion model which could be extremely difficult for high order systems. Simulation results are shown to validate the performance goals.

Keywords: Unscented transformation, SLAM, FastSLAM.

1 INTRODUCTION

SLAM solves the problem of building a map and then recovering the robot pose with observations obtained from sensors mounted on the robot. The robot senses its own motion and at the same time identifies nearby landmarks. The SLAM problem can be presented as a probabilistic process known as a Markov process [5]. In particular, the robot motion is usually considered as a Markov process. The robot's pose at time t will be denoted by x_t. The robot's environment possesses N static landmarks. Each landmark is denoted by θ_k for $k = 1, \ldots, N$. The set of all landmarks will be denoted by θ.

SLAM algorithms calculate the posterior over the entire path along with the map such as

$$p\left(x^t, \theta \mid z^t, u^t, n^t\right) \tag{1}$$

where the path of the robot is denoted by $x^t = x_1, \ldots, x_t$, $z^t = z_1, \ldots, z_t$ is a sequence of measurements and $u^t = u_1, \ldots, u_t$ is a sequence of control inputs. The variables $n^t = n_1, \ldots, n_t$ are data association variables, in which each n_t specifies the identity of the landmark observed at time t. To compute the posterior in Eq. (1), the evolution of poses according to a probabilistic law is commonly referred to as a nonlinear motion model $p\left(x_t \mid x_{t-1}, u_t\right)$. The current pose x_t is a probabilistic function of the robot control u_t and the previous pose x_{t-1}. As the robot moves around, it takes measurements of its environment. Moreover, sensor measurements are governed by a probabilistic law referred to as a nonlinear measurement model $p\left(z_t \mid x_t, \theta, n_t\right)$.

In recent years, many research on SLAM was originated from a seminal paper by Smith and Cheesman [6], in which the use of the extended Kalman fillter (EKF) was proposed for solving SLAM and it was firstly implemented by [7].

However, there are two limitations of the EKF approach. One is the high computational cost to maintain a multivariate Gaussian vector which requires quadratic time in the dimension of the map. Therefore, it was proposed in [4, 8] to build a set of smaller maps and then combined them to build a large one. The other is related to the data association problem. It is critical to choose the correct data association hypotheses because different data association hypotheses lead to different maps. Maintaining posteriors over multiple data associations makes the SLAM algorithms more robust. Unfortunately, Gaussian distributions cannot represent multi-modal ones, so only the most likely data association can be incorporated. As a result, the approach tends to fail catastrophically when the incorporated data association is incorrect.

Another family of SLAM algorithms is called FastSLAM [2]. It was pointed out in [9] that the errors of the feature estimates would be independent if a robot path was given. This property is a base of FastSLAM algorithms to solve the SLAM problems. Particle filters are used to estimate the robot path. Conditioned on these particles, the mapping problem is factored into separate problems. Therefore, one EKF for each feature is used to update the feature estimate.

However, the standard FastSLAM frameworks used an EKF to improve the accuracy of a proposal distribution, but the EKF involves Jacobian matrices and the linear approximations of the nonlinear functions. Calculating the Jacobian is unwelcome effort, and inaccurate approximation to the posterior covariance deteriorates the estimate accuracy and the filter consistency. Therefore, in this paper we introduce an unscented transformation in the FastSLAM framework to eliminate the linearization as well as the Jacobian calculation.

The structure of this paper is as follows. In section 2 we generally describe about the FastSLAM framework and present the unscented transformation for the FastSLAM. A simulation setup for a SLAM problem is shown in section 3, as well as discussion on the simulation results. The paper is concluded in section 4.

2 FASTSLAM FRAMEWORK

2.1 Introduction to FastSLAM algorithm

The FastSLAM algorithm, introduced by Montemerlo et al. [1], is an efficient algorithm for the SLAM problem that is based on a straightforward factorization. This algorithm partitions the SLAM posterior in Eq. (1) into a localization problem and an independent landmark position estimation problem conditioned on the robot's pose estimate. It can be shown in the following form:

$$\begin{aligned} & p\left(x^t, \theta \mid z^t, u^t, n^t\right) \\ & = p\left(x^t \mid z^t, u^t, n^t\right) \prod_{k=1}^{N} p\left(\theta_k \mid x^t, z^t, u^t, n^t\right) \end{aligned} \tag{2}$$

This factorization is a fundamental idea behind the FastSLAM [9]. The FastSLAM uses a particle filter to approximate a recursive Bayesian filter for estimating the robot's poses. Each particle in the FastSLAM is formed as $X_t^{[m]} = \left\langle x_t^{[m]}, \mu_{1,t}^{[m]}, \Sigma_{1,t}^{[m]}, \ldots, \mu_{N,t}^{[m]}, \Sigma_{N,t}^{[m]} \right\rangle$ where the superscript $[m]$ indicates the index of the particle, $x_t^{[m]}$ is its path estimate, and $\mu_{k,t}^{[m]}$ and $\Sigma_{k,t}^{[m]}$ are the mean and covariance of the Gaussian vector, representing the kth landmark location attached to the mth particle.

There are two versions of FastSLAM, named as FastSLAM1.0 and FastSLAM2.0. In the FastSLAM2.0, the robot poses are sampled under the consideration of both the control u_t and the measurement z_t, while in the FastSLAM1.0, this consideration is based on only the motion control u_t. As a result, the FastSLAM2.0 is superior to the FastSLAM1.0 in all aspects [3]. The weight of each sample used in the resampling step is called the importance weight, which is denoted by $w_t^{[m]}$ and given by

$$\begin{aligned} w_t^{[m]} &= \frac{\text{target distribution}}{\text{proposal distribution}} \\ &= \frac{p\left(x^{t,[m]} | z^t, u^t, n^t\right)}{p\left(x^{t-1,[m]} | z^{t-1}, u^{t-1}, n^{t-1}\right) p\left(x_t^{[m]} | x^{t-1,[m]}, z^t, u^t, n^t\right)} \end{aligned}$$

For a complete derivation of the importance weight in the FastSLAM2.0, see [1] and [3].

Using a particle filter along with an EKF for robot pose estimation contains the linearization errors, and so that it may be prevented from a successful data association and cannot make an accurate map. To solve these problems, we propose the unscented transformation for robot's poses to the FastSLAM framework in the following section.

2.2 An unscented transformation for a FastSLAM framework

In general, the FastSLAM2.0 framework consists of three parts: the robot state estimation, the feature state estimation, and the importance weight calculation. In this section, the unscented transformation to the first part is discussed in detail. The last two parts still remain unchanged as applying to FastSLAM2.0. On our mind, the first part is crucial to develop accurate maps as well as to reduce overall computational cost.

Instead of linearinzing the nonlinear models through the 1st-order Taylor series expansion at the mean of the robot state, the proposed method introduces a set of deterministic points known as sigma points to propagate them through nonlinear model [11]. Since an observation is not always detected, constructing the proposal distribution and sampling from this prior have two steps. One is the prediction step and the other is the measurement update step. At first, the state vector is augmented with a control input and the observation

$$x_{t-1}^{a[m]} = \begin{bmatrix} x_{t-1}^{[m]} \\ 0 \\ 0 \end{bmatrix}, \quad P_{t-1}^{a[m]} = \begin{bmatrix} P_{t-1}^{[m]} & 0 & 0 \\ 0 & Q_t & 0 \\ 0 & 0 & R_t \end{bmatrix}$$

Here, $x_{t-1}^{a[m]}$ and $P_{t-1}^{a[m]}$ are the augmented vector for the state and related covariance, respectively. $x_{t-1}^{[m]}$ is the previous mean of the robot as well as it covariance, $P_{t-1}^{[m]}$. Q_t and R_t are the control noise covariance and the measurement noise covariance, respectively.

A symmetric set of $2L+1$ sigma points $\chi_{t-1}^{a[i][m]}$ for the augmented state vector can be calculated as

$$\chi_{t-1}^{a[i][m]} = \left[x_{t-1}^{a[m]} \ \cdots \ x_{t-1}^{a[m]}\right] + \gamma \left[0 \ \sqrt{P_{t-1}^{a[m]}} \ -\sqrt{P_{t-1}^{a[m]}} \right]$$

where $\gamma = \sqrt{L+\lambda}$ and L is the augmented state vector dimension. The $\lambda = \alpha^2 (L+\kappa) - L$ and α $(0 < \alpha < 1)$ should be a small number to avoid sampling nonlocal effects when the nonlinearities are strong. κ is a scaling parameter that determines how far the sigma points are separated from the mean and a good default choice is $\kappa = 0$ [11]. The set of sigma points $\chi_{t-1}^{a[i][m]}$ is then propagated through the motion model $\mathbf{f}(\cdot)$ given by

$$\bar{\chi}_t^{[i][m]} = \mathbf{f}\left(\chi_t^{[i][m]}, \chi_t^{u[i][m]}\right) \tag{3}$$

Here, $\bar{\chi}_t^{[i][m]}$ is the transformed sigma points of the robot state. $\chi_t^{[i][m]}$ and $\chi_t^{u[i][m]}$ are the part of augmented sigma points related to the robot poses and control component, respectively. The first two moments of the predicted robot state are computed by the following equations:

$$x_{t|t-1}^{[m]} = \sum_{i=0}^{2L} w_m^i \bar{\chi}_t^{[i][m]} \tag{4}$$

$$P_{t|t-1}^{[m]} = \sum_{i=0}^{2L} w_c^i \left(\bar{\chi}_t^{[i][m]} - x_{t|t-1}^{[i][m]}\right) \left(\bar{\chi}_t^{[i][m]} - x_{t|t-1}^{[i][m]}\right)^T \tag{5}$$

where the constant weights w_m^i and w_c^i are parameters related to computing mean and covariance given as follows [11]:

$$w_m^0 = \frac{\lambda}{(L+\lambda)}, \quad w_c^0 = w_m^0 + \left(1 - \alpha^2 + \beta\right)$$
$$w_m^i = w_c^i = \frac{1}{2(L+\lambda)}, \qquad i = 1, 2, \ldots, 2L$$

Here, the parameter β is used to incorporate the knowledge of the higher order moments of the posterior distribution.

As some features are observed, the data association provides their identities, and the updating step can be performed. The measurement sigma points $\bar{Z}_t^{[i][m]}$ are calculated using the observation model $\mathbf{h}(\cdot)$, function of sigma points of robot poses $\bar{\chi}_t^{[i][m]}$ and measurement noise $\chi_t^{z[i][m]}$ given belows:

$$\bar{Z}_t^{[i][m]} = \mathbf{h}\left(\bar{\chi}_t^{[i][m]}, \chi_t^{z[i][m]}\right) \tag{6}$$

Then, the measurement mean $\hat{\mu}_t^{[m]}$, covariance $S_t^{[m]}$, and cross covariance $\Sigma_t^{x,n[m]}$ as well as the Kalman gain $K_t^{[m]}$ can be computed as follows:

$$\hat{\mu}_t^{[m]} = \sum_{i=0}^{2L} w_m^{[i]} \bar{Z}_t^{[i][m]} \tag{7}$$

$$S_t^{[m]} = \sum_{i=0}^{2L} w_c^{[i]} \left(\bar{Z}_t^{[i][m]} - \hat{\mu}_t^{[m]}\right) \left(\bar{Z}_t^{[i][m]} - \hat{\mu}_t^{[m]}\right)^T \tag{8}$$

$$\Sigma_t^{x,n[m]} = \sum_{i=0}^{2L} w_c^{[i]} \left(\bar{\chi}_t^{[i][m]} - x_{t|t-1}^{[m]}\right) \left(\bar{Z}_t^{[i][m]} - \hat{\mu}_t^{[m]}\right)^T \tag{9}$$

$$K_t^{[m]} = \Sigma_t^{x,n[m]} \left(S_t^{[m]}\right)^{-1} \tag{10}$$

The estimated mean and its covariance of the robot state at time t are calculated by

$$x_t^{[m]} = x_{t|t-1}^{[m]} + K_t^{[m]} \left(z_t - \hat{\mu}_t^{[m]}\right) \tag{11}$$

$$P_t^{[m]} = P_{t|t-1}^{[m]} - K_t^{[m]} S_t^{[m]} \left(K_t^{[m]}\right)^T \tag{12}$$

3 EXPERIMENTS

In order to verify the performance of the proposed framework, some experiments were conducted using simulation data with 20 feature landmarks and known data association. The simulator was developed based on the work in [10]. The exploration area of the robot is 40 meters wide and 100 meters long, and the landmarks are randomly located in the area.

Fig. 1 shows the landmark and true robot trajectory setup for this simulation. The robot starts at the initial pose (0 m, 0 m, 0°) and travels with a nominal speed and a steering angle of 3 m/s and 30°, respectively. The nominal control values are corrupted with Gaussian noises with standard deviations 0.3 m/s and 3°, respectively for each 0.025 s sampling interval. The sensor takes measurements for each 0.2 s time interval and the nominal measurement values are also assumed to be corrupted with Gaussian noises with standard deviations 0.1 m and 1°, respectively. In this simulation, we set the number of particles equal to 100 for both estimators.

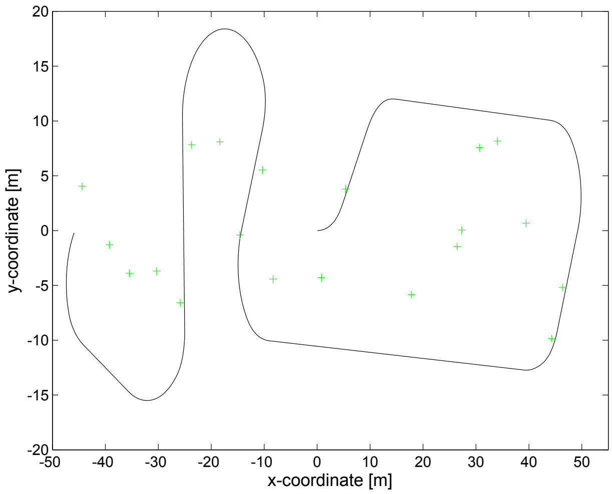

Fig. 1. True trajectory and landmark.

3.1 Motion Model and Observation Model

In our experiments, the motion model of the robot is assumed to be described as follows:

$$\begin{bmatrix} x_{t+1} \\ y_{t+1} \\ \phi_{t+1} \end{bmatrix} = \begin{bmatrix} x_t + V \cdot dt \cdot \cos(G + \phi_t) \\ y_t + V \cdot dt \cdot \sin(G + \phi_t) \\ \phi_t + \frac{V \cdot dt}{l} \cdot \sin(G) \end{bmatrix}$$

where x_t, y_t and ϕ_t are the vehicle position coordinates and its orientation in time step t, respectively. V is the vehicle velocity, and G is the vehicle steering angle. A parameter l is the vehicle wheel-base.

This vehicle is equipped with a range and bearing sensor. It can sense an object bounding in ± 30 degree semi-circle with the maximum range of 30 meter. The measurement equation is as follows:

$$\begin{aligned} \mathbf{z}_t &= \mathbf{h}(x_t, f_i) + \mathbf{w}_t \\ &= \begin{bmatrix} \sqrt{(f_{i,x} - x_t)^2 + (f_{i,y} - y_t)^2} \\ \tan^{-1}\left(\frac{f_{i,y} - y_t}{f_{i,x} - x_t}\right) - \phi_t \end{bmatrix} + \mathbf{w}_t \end{aligned}$$

where f_i is a landmark feature available at time when the sensor takes a measurement. This landmark feature is assumed to be static and represented as a Cartesian coordinate system as $(f_{i,x}, f_{i,y})$. $\mathbf{w}_t \sim \mathrm{N}(0, R_t)$ is a zero-mean Gaussian white measurement noise with $R_t = \text{diag}\left(0.1^2,\ 1^2\right)$.

3.2 Experimental Results

Fig. 2 shows the result of the FastSLAM2.0 and the proposed method. It is clear that the proposed method always follows the true trajectory with minimum error.

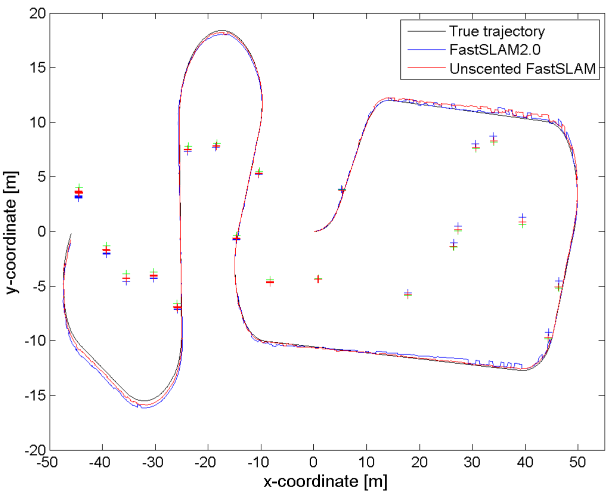

Fig. 2. Estimates by FastSLAM2.0 and unscented FastSLAM.

Furthermore, we then calculated the root mean square (rms) error of x-axis, y-axis, and orientation ϕ. The results of both filtering estimates are shown in Table 1 and it is proved that the unscented FastSLAM has better performance over the original FastSLAM2.0.

Table 1. RMS Errors

Method	x	y	ϕ
FastSLAM2.0	0.00685	0.74290	0.00009
Unscented FastSLAM	0.00357	0.33958	0.0014

4 CONCLUSION

In this paper, an unscented transformation for robot's pose estimation has been applied to a FastSLAM framework and its performance has been also evaluated. The simulation showed that the proposed method gave better estimation, compared to the previous FastSLAM2.0. It was demonstrated by comparing the actual robot trajectories with the FastSLAM2.0 and the unscented FastSLAM. The rms errors of x-axis, y-axis, and robot orientation ϕ proved that the proposed method had better performance over the FastSLAM2.0. In future work, we are focusing on investigating new sampling techniques of unscented transformation aiming for better performances and lowering computational cost.

Abstract: We present a method for pedestrian detection applied to near infrared images. Near infrared ray is invisible, so that near infrared images are useful for surveillance systems day and night under near infrared light. In our method we use histograms of oriented gradient features and support vector machine. Furthermore, we present pedestrian trajectories using mean shift and nearest neighbor methods.

Keywords: surveillance system, pedestrian detection, pedestrian tracking, near infrared image

1 INTRODUCTION

Recently, research and development of surveillance systems are advanced as the heinous crimes increase. However, in present surveillance systems, it is necessary to monitor surveillance images 24 hours a day and a large load rests upon the person. It is very difficult to find crimes in real time. When the crime occurs, we often use the surveillance images later in the confirmatory purpose and the evidence purpose. Therefore, remote monitoring system that can inform us of the crime in the faraway place is needed even if we don't keep monitoring surveillance images. We also need that it records surveillance images and analyzes person action. The most important issue in surveillance systems is pedestrian detection [1], [2]. Pedestrian detection is a difficult task of a machine vision perspective because there is a wide range of possible pedestrian appearance, due to changing pose, clothing, lighting, and background. For pedestrian detection many features have been proposed (e.g. Haar-like features [3], histogram of oriented gradient (HOG) features [4], edgelet features [5]). In this paper, we present a method for pedestrian detection applied to near infrared images. Because near infrared light is invisible, near infrared images are useful for surveillance systems day and night under near infrared light. In this method we use HOG features and support vector machine (SVM). Furthermore, we present pedestrian trajectories using mean shift and nearest neighbor methods.

2 OUTLINE OF OUR APPROACH

Fig.1 shows the flowchart of our method. We use HOG features and a linear SVM classifier for pedestrian detection. We cluster detection windows using mean shift method [6]. Then we integrate the detection windows using nearest neighbor method and we determine pedestrian detection window which has 3 or more integrated detection windows. We track the pedestrian window based on probability of the same pedestrian in the previous image and the present image.

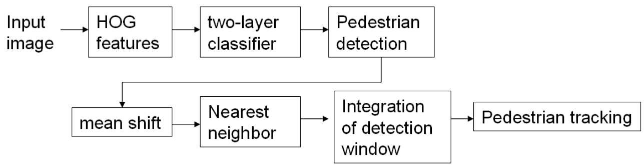

Fig. 1. The flowchart of our method

3 PEDESTRIAN DETECTION

3.1 Histograms of oriented gradients

Histograms of Oriented Gradients (HOG) feature [4] is a gray-level image feature based on a normalized local histograms of image gradient orientations. We divide each detection window in the image is divided into cells of size 8 $\times$ 8 pixels and accumulate a histogram of 9 gradient direction over pixels of the cell. 2$\times$2 cells are integrated into a block in a slide fashion, so that blocks overlap with each other. Thus each block is represented by a 36 dimensional normalized feature vector. Each detection window, which consists of 64$\times$128 pixels, is represented by 7$\times$15 blocks, giving 3780 dimensional feature vector. Then we train a linear SVM classifier using this feature vector. We use INRIA person dataset [7] as training data and test data.

3.2 Two-layer classifier

Pedestrian detection takes about 1 second per image (640$\times$480 pixels) using all the components of 3780 dimensional feature vector. Thus, we investigate amount of overlap between the probability distributions of classifier output values for each block of person and non-person images using Bhattacharyya coefficient. We select some blocks with lower Bhattacharyya coefficient, which have higher contribution to pedestrian detection and obtain lower dimensional feature vector from these blocks. Then we build two-layer classifier, in which the first layer consists of the selected lower dimensional feature vector and the second layer consists of 3780 dimensional feature vector, shown in Fig. 2.

Fig. 3 shows selected 3, 7, and 16 blocks, which means that the person area has higher contribution to pedestrian detection. Detection rates of pedestrian using two-layer classifier of 3 blocks and 105 blocks, 7 blocks and 105 blocks, and 16 blocks and 105 blocks are shown in Fig. 4.

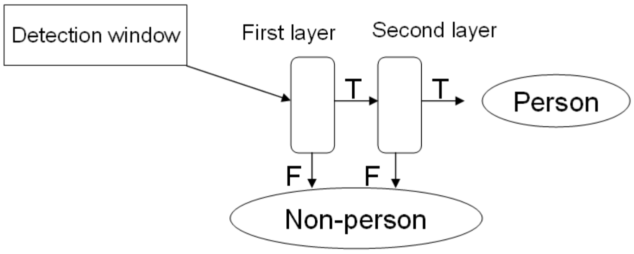

Fig. 2. Two-layer classifier

Fig. 4. Detection performance in visible images
(a) 105 blocks, 3 blocks, 7 blocks and 16blocks
(b) 105 blocks and two-layer (16 and 105 blocks)

3.2 Near infrared images

Near infrared light is invisible so that near infrared images are useful for surveillance systems day and night under near infrared light. Furthermore a near infrared image is a image of reflection light like a visible image. Thus, we can detect pedestrians in the same method as pedestrian detection in visible images. However a near infrared image is a blurred one as compare with a visible image. Therefore detection rate of pedestrian in near infrared images is lower than that in visible images. Fig. 5 shows detection rate of pedestrian in near infrared images.

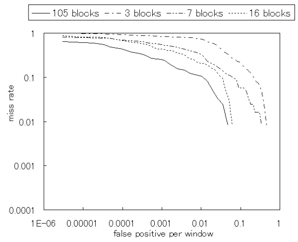

Fig. 5. Detection performance using 105, 3, 7, 16 blocks in near infrared images

4 INTEGRATION OF DETECTION WINDOWS

4.1 Mean shift method

We cluster detection windows using mean shift method [6]. Mean shift is a procedure for locating the maxima of a density of discrete data. We represent discrete data $\{x_i\}_{i=1,\dots,n}$ and use the Gaussian kernel. The mean shift vector Δx_i is weighted mean of the density determined by the kernel as follows:

$$\Delta x_i = \frac{\sum_j x_j \exp\left\{ (x_i - x_j)^2 / h^2 \right\}}{\sum_j \exp\left\{ (x_i - x_j)^2 / h^2 \right\}}$$

and $x_i \rightarrow x_i + \Delta x_i$ until $\Delta x_i <$ threshold.

4.2 Nearest neighbor method

We integrate the detection windows using nearest neighbor method and when the integrated window consists of three or more detection windows, it is considered as pedestrian detection window..

5 TRACKING

We track the pedestrian window based on probability of the same pedestrian in the previous image and the present image.

6 EXPERIMENTS

6.1 Experimental environment

We use a surveillance camera (SM-CKBE51AV, Wireless Tsukamoto Co.) which captures visible and near infrared images in daylight and in near infrared light, respectively. Near infrared floodlight is SM-140-850 (Wireless Tsukamoto Co.) emitting 850nm infrared light. The images are transformed into a digital signal by an A/D converter (ADVC-300, Thomson Canopus) and the signal was input into a computer with an IEEE 1394 interface board (1394-PCI3/DV6, IO Data Device). We used a computer (CPU: Intel Core i7 3.33GHz, main memory: 6 GB, and OS: Windows 7, Microsoft). For programming, we use Microsoft Visual C++ 2008 and Intel OpenCV 2.1 [7], SVM^{light} 6.02 [8].

The surveillance camera is setup at the window on the third floor of the lecture building on the campus of Kyoto Prefectural University and captures pedestrians walking out of door in visible light and near infrared light.

6.2 Condition

We find that there is much incorrect recognition when pedestrian detection is carried out in all the regions of images. Therefore, we setup pedestrian detection region and pedestrian tracking region in images shown in Fig. 6. In the pedestrian detection region, we detect pedestrians. Then we track these pedestrian in the pedestrian tracking region.

The experimental parameters of pedestrian detection are as follows:

(1) visible light images

Scanning step of detection window is 8 pixels in x-direction and 16 pixels in y-direction. SVM classifier thresholds of 105 and 16 blocks are 0.4 and 1.5, respectively.

(2) Near infrared images

Scanning step of detection window is 8 pixels in x-direction and 8 pixels in y-direction. SVM classifier thresholds of 105 and 16 blocks are 0.5 and 1.5, respectively.

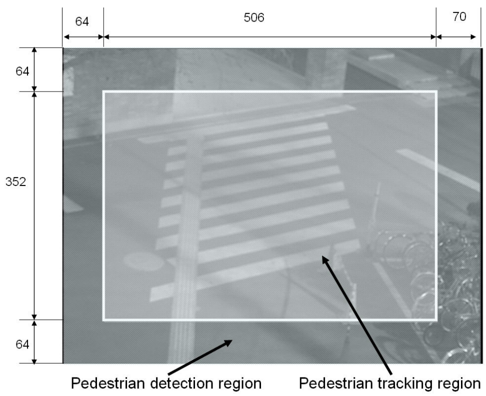

Fig. 6. Pedestrian detection and tracking regions

6.3 Results

The experimental results are shown in Fig. 7 and 8. A white rectangle indicates a pedestrian detection window and a white line indicates a pedestrian tracking. Pedestrian detection and tracking time is shown in Table 1.

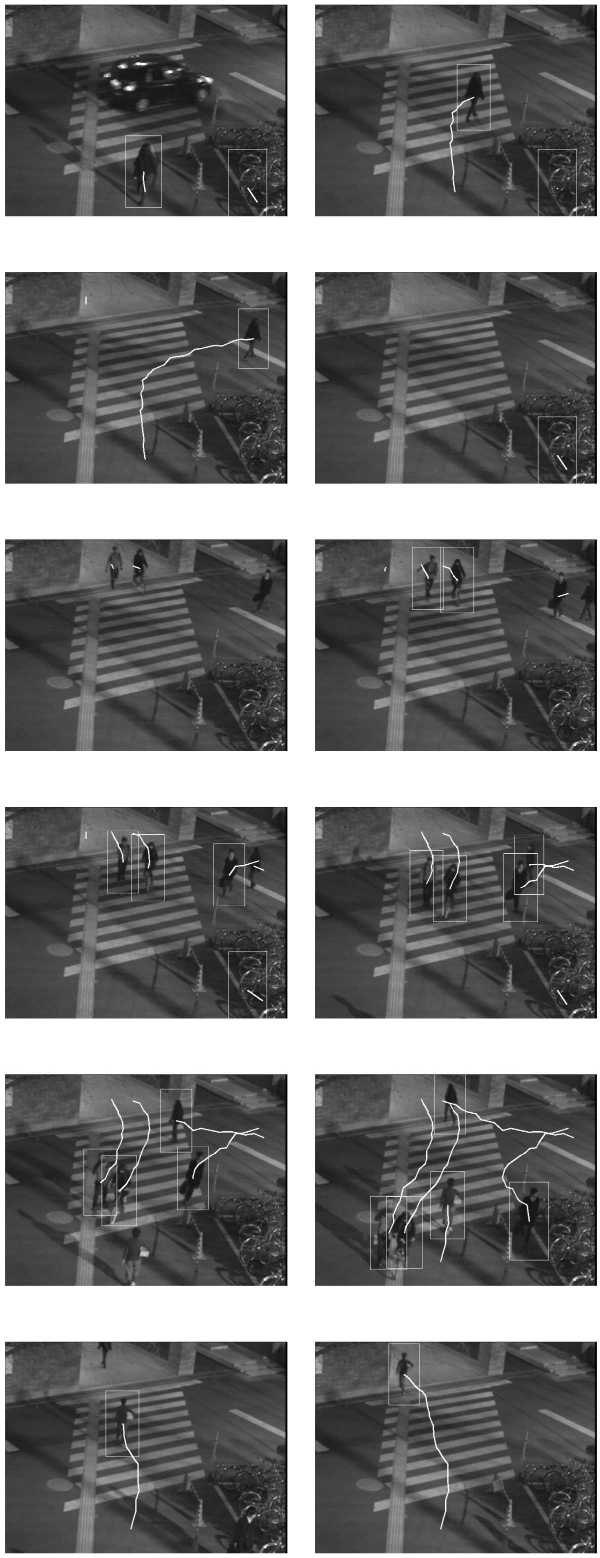

Fig. 7. Pedestrian tracking in visible images

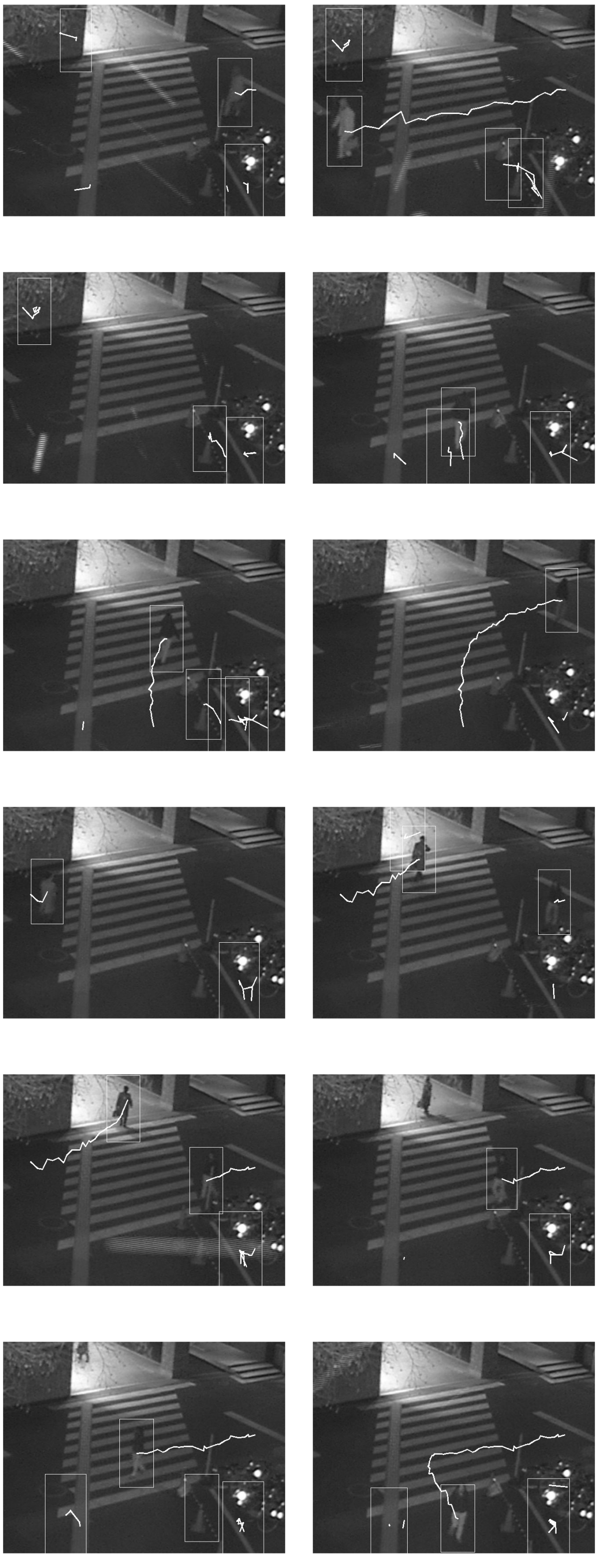

Fig. 8. Pedestrian tracking in near infrared images

Table 1. Pedestrian detection and tracking time in a visible image and in a near infrared image using 105 blocks and two-layer classifier (16 and 105 blocks)

	105 blocks	Two-layer classifier
Visible	453ms	413ms
NIR	960ms	833ms

7 CONCLUSION

In this paper, we present a method for pedestrian detection and tracking applied to visible and near infrared images. Pedestrian detection rates in visible images and near infrared images are 95.7 % and 92.2 %, respectively. In the future we want to reduce incorrect recognition of person detection by improving the person detection method, and to consider the application of those other than a surveillance system.

A system for facial expression recognition of a speaker using front-view face judgment, vowel judgment and thermal image processing

T. Asada, Y. Yoshitomi, and M. Tabuse

Abstract: For facial expression recognition, we previously selected three images: (i) just before speaking and speaking (ii) the first vowel and (iii) the last vowel in an utterance. A frame of the front-view face in a dynamic image was selected by estimating the face direction. Based on our method, we have been developing an on-line system for recognizing the facial expression of a speaker using front-view face judgment, vowel judgment, and thermal image processing. In the proposed system, we used three personal computers connected by cables to form a local area network. As an initial investigation, we adopted the utterance of the Japanese name "Taro," which is semantically neutral. Using the proposed system, the facial expressions of one male subject were discriminable with 76% accuracy when he exhibited one of the intentional facial expressions of "angry," "happy," "neutral," "sad," and "surprised."

Keywords: facial expression recognition, on-line system, speech recognition, vowel judgment, thermal image processing, front-view face judgment

1 INTRODUCTION

To better integrate robots into our society, a robot should be able to interact in a friendly manner with humans. The goal of our research is to develop a robot that can perceive human feelings and mental states.

The first stage is to develop a method for integrating the information of human expression. The basic information for integration is the visible ray (VR) image, thermal image, and voice. In this first stage, an automatic, real-time, interactive system is not necessary. It is very difficult to equip a robot with a computer that can process information with the same efficiency as the human brain. Therefore, we chose to enable the robot to use a type of information, such as thermal imaging, that the human brain cannot process. Thermal imaging is a good example because it is impossible for a human to perceive heat via the naked eye.

The second stage is to develop an automatic, real-time, interactive system that has the information integration of human expression as a processing characteristic. The third stage is to develop a robot that has a function developed from the synthesis of the first and second stages for use in our daily lives.

The present investigation focuses on the first stage of development, in which a robot can visually detect human feelings or inner mental states. Although recognizing facial expressions has received considerable attention in the field of computer vision research, the mechanism of recognition still falls far short of human capability, especially from the viewpoint of robustness under widely varying lighting conditions. One of the reasons is that the nuances of shade, reflection, and local darkness influence the accuracy of facial expression recognition through the inevitable change of gray levels.

To avoid this problem and to develop a robust method for facial expression recognition applicable under widely varied lighting conditions, we did not use a VR image, as would be expected. Instead, we used an image produced by infrared rays (IR), which describe the thermal distribution of the face [1]–[11]. Although a human cannot detect IR, it is possible for a robot to process the information of the thermal images created by IR. Therefore, as a new mode of robot vision, thermal image processing is a practical method that is viable under natural conditions.

The timing of recognizing facial expressions is also important for a robot because the processing could be time-consuming. In a previous report, we adopted an utterance as the key to expressing human feelings or mental states because humans tend to speak when expressing a feeling [5]–[11].

In addition, we added a judgment function of a front-view face to our method for facial expression recognition [11]. A frame of the front-view face in a dynamic image was selected by estimating the face direction. The judgment function of a front-view face measures four feature parameters by thermal image processing.

In this paper, we propose an on-line system for recognizing the facial expression of a speaker using front-view face judgment, vowel judgment and thermal image processing, based on our method [10], [11].

2 IMAGE ACQUISITION

The principle behind thermal image generation is the Stefan–Boltzmann law, expressed as $W = \varepsilon\sigma T^4$, where ε is emissivity, σ is the Stefan–Boltzmann constant (=5.6705×10^{-12} W/cm^{2}K^4), and T is the temperature (K). For human skin, ε is estimated as 0.98 to 0.99 [12], [13]. In this study, the approximate value of 1 was used as ε for human skin because the value of ε for almost all substances is lower than that of human skin [12]. Consequently, the human face region is easily extracted from an image using the value of 1 for ε when a range of skin temperatures is selected to produce a thermal image [1]–[11], [14]. Fig. 1 shows examples of face images of a male, obtained by VR and IR. We can obtain a thermal image of the face without light, even at night. In principle, the temperature measurement by IR does not depend on skin color [13], darkness, or lighting condition. Therefore, the face region and its characteristics are easily extracted from the thermal image.

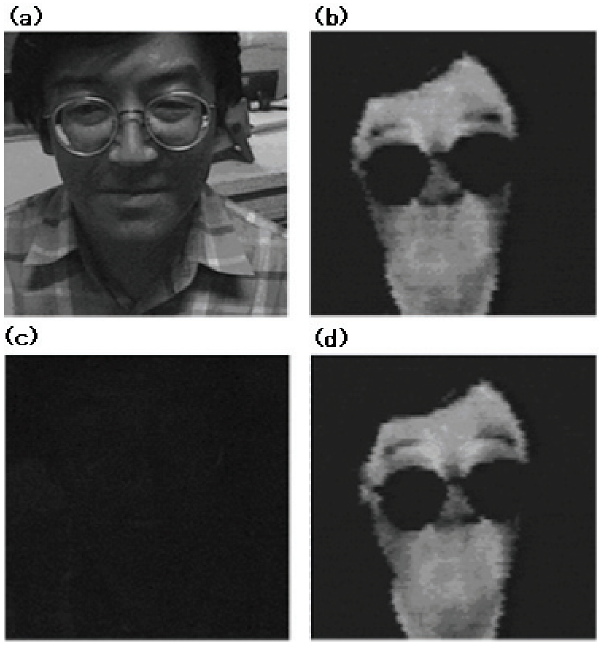

Fig. 1. Examples of a face image at night:
(a) VR with lighting, (b) IR with lighting,
(c) VR without lighting, (d) IR without lighting [3]

3 PROPOSED SYSTEM

In this study, as a pre-processing module, we added a judgment function [11] of a front-view face to our previously reported method [8] for facial expression recognition.

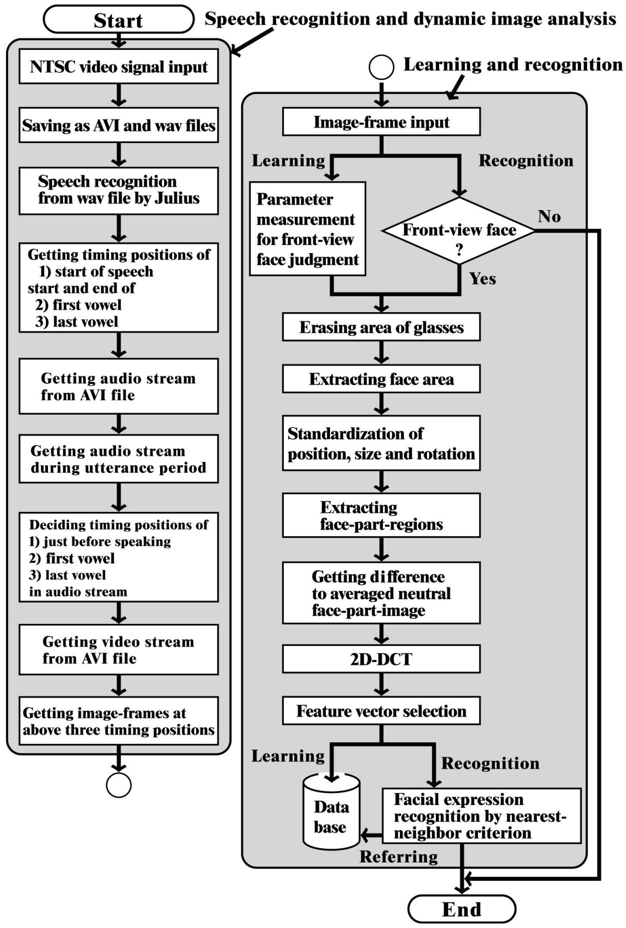

Fig. 2. Flowchart of our method [11]

Fig. 2 illustrates the flowchart of our method [11]. We have two modules in our system. The first is a module for speech recognition and dynamic image analysis, and the second is a module for learning and recognition. In the latter, we embedded the module for front-view face judgment.

3.1 Front-view face judgment

The training data is calculated from the images of a front-view face. We first define the face rotation around the X, Y, and Z axes. After normalizing the horizontal Feret's diameter of the segmented face image, the centerline of the face region is drawn as the first standard line. Each pixel point in the centerline has the same number of pixels on both the left and the right sides of the point. Then, a straight line as the second standard line is drawn from the upper to the lower edge points of the centerline. The two standard lines are used to estimate the deviation from the front-view face. To evaluate the face direction, we use four feature parameters (*nod*, *up*, *rotate*, *lean*), explained in detail in our previously reported paper [11].

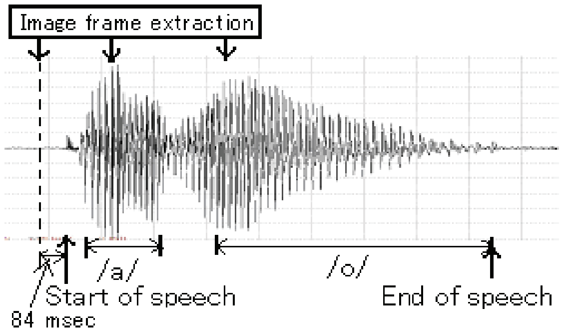

Fig. 3. Speech waveform of "Taro" and timing positions for image frame extraction [8]

3.2 Speech recognition and dynamic image analysis

We use a speech recognition system named Julius [15] to obtain the timing positions of the start of speech and the first and last vowels in a WAV file [8]–[11]. Fig. 3 shows an example of the waveform of the Japanese name "Taro"; the timing position of the start of speech and the timing ranges of the first vowel (/a/) and the last vowel (/o/) are decided by Julius. Using the timing position of the start of speech and the timing ranges of the first and last vowels obtained from the WAV file, three image frames are extracted from an AVI file at the three timing positions. For the timing position just before speaking, we use the timing position of 84 ms before the start of speech, as determined in our previously reported study [8]. For the timing position of the first vowel, we use the position where the absolute value of the amplitude of the waveform is the maximum while speaking the vowel. For the timing position of the last vowel, we apply the same procedure used for the first vowel.

3.3 Learning and recognition

For the static images obtained from the extracted image frames, the process of erasing the area of the glasses, extracting the face area and standardizing the position, size, and rotation of the face are performed according to the method described in our previously reported study [7]. Fig. 4 shows the blocks for extracting the face areas in a thermal image having 720 × 480 pixels. In the next step, we generate difference images between the averaged neutral face image and the target face image in the extracted face areas to perform a 2D discrete cosine transform (2D-DCT). The feature vector is generated from the 2D-DCT coefficients according to a heuristic rule [6], [7]. As stated above, we use the speech recognition system named Julius. Julius sometimes makes a mistake in recognizing the first and/or last vowel(s). For example, /a/ for the first vowel was misrecognized as /i/. In the training data, we correct the misrecognition. However, the test data cannot be corrected. The facial expression is recognized by the nearest-neighbor criterion in the feature vector space using the training data just before speaking and when speaking the phonemes of the first and last vowels. When we use the training data for all combinations of the first and last vowels [10], we can apply the proposed system to a speaker for any utterance.

3.4 Proposed system

Fig. 5 shows the structure of the proposed system. Figs. 6 and 7 show flow charts of the proposed system during facial expression learning and recognition, respectively. Figs. 6 and 7 demonstrate the processing shared by three computers (PC1, PC2, and PC3) connected by cables to

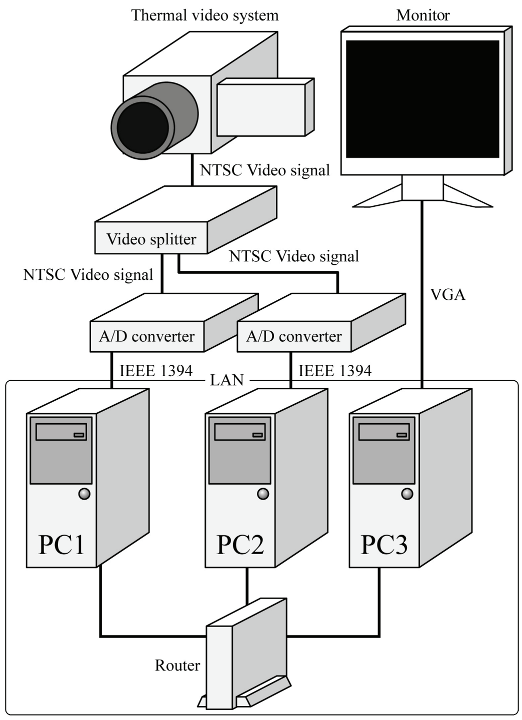

Fig. 5. Structure of the proposed system

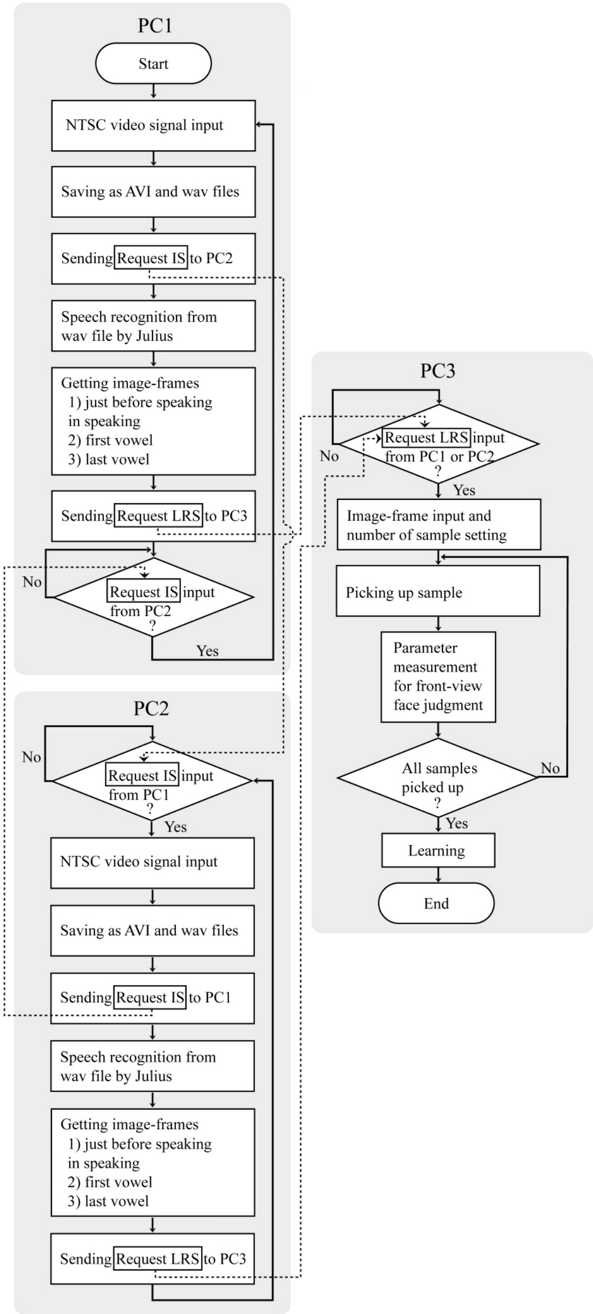

Fig. 6. Flow chart of the proposed system in learning for facial expression recognition

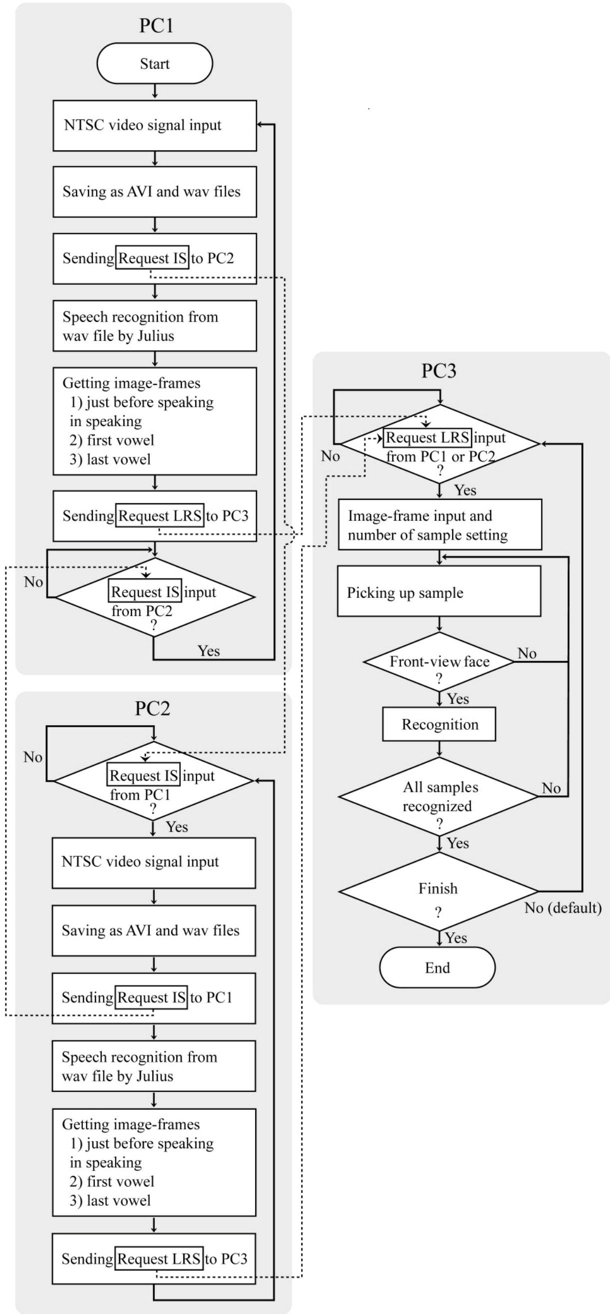

Fig. 7. Flow chart of the proposed system during facial expression recognition

form a local area network for performing the flow chart shown in Fig. 2. In Figs. 6 and 7, a line with an arrow attached denotes a process order, while a dotted line with an arrow attached denotes a communication from a PC to another PC in the local area network. The only difference between Figs. 6 and 7 is the processing in PC3. As shown in Figs. 6 and 7, an NTSC video signal from a thermal video system is successively inputted to either PC1 or PC2 to obtain image-frames: (i) just before speaking, and speaking (ii) the first vowel and (iii) the last vowel in an utterance. We use the proposed system for front-view face judgment using our previously reported method [11].

4 EXPERIMENTS

4.1 Condition

The thermal image produced by the thermal video system (Nippon Avionics TVS-700) and the sound captured from an Electret condenser microphone (Sony ECM-23F5), as amplified by a mixer (Audio-Technica AT-PMX5P), were transformed through an audio and video distribution amplifier (Maspro Denkoh VSP4) into a digital signal by two A/D converters (Thomson Canopus ADVC-100 for PC1 in Fig. 5 and Thomson Canopus ADVC-300 for PC2 in Fig. 5) and input into two computers (PC1 and PC2 in Fig. 5) with the same specification (Dell Optiplex 780, CPU: Intel Core 2 Duo E8400 3.00 GHz, main memory: 4.00 GB, OS: Windows 7 Professional (Microsoft) with an IEEE1394 interface board (I·O data device 1394-PCI3/DV6)). As PC3 in Fig. 5, we used a computer (Dell Precision T1600, CPU: Intel Xeon CPU E31225 3.10 GHz, main memory: 8.00 GB, OS: Windows 7 Professional (Microsoft)). The three computers (PC1, PC2, and PC3) were connected through a router (Buffalo WZR-HP-AG300H) with cables. We used Visual C++ 6.0 (Microsoft) as the programming language. To generate a thermal image, we set the condition that the thermal image had 256 gray levels for the detected temperature of 304 to 309 K. Therefore, one gray level corresponded to 1.95×10^{-2} K. The temperature range for generating a thermal image was decided to easily extract the face area on the image. We saved the visual and audio information in the computer as a Type 2 DV-AVI file, in which the video frame had a spatial resolution of 720×480 pixels and 8-bit gray levels, and the sound was saved in a stereo PCM format, 48 kHz and 16-bit levels.

Subject A exhibited in alphabetic order each of the intentional facial expressions of "angry," "happy," "neutral," "sad," and "surprised," while speaking the semantically neutral utterance "Taro." Fig. 8 shows examples of the thermal images of subject A. Subject A was a male wearing glasses.

In the experiment, subject A intentionally kept front-view faces in the AVI files saved as both the training and test data. We assembled 20 samples as training data and 10 samples as test data. From one sample, we obtained three images at the timing positions of just before speaking and just speaking the phonemes of the first and last vowels.

We obtained the feature parameter ranges for judging the front-view faces using the training data and the method stated in Section 3.1. The range was calculated as $a_i - min_i \le x_i \le a_i + max_i$ for all feature parameters in all other cases in the experiment, where x_1, x_2, x_3, x_4 were *nod*, *up*, *rotate*, and *lean* and a_1, a_2, a_3, a_4 were their

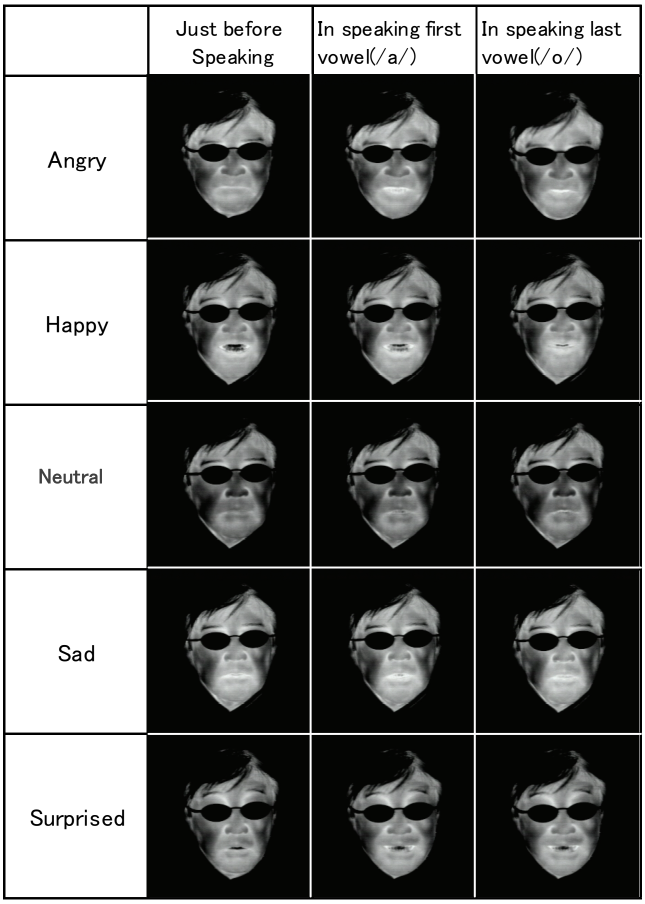

Fig. 8. Examples of thermal images of subject A having each facial expression in speaking

mean values, and $min_1, min_2, min_3, min_4$ were their minimum values and $max_1, max_2, max_3, max_4$ were their maximum values, respectively. We assembled twenty samples as training data and ten samples as test data for each facial expression. All facial expressions of test data for all subjects were judged as front-view faces by the method described in Section 3.1. For each sample, we obtained three images at the timing positions of just before speaking and while speaking the phonemes of the first and last vowels. If Julius misrecognized the vowel of the test sample, the corresponding image was not used for facial expression recognition. We had four cases of misrecognition for the vowel(s): (1) no misrecognition for the first and last vowels, (2) misrecognition only for the first vowel, (3) misrecognition only for the last vowel, (4) misrecognition for both the first and last vowels. We prepared feature vectors of the training data for each of the four cases.

4.2 Results and discussion

Table 1 shows the facial expression recognition accuracy for each facial expression. In the test data, only one thermal image just before speaking was judged as not having a front-view face, and thus the sample was removed and another sample, whose three thermal images were

Table 1. Recognition accuracy for subject A

		Input facial expression				
		Angry	Happy	Neutral	Sad	Surprised
Output	Angry	**90**	10			10
	Happy		**50**			10
	Neutral			**90**	10	10
	Sad		20	10	**90**	10
	Surprised	10	20			**60**

judged as having a front-view face, was added. The mean recognition accuracy was 76%. The facial expressions of "happy" and "surprised" were more difficult to recognize than those of "angry," "neutral," and "sad," which were almost perfectly recognized with 90% accuracy (Table 1).

In the present experiment, a subject spoke one word that was the semantically neutral utterance "Taro." The system recognized the facial expression in speaking each word. When we are ready to apply the proposed system for recognizing facial expressions in daily conversation, we should be able to recognize the facial expression during speaking for a certain interval, such as sentence by sentence. This is because we focus on human feeling through facial expression and it is difficult for humans to change their feeling while speaking word by word. When we use the training data for all combinations of the first and last vowels [10], we can apply the proposed system to a speaker for any utterance.

5 CONCLUSION

We propose an on-line system for recognizing the facial expression of a speaker using front-view face judgment, vowel judgment and thermal image processing, based on our previously reported method [10], [11]. Using the proposed system, the facial expressions of a subject were discriminable with 76% accuracy for the facial expressions of "happy," "neutral," and "others" when the subject exhibited one of the intentional facial expressions of "angry," "happy," "neutral," "sad," and "surprised." We expect the proposed system to be applicable for recognizing facial expressions in daily conversation.

Abstract: We previously developed a method for the facial expression recognition of a speaker. For facial expression recognition, we selected three static images: (i) just before speaking and speaking (ii) the first vowel and (iii) the last vowel in an utterance. Then, only the static image of the front-view face was used for facial expression recognition. However, frequent updates of the training data were time-consuming. To reduce the time for updates, we found that the classifications of "neutral," "happy," and "others" were efficient and accurate for facial expression recognition. Using the proposed method with updated training data of "happy" and "neutral" after an interval such as approximately three and a half years, the facial expressions of two subjects were discriminable with 87.0% accuracy for the facial expressions of "happy," "neutral," and "others" when exhibiting the intentional facial expressions of "angry," "happy," "neutral," "sad," and "surprised."

Keywords: facial expression recognition, speech recognition, vowel judgment, thermal image processing, front-view face judgment

1 INTRODUCTION

The present investigation concerns the first stage of the development of a robot that has the ability to visually detect human feelings or mental states. Although the mechanism for recognizing facial expressions has received considerable attention in the field of computer vision research, it still falls far short of human capability, especially from the viewpoint of robustness under widely varying lighting conditions. One of the reasons for this lack of robustness is that nuances of shade, reflection, and local darkness influence the accuracy of facial expression recognition through the inevitable change of gray levels.

To avoid this problem and to develop a method for facial expression recognition applicable under widely varied lighting conditions, we did not use visible ray images. Instead, we used images produced by infrared rays (IR), which show the thermal distribution of the face [1]-[11]. Although a human cannot detect IR, it is possible for a robot to process the information in IR thermal images. Therefore, as a new mode of robot vision, thermal image processing is a practical method that is viable under natural conditions.

The timing of recognizing facial expressions is important for a robot because the processing can be time-consuming. We adopted an utterance as the key to expressing human feelings or mental states because humans tend to express feelings vocally [5]-[11].

In addition, we added a judgment function of a front-view face to our method for facial expression recognition [10]. A frame of the front-view face in a dynamic image was selected by estimating the face direction. The judgment function of a front-view face measures four feature parameters by thermal image processing.

In the present study, we have been investigating a method for efficiently updating the training data because frequent updates are time-consuming. Through experiments, we concluded that updating the training data corresponding to the facial expressions of "happy" and "neutral" is practical. These two facial expressions are not only very common in our daily lives, but are also easier to express than other facial expressions. Furthermore, the classifications of "neutral," "happy," and "others" are efficient for facial expression recognition under the condition that updating the training data of facial expressions is not often performed. The proposed method with updated training data of "happy" and "neutral" after an interval such as approximately three and a half years is applied to recognition of the facial expressions of two subjects when exhibiting the intentional facial expressions of "angry," "happy," "neutral," "sad," and "surprised."

2 IMAGE ACQUISITION

The principle behind thermal image generation is the Stefan–Boltzmann law, expressed as $W = \varepsilon\sigma T^4$, where ε is emissivity, σ is the Stefan–Boltzmann constant (=5.6705×10^{-12} W/cm^{2}K^4), and T is the temperature (K). For human skin, ε is estimated as 0.98 to 0.99 [12], [13]. In this study, the approximate value of 1 was used as ε

for human skin because the value of ε for almost all substances is lower than that of human skin [12]. Consequently, the human face region is easily extracted from an image by using the value of 1 for ε [1]–[11]. In principle, the temperature measurements by IR do not depend on skin color [13], darkness, or lighting condition, and so the face region and its characteristics are easily extracted from a thermal image.

3 PROPOSED METHOD

In this study, as a pre-processing module, we added a judgment function [10] of a front-view face to our previously reported method [8] for facial expression recognition.

Fig. 1 illustrates the flowchart of our method [10]. We have two modules in our system. The first is a module for speech recognition and dynamic image analysis, and the second is a module for learning and recognition. In the module for learning and recognition, we embedded the module for front-view face judgment.

3.1 Front-view face judgment

The training data is calculated from the images of a front-view face. We first define the face rotation around the *X*, *Y*, and *Z* axes. After normalizing the horizontal Feret's diameter of the segmented face image, the centerline of the face region is drawn as the first standard line. Each pixel point in the centerline has the same number of pixels on both the left and the right sides of the point. Then, a straight line as the second standard line is drawn from the upper to the lower edge points of the centerline. The two standard lines are used to estimate the deviation from the front-view face. To evaluate the face direction, we use four feature parameters (*nod*, *up*, *rotate*, *lean*), explained in detail in our previously reported paper [10].

3.2 Speech recognition and dynamic image analysis

We use a speech recognition system named Julius [14] to obtain the timing positions of the start of speech and the first and last vowels in a WAV file [8]–[10]. Fig. 2 shows an example of the waveform of the Japanese name "Taro"; the timing position of the start of speech and the timing ranges of the first vowel (/a/) and the last vowel (/o/) are decided by Julius. By using the timing position of the start of speech and the timing ranges of the first and last vowels obtained from the WAV file, three image frames are extracted from an AVI file at the three timing positions. For the timing position just before speaking, we use the timing position of 84 ms before the start of speech, as determined in our

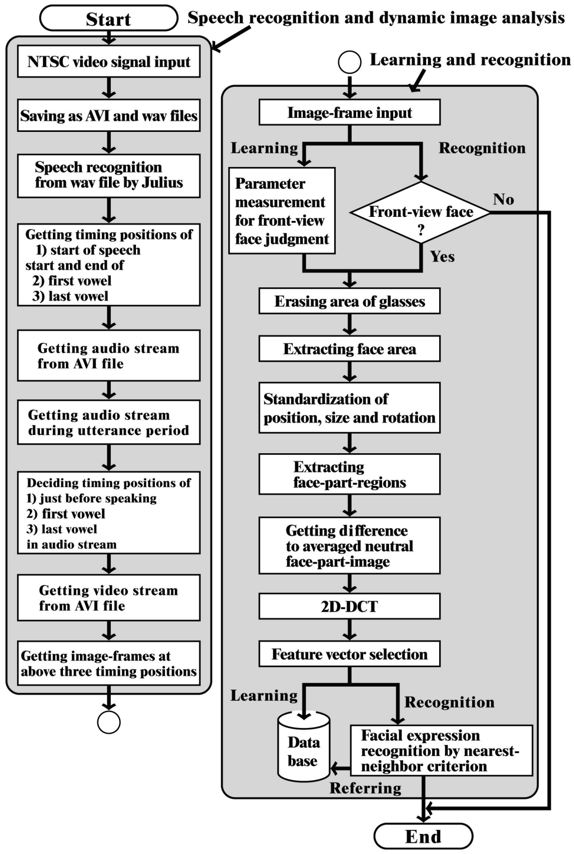

Fig. 1. Flowchart of our method [10]

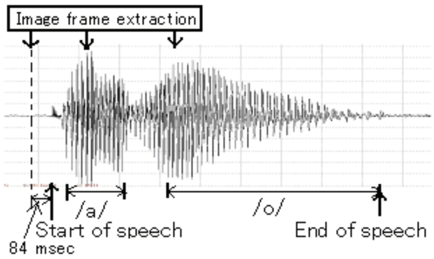

Fig. 2. Speech waveform of "Taro" and timing positions for image frame extraction [8]

previously reported study [7]. For the timing position of the first vowel, we use the position where the absolute value of the amplitude of the waveform is the maximum while speaking the vowel. For the timing position of the last vowel, we apply the same procedure used for the first vowel.

3.3. Learning and recognition

For the static images obtained from the extracted image frames, the process of erasing the area of the glasses, extracting the face area, and standardizing the position, size, and rotation of the face are performed according to the method described in our previously reported study [7]. In the next step, we generate difference images between the averaged neutral face image and the target face image in the extracted face areas to perform a 2D discrete cosine transform (2D-DCT). The feature vector is generated from the 2D-DCT coefficients according to a heuristic rule [6], [7]. As stated above, we use the speech recognition system named Julius. Julius sometimes makes a mistake in recognizing the first and/or last vowel(s). For example, /a/ for the first vowel might be misrecognized as /i/. In the training data, we correct the misrecognition. However, the test data cannot be corrected. The facial expression is recognized by the nearest-neighbor criterion in the feature vector space by using the training data just before speaking and when speaking the phonemes of the first and last vowels. After preparing the training data for all combinations of the first and last vowels, we could apply our method [8] to a speaker for any utterance [11].

4 EXPERIMENTS

4.1 Condition

The thermal image produced by the thermal video system (Nippon Avionics TVS-700) and the sound captured from an Electret condenser microphone (Sony ECM-23F5), as amplified by a mixer (Audio-Technica AT-PMX5P), were transformed into a digital signal by an A/D converter (Thomson Canopus ADVC-300) and input into a computer (DELL Optiplex 780, CPU: Intel Core 2 Duo E8400 3.00 GHz, main memory: 3.21 GB, and OS: Windows 7 Professional (Microsoft) with an IEEE1394 interface board (I·O Data Device 1394-PCI3/DV6)). We used Visual C++ 6.0 (Microsoft) as the programming language. To generate a thermal image, we set the condition that the thermal image had 256 gray levels for the detected temperature range of 5 to 12.9 K. Therefore, one gray level corresponded to 1.95×10^{-2} to 5.04×10^{-2} K. The temperature range for generating a thermal image was decided for each subject to easily extract the face area on the image. We saved the visual and audio information in the computer as a Type 2 DV-AVI file, in which the video frame had a spatial resolution of 720×480 pixels and 8-bit gray levels, and the sound was saved in a stereo PCM format, 48 kHz and 16-bit levels.

Two subjects exhibited in alphabetic order each of the intentional facial expressions of “angry,” “happy,” “neutral,” “sad,” and “surprised,” while speaking the semantically neutral utterance “Taro.” In this study, we categorized all of “angry,” “sad,” and “surprise” expressions as “others” in making the recognition results. Figs. 3 to 7 show examples of the thermal images of each subject. Subjects A and B were males with glasses. We captured the thermal images on June 20, 2006 (hereinafter referred to as First_period_A) (Fig. 3), at approximately 3 pm on January 22, 2010 (hereinafter referred to as Second_period_A) (Fig. 4), and at approximately 5 pm on January 22, 2010 (hereinafter referred to as Third_period_A) (Fig. 5) for subject A, and on June 20, 2006 (hereinafter referred to as First_period_B) (Fig. 6) and January 25, 2010 (hereinafter referred to as Second_period_B) (Fig. 7) for subject B.

In this study, we investigated several combinations of training and test data for each subject as listed in Tables 1, 2, and 3 in Section 4.2. Case-A-1-2 for subject A consisted of the following cases: (1) thermal images for both training and test data captured on First_period_A, (2) thermal images for both training and test data captured on Second_period_A, (3) thermal images for training and test data captured on First_period_A and Second_period_A, respectively, and (4) thermal images of training data of the facial expressions of “happy” and “neutral” captured on Second_period_A, thermal images of training data of the facial expressions of “others” captured on First_period_A, and the test data were captured on Second_period_A. In addition, Case-A-2-3 for subject A consisted of four cases decided by changing the data of First_period_A and Second_period_A in Case-A-1-2 to those of Second_period_A and Third_period_A, respectively. Case-B-1-2 for subject B consisted of the four cases defined in the same manner described above as Case-A-1-2 for subject A.

For Case-A-1-2, Case-A-2-3, and Case-B-1-2, we compared (3) and (4) for investigating the effects of updating the training data of the facial expressions of “happy” and “neutral”, whereas (1) and (2) were added for reference of thermal images for the training and the test data captured without intentional intervals.

Subjects A and B intentionally kept front-view faces during the capturing of thermal images for the training data in all cases, and subject A did so during the capturing of thermal images for the test data on First_period_A and Third_period_A. In addition, subject B intentionally kept front-view faces during the capturing of thermal images for the test data on First_period_B. Subjects A and B freely changed their face direction during the capturing of thermal images for the test data on Second_period_A and Second_period_B, respectively. We obtained the feature parameter ranges for judging the front-view faces by using the training data and the method mentioned in Section 3.1. The range was calculated as $a_i - 3\sigma_i < x_i < a_i + 3\sigma_i$ for all parameters of Case-A-2-3 (3), and $a_i - 2\sigma_i < x_i < a_i + 2\sigma_i$ for all feature parameters in all other cases in the experiment,

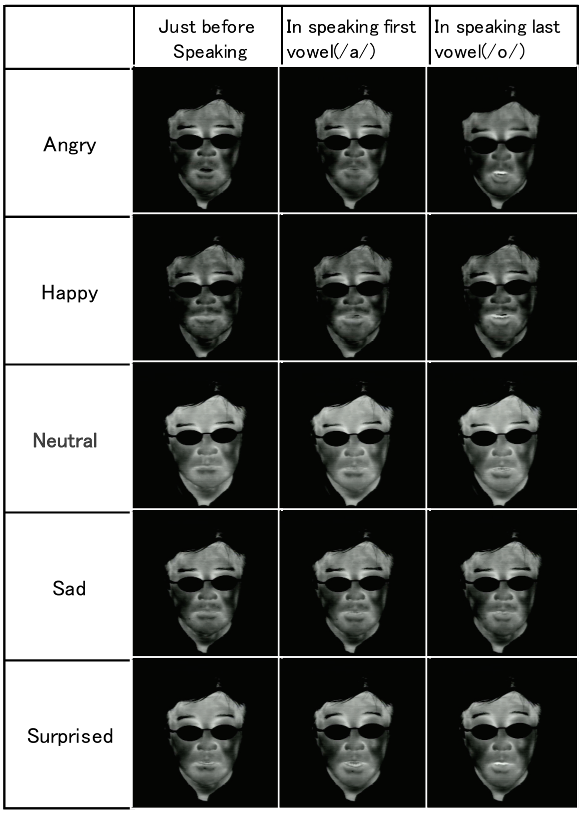

Fig. 3. Examples of thermal images of subject A captured on First_period_A and having each facial expression

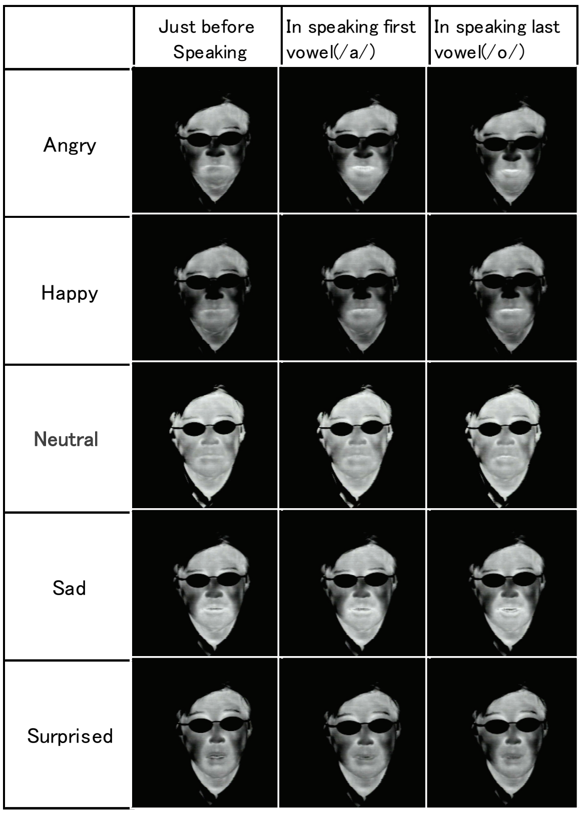

Fig. 4. Examples of thermal images of subject A captured on Second_period_A and having each facial expression

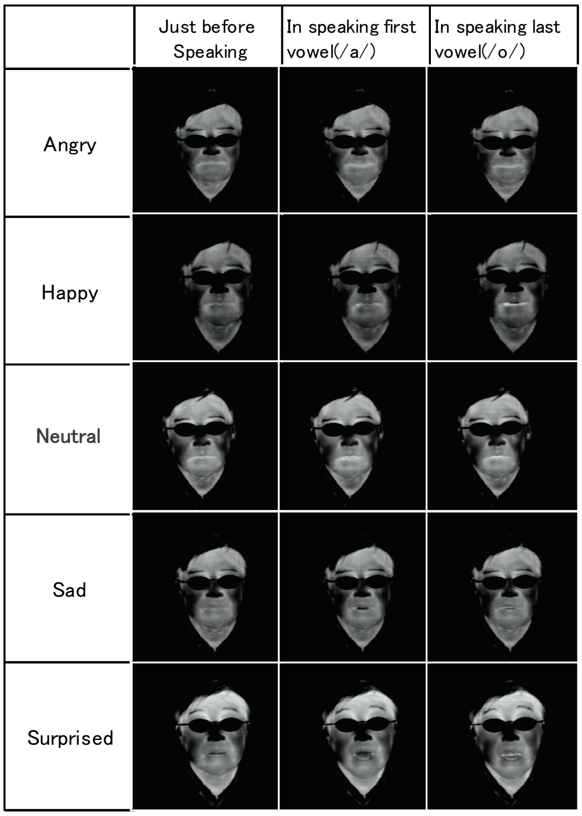

Fig. 5. Examples of thermal images of subject A captured on Third_period_A and having each facial expression

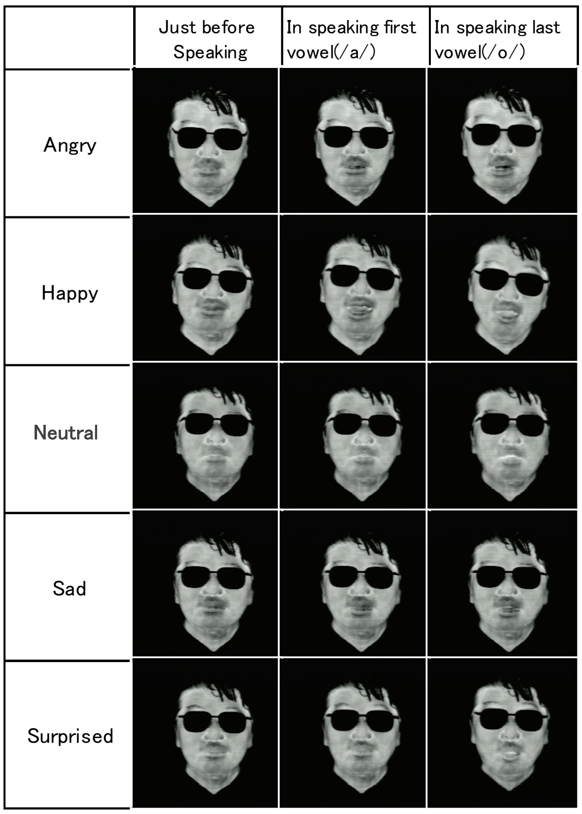

Fig. 6. Examples of thermal images of subject B captured on First_period_B and having each facial expression

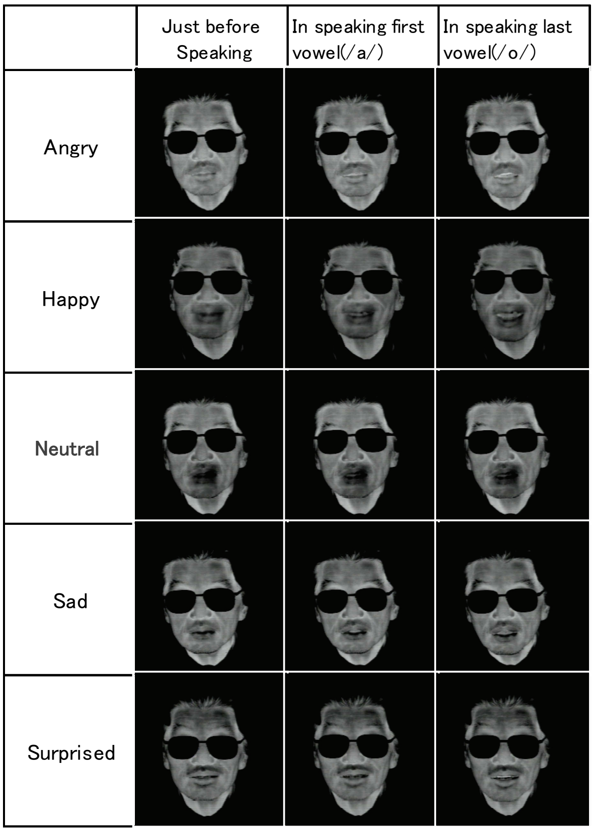

Fig. 7. Examples of thermal images of subject B captured on Second_period_B and having each facial expression

where x_1, x_2, x_3, x_4 were *nod*, *up*, *rotate*, and *lean*, and a_1, a_2, a_3, a_4 were their mean values, and $\sigma_1, \sigma_2, \sigma_3, \sigma_4$ were their standard deviation values, respectively. In Case-A-2-3 (3), the difference between the feature parameters obtained on Second_period_A and Third_period_A was so large that the feature parameter ranges for judging the front-view face were set to be wider than the ranges for the other cases. We assembled twenty samples as training data and ten or fewer samples as test data for each facial expression in each case, in which all facial expressions of test data for all subjects were judged as being exhibited on front-view faces by the method mentioned in Section 3.1. As one sample, we obtained three images at the timing positions of just before speaking and while speaking the phonemes of the first and last vowels. If Julius misrecognized the vowel of the test sample, the corresponding image was not used for facial expression recognition. We had four cases of misrecognition for the vowel(s): (1) no misrecognition for the first and last vowels, (2) misrecognition only for the first vowel, (3) misrecognition only for the last vowel, (4) misrecognition for both the first and last vowels. We prepared feature vectors of the training data in each of the four cases.

Table 1. Recognition accuracy of Case-A-1-2

(1) Training and test data: First_period_A

		Input facial expression		
		Happy	Neutral	Others
Output	Happy	100		23.3
	Neutral		90	
	Others		10	76.7

(2) Training and test data: Second_period_A

		Input facial expression		
		Happy	Neutral	Others
Output	Happy	80	10	
	Neutral		90	
	Others	20		100

(3) Training data: First_period_A,
Test data: Second_period_A

		Input facial expression		
		Happy	Neutral	Others
Output	Happy	100	10	86.7
	Neutral		90	
	Others			13

(4) Training data:
"happy" and "neutral"; Second_period_A,
"others"; First_period_A,
Test data: Second_period_A

		Input facial expression		
		Happy	Neutral	Others
Output	Happy	100		6.7
	Neutral		90	
	Others		10	93.3

Table 2. Recognition accuracy of Case-A-2-3

(1) Training and test data: Second_period_A

		Input facial expression		
		Happy	Neutral	Others
Output	Happy	80	10	
	Neutral		90	
	Others	20		100

(2) Training and test data: Third_period_A

		Input facial expression		
		Happy	Neutral	Others
Output	Happy	100		
	Neutral		50	
	Others		50	100

(3) Training data: Second_period_A,
Test data: Third_period_A

		Input facial expression		
		Happy	Neutral	Others
Output	Happy	0		
	Neutral		100	
	Others	100		100

(4) Training data:
"happy" and "neutral"; Second_period_B,
"others"; First_period_B,
Test data: Second_period_B

		Input facial expression		
		Happy	Neutral	Others
Output	Happy	100		73.3
	Neutral		90	16.7
	Others		10	10

4.2 Results and discussion

Tables 1, 2, and 3 show the facial expression recognition accuracy for each case. The mean recognition accuracy on the condition of (3) in Tables 1, 2, and 3 was 58.1%, whereas that on the condition of (4) in Tables 1, 2, and 3 was 87.0%, which was slightly lower than the 90.7% obtained on the condition of (1) and (2) in Tables 1, 2, and 3. Updating the training data for the facial expressions of "happy" and "neutral" improved the accuracy of facial expression recognition by 28.9 % as the mean value.

5 CONCLUSION

We previously developed a method for facial expression recognition of a speaker using thermal image processing and a speech recognition system. In this paper, we propose a method for efficiently updating training data, such that the training data of only the facial expressions of "happy" and "neutral" were updated after an interval such as approximately three and a half years. By using the proposed method, the facial expressions of two subjects were discriminable with 87.0% accuracy for the facial expressions of "happy," "neutral," and "others" when they exhibited one of the intentional facial expressions of "angry," "happy," "neutral," "sad," and "surprised."

Abstract: The purpose of our study was to develop a system for communication between a speaker and a computer-generated (CG) character for making the speaker feel more peaceful and cheerful. In our system, the CG character can synchronize its nodding with a speaker's nodding by predicting the speaker's nodding angle. The CG character starts predicting it for nodding just after a human begins to speak, and the CG character stops nodding while maintaining a front-view face when the human maintains a front-view face and is silent. The CG character starts predicting it again for nodding when the human begins to speak again. The measured feature parameter is the input to a fuzzy algorithm system to obtain the nodding angle of the speaker in front of an infrared ray camera, and then a moving-average model is used to predict the nodding angle of the speaker.

Keywords: computer generated character, human computer interaction, sound analysis, thermal image.

1 INTRODUCTION

Nonverbal communication, such as a facial expression, a nod, or a hand gesture, is very important for reciprocal communication between humans. The realization of suitable communication between a human and a computer will help the development of computers, networking, and robots for people living alone. In an aging society such as that in Japan, the opportunity to talk diminishes for older people living alone. Embodied communication technologies have been developed using the relationship between speech and nodding [1]-[4]. In addition, several studies have investigated head gesture recognition [5]-[9]. However, in our daily lives, it is more difficult to take visual information from a person's head movements to synchronize the nod of a computer generated (CG) character compared with using audio information for the same purpose. The main reason for this difficulty is that the nuances of shade, reflection, and local darkness strongly influence the accuracy of head gesture recognition because of the inevitable changes in gray levels. In this study, an image registered by infrared rays, which display the thermal pattern of the face and neck, was used to develop a system of communication between a speaker and a CG character. To make the communication between the speaker and the CG character more natural, we have added some modules to detect the utterance of a human to our reported system [10].

2 BASIC PROCESSING FLOW

Fig. 1 shows the flow chart of our method. We use the fuzzy rules of the ratio of the horizontal length to the vertical length of the face region on the thermal image (hereinafter referred to as nod) and the face direction vector having a norm of 1 (hereinafter referred to as $\boldsymbol{n}$) [10]. Using the fuzzy algorithm [10] and the input of the nod , $\boldsymbol{n}$ is output as three estimated values of the elements of the vector and used for expressing the nodding of the CG character.

First, we obtain a pair of thermal images of the frontal and downward face directions of a subject to normalize the value of the nod as 1 in the case of the frontal direction, and to transform the value of the nod of the subject to that of a typical subject [10]. The normalization and the transformation of the value of the nod have been explained in detail in our previously reported paper [10]. Then, after capturing sound data to obtain constant thresholds, the sound data are judged by the thresholds to determine whether the subject has spoken an utterance. The preprocessing operation for measuring the nod includes segmentation with another constant threshold, erasing the isolated points, extracting the face area, standardizing the size of the face, and automatic segmentation [11], which are all performed for the thermal image [10]. Then, the nod is measured. To predict the nod of a human, we use the moving-average model [10]. Then, if the subject maintains a frontal face for longer than approximately 0.7 second, the CG character maintains a frontal face until the sound is judged to indicate an utterance. When the sound is judged as an utterance, the processing is restarted from the thermal image input. Otherwise, the processing is set back to the sound input and judgment of the utterance. The processing of utterance-driven nodding of the CG character is explained in detail in Section 3.

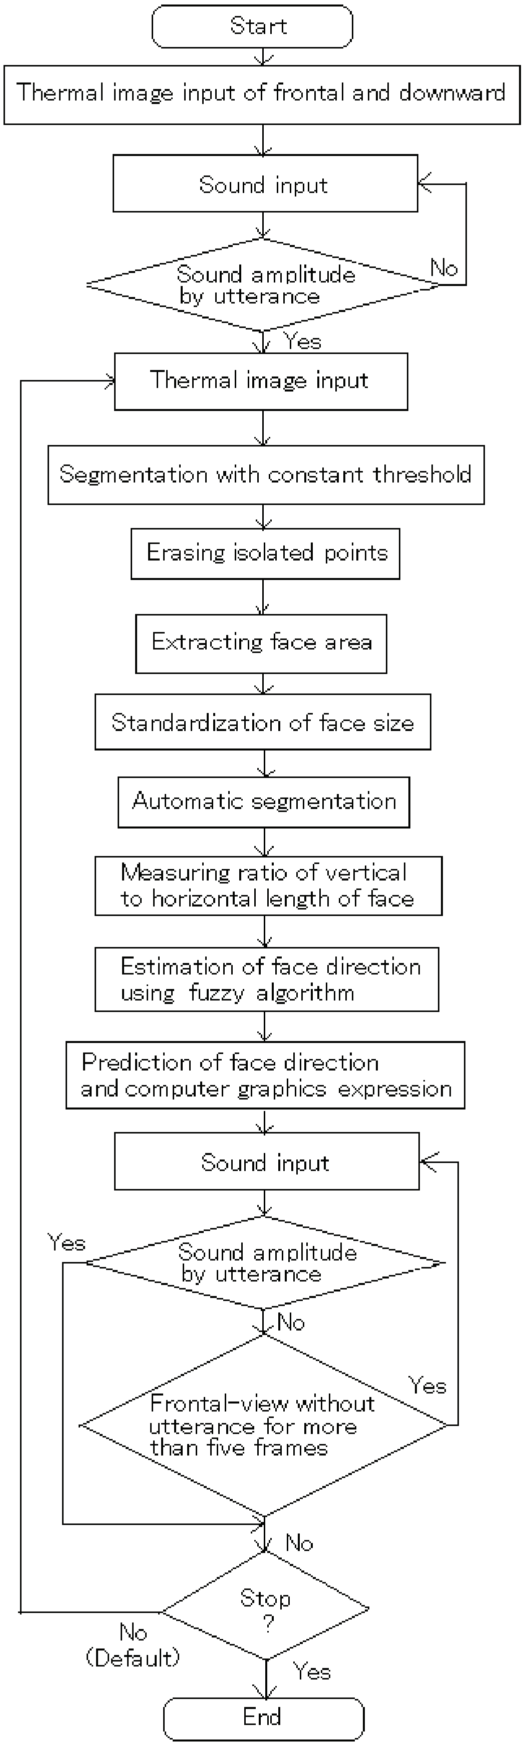

Fig. 1. Flow chart of our method

3 UTTERANCE-DRIVEN NODDING OF THE CG CHARACTER

The thresholds for the sound data value are set as $\bar{x}_s - 5\sigma_s$ and $\bar{x}_s + 5\sigma_s$, where $\bar{x}_s$ and σ_s express the average and the standard deviation, respectively, of the sound data value for one second under the condition of no utterance. The sound data for 0.5 second with an interval of approximately 0.2 second are performed to erase noises and then two series of samplings with an interval of 0.084 second are performed by using the method reported in [12]-[14]. Then, it is determined whether every sampled data fall within $[\bar{x}_s - 5\sigma_s, \bar{x}_s + 5\sigma_s]$, which is considered to be the range of no utterance. When at least one sampled datum has a value outside $[\bar{x}_s - 5\sigma_s, \bar{x}_s + 5\sigma_s]$, our system judges that the sound data contain an utterance. Once the sound data are judged as containing an utterance, the preprocessing operation for measuring the *nod* is started. When the subject maintains a frontal face for longer than approximately 0.7 second, the CG character maintains a frontal face until the sound is judged as an utterance. When the sound is judged as an utterance, the processing is restarted from the thermal image input. Otherwise, the processing is set back to the step of the sound input and the judgment of the utterance.

4 PREDICTION OF NODDING ANGLE

Fig. 2 shows the three-dimensional coordinate system used in this study. Here, $\boldsymbol{n} = (0,0,1)$ corresponds to the face direction when the face is facing the front. The three elements of $\boldsymbol{n} = (\alpha, \beta, \gamma)$ are used as consequent parameters in the fuzzy rules. Fig. 3 shows the downward rotation of the face. The *nod*, which is used as an antecedent parameter in the fuzzy rules, is measured as the ratio of the vertical length to the horizontal length of the face. To reduce the influence of hair style and throat region on the binary image, some image processing is performed [10].

The fuzzy rules are described in (1) [10]. The fuzzy algorithm is described in (2)–(5) [10].

$$\text{If } X = A_i \text{ then } Y_1 = B_{i1}, Y_2 = B_{i2}, Y_3 = B_{i3}, \quad (i = 1, 2, 3) \tag{1}$$

$$\mu^*_{B_{ij}}(Y_j) = W_i \mu_{B_{ij}}(Y_j), \ (i = 1, 2, 3, \ j = 1, 2, 3) \tag{2}$$

$$W_i = \mu_{A_i}(X^*), \ (i = 1, 2, 3) \tag{3}$$

$$B^0_j = \bigcup_{i=1}^{3} B^*_{ij}, \ (j = 1, 2, 3) \tag{4}$$

$$Y^*_j = \frac{\int \mu_{B^0_j}(Y_j) Y_j dY_j}{\int \mu_{B^0_j}(Y_j) dY_j}, (j = 1, 2, 3), \tag{5}$$

where X denotes the antecedent parameter; Y_1, Y_2, and Y_3 denote consequent parameters; A_i, B_{i1}, B_{i2}, and B_{i3} denote the corresponding fuzzy labels for X, Y_1, Y_2, and

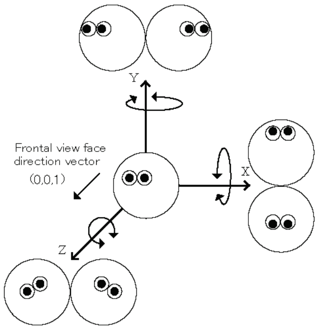

Fig. 2. Three-dimensional coordinate system [10]

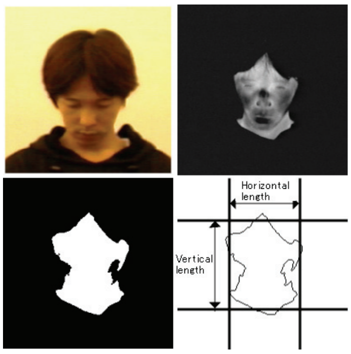

Fig. 3. Downward rotation [15]
Upper left: visible image, Upper right: thermal image, Lower left: binary image, Lower right: schematic diagram for explaining parameter *nod*

Y_3, respectively; W_i denotes the fitness value of the *i*-th rule to the input X^* for X; $Y_j{}^*$ denotes the output for Y_j. The integral in (5) is performed for the whole range of Y_j. In this study, X=*nod* , $Y_1=\alpha$, $Y_2=\beta$, $Y_3=\gamma$. We use three fuzzy rules to describe "frontal," "somewhat downward," and "downward." To determine the actual shape of each membership function, we use the measured values for the corresponding parameter [10]. For each measured value, we use an average for six people [10]. In addition, the value of *nod* is normalized by dividing by the value in the case of "frontal." We use a fuzzy algorithm for outputting $\boldsymbol{n}$ with the three fuzzy rules and the value of *nod* as the input. For integrating outputs from all the rules, we use (4) and (5). The nodding angle θ (°) which is calculated with γ and using the value of (6), where θ (°) is defined as follows.

$$\theta = 57.3\cos^{-1}\gamma \tag{6}$$

In this study, θ is positive in the case of downward rotation. Also in this study, we use (7), which was given in our previous study [10].

$$\begin{aligned}\hat{\theta}(i) = {} & 1.39\hat{\theta}(i-1) - 0.19\theta(i-2) - 0.24\theta(i-3) - 0.11\theta(i-4) \\ & + 0.053\theta(i-5) + 0.032\theta(i-6) - 0.043\theta(i-7) - 0.028\theta(i-8) \\ & + 0.024\theta(i-11) + 0.03\theta(i-10) + 0.12\theta(i-11) - 0.15\theta(i-12) \\ & - 0.005\theta(i-13) + 0.0073\theta(i-14) + 0.11\theta(i-15) \\ & + 0.031\theta(i-16) - 0.14\theta(i-17) - 0.041\theta(i-18) + 0.18\theta(i-19) \\ & - 0.056\theta(i-20) + 0.052\theta(i-21) - 0.18\theta(i-22) - 0.14\theta(i-23)\end{aligned} \tag{7}$$

where $\hat{\theta}(i)$ is the predicted value for $\theta(i)$, which is the nodding angle of the subject. We do not know the value of $\theta(i-1)$ at the timing position of $i-1$ because it took approximately 0.13 s to obtain $\theta(i-1)$ [10]. Accordingly, we used $\hat{\theta}(i-1)$ instead of $\theta(i-1)$, as described in (7).

5 FACE DIRECTION EXPRESSION USING COMPUTER GRAPHICS

We use the virtual reality modeling language (VRML) and Java for expressing the CG character. Fig. 4 shows examples of the CG character expressions of nodding. When $\hat{\theta}(i) < 5°$ in (7), $\hat{\theta}(i)$ is converted to 0° because the CG character having $\hat{\theta}(i) < 0°$ throws its head back and the character having the small value of $\hat{\theta}(i)$ fluctuating near 0° displays an unnaturally shaking attitude. Therefore, in this study, all nodding values of CG character are restricted to be above 5°.

6 EXPERIMENT AND DISCUSSION

6.1 Experimental environment

The thermal image produced by a thermal video system (Thermo Shot F30, NEC Avio Infrared Technologies Co.) was transformed into a digital signal by an A/D converter (ADVC-300, Thomson Canopus) and the signal was input into a computer with an IEEE 1394 interface board (1394-PCI3/DV6, IO Data Device). We used a computer (Dell Optiplex 745, CPU: Intel Core 2 Duo 6600 2.4 GHz, main memory: 2 GB, and OS: Windows XP, Microsoft) (hereinafter referred to as PC1). For programming, we used Visual C++ 6.0 (Microsoft) and Java 2 SDK standard edition version 1.3, and VRML 2.0. The thermal image to be processed in the computer had a spatial resolution of 240 × 160 pixels and an 8-bit gray level at each pixel. The sound data captured by a wireless microphone (WM-1320, TOA Corporation) and a wireless tuner (WT-750B, TOA Corporation), were amplified by a blender (AT-PMX5P, Audio-technica) and transformed into a digital signal by the A/D converter, and the signal was input into a computer with the IEEE 1394 interface board (1394-PCI3/DV6, IO

Data Device). We used a second computer (Dell Optiplex GX620, CPU: Intel Premium 4 3.4 GHz, main memory: 1.99 GB, and OS: Windows XP, Microsoft) (hereinafter referred to as PC2). The CG character was expressed on PC2, which used Microsoft Internet Explorer 7.0 and Parallel Graphics Cortona VRML client Version 3.1.

PC1 was connected to PC2 by a cable to form a local area network. The thresholds for sound amplitude were decided in PC2. When the sound data were judged to be above the threshold as coming from the utterance, PC1 started a series of processing for measuring the *nod* just after receiving the signal from PC2 through the cable. Moreover, when the signal indicated that the subject was judged to have maintained a frontal face for longer than approximately 0.7 second, the signal was sent from PC1 to PC2 through the cable. Then, the CG character on PC2 maintained a frontal face until the sound was judged in PC2 as an utterance. When the sound was judged as an utterance in PC2, PC1 restarted the series of processing for measuring the *nod* from the thermal image input, just after receiving the signal from PC2 through the cable.

6.2 Conditions

The 11 subjects participating in the experiments consisted of the following: 2 males in their 20s, Subjects A and B; 3 females in their 20s, Subjects C, D, and E; 1 male in his 30s: Subject F; 1 female in her 30s, Subject G; 1 male in his 40s, Subject H; 1 female in her 50s, Subject I; 1 male in his 60s, Subject J; and 1 female in her 60s, Subject K. When the CG character synchronized its nodding to that of the subject during speaking, the subject's impression of the CG character's reaction was investigated with two kinds of experiments. The first experiment (hereinafter referred to as Experiment No. 1) was as follows. After watching a video digesting the soccer finals of the 2011 FIFA Women's World Cup for approximately five minutes, each subject verbally gave a summary and an impression of the video while in front of the computer monitor on which the CG character of our system was shown. The CG character synchronized its nodding to that of the subject.

The second experiment (hereinafter referred to as Experiment No. 2) was as follows. Each subject watched a video for approximately two minutes. The video was a comic skit by the Sandwich Man, a Japanese comedy duo. The subject sat in front of the computer monitor, on which the CG character of our system was shown. The CG character synchronized its nodding to that of the subject.

Fig. 5 shows a scene of Experiments No. 1 and No. 2. These two experiments were performed to investigate the

Experiment No.1 No.2

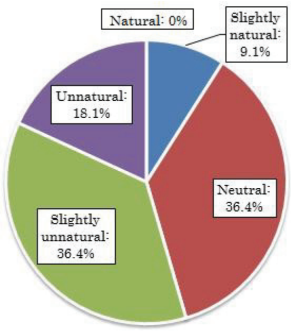

Fig. 8. Impression on reaction of a CG character

effect and the challenges of our system. After the two experiments, all subjects answered a questionnaire.

6.3 Results and discussion

Figs. 6-8 show the results of the questionnaire for Experiment No. 1. In the questionnaire, 27.3% (9.1% + 18.2%) of the subjects were encouraged to say something to our system, whereas an equal number (27.3%) were discouraged from saying anything to our system (Fig. 6). The movement speeds of the CG character were considered to be slightly low by approximately one-third of the subjects, as shown in Fig. 7. One of the reasons why the reaction of the CG character was considered to be unnatural or slightly unnatural by 54.5% of subjects, as shown in Fig. 8, was that the CG character only nodded and did not change its facial expression. Furthermore, when the hand of a subject appeared in the thermal image, the CG character nodded. This reaction could give the subject an unnatural impression of the CG character. At the initial stages of Experiments No. 1 and No. 2, the thermal images of the frontal and downward faces of each subject were captured for calculating the feature parameter *nod* of the subject. In our system, the degree of nodding of the CG character was obtained with the thermal images and the technique for converting the feature parameter *nod* of the subject to that of a standard subject [10]. Therefore, when the degree of nodding of the CG character was overly large for the initial downward face of the subject, the nodding of the downward face in the experiments became greater than that of the nodding of the subject. In the case of Subject I, this situation happened, resulting in the highest nodding angle (157.2°) of the CG character in Experiment No. 1. In contrast, the nodding angle of the CG character in Experiment No. 1 was within 60° for the other subjects. A ratio of the nodding angle that is more than 5° was assumed to express degree on communication between a subject and the CG character. The ratio seemed to depend on the subject. As shown in Table 1, the ratio was in the range of 0 to 53.4. Subjects B, D, I, and K, who had relatively small ratios of the nodding angle that is more than 5°, had the impression that the CG character moved slowly, and subjects B, D, and K had the impression that the total expression of the CG character was neutral. These impressions might be caused by the fact that the CG character could nod only when the subject nodded. However, subjects C, E, H, and J, who had relatively large ratios of the nodding angle that is more than 5°, had the impression that the CG character moved well, and subjects C, H, and J had the impression that the reaction of the CG character was unnatural or slightly unnatural. According to the comments of some subjects, the appearance and the static facial expression of the CG character did not give a natural impression.

Figs. 9-11 show the results of the questionnaire for Experiment No. 2. Because the sound from the loudspeakers of PC2 could influence the judgment of the utterance of a subject, the volume of the loudspeakers was kept at a low level. Therefore, some subjects commented that the voice of the video was not easy to hear. Most subjects concentrated their attention on the video of the comic skit while sitting still, so that the CG character maintained a frontal face. The ratio of the nodding angle that is more than 5° seemed to depend on the subject's personality and fell in the range of 0.9 to 78.7, as shown in Table 2. Subjects C, H, J, and K, who had a relatively large value of the ratio of the nodding angle that is more than 5°, had the impression that their attention was drawn to the CG character. According to the comments by some subjects, the CG character needed more kinds of appearances, reactions, facial expressions, and voices, so that their attention might be more drawn to the CG character, resulting in less attention to the video.

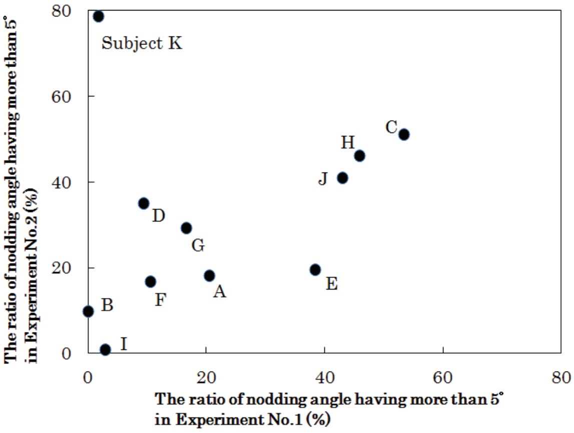

Fig. 12. Subject's personality expressed by the nodding of the CG character.

Fig. 12 shows subject's personality expressed by the nodding of the CG character. In the case of Subject K, she concentrated her attention on the video and sat almost still through Experiment No. 1, while she sat nodding to some extent in Experiment No. 2. In the cases of the other subjects, we found that the easiness of the interaction between the subject and the CG character depended on the subject's personality.

7 CONCLUSIONS

We developed a system for communication between a speaker and a CG character by using thermal image processing. The CG character synchronized its nodding with a speaker's nodding by predicting the speaker's nodding angle. The CG character itself had a great influence on the impressions of the user. In future work, we need to improve the CG character by considering the use of the system and the individual user's taste.

Acknowledgments

We would like to thank all the participants who cooperated with us in the experiments.

Abstract: Music therapy to improve recognition ability may be more effective when the favorite music of each person is adopted. A method is proposed that combines collaborative filtering and music recommendation based on impression words. In the proposed method, once the recommendation process using collaborative filtering is terminated because the number of users is zero in the reference user list of users with the same preference of recommended music, the second recommendation process finds the most similar music from the scores of impression words, so that music is successfully recommended from music not previously recommended. In experiments, 12 users rated 52 songs in a textbook database of songs for elementary schools. The number of recommended songs by the proposed method was 10 per user, whereas that of collaborative filtering was 6.25 per user. The recommendation accuracy of the proposed method was 68.3%, whereas that of collaborative filtering was 66.9%.

Keywords: Recognition ability, Music therapy, Collaborative filtering, Impression word, and Music recommendation.

1 INTRODUCTION

In Japan, the average age of the population has been increasing, and this trend is expected to continue. Recently, music therapy has been used for improving the recognition ability of people, particularly older people. Music therapy may be more effective when the favorite music of each person is adopted. We have been developing the technology of music recommendation aimed at improving recognition ability [1]. When using the reported method [1], it is not easy to recommend much music to a user. To overcome this difficulty in the present study, we propose a music recommendation method that combines collaborative filtering and our music recommendation process based on impression words. We evaluate the proposed method by using children's songs, which tend to be familiar to older people.

2 MUSIC RECOMMENDATION METHOD USING IMPRESSION WORDS

We use ten pairs of impression words (Table 1). Table 2 shows an example of user scores for one pair of impression words (quiet - busy). The original user scores consisted of seven levels, which are transformed to those having three levels, as shown in Table 2. In a music database, 52 songs are assigned scores $i\,(-3 \le i \le 3)$ for each pair of impression words evaluated by subjects. Fig. 1 shows a flowchart of the music recommendation based on impression words. When music not recommended to a user has the same values except "0" as that for at least one recommended music having a high evaluation on the three-

-2	1	quiet
-3		very quiet

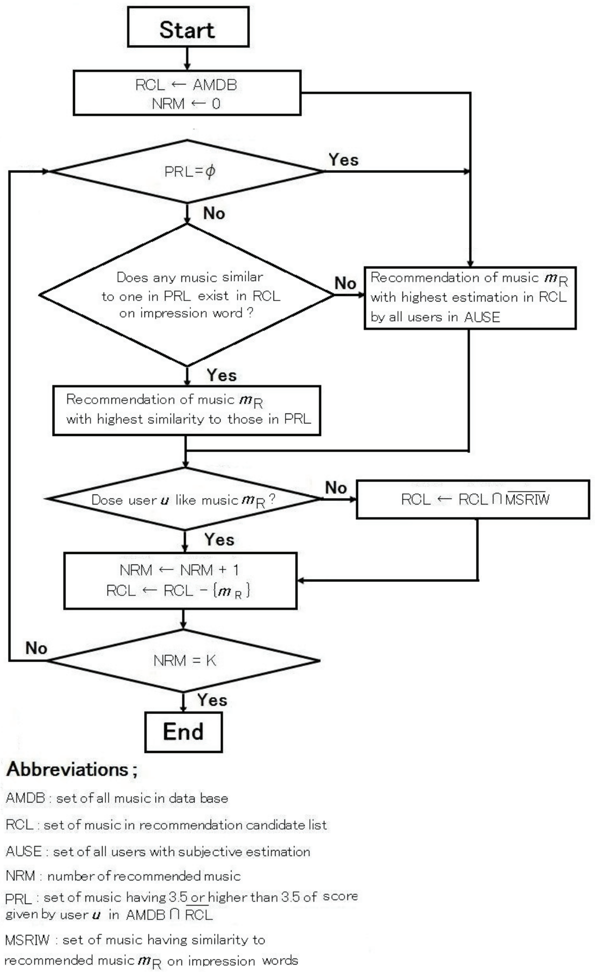

Fig. 1. Flowchart of music recommendation by using impression words

level score for at least five impression words, the music is treated as having a positive evaluation by the user. In contrast, when music not recommended to the user has the same scores except "0" as that for another music just recommended to the user and having a low evaluation on the three-level score for at least seven impression words, the music is assumed as having a negative evaluation by the user. In Fig. 1, when none of the music not recommended receives a positive evaluation by the user, another recommendation is performed by using the estimations of all users whose subjective estimations are stored in the database. It is expressed by "with highest similarity" in Fig. 1 that the music has the highest ratio of the same three-level scores except "0" as that of other music recommended to the user and having a positive evaluation among the music not recommended to the user. In Fig. 1, the "set of music with a similarity to the recommended music based on impression words" (MSRIW) is decided by using at least seven impression words in the case of a negative evaluation.

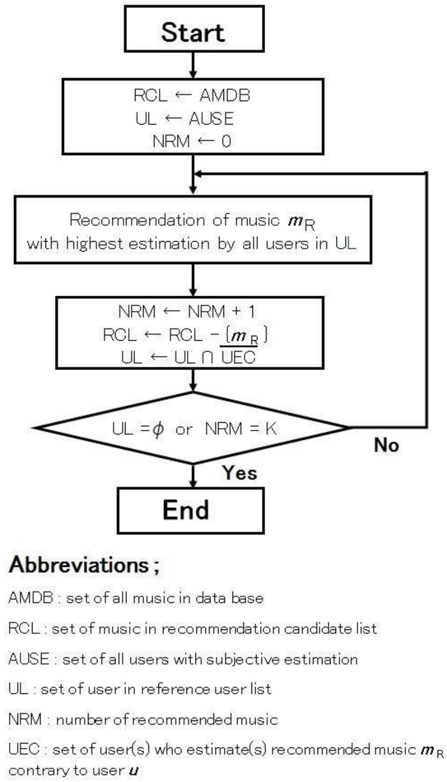

Fig. 2. Flowchart of music recommendation by collaborative filtering

3 PROPOSED METHOD

Figs. 2 and 3 show two music recommendation methods, Method 1 and Method 2, respectively. Method 1 (Fig. 2) is collaborative filtering only and it is compared with Method 2 (Fig. 3), which is the proposed method that combines collaborative filtering and our music recommendation process based on impression words (Fig. 1). In the proposed method, the recommendation process using collaborative filtering is terminated when the number of users is zero in the reference user list of users showing exactly the same evaluation for the recommended music as that of the subject up to that moment. Then, the recommendation process performs by finding out the most similar music, from the viewpoints of three-level scores except "0" on impression words, to that successfully recommended among music not yet recommended. Our system recommends music stored in the database to user u, as shown in Fig. 3. Both the recommendation process using collaborative filtering and that using the proposed method are terminated when the number of recommended music reaches the upper limit K, which was decided previously.

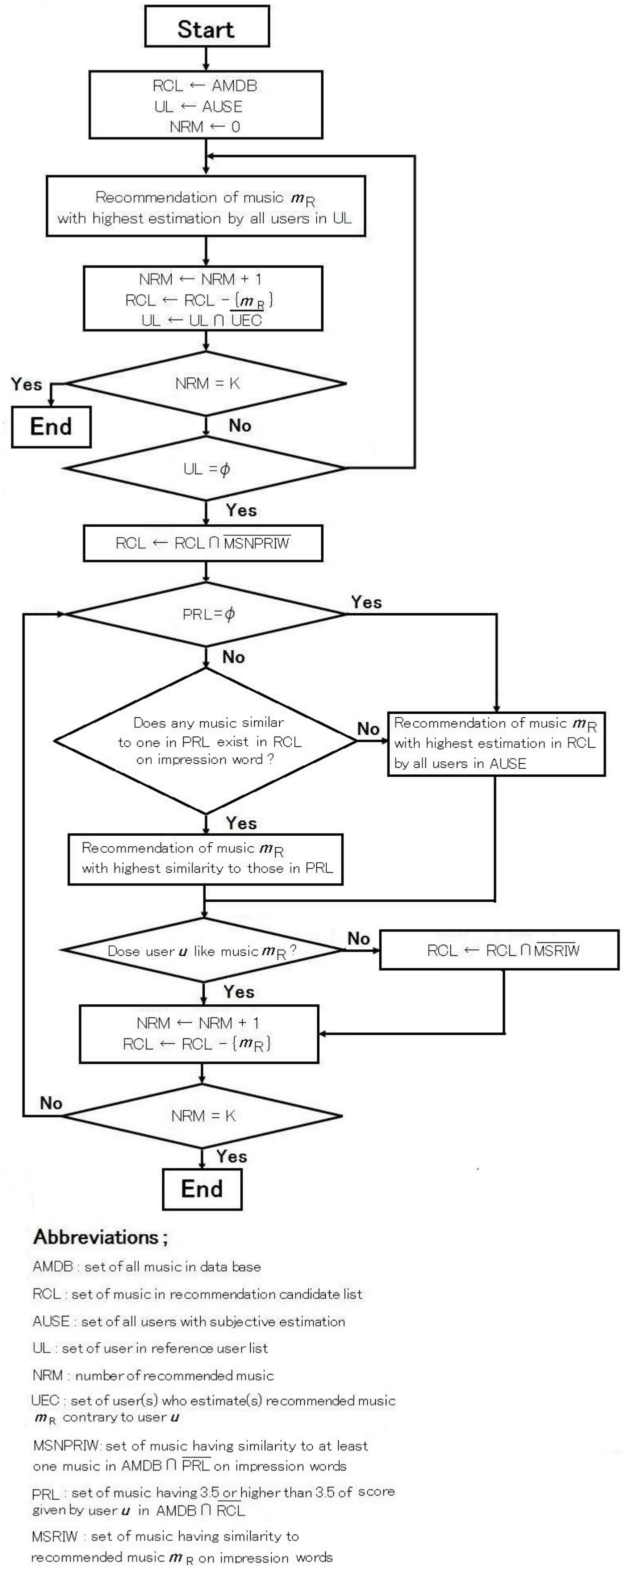

Fig. 3. Flowchart of music recommendation of the proposed method

In the flowcharts of Method 1 and Method 2, shown in Figs. 2 and 3, the estimation of user u for music m_R is set as 1 when the score of user u for music m_R is 4 or 5 ("slightly favorite" or "favorite"), and it is set as 0 when the score is 1 to 3 ("dislike," "slightly dislike," or "neutral").

4 PERFORMANCE EVALUATION

4.1 Conditions

Because older people tend to prefer children's songs [3], we selected a CD described as an anthology of older songs enjoyed by older people with dementia [4], and then we selected 52 songs on the CD that were also included in a music textbook database for elementary schools [5]. To evaluate the music recommendation methods, all 52 of the selected songs in the database were assigned scores s $(1 \le s \le 5)$ by 12 users of the following ages: teens: 1, twenties: 6, fifties: 5. We used 10 as the value of K in Figs. 2 and 3. For evaluating the two music recommendation methods described in Section 3, we chose each of the 12 users as user u and put the remaining users in the reference user list UL described in Figs. 2 and 3. Each user was user u one time and in the reference list 11 times. In addition, all 52 of the selected songs in the database were assigned scores i $(-3 \le i \le 3)$ for each pair of impression words by five subjects of the following ages: twenties: 3, forties: 1, fifties: 1. Of the five subjects, one, who was in his fifties, was the same as the user who assigned scores s . The average of scores i obtained by the five subjects for each pair of impression words was used as scores i for the performance evaluation. The 15 songs having the values except "0" as the three-level score for one impression word at most were not recommended in the process of recommendation based on impression words because they did not have distinct characteristics from the viewpoints of impression words. Then, we obtained the result of the music recommendation for each user for each method described in Section 3.

4.2 Results and discussions

As an example, Table 3 shows the process of the music recommendation for user 3. As shown in Table 3, Method 2 tended to recommend more music than did Method 1. Fig. 4 shows the performance of the two methods. The number of recommended songs by the proposed method (Method 2) was 10 per user, whereas that of only collaborative filtering (Method 1) was 6.25 per user. The recommendation accuracy of the proposed method was 68.3%, whereas that of only collaborative filtering was 66.9%. In the collaborative filtering (Method 1), the recommendation process was terminated at the rate of 10/12, because the number of users staying in the UL became zero (Fig.4(b)).

In contrast, in the proposed method (Method 2), the recommendation process was performed until the number of recommended songs reached the upper limit K decided previously. As a result, as compared with only using the collaborative filtering (Method 1), we could increase the number of recommended songs while keeping the accuracy of the recommendation by joining the recommendation based on the impression words to the collaborative filtering.

Table 3. Music recommendation process for user 3

[Method 1]

Order	Recommended music No.	Acceptance	User No. in UL
1	52	○	1,2,4,5,7,8,9,10,11,12
2	41	○	1,2,4,5,7,8,9,10,11,12
3	17	×	4
4	50	○	4
5	49	○	4
6	44	×	none

[Method 2]

Order	Recommended music No.	Acceptance	User No. in UL
1～6	Same as Method 1		
7	26	○	
8	21	○	
9	36	×	
10	5	○	

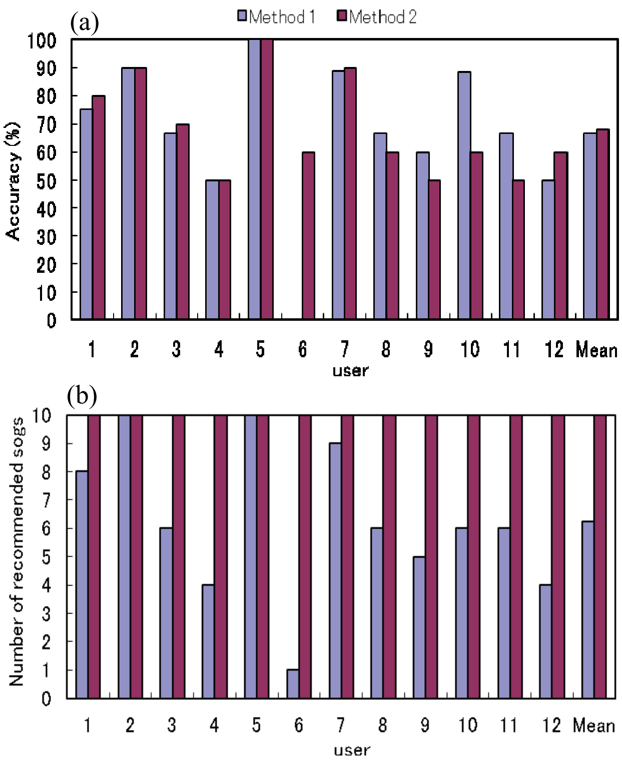

Fig. 4. Performance of music recommendation methods: (a) recommendation accuracy, (b) number of recommended songs

5 CONCLUSION

We propose a music recommendation method that combines collaborative filtering and music recommendation based on impression words. We showed that the proposed method was more effective for music recommendation than the method of only collaborative filtering when used on a music database composed of children's songs. In future work, we will increase the number of users who evaluate the music in the database and apply the proposed method to people who are much older and/or have a cognitive impairment.

Acknowledgments

We would like to thank Associate Professor M. Tabuse of Kyoto Prefectural University for his valuable advice and support. We would also like to thank all the participants who cooperated with us in the experiments.

Keywords: Personal Software Process, Agent System, Personal Digital Assistant, Android Platform support

I. INTRODUCTION

Software architecture has emerged as an important sub discipline of software engineering [1]. PSP support system is built using this. Moreover, We think that the data inputted can acquire software development process by sorting out using a user action record table [2].

In this paper, the Personal Software Process (PSP) practice support system that we realize record-keeping support of flame work performing data acquisition of process flow offered in PSP in other Android carrying end with a software development environment using based on the Multiagent technologies [3]. It is thought that we can tie that we come true with an Android mobile terminal when we perform the convenience that we don't affect to a software development environment and reference of a document if dated consciousness of flow. So, We can be conscious of process flow in every environment with development by this system can transmit programming to specific human among many software processes using Agent's technology. Intelligent agents and multiagent systems are one of the most important emerging technologies in computer science today [4]. Multiagent systems deal with coordinating intelligent behavior among a collection of autonomous agents. Emphasis is placed on how the agents coordinate their knowledge, goals, skills, and plans jointly to take action or to solve problems. Constructing the multiagent systems is difficult [5,6].

Applying the proposed method to a personal process remove task, a flexible programming for quality of software.

II. Android Personal Digital Assistant

The PSP data has record on the framework prescribed by the aforementioned individual specific exercise in support system. Therefore, Record time has been take many form to conducts based on the PSP base-line framework. Support System should be record processes by different development, quality control and large forms. So, it will be not very worried about an activity recording a process form that dealt in an experienced developer of the PSP and working-out of software for a long time. However, it increases that kept record of a form about becomes vague of that still pressed by everyday various works. In order to perform accurate record, their needs for support system automate and reduce the work measurement process.

It content is missing records, which it does not exactly the plan. Therefore, support systems is to record all the work, record and share information, and record information with other differences between them, what do you consider that characterize the individual.

This will be an important resource to support the ability to provide the information necessary to improve the process. However, to be commissioned to present the contents of any process improvement is not help from the Android devices. The recorded information itself, are working will consider process to improvement. An important aspect of this device, by allowing all times and there is early detection of leaks of personal records.

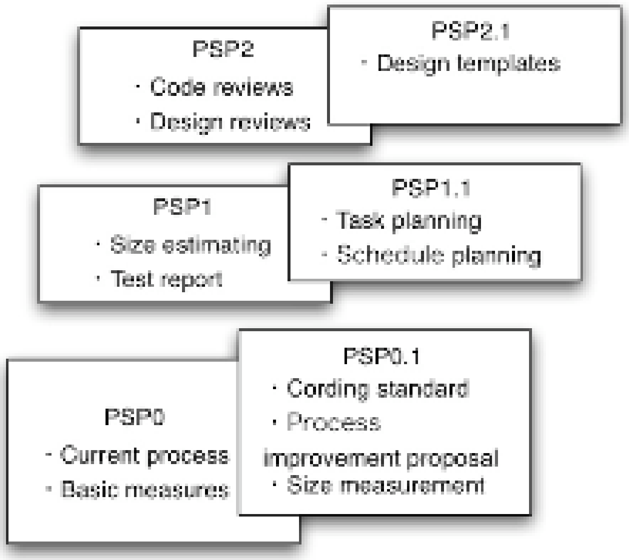

Fig.1. PSP Process Evolution

III. PSP (Personal Software Process)

The PSP is a self-improvement process that helps you to control, manage, and improve the way you work. It is a structured framework of forms, guidelines, and procedures for developing software [2]. Properly used, the PSP provides the data you need to make and meet commitments, and it makes the routine elements of your job more predictable and efficient.

The PSP's sole purpose is to help you improve your software engineering skills. It is a powerful tool that you can use in many ways. Rather than using one approach for every job, you need an array of tools and methods and the practiced skills to use them properly. The PSP provides the data and analysis techniques you need to determine which technologies and methods work best for you. PSP write several program using the evolving process shown Figure 1.

The PSP is not a magical answer to all of your software engineering problems, but it can help you identify where and how you can improve. However, you must make the improvements yourself. PSP0 and PSP0.1 hierarchy include introduces process discipline and measurement. PSP1 and PSP1.1 hierarchy include introduces estimating and planning. PSP2 and PSP2.1 hierarchy include Introduces quality management and design. Team Software Process exists over the PSP hierarchies.

So, This any measure record to support agent consider with using this Agent Learner expanded of PSP support. A person engaging in a person who experienced PSP and software development for many years is not very worried about a form record-keeping work.

Record keeping is vague, and what is performed of a person pressed by a work still increases. Necessity to perform automatically is important in a soldier, remission of an activity and process assay to record an activity precisely.

IV. Digital Assistant for Android mobile tools at Software Estimate Efficiency based on Agent Techniques

In this section, explain assistant of Software Estimate used to the Android Digital Assistant based on internal Agent Learner for Intelligent Agent. Intelligent Agent techniques give connects in other Intelligent Agent record data on PSP. Hence, that Intelligent Agent put the Agent Learner on necessary thoughts in Multi-agent [7].

In the PSP, engineers use the time recording log to measure the time spent in each process phase. In this log, they note the time they started working on a task, the time when they stopped the task, and any interruption time. For example, an interruption would be a phone call, a brief break, or someone interrupting to ask a question. By tracking time precisely, engineers track the effort actually spent on the project tasks. Since interruption time is essentially random, ignoring these times would add a large random error into the time data and reduce estimating accuracy.

Since the time it takes to develop a product is largely determined by the size of that product, when using the PSP, engineers first estimate the sizes of the products they plan to develop. Then, when they are done, they measure the sizes of the products they produced. This provides the engineers with the size data they need to make accurate size estimates. However, for these data to be useful, the size measure must correlate with the development time for the product. While a line of code (LOC) is the principal PSP size measure, any size measure can be used that provides a reasonable correlation between development time and product size. It should also permit automated measurement of actual product size.

1. Software Estimate Design of Agent Learner

The Software Design Estimate kept in Intelligent Agent. Figure 2 shows the Agent internal Data, PSP database and user logs connection modules in other communication method. In this case, Intelligent Agent supports the PSP time and size (LOC: Line of Code) measures record to user manipulation data. Intelligent Agent used to learning Control on internal database for AiD.

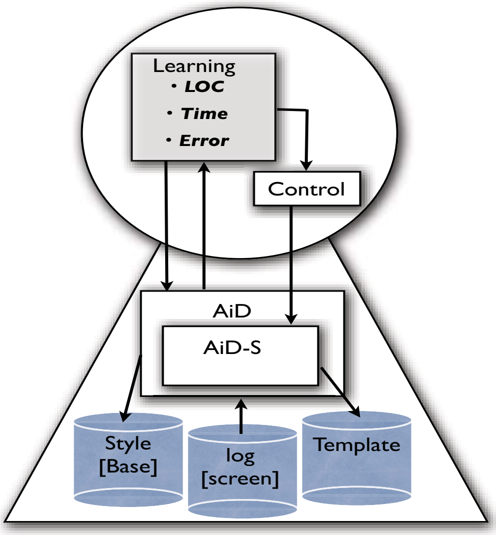

Fig.2. The AiD Data transferred from Agent Learner to action logs

2. The Estimating Probe Method of Agent Software Design

The Probe Method guides user in using historical data to make estimates. With estimated proxy size *E*, Intelligent Agent can calculate the projected program size *P* and did total estimate development time. The parameters β_0 and β_1 are used in the following equation to calculate projected added modified size:

Projected Added & Modfied size $P = \beta_0 + \beta_1 \cdot E$ (1)

When two sets of data are strongly related, Intelligent Agent can use the linear regression method to represent that relationship. This means that linear regression is often appropriate. The parameters β_0 and β_1 are calculated from user historical data.

3. The Android Digital Assistant Interface of Intelligent Agent Software Design

As for the Android terminal unit, it process take possible for archiving to convey the information that it is necessary in the PSP activity through a screen to an internal intelligent agent. Information to convey has memorized the time that activity content in form archiving was really performed.

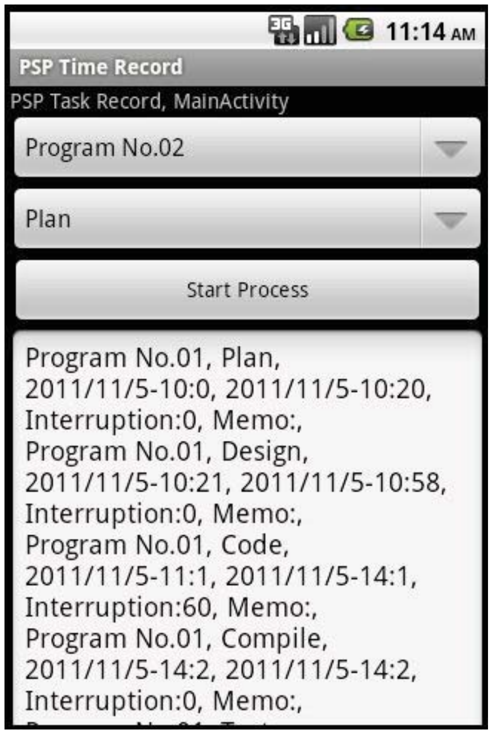

Fig.3. The Android Terminal Unit for first phase on the Agent Interface

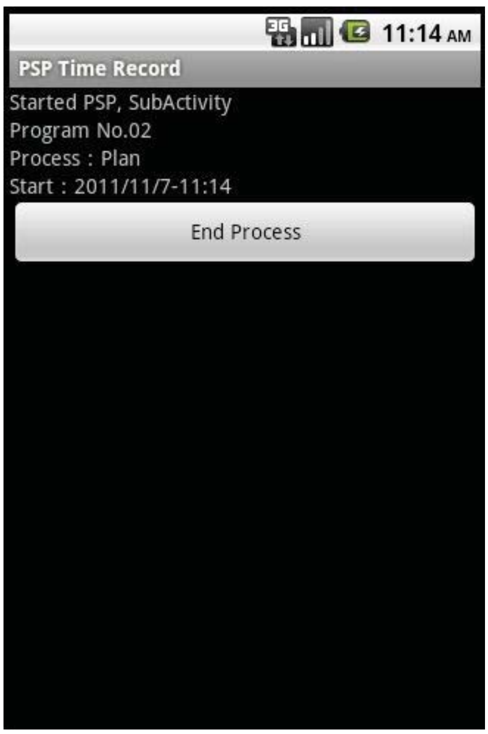

Fig.4. The Android Terminal Unit for second phase on the Agent Interface

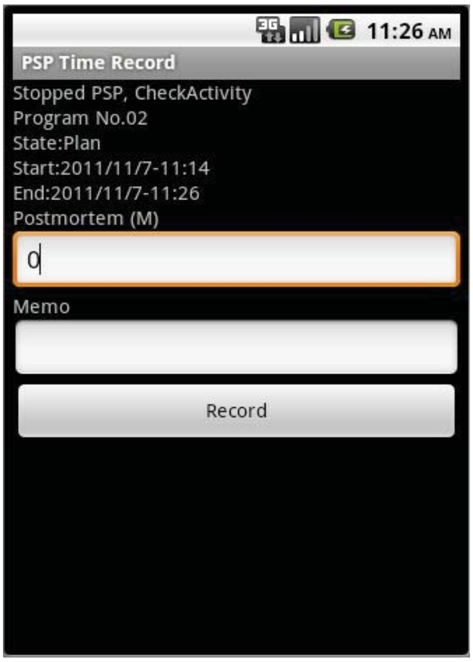

Fig.5. The Android Terminal Unit for third phase on the Agent Interface

When "Record" button be push the Android terminal unit Screen, in order of Figure 3, Figure 4, Figure 5, and activity changes screen design. Because a screen design changes, button of a new context format appears. Agent express current activity contents sequentially whether it has been work-in-process hereby whether it is activity record keeping.

An optional category have take the problems number, work-in-process practicing now. This work-in-process consists of all seven items that the Agent put activity break in as well as six items established in PSP. About activity cutoff, I step over a day and can record an activity.

Actually, I am recordable like Figure 4 when the Agent stepped over a day. A work to perform in this interface, work-in-process is recorded by the operation that it is easy only pushing it in button sequentially.

VI. CONCLUSION

In this research we were analyses PSP Practice Support System used to of flame work performing data acquisition of process flow offered in PSP by the Android terminal unit Interface. We were able to evidence user software working process data. We create agent learner data in real time work data beside with agent running and wrote PSP Practice process type and problem number.

For future works, we will consider methods used on record time data for agent learner in machine learning and user experience. It is necessary for us to consider only a clock through this system about the cause that a description error to be generated by human error.

Future versions of PSP Practice Support System based on Android Terminal Unit record of error type code or fact process from error message of compiler and executer to test pattern data. But, This model will show at the system in a more natural, unscripted scenario, involving multiple parts in addition to other forms of process and error type phenomenon. Now, This system Interface cannot edit by the record data that evidence and work in a process task on Agent Learning data. We consider to support system by what cannot edit record data activity archiving be able to offer the usability as evidence to the intelligent agent techniques.

Abstract: In this research, a programming learning support system incorporating game based learning is proposed. The aim of the game based learning approach is to stimulate and sustain the motivation of the learner during programming training. In the developed system, a puzzle solving interface to programming training and a competitive scoring system was implemented to incorporate game based learning. The proposed system was applied to an actual college programming course to verify the effectiveness of the proposed system. Finally, future works based on the results are discussed.

Keywords: E-learning, Programming, Game Based learning.

1 Introduction

The field of study of students choosing to take courses in educational institution of computer and information sciences has broadened, to include not only computer science fields but also the arts fields including Web design, game, and multi-media. In such learning environments where students with different backgrounds take the same course, one method is to divide the course into classes depending on the initial skill or experience of the students. Even in such cases, depending on the teaching staff resources, each classroom may have as many as 50 students. In larger classes, it becomes more difficult to care for each individual student, and slower students fall behind, while advanced students become dissatisfied with the slow speed of progress. In either case, the student's motivation to study deteriorates. This has lead to the increased interest in improving the motivational aspects of learning in computer related courses.

For previous research on programming learning systems, a method which automatically creates fill-in-the-blanks style program source code problems from instructions embedded in the program code has been reported[1]. On the other hand, research on motivational learning methods for programming education based on the ARCS model[2] has also been reported[3]. But there have been no previous reports on implementation and evaluation of a motivational learning model in an actual e-learning system for programming training.

In this research, we proposed a game-based learning feature for a programming learning support system, in order to realize a learning environment which stimulates and sustains the learning motivation.

In this paper, we describe the overview of the proposed game-based programming learning support system and the features of game-based learning. The proposed system was applied to an actual college programming course to verify the effectiveness of the proposed system, and future works based on the results are discussed.

2 Purpose of the programming learning support system

From past experience, the low motivation of learners who have difficulty in programming is strongly related to stumbling in the early stages of programming training. We considered that a game-based programming learning environment that focuses on program structure recognition and training would stimulate and sustain the learning motivation as well as improve programming skill. From this, we proposed a programming training system with game based learning features to stimulate and sustain motivation for beginners and slow learners in programming. We aimed at developing a learning environment that can expect the following learning effects.

(a) To introduce programming training through a gaming experience in order to stimulate interest in programming.

(b) To improve understanding of programming structures and control flow through a gaming experience, instead of focusing on the language syntax or particular algorithms.

In order to provide a learning environment to achieve both (a) and (b), we proposed the following development goals to realize game-based programming learning features;

(1) Puzzle-based interface to realize a gaming experience programming environment.

(2) Building confidence in learners by presenting exercises that matches the learner's proficiency.
(3) Visual stimulation and effective breaks can be introduced in the learning process by displaying animation and illustrations.
(4) Sense of accomplishment can be given to the learner by displaying the study history and the acquired training contents.
(5) Implement a competing environment to strengthen the gaming experience in programming problem solving.
(6) Improve the satisfaction of learners by providing real-time progress monitor to teachers, allowing teachers to quickly find and support learners who fall behind or repeatedly error on particular problems.

3 Feature of the programming learning support system

We have already reported [4][5][6] about CAPTAIN (Computer Aided Programming Training And Instruction), a puzzle-based programming training system with motivational learning methods, in which learners create programs similarly to solving a puzzle game. In this research, we developed programming learning functions described in Section 2 and implemented these functions in CAPTAIN ver.3 (CAPTAIN3), based on the previous version of CAPTAIN. The main features of CAPTAIN3 are shown in Table 1 and the content of each function is described below.

3.1 Puzzle style program exercise function

This function implements puzzle-based interface in order to introduce programming training through a gaming experience. Programming training from the viewpoint of program structure comprehension and program flow comprehension can be compared to solving a 2-dimensional puzzle by logically laying out the puzzle pieces. From this standpoint, this function breaks up a program into puzzle pieces, and the user must reconstruct the program by selecting the correct program puzzle pieces in the correct order. Fig.1 shows a screenshot of the puzzle interface of CAPTAIN3 during programming exercise.

3.2 Automatic generation of programming exercise function

This function automatically creates puzzle pieces from the problem source code according to the progress and comprehension level of the learner using genetic algorithm. In CAPTAIN3, new functions to automatically insert incorrect and unnecessary puzzle pieces were added.

Table 1 main function of CAPTAIN3

No	main function	contents
1	Puzzle style program exercise function	This function offers the puzzle based interface for program exercise.
2	Automatic generation of programming exercise function	This function automatically creates puzzle pieces from the problem source code according to the progress and comprehension level of the learner.
3	Animation display function	This function displays animation and the illustration.
4	Learning history display function	This function displays individual learning history with the progress report and the accuracy rate.
5	Competitive learning function	This function displays the learner's relative level compared to other learners in the same group.
6	Learning progress monitoring function	This function displays every learner's progress status for the instructor.

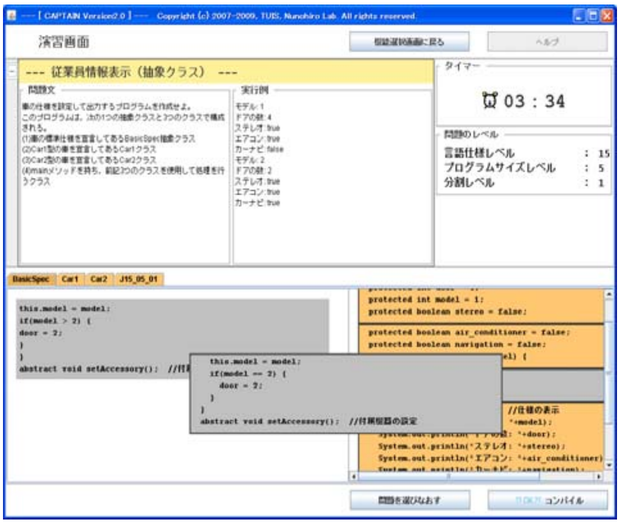

Fig.1 Programming training screenshot

3.3 Animation display function

This function aims to give effective breaks and to keep the motivation by using the visual stimulus such as display of the animation depending on the learner's exercise result and progress report in the programming training.

3.4 Learning history display function

This function aims to give the sense of accomplishment to the learner. The learner can confirm the exercise which were answered correctly and correct answer rate on the progress monitoring screen.

3.5 Competitive learning function

This function visually shows the learner's progress and the learner's relative level compared to other learners in the same group, in order to stimulate the learner's attention and motivation.

3.6 Learning progress monitoring function

This function displays the learning progress status of each learner in real-time. The instructor can monitor the progress of each learner in the classes using this information. Fig.2 shows the instructor's monitoring screen displayed as a Web application. The monitoring program retrieves updated progress status of all learners from the database on a short time interval, and displays the progress visually on a Web browser.

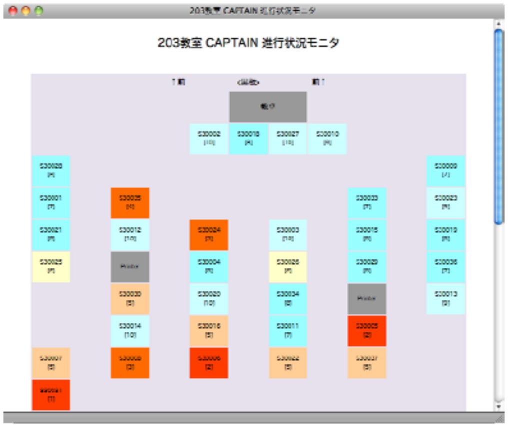

Fig.2 Progress monitoring Web application

4 Application and evaluation of Captain system

4.1 Application

CAPTAIN3 was applied in a Java programming course for 2nd year students in the Department of Information Systems, Tokyo University of Information Sciences. In this course, the students were divided into 3 classes (advanced, intermediate, introductory) according to the results of a preliminary test. CAPTAIN3 was applied in the introductory class. The applied programming course is a full year course consisting of 90 minutes lecture and 90 minutes lab per week.

4.2 Evaluation

In order to evaluate the learning effect by using CAPTAIN3, we executed the same progress evaluation test (5 mid-term exams and 1 final exam) for 3 classes (advanced, intermediate, introductory) and evaluated the results. An anonymous questionnaire was taken in the introductory class. The evaluation period is from April in 2010 to January in 2011 and the evaluation was applied to student data (20 students in the advanced, 28 students in the intermediate and 15 students in the introductory classes) who had attended all mid-term and final exams.

The test problems were classified into the following five skill groups, and the maximum total points for each test were 35 points.

(a)Basic knowledge for Java programming
(b)Program creation (fill in the blanks without answer group)
(c)Program analysis (execution results analysis without answer group)
(d)Program creation (fill in the blanks with answer group)
(e)Program reconstruction (program reconstruction using program pieces with answer group)

One of the main goals of CAPTAIN3 is to assist the learner in understanding programming structures and flow control through a base based interface. Therefore, we expected that the effect of training using CAPTAIN3 will be most visible in skill group (e). Following this expectation, we evaluated the effect of CAPTAIN3 for the following two cases.

case 1: total point for evaluation test (skill group (a) to (e)) : maximum 35 points
case 2: points for problems in skill group (e) : maximum 5 points

Table 2 shows statistical test results for case1. Table 2 shows that a significant difference was noted at 5% significance level between the advanced/intermediate and introductory classes in both the confirmation test 1 and the final test, meaning that there is still a significant difference in skill between the advanced/intermediate class and introductory class after the final exam. However, Fig.3 shows the difference of average score for these tests between the advanced/intermediate and introductory classes has become smaller.

Table 3 shows statistical test results for case2. Table 3 shows that for test 1, the difference of the average score between advanced/intermediate and introductory classes was also large and a significant difference between classes was shown by the t-test. But for the final exam, the difference of the average score between classes became smaller and a significant difference could not be seen in the result by the t-test. Fig.4 also shows that the difference of the average score between classes has become smaller.

These results showed that the introductory class using CAPTAIN3 was able to narrow the skill difference between the more advanced 2 classes.

Table 2 Comparison of advanced/ intermediate and introductory classes (case 1)

class		confirmation test 1 (6/2)	final test (1/26)
advanced/intermediate (CAPTAIN3 not used)	Average	29.7	29.1
introductory (CAPTAIN3 used)	Average	15.6	21.1
t-test between classes	*t* value	8.80	4.33
	significance	P<0.05	P<0.05

Table 3 Comparison of advanced/ intermediate and introductory classes (case 2)

class		confirmation test 1 (6/2)	final test (1/26)
advanced/intermediate (CAPTAIN3 not used)	Average	4.0	4.3
introductory (CAPTAIN3 used)	Average	1.7	3.8
t-test between classes	*t* value	6.03	1.59
	significance	P<0.05	none

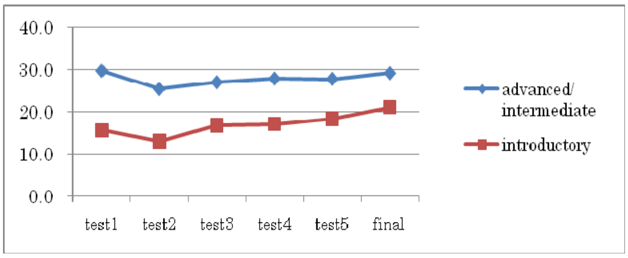

Fig.3 Transition of average for case1

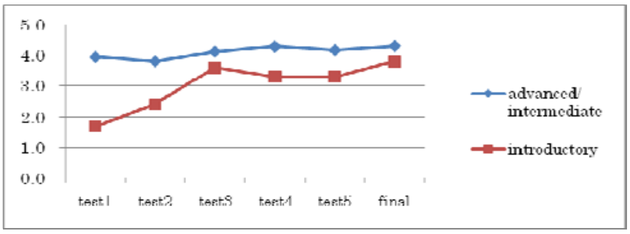

Fig.4 Transition of average for case2

5 Conclusion and future works

In this paper, we developed game based learning features in a programming learning support system, to offer a learning environment that stimulates and sustains the motivation of the learner during programming training. The proposed system was applied to an actual college programming course to verify the effectiveness of the proposed system.

From the result of transition of the average score for mid-term and final exams, we concluded that the developed CAPTAIN system was effective in the viewpoint that the student showed interested in programming. Moreover, from the result of case 2, it can be seen that this system was effective for the purpose of understanding the structure and processing flow of the program. However, from the result of t-test for case 1, it could not be established that the proposed method had a positive effect in improvement of the programming skill, and improvement of the learning features and revision on method of applying the proposed system in the programming course is necessary.

Abstract: Tokyo University of Information Sciences maintains and distributes MODIS (Moderate Resolution Imaging Spectroradiometer) data as part of the research output for Frontier project. We have published many studies using MODIS data and many other researchers use them for their researches. On other hand, it is possible to use MODIS satellite data, especially NDVI (Normalized Difference Vegetation Index) for education. But it is necessary to visualize the data clearly for many users. In this research, we proposed a method to visualize satellite data for education and processed real MODIS data using the proposed method.

Keywords: MODIS, NDVI, Visualization, Education

1 INTRODUCTION

The Moderate Resolution Imaging Spectroradiometer (MODIS) is a scientific instrument aboard Terra satellite and Aqua satellite launched by NASA. MODIS data are used for various environmental researches.

Tokyo University of Information Sciences receives MODIS data and provides the processed data to university and research institutes. We have reported various researches [1][2][3][4][5] using MODIS data. Furthermore, it is possible to use satellite data for education. But in this case, satellite data should be displayed in the form that is easy to understand.

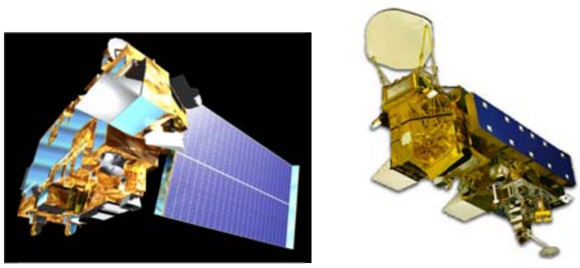
Recently, there has been more computer graphics (CG) teaching materials employed in classes for elementary and secondary education than in the past [6][7][8]. Applying CG teaching material in class can stimulate the interest of the students through visual effects, and improve the comprehension and learning experience.

In this research, we investigate a method to visualize satellite data for education, especially junior high school and high school students. Using proposed method, MODIS data, especially NDVI (Normalized Difference Vegetation Index), can be displayed simple 3D CG. Furthermore, we processed real NDVI by proposed method.

2 MODIS data and NDVI

2.1 MODIS data

The moderate resolution imaging spectroradiometer (MODIS) is a scientific instrument launched into Earth orbit by NASA in 1999 on board the Terra Satellite, and in 2002 on board the Aqua satellite. Terra's orbit around the Earth is timed so that it passes from north to south across the equator in the morning, while Aqua passes south to north over the equator in the afternoon. Terra MODIS and Aqua MODIS allow the viewing of the entire Earth surface every 1-2days. MODIS capture data in 36 spectral bands, or group of wavelengths. Moderate-resolution remote sensing allows the quantifying of land-surface type and extent, which can be used to monitor changes in land cover and land use for extended periods of time. These data are used to monitor and understand global dynamics and the processes occurring on the land, and in the oceans and the lower atmosphere.



(a) Terra (b) Aqua

Fig. 1. Terra and Aqua satellites

2.2 NDVI

The normalized difference vegetation index (NDVI) is an index that provides a standardized method of comparing vegetation greenness between satellite images. NDVI is defined as follows,

$$NDVI = (RED - NIR) / (RED + NIR) \qquad (1)$$

where RED is visible red reflectance, and NIR is near infrared reflectance.

3 Visualization of NDVI

3.1 Development environment

In this research, we developed a simple system to change NDVI data to simulated color NDVI images and 3-D NDVI images. The system configuration is shown in Fig.2. Data used for visualization are read from the satellite database. The system was developed using Java language and Java 3-D for the 3-D API. Processing results of the system is output on the display and written to files.

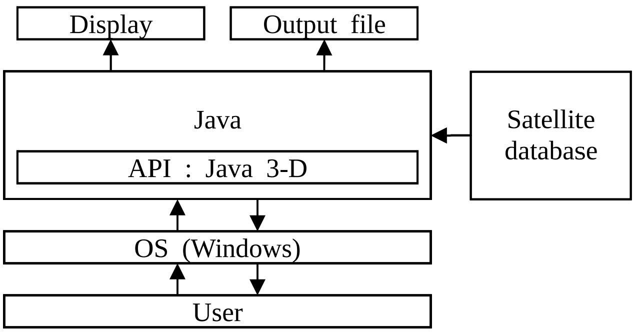


Fig. 2. System Configuration

3.2 Visualization Procedure

Visualization procedure is shown in Fig.3.

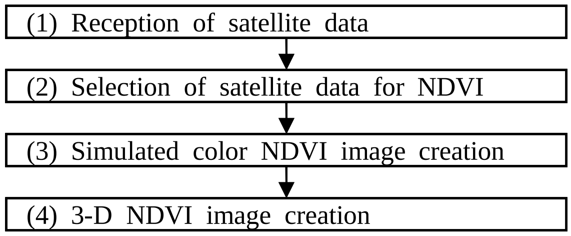

Fig. 3**.** Visualization procedure

(1) Reception of satellite data

Satellite data are received by the satellite data reception system at Tokyo University of Information Sciences. The satellite data are stored to the satellite database.

(2) Selection of satellite data for NDVI

Data necessary for calculation of NDVI are selected from the received MODIS data. The NDVI value can be calculated by formula (1). The satellite data reception system developed at the authors' university already supports NDVI creation, and NDVI values can be retrieved directly as a grayscale NDVI image. Examples of grayscale NDVI images are shown in Fig.4.

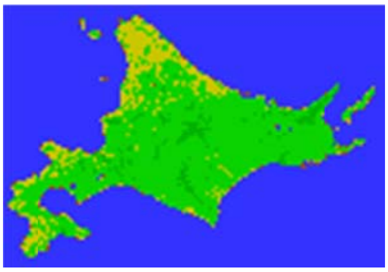
(a) Hokkaido region

(b) Kyusyu region

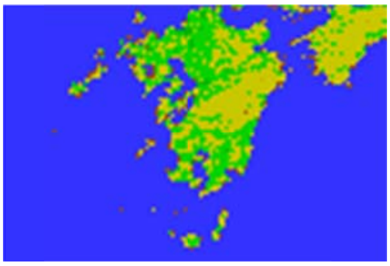
Fig. 4**.** Examples of grayscale NDVI images

(3) Simulated color NDVI image creation

The system changes grayscale NDVI images into simulated color NDVI images. The system maps high NDVI values to gradations of green to visualize vegetation areas, maps low NDVI values to gradations of brown to visualize non-vegetation areas, and maps extremely low NDVI values close to 0 to blue to visualize water covered areas. Examples of simulated color images are shown in Fig.5.



(a) Hokkaido region



(b) Kyusyu region

Fig. 5. Examples of simulated color NDVI images

(4) 3-D NDVI image creation

3-D NDVI image is generated by treating NDVI values as height to the z-axis direction. Furthermore, the viewpoint can be changed by dragging the mouse so that it is easy to understand the results. Examples of 3-D NDVI images with different viewpoints are shown in Fig.6.

4 Educational use

We developed a prototype system to be used as educational material in science or social studies classes. The system allows a simplified visual presentation of complex satellite data, assisting the learner to understand the subject matter visually, improving the educational effect.

But to support various educational uses, it is necessary to display color 3-D NDVI images, as well as to support views for displaying representative values for given areas or districts and regions.

5 CONCLUSION

In this paper, the authors presented a visualization method of satellite data for educational use. In this research, we developed a system which simplifies the display of complex satellite data for junior high school and high school students.

The system is still a prototype, so we need to investigate necessary functions and implement them in the system. The system is scheduled to be implemented as a Web application to facilitate deployment in educational environments.

For future works, the authors plan to improve display of 3-D NDVI image and man machine interface, and evaluate the learning effect.

ACKNOWLEDGEMENTS

The authors wish to thank Dr. Yukio Yanagisawa, Dr. Masao Igarashi of Nihon University, Dr. Keitaro Hara and Dr. Ichio Asanuma of Tokyo University of Information Sciences for their valuable advice and collaboration.

This research was supported by the Research project of Tokyo University of Information Sciences for the sustainable development of economic and social structure dependent on the environment in eastern Asia.

(ohshiro@rsch.tuis.ac.jp)

Abstract: The authors have developed a programming training system CAPTAIN (Computer Aided Programming Training And INstruction) and have applied the system in an actual programming course. In this training system, learners create programs similarly to solving a puzzle game as follows. Each complete runnable program is fragmented randomly into a few lines by the system. Users must sort the lines as an original source program. The system compile the source program sorted by the user and check the correctness of it. In such a learning support system, it is important that the learner can view one's learning progress objectively. Furthermore, if the learning progress could be compared with those of other learners, competition will occur to stimulate the learner's motivation. In our previous paper, we proposed and implemented the real-time monitoring feature for the support system. The new system monitors the statuses of all students' progresses and evaluates their degrees of achievement and ranks them in real time and continuously. The proposed features allow the learner to view one's own progress ranking compared to the whole class, and also enables the teacher to monitor each individual learner, in order to quickly spot and support learners having difficulty. In this paper, we propose a new feature for the system using nicknames. The system assigns different nicknames to each student individually and randomly in the beginning of every class. The system displays ranking using nicknames to all students and teachers in public. Therefore, each student can know his or her absolute and relative rank in their community because they may tell his and her own nickname to their friends. In this situation, nickname makes learners ' rank public and protects their privacy. Every community seems to consist of members with similar comprehension degree. Furthermore, the ranking display is updated automatically at intervals of thirteen seconds. Therefore, learners can observe dynamic transition of his or her rank in real time. It seems that the feature improves students' motivation much more similarly to competitive games. We attached the feature to our programming learning support system and applied actual classes.

Keywords: programming, learning, game, java, nickname

1 INTRODUCTION

We have developed a programming training system CAPTAIN (Computer Aided Programming Training And INstruction) written by java. Fig.1 is a login window of CAPTAIN[1, 2, 3, 4, 5]. We have applied the system in an actual programming course. In the system, learners create programs similarly to solving a puzzle game as follows. Each complete runnable program is fragmented randomly into a few lines by the system. Users must sort the lines as an original source program. The system compile the source program sorted by the user and check the correctness of it. If the answer is correct, user can run it and observe it's behavior (Fig.2).

In such a learning support system, it is important that the learner can view one's learning progress objectively. Furthermore, if the learning progress could be compared with those of other learners, competition will occur to stimulate the learner's motivation. Therefore, we introduced a feature, an index-value for comprehension of each user and a ranking view using the index-value in the previous version of the system[5] as shown in Fig.3.

Fig. 1. CAPTAIN

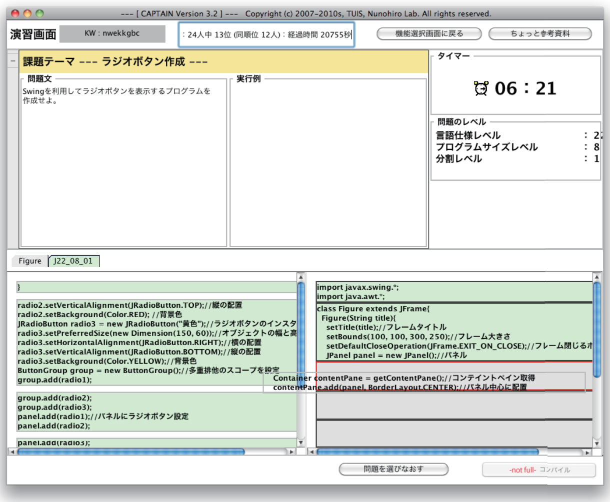

Fig. 2. Each learner must sort fragmented and randomly listed parts of a program into the correct order.

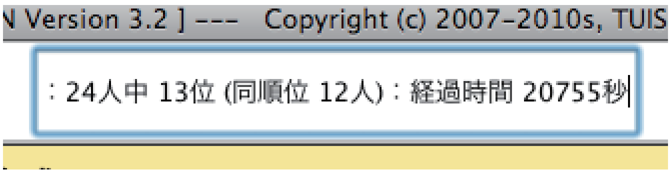

Fig. 3. A ranking display shows the ranking of the learner. For this example, the ranking of this learner is the 13th among 24 users and there are 12 learners in the same ranking). This ranking view is displayed in top of the main window and updated every 20 seconds by a thread.

In this paper, we update this ranking feature using nickname to improve learners' motivation using nicknames more efficiently.

2 PROBLEMS OF SIMPLE RANKING SYSTEM

We have noticed some problems of the simple ranking system for a competitive game.

2.1 Problems of a large group ranking

Can you keep your motivation for playing a competitive game in a large group? Every game player wants to see it's own rank rising by some efforts. Perhaps, in such a large group, your rank will not rise rapidly in spite of your efforts, therefore you may be tired of studying using the system. If your rank is very low in a large group, it seems that you will give up easily. We assumed that appropriate population is important for keeping and improve learners' motivation in such a competitive game. It can be considered that the best size of population for a learner depends on the comprehension degree of the learner. For example, the learner with the high degree of comprehension may not lose one's motivation even in a large group. On the other hand, the learner with the low degree of comprehension may be able to keep one's motivation only in a small group that consists of the people with similar degree of that. Fig.4 shows this problem schematically.

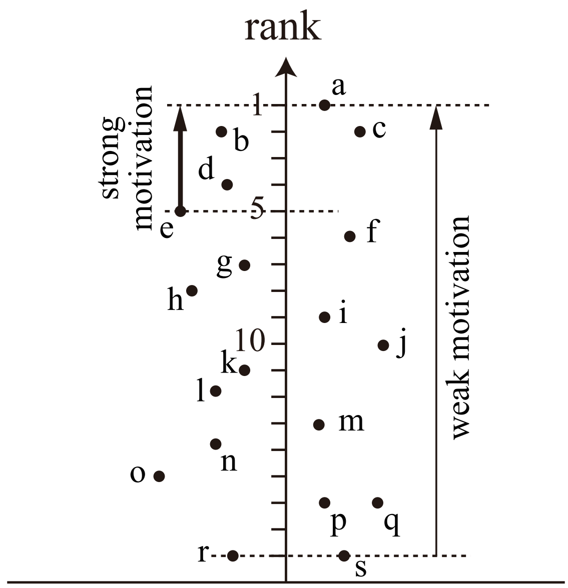

Fig. 4. Strength of each learner's motivation. The length and the thickness of each arrow toward to the apparent goal (i.e., the 1st rank) describe the strength of motivation of each learner. As thick and short arrows represent the motivation is strong. For example, the learner 'e' has strong motivation. On the other hand, the learner 's' has only weak motivation. The horizontal axis has no role in this figure.

2.2 Problems of a real name ranking

In the previous version of the system, each learner can know only their own rank, so every learner can't know other's rank and who their competitors are. In a typical competitive game, obvious competitors stir the player up and make him or her grow up. A game player often wants to know the ranks of their friends because people want to be not inferior to their friends, if possible, be superior to them. We considered whether to add the feature that real names of learners are displayed with their ranks or not. Finally, we gave up the real name display because if the real names of learners are displayed with the ranks, it violates their privacy as a result.

3 NICKNAME RANKING

We paid attention to the fact that students are divided and organized into some small groups of their own accord. It seems that these groups, their own communities, consist of their own friends with similar degree of comprehension. They often tell their results of tests each other in the small community. We tried to resolve the problems mentioned in the prior section by a nickname ranking system using the characteristic of such a small community of students. In the newest version of CAPTAIN, enough fictional nicknames are stored in our database and every learner is reassigned a unique nickname when the learner logs in the system everyday as shown in Fig.5. We adopted the names of famous heroes and heroines as nickname to attract the attention of the learners. The ranking list using nicknames (Fig.6) is displayed in an extra window as shown in Fig.7.

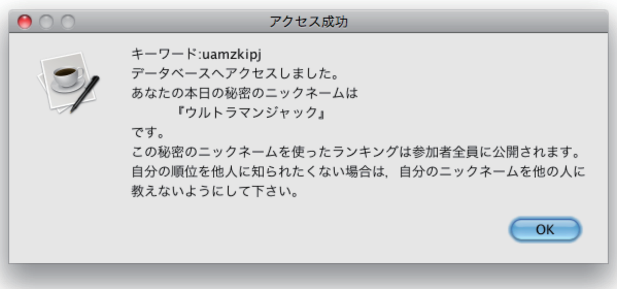

Fig. 5. Nickname assignment dialog window. This dialog is displayed after loggin in the system. It shows the today's nickname of the learner.

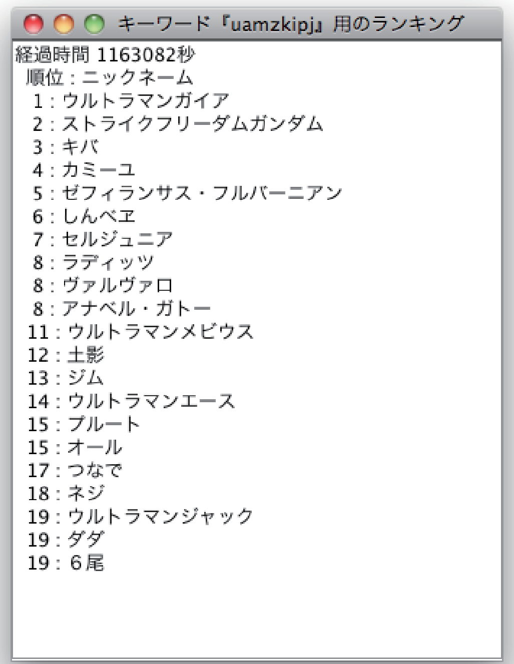

Fig. 6. A ranking list using nicknames. The list is updated every 20 seconds by a thread.

The comments of the nickname assignment dialog describe as follows "It is a today's your secret nickname. The ranking list using these secret nicknames will be displayed to every learner. Therefore, don't tell your nickname to other leaners if you want protect your privacy." It is expected that the learners tell their own secret nickname to his or her friends in the community for playing and enjoying a competition game in the system. It seems that the nickname system can protect learners' privacy and let the learners know who the competitors are only in his or her own community. Fig.8 schematically shows such a situation. In the case, there are many strong motivations in each community.

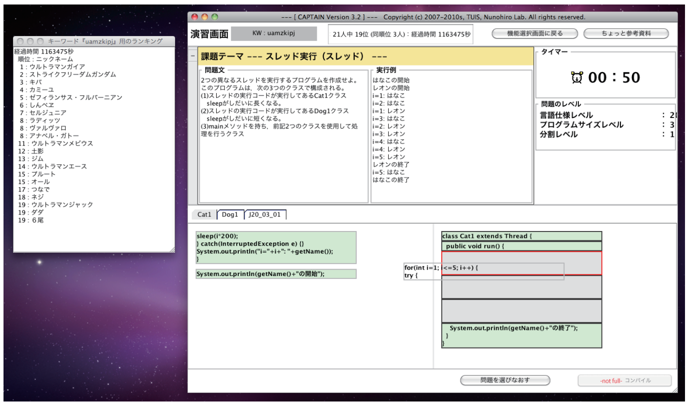

Fig. 7. A window configuration of the system. The ranking list using nicknames is displayed as an extra window during the lesson using the system.

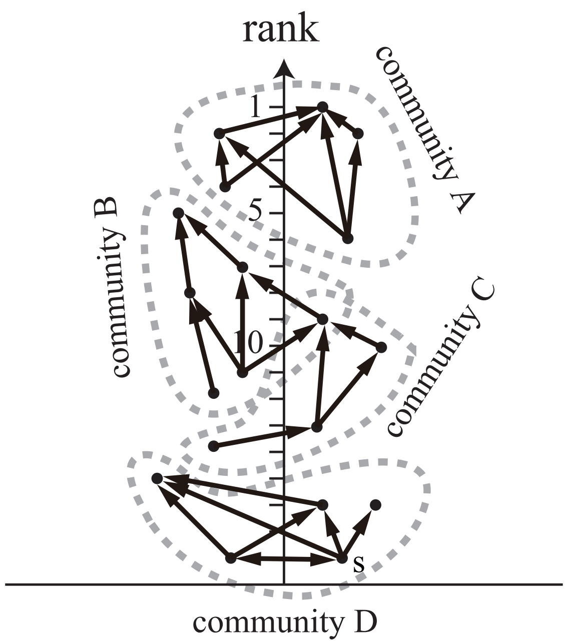

Fig. 8. An ideal situation under nickname ranking method. The horizontal axis represents some relationship between learners.

As for the learners in the community with low degree of comprehension, e.g. D in Fig.8, it seems that they can keep their motivation because they needn't mind the absolute rank and have only to compete with other members of their own community for the present.

4 CONCLUSION

It is expected that the nickname ranking can resolve the problems of the ranking in a large group and the learners' privacy. We are using the nickname ranking system in CAPTAIN for learners during actual class. We need to examine the effect of the experiment by analyzing the records of the learners' degree of comprehension and results of a questionnaire survey.

Abstract: In education, lecture is required to use computer software such as PowerPoint, flash, and so on. One of the utilization purposes of this is education effect improvement. Usually, showing animated figures is said to be good for education. So, many education systems using animated figures have been proposed. However, only few attempts have so far been made at discussion of these effects. Especially, it has not been comparing the education system using animated figures with the chalk talk. So, we research effects of a lecture using animated figures. This is a comparative research of a lecture using animated figures and a chalk talk lecture in a beginner's programming education course of university. Students of beginner's programming education course have been divided into three groups. We focus on only two groups of these. One of the groups is shown program behavior by Microsoft PowerPoint animations and follows the program statements step-by-step and show changing values of program variables by abstraction figures. Another group is a chalk talk lecture. Each group is the same syllabus, same assignments, same practical training, same final examination and same impressions questionnaire of lecture. So, difference of each group is only representation method. Thus, the proficiency effect of using animated figures is appears in a final examination. And, other effects (such as the desire to learn, satisfaction and so on) appear in the impressions questionnaire. We shows check fiver year's worth of the final examination and the impression questionnaire. As a result, this research has a little advantage of the lecture using animated figures in the representation method in this example. However, it does not show definite advantages of the lecture using animated figures.

Keywords: Computer aided education, E-Learning, Programming Education, Education Impression, Animated Figure

1 INTRODUCTION

In education, lectures are required to use computer software such as PowerPoint, flash, and so on. Usually, showing animated figures is said to be good for education in physics and geometry. Animated figures using computer can visualize an invisible motion of the physical laws like tiny or huge object motion. So, learners can understand invisible motions.

Usually, an execution of computer program just only shows results of program. Therefore, a behavior of computer by the program is invisible. Nevertheless, computer programming learner is required to understand behavior of computer by a program.

So, some system which shows a computer behavior by a program has been proposed. For example, one of the proposed systems is “Proposal of Program Text Markup Language through Program Visualization Tool” and “Effective IT Learning Method Using Schematic Diagram Approach”, which shows a behavior of a program [1][2]. And, VisuSim has been proposed, which is a visual computer simulator for education [3]. In addition, many teachers have made one-of-a-kind animated figures which show the behavior of computer by a program for education. However, many education systems using animated figures have been proposed. However, only few attempts have so far been made about the effectiveness of this method.

So, we researched effectiveness of a lecture using animated figures for the programming education. This class is teaching JAVA programming for beginner. Students of this class divide into three groups and each class are same syllabus, same practical exercise and same final examination. One of the group's lectures is using animated figure of program behavior. Other group's lecture is chalk-talk (using blackboard). So, we checked differences of each class.

The proficiency effect appears in evaluations of learning result. And, other effects (such as the desire to learn, satisfaction and so on) appear in impression questionnaire. Therefore, differences of the evaluations of learning result and the impression questionnaire are effects of a lecture showing animated figure for programming education.

In this paper, we report a comparison of evaluations of learning results and impression questionnaires in a JAVA programming education class for beginner in our university for five years for checking effects of lecture using animated figure.

2 BASIC IDEA

Checking effectiveness of animated figures for a lecture requires several divided groups of students which have same syllabus but just only presentation method is different. So, we focused on a beginner programming education course in our university. The exercise lesson (such as the programming exercise) requires tutorial process. In this case, too many students in a classroom make it difficult to program tutorial exercise. Thus, the exercise lesson consists of a small group of students.

However, even if these are several groups of students in class, usually these have same syllabus in our university. Therefore, an exercise lesson in our university is same lesson content, same exercise program, same final examination and same grade point assessment criterion of the academic achievement commonly. In this case, the difference of each group is just only the method of lecture by teachers. If one of the teacher using animated figures and another teacher using only blackboard in lecture, checking the academic achievement and the impression questionnaire is appearing differences of each other. These differences mean the effectiveness of a lecture using animated figures.

3 SURVEYED COURSES

We researched a class of the programming training course for beginners in our university. This class is teaching JAVA programming for beginner. The process of this class lesson is showed as follows;

1st: Teacher teaches today's content of a lecture.
2nd: Students take practical studies to JAVA programming assignments.

Students of this class divide into three groups and each class are same syllabus, same practical exercise and same final examination. One of the group's lectures is using animated figures of a program behavior. Other group's lecture is chalk-talk (using blackboard). And these classes have same lesson content, same exercise program, same final examination and same grade point assessment criterion of the academic achievement commonly. An image of the surveyed course is shown in Fig 1.

So, we focused on the two groups. Group A is using the power point animated figures. But Group B is using only black-board (Static figure). The difference of final result of Group A and Group B means effectiveness of the lecture using animated figures. In addition, this course has the impression questionnaire at the day of the final lecture. Thus, effects of the desire to learn, satisfaction and so on appear in impression questionnaire. So, we have checked the final result and the impression questionnaire of these classes for five years.

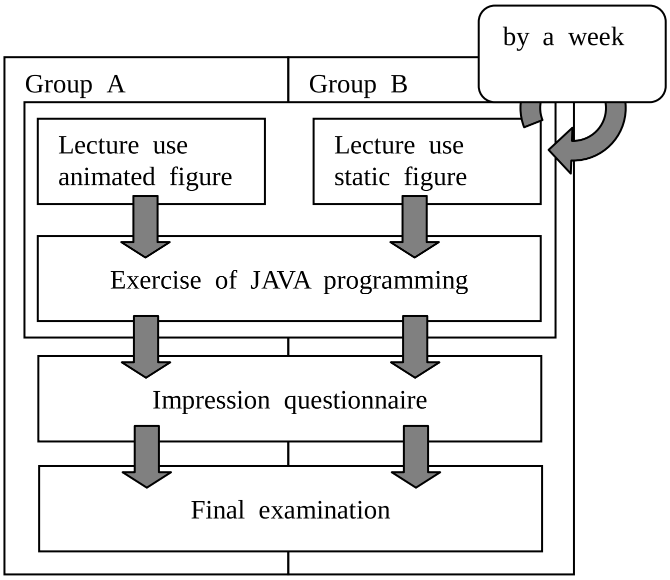

Fig. 1. An image of surveyed course

4 RESULTS

Table 1 shows the highest point, the lowest point, the standard deviation and the average of the final result of two groups for each five years. The maximum of this final result points is 113 and minimum of this points is 0. Table 1 shows Group A and Group B were similar result points.

Table 1. Final result of two groups for each five years

Year	Group	Average	Highest point	Lowest point	Standard deviation	Number of Sample
2007	A	88.6	112	8	17.2	46
	B	82.3	110	5	21.4	45
2008	A	83.0	112	0	22.3	62
	B	83.6	111	0	22.9	30
2009	A	72.3	102	0	21.3	64
	B	83.3	111	0	19.8	66
2010	A	89.6	108	0	19.2	63
	B	82.3	112	0	25.7	65
2011	A	85.0	111	0	22.0	46
	B	83.6	112	0	22.9	43

Table 2. Impression questionnaire of two groups for each five years

Questions	Were you able to understand lecture contents?		Were you able to learn new knowledge?		Was the speech skill of a teacher good for you?		Was the expression method plain for you?		Was the class executed according to syllabus?	
Group	A	B	A	B	A	B	A	B	A	B
2007	4.1	4.1	4.6	4.5	4.4	4.4	4.1	4.1	4.2	4.2
2008	4.1	4.1	4.3	4.5	4.4	4.3	4.1	4.2	4.1	4.3
2009	4.1	4.1	4.4	4.4	4.4	4.1	4.3	4.0	4.2	4.0
2010	4.1	3.9	4.6	4.4	4.6	4.1	4.2	3.8	4.3	4.0
2011	3.9	4.2	4.3	4.3	4.1	4.4	3.9	4.2	4.1	4.4

Questions	Was the volume of a lecture appropriate for you?		Were enthusiasm and good faith of a teacher felt for you?		Did the teacher deal with a question of a student faithfully?		Was it a valuable class for you?		As for you, did learning will increase by having attended this class?	
Group	A	B	A	B	A	B	A	B	A	B
2007	4.3	4.0	4.4	4.3	4.6	4.3	4.5	4.4	4.4	4.3
2008	4.0	4.3	4.3	4.2	4.4	4.5	4.4	4.5	4.3	4.2
2009	4.2	4.1	4.4	4.2	4.5	4.3	4.5	4.2	4.4	4.1
2010	4.3	4.1	4.5	4.2	4.7	4.0	4.6	4.4	4.3	4.1
2011	4.1	4.4	3.9	4.4	4.0	4.4	4.2	4.4	3.9	4.1

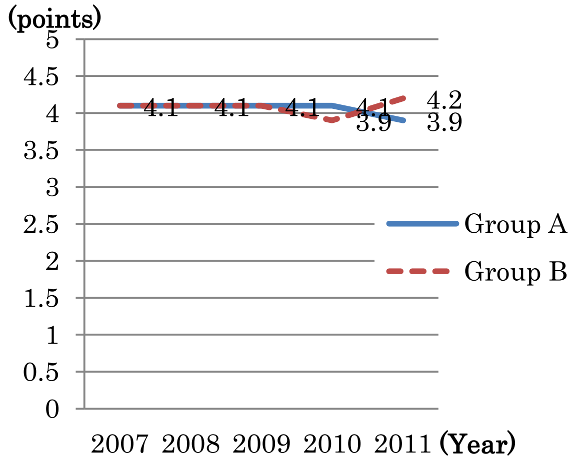

Fig. 2. Answer of question "Were you able to understand lecture contents?"

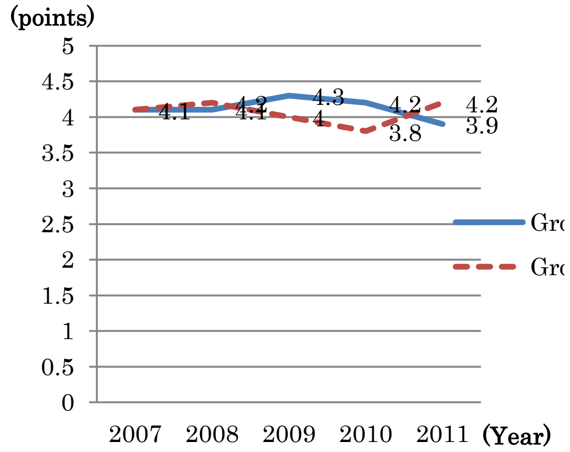

Fig. 3. Answer of question "Was the expression method plain for you?"

Table 2 shows the average of the impression questionnaire of two groups for each five years. This questionnaire is written in Japanese. The maximum of this point is 5 and minimum of this point is 0. Table 2 shows Group A and Group B were similar points.

The educational effectiveness of understanding appears as answers of the question "Were you able to understand lecture contents?" of a questionnaire. So, we show this answer of questionnaire in Fig.2.

The educational effectiveness of using animated figures appears as answers of the question "Was the expression method plain for you?" of a questionnaire. So, we show this answer of questionnaire in Fig.3.

5 CONSIDERATIONS

From Fig. 1 and Fig. 2, the understanding of learning fluctuates by each year. However, it is almost the same in the Group A and the Group B.

And, from Fig. 3, the expression method of Group A was a little higher. However, it has not shown definite advantages of lecture using animated figures.

In this research, the final result and the impression questionnaire of Group A and Group B are similar. This result means an educational effectiveness of a lecture using animated figures and a lecture using static figures is similar.

We consider a reason of this result is the effect of practical exercises. The practical exercise is more effective in this research. Therefore, more effective programming education requires an improvement of a practical exercise.

6 CONCLUSION

In this paper, we report a comparison of evaluations of learning results and impression questionnaires in a JAVA programming education class for beginners in our university for five years for checking effects of a lecture using animated figures.

In this research, an education effect of a lecture using animated figure and a lecture using static figure is similar. So, it has not shown the definite advantage of lecture using animated figures.

Abstract: In higher education, a decline in the academic abilities of students has become a serious problem. In this paper, we propose a system to increase learning motivation with the ultimate aim to increase the academic ability of students. To achieve this aim, we provide an environment for students to facilitate self-e-learning system in classes using blended learning. We report the development of this environment and the results obtained.

Keywords: Motivation for Learning, Self-Learning, Support System, Academic Ability

1 INTRODUCTION

With the development of information technology (IT), the number of learning options is continually increasing for students in IT-related course studies (both in universities or other institutions). However, due to reduction in the enrollment of students and increases in the advancement rate from high schools to universities, students' motivation for learning decreases. As a result, many universities are facing the problem of students with low academic abilities[1].

For effective learning and efficient operation of courses, blended learning, which is a combination of face-to-face lectures and e-learning, is widely used[2].

This research aims to increase learning motivation and consequently the academic abilities of students by developing an environment that facilitates a self-e-learning system for classes using blended learning. students'

2 APPROACH

For blended learning using face-to-face lectures and a course or learning management system, we propose to facilitate self-learning by students by providing a self-learning environment in a course management system and applying it to an existing class framework. This paper shows an experimental application for basic programming using Moodle, which is an open-source course management system.

3 REQUIREMENTS

Self-learning involves scheduled reviews of materials presented in a previous class or preparation of materials for the next class.

What is needed to promote self-learning, particularly preparation, in students? In programing classes involving the use of exercise, it is important that students acquire or review the prerequisite knowledge and skills while preparing for the class.

To assist students in self-learning using a course management system, short questions and quizzes are believed to be necessary. However, if the order and the contents of quizzes is same for every time or for every students, it can lower willingness to study. Therefore, it is required that the order and the contents of of the same quiz will be changed for every time by preparing many questions for the same difficulty and for the same learning item and by random selection of them.

4 SYSTEM

To achieve the requirements described in section 3, we implemented new functions using Moodle, an open-source course management system. In section 4.1, we introduce Moodle functions related to our requirements, such as quizzes, question banks and random questions. In section 4.2, we describe the design of the newly implemented function.

4.1 Moodle functions: Quizzes and Questions

In Moodle, a *quiz* is constructed using *questions* registered in a *question bank*. Categories are used to create hierarchy of questions in a question bank. To provide quizzes to students, teachers are required to create questions into the question bank and create quiz pages using them. Students can therefore take a quiz created by their teacher.

Moodle has a feature named *random question* which is used to create a quiz by randomly selecting a specific number of unique questions from a particular category. For example, if a category has 20 questions and a teacher specifies that four questions should be selected from the category, they will be randomly selected when each student takes the quiz. Each attempt of a student will result in a new selection of questions. This feature is therefore useful for both preparation and reviews of materials already learnt. This feature also decreases the probability that a student may hear correct answers from other students who have already completed the quiz. However, to ensure that the difficulty level is consistent for each attempt, teachers should develop sufficient number of questions with the same difficulty level in each category. Moreover, if a teacher wants to create a quiz with questions from different categories, many categories and many questions for each category should be created. Such situations cause inefficient maintenance and/or operation of the question bank.

4.2 Extended Random Question

To solve the problem mentioned in section 4.1, we have developed the feature of *extended random question* that allows *random questions* to be more easily managed and maintained. Random questions are selected according to question categories, whereas in extended random questions are selected according to a question category and the specified question tag. Extended random questions are as useful as random questions, and this feature allows maintenance of question banks.

Extended random questions also contain another feature. If a teacher wants to use random questions for a class examination instead of self-learning, the feature gives students belonging to a specific group the same selection of questions instead of giving different selections to each student. Hence, extended random questions allow question selection not only when each student attempts a quiz but also when a teacher creates a quiz. That is, all students who attempt the quiz get the same questions that were randomly selected when the teacher created the quiz.

To implement extended random questions, we add a *tags* field into the question table in the quiz module, in which teachers can specify a *tag* for each question. By using this extension, when a teacher creates a quiz, he/she can select an extended random question in the same manner as a random question and specify a tag for the qualified selection. Unless a teacher specifies a tag for an extended random question, questions are selected from the entire question bank of a specific question category, as in the case of the original random questions.

5 USAGE EXAMPLE

Moodle is used to implement the functions described previously in a real classroom.

5.1 Use case for basic programming

Basic programming classes do not usually involve classroom lectures and contain only practical session. Assume that there are six classes each containing 40 students. Normally, a class consists of seven practical sessions and one examination. We applied our system with the self-study quiz in a class comprising only repeater (35 students, 2 classes). Because the exercises in the class had already been implemented in the previous year, the students were graded on the basis of only three examination results.

Table 1. Category of quizzes

category
variable type and operator
array
input and output
conditional branch
loop
function
structure
string
file i/o

It was optional for the students to take a quiz and there were no restrictions on the number of attempts. Quizzes contained questions belonging to each of the nine categories listed in Table 1. Each quiz contained four questions: the question for confirming materials, the basic question, and the applied questions for each category. For example, a quiz covering the category "structure" contained four questions randomly chosen from each of the following categories: a set of questions for confirming materials covering the category "structure", a set of questions related to definitions of data structures and data access, a set of questions related to data structures and functions, and a set of questions related to data arrays.

Detailed explanations of answers are provided for all questions. The explanation for each question is displayed after the exam irrespective of whether a student's answer to the question is correct. Our aim is to ensure that even if students do not understand the topic covered by a question, they can obtain a sufficiently high score in the next attempt by understanding the explanation.

6 EVALUATION AND CONSIDERATION

6.1 Usage Results of Quizzes

We prepared a quiz for each of the categories described in section 5. A total of nine quizzes were prepared. Table 2 shows the total number of attempts for all nine quizzes for 70 repeaters. Thirteen students had never used quizzes and the total number of attempts for nine students was less than five, even though there were nine quizzes. In contrast, more than half the students had attempted the quizzes 15 or more times. In particular, the top seven high scorers had attempted 40 times or more.

6.2 Results of Certification Exams

Certification examinations are held three times per semester. Each examination is worth 30 points, with a total of 90 points. At the time of writing this paper, the scoring of all examinations was not completed. Table 3 shows the temporary scores by autoscoring. Although the scores are

Table 2. Distribution of number of attempts in all nine quizzes

number of attempts	head-count
40+	7
35 - 39	1
30 - 34	4
25 - 29	8
20 - 24	6
15 - 19	4
10 - 14	8
5 - 9	10
1 - 4	9
0	13

Table 3. Distribution of temporary score in certification exams

total score	head-count
70	1
60	2
50	8
40	7
30	11
20	14
10	14
0	13

generally low, they are considered to be satisfactory given that all the subjects failed this course in the previous year.

6.3 Questionnaire Survey

After the third certification exam, we carried out a survey pertaining to the quizzes. Responses were received from 59 out of the 70 students.

In the questionnaire, we asked "How often do you use quizzes for preparation?" The results indicate that over 70% students used the quizzes often (Table 4).

Because each quiz has randomly selected questions for each attempt, it is expected that each student would have taken the same quiz more than once. Hence, we asked "How many times did you take the same quiz?" The results obtained indicated that over 70% students had taken the same quiz more than once (Table 5).

We also asked the usefulness of the quizzes for preparation, reviews, and exams (Tables 6, 7, and 8, respectively). The results indicated that approximately 80% students found them to be very useful or useful for preparation, reviews and exams (Tables 6, 7, and 8). These results shows the usefulness of quizzes for the entire course.

We also asked the students about the usefulness of random selection of questions provided by extended random questions. Many students answered that it was very useful or useful (Table 9).

To increase understanding of a topic, we prepared explanations for each question. The explanations were displayed after each student took a quiz. In our survey, we asked about the ease of understanding of these explanations, and 70% of students indicate that they were very easy to understand or comprehensible (Table 10).

A free-description question asked students for ideas concerning how the quizzes could be improved. Three students suggested that the number of questions be increased, four students suggested that the difficulty level be changed, seven students suggested that more practical questions than fill in the blank questions be included, two students suggested other

Table 4. Result of "How often do you use quizzes for preparation?"

head-count		answer
17	(29%)	usually
26	(44%)	often
15	(25%)	sometimes
1	(2%)	never
0	(0%)	I don't know

Table 5. Distribution of the results of "How many times did you take the same quiz?"

head-count		answer
17	(29%)	4+
14	(24%)	3
10	(17%)	twice
15	(25%)	once
3	(5%)	I don't know

Table 6. Results of "How useful are the quizzes for preparation?"

head-count		answer
18	(31%)	very useful
28	(47%)	useful
3	(5%)	less helpful
3	(5%)	useless
7	(12%)	I don't know

Table 7. Results of "How useful are the quizzes for reviews?"

head-count		answer
22	(37%)	very useful
28	(47%)	useful
5	(8%)	less helpful
1	(2%)	useless
3	(5%)	I don't know

Table 8. Results of "How useful are the quizzes for exams?"

head-count	answer
16 (27%)	very useful
30 (51%)	useful
5 (8%)	less helpful
3 (5%)	useless
5 (8%)	I don't know

Table 9. Results of "How useful is the random selection of questions?"

head-count	answer
26 (44%)	very useful
23 (39%)	useful
7 (12%)	less helpful
1 (2%)	useless
2 (3%)	I don't know

Table 10. Results of "How comprehensible are the explanations?"

head-count	answer
18 (31%)	very easy to understand
23 (39%)	comprehensible
12 (20%)	somewhat cofusing
4 (7%)	difficult to understand
2 (3%)	I don't know

Table 11. Relationship between quiz attempts and temporary score of exam

total attempts	head-count	average score	max score	min score
30+	12	22.5	40	10
20-29	14	36.4	60	10
10-19	12	31.7	60	10
1-9	19	20.5	70	0
0	13	5.4	20	0

ideas, and the remaining 43 students did not provide any answer or saw no need to improve the quizzes.

We also asked for ideas to improve the explanations for each questions. Seven students wanted the explanation to be more comprehensible, five students wanted the answer for each question, as opposed to its explanation, two students had other ideas, and the remaining 45 students did not provide any answer or saw no need to improve the explanations.

The general feedback received in our survey was that the responses had high subjective evaluation.

6.4 Consideration of motivation for learning

The results of the usage of the quizzes and the accompanying survey show that many students took these quizzes although it was optional to take them.

It is believed that continued use of the quizzes will provide an environment that will assist students in maintaining their motivation for learning. However, a fair evaluation could not be achieved because all subjects were repeaters.

Furthermore, students who attempt the quizzes many times without reading and understanding explanations displayed after their attempts may continue to repeat their course until they earn full points. A detailed analysis of quiz attempts may be required.

6.5 Consideration of academic ability

Table 11 shows the distribution of then number of quiz attempts and the average temporary score of the certification exam for each distribution range. These results show that students who attempt quizzes multiple times may not necessarily obtain a good score on exams. It is therefore difficult to infer whether the introduction of quizzes for self-learning directly increases the academic ability of students. As already mentioned in section 6.4, students who attempt quizzes many times do not always read the explanation displayed. It is estimated that after taking a quiz two or three times, students who read and understand the explanations comprehend the contents in each category. It is thought that the advisable maximum number of quiz attempts is two or three for each quiz, that is, the total number of attempts for all quizzes ranges 18-27. As shown in Table 11, students who attempted the quiz 20-29 times had the highest average score.

Table 12. Relationship between quiz score and temporary score of exam

quiz score	head-count	average score	max score	min score
100	5	22.00	30	10
90-99	5	34.00	50	20
80-89	8	35.00	60	10
70-79	11	33.64	70	0
60-69	11	24.55	60	0
50-59	4	30.00	50	10
40-49	4	30.00	30	30
30-39	2	15.00	20	10
20-29	4	10.00	20	0
10-19	2	15.00	20	10
0-9	14	5.71	20	0

Table 12 shows the distribution of the score of quizzes and the average of temporary score of the certification exam for each distribution range Quiz score is the average of the highest scores in each quiz for each student. One hundred indicates that the student continues to take the quiz until he/she attains a score 100. This result also shows that students who achieve high quiz scores do not always achieve high certification exam scores. It has already been mentioned that some students repeatedly take quizzes without understanding the explanations displayed after quiz attempts. Because the number of prepared questions is limited, it is possible that some students who memorize correct answers after frequent quiz attempts without understanding the concepts involved get high quiz scores despite the random selection of questions.

7 CONCLUSION

We analyzed the required features of course management systems for increasing learning motivation and facilitating self-learning. On the basis of our analysis, we developed the required feature using Moodle, which is an open-source course management system. We introduced the feature into an actual course for learning programming and evaluated the use of the feature by a survey. We provided an environment that assists students in maintaining their motivation for learning by providing interesting system features and developing educational materials that utilize this feature. However, the features and materials do not always have the effect of increasing the academic ability of students. Therefore, a detailed analysis of the results and improvement of both features and educational materials is required. Finally, we express sincerely thank Version2, Inc. for its cooperation in the development of the Moodle feature.

Abstract: This paper proposes Web-Com Service and Web-Com API. Web-Com Service enables to create/share easily multimedia learning contents on the Web. And, Web-Com API enable to access to the functions of Web-Com Service from other web sites by some program. Web-Com API provides as a web API for the usability. Web-Com API aims at the improvement in convenience of Web-Com service. The requirements of Web-Com API are "functions of Web-Com Service are available from other web sites", and "generation of a code for embedding the functions to other web sites". By realization of Web-Com API, the improvement in convenience of Web-Com service is expectable.

Keywords: e-learning, Web-Com Service, Web-Com API, multimedia learning content

1 INTRODUCTION

Recently, e-learning is introduced by the training in educational facilities and several companies. The main stream about e-learning is use of WBT (Web Based Training) because of the convenience in introduction or an aspect of practical use. There are authoring tool for e-learning contents [1][2] and LMS (Learning Management System) by using web browser [3][4]. However, problem of authoring tool is that it is difficult to share the learning contents, because shared mechanism of the contents is not provided. On the other hand, in LMS, while a learner can learn only by a web browser, the complicated work for which the contents creator used dedicated software is needed in many cases. The short supply of the learning contents is a problem. Thus, there are merits and demerits in authoring tool and LMS.

Then, the authors have proposed a learning contents creation service named Web-Com Service. Web-Com Service is a web service which users can create/share the multimedia contents including annotations of voice, free line, and etc. Web-Com Service has two functions. These are web authoring tool for learning content (as a web page), and creation/sharing function of Web-Com content on the web. Therefore, the learner can learn preparation and review of a class. On the other hand, the contents creator can create the learning contents with a workload comparable as an actual class.

In this paper, the authors propose Web-Com API (Application Programming Interface) to access to the functions of Web-Com from other web sites by some program. Web-Com API provides as a web API for the usability. Web-Com API aims at the improvement in convenience of Web-Com service. The requirements of Web-Com API are "functions of Web-Com Service are available from other web sites", and "generation of a code for embedding the functions to other web sites". By realization of Web-Com API, the improvement in convenience of Web-Com service is expectable.

2 WEB-COM SERVICE

2.1 Overview

The Web-Com Service had been developed as the Web service. Specifically, the service has two functions, which are web authoring tool for learning content (as a web page), and creation/sharing function of Web-Com content on the web [5].

The features of the service are below.

(1) Creation, edit, and use of the Web-Com contents on the web.
(2) Upload of the Web-Com contents created on the other computer.
(3) The creation of the web contents without technical knowledge, such as HTML and Flash.
(4) Expression of contents including a science-and-engineering system.
(5) The creation of the secondary contents using the primary contents created by the service.
(6) The mutual link between Web-Com contents.
(7) Embedding Web-Com contents to the web page.

The users of this service are an upload user, a creation user, an inspection user, and an embedding user. The upload user uploads the Web-Com contents created by existing Web-Com [1]. Then, the existing Web-Com contents are converted into Flash contents, and it can be browsed on the Web. The creation user is a user who creates the primary contents and secondary contents. The inspection user inspects the contents, and the embedding user embeds contents to Web pages. When the secondary contents are created, the iframe tag for embedding is generated automatically, and then the contents can be embedded at an external site.

The flow chart of contents creation is shown in Fig.1. On the upper part of the Fig.1, the user creates the primary contents, and inputs required information using the authoring tool. When the continuation page over two pages is created, each pages are mutually linked automatically. The creation of secondary contents is also continuously possible after the creation of primary contents. In creation of the secondary contents shown in the lower part of Fig.1, the user specifies URL of the created primary contents or a website, and adds notes information, including a sound, a free line, etc. Then, required information is inputted by the same way as the primary contents. In addition, the continuous secondary contents can be also created.

As mentioned above, the user can create the flexible and variegated contents on a web browser easily without technical knowledge. Furthermore, accumulation and sharing of various contents which the user created are attained by the Web Service.

Currently, this service is launched on the intramural server and the unregistered user can use only the function of an inspection and embedding. Use of the function of all above is permitted by registering as a user. In addition, Fig.2 is a top page of this service.

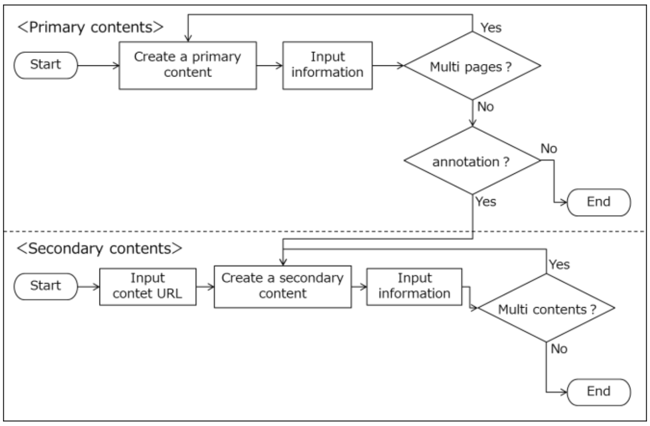

Fig. 1. Flowchart of creation of content

Fig. 2. Top page of Web-Com Service

Table 1. Functions of Web-Com API

No.	Function	API	Provide
1	Login	signin	JavaScript
2	Logout	signout	JavaScript
3	User registration	Signup	iframe tag
4	User deletion	deleteuser	JavaScript
5	Create a primary contents	createpage	iframe tag
6	Create a secondary contents	createcontent	iframe tag
7	Play	view	iframe tag
8	Search	search	iframe tag

2.2 Issue of Web-Com Service

By the launch of this service, the subject about the Web-Com has been solved basically. For the accumulation of contents, it is important to be recognized by more users and to be used for them. However, it is not used by many users although there is contents shared structure in this service.

Then, if the function of this service is available from the external site as API, the service would be recognized by more users, and the improvement in convenience of this service is also expected by cooperation with other services. This leads to accumulation of contents.

3 WEB-COM API

3.1 Purpose

Web-Com API was developed for the purpose of the improvement in convenience of the Web-Com Service. The requirements for Web-Com API are two points, "the function of this service can be used from the external site", and "the function is generated as a code, which can be embedded on a Web page."

3.2. Overview

In Web-Com API, eight functions shown in Table 1 are offered. Since each function is offered in the form of JavaScript or an iframe tag, a user without technical knowledge can also embed it easily at a Web page. The available URL is as follows. In addition, the API name corresponds with Table 1. Then, each function of API is explained. Detailed explanation is available on a reference page [6].

URL : http://yonyx1.cis.ibaraki.ac.jp/webcomcgm/api/[API name]

3.3. Functions

3.3.1 User Authentication

Here, the user management function of login, logout, user's registration, and user deletion is explained. The screen transition diagram of login, logout, and user deletion is shown in Fig.3. After the completion of login, the login button changes to logout, and the withdrawal button is displayed. This function can be used by embedding the code offered by JavaScript in the source code of the Web page.

The registration to this service is available by inputting registration information in the function of user's registration. This function is offered with an iframe tag.

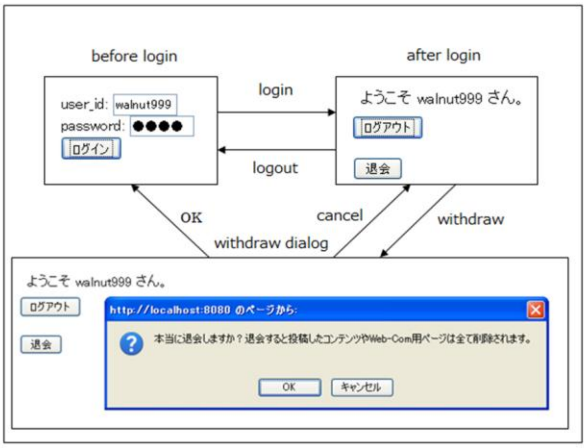

Fig. 3. Screen transition diagram of login process

3.3.2 Primary Contents

Fig.4 shows the creation screen of primary contents. In Fig.4, the Web authoring tool of this service is used from an external site. After contents creation, the screen changes to an information input screen and the user inputs required information. At this time, the user can choose disclosure or nondisclosure of contents. If disclosure is chosen, the contents are registered to this service as primary contents, and if nondisclosure is chosen, it can be downloaded as a html file, without being registered to this service.

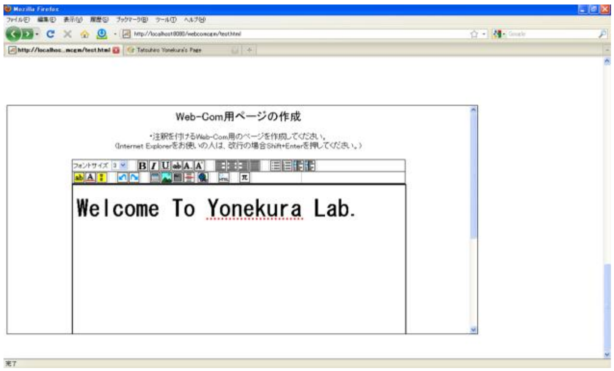

Fig. 4. Creation of primary content

3.3.3 Secondary Contents

Fig.5 is the creation screen of secondary contents. In Fig.5, the secondary contents creation function of this service is used from an external site. After contents creation, the screen changes to an information input screen and the user inputs required information. At this time, the user can choose disclosure or nondisclosure of contents as the same as primary contents. It can download as a swf file renewable by Flash Player, without registering to this service as secondary contents, if nondisclosure is chosen. And it is registered to this service, if disclosure is chosen (Fig.6).

For creation of primary contents and secondary contents, the user needs to log in to this service. However the user does not need to log in to use Web-Com API. This is for reducing the barrier of this service use in consideration of the use from an external site. In addition, when using without logging in, the user name should be specified as "Anonymous".

Fig. 5. Creation of Web-Com content

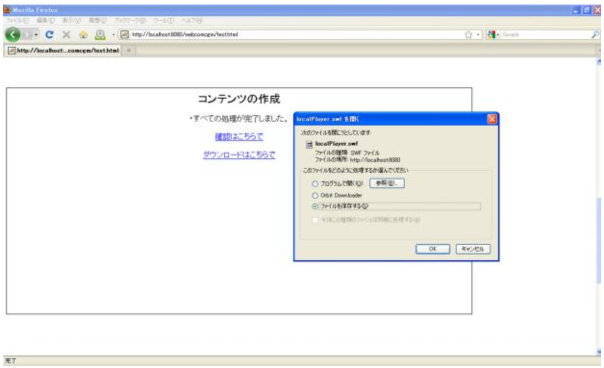

Fig. 6. Download of Web-Com content

3.3.4 Play

Fig.7 is the play screen of secondary contents. These contents can be played on the web browser in which FlashPlayer was installed.

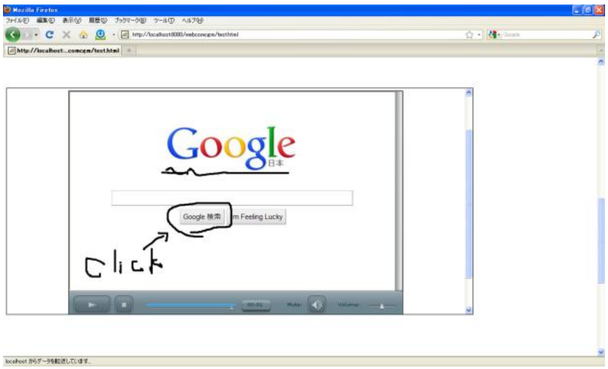

Fig. 7. Play of Web-Com content

3.3.5 Search

It is available to search of the secondary contents registered into this service from the external site. By specifying a keyword into the search window in iframe, the contents which correspond with the keyword are displayed.

3.4 Discussions

Almost all the functions of the Web-Com service were provided as API. And each function can be used from the external site. By having developed API which can be used only by the embedding of a code, the user without technical knowledge can use them easily. Thereby, the requirements shown with Section 3.1 have been satisfied.

However, contents creation and search have some subjects t o be solved. Now, it cannot respond to addition of the notes to a continuation page. On the other hand, the search functi on corresponds only to secondary contents. These are future subjects.

3.5 Use Scene

As a usage scene, cooperation with Learning Management System (LMS) can be considered. By providing of API, the function of the Web-Com Service can be used from the LMS site, and creation of the multimedia teaching-materials contents on LMS is enabled.

Furthermore, the application to the SCORM (Sharable Content Object Reference) [7] which is the e-learning standards designed by U.S. ADL (Advanced Distributed Learning Initiative) is also an important issue. Since the SCORM contents and LMS can be employed mutually, the present e-learning product employs SCORM.

By adoption to the SCORM of the secondary contents cre ated with this service, usage of multimedia learning contents are supposed to be available to many LMSs.

4 CONCLUSION

In this paper, the Web-Com Service and the Web-Com API were proposed. The Web-Com Service enables to create the e-learning teaching-materials. And the Web-Com API provides functions of the Web-Com Service. These realized the creation and the sharing of the multimedia teaching-materials contents on Web. By API, the improvement in convenience of Web-Com service is expectable.

In the future, the correction of the function of Web-Com API, the application of SCORM to secondary contents, the cooperation with LMS, and evaluations of those are due to be performed. And the enhancement of the contents of the Web-Com Service is needed. In addition, as internationalization, the provision by English and Chinese is being planned.

Abstract: Applying e-learning to hands-on education such as physical education has been difficult due to hardware and network restrictions in an out-of-classroom environment. In this research we propose using smartphones for sports education to improve the learning curve of athletes. There has been previous research reported on using carrier specific cellular phone applications for sports education. While the previous approach reported effectiveness on using mobile devices for education assistance, the carrier specific cellular phone approach had functional and interface limitations due to the hardware restrictions. For this research, we developed a Google Android application for sports education, namely track and field use, to support both the learner (athlete) and the educator (trainer). For the proposed application, we made use of the touch panel feature of Android hardware to facilitate data entry for the users. Validity of the proposed system was verified through experiment.

Keywords: Smartphones, Google Android application, sports education, e-learning

1 INTRODUCTION

Applying e-learning to hands-on education such as physical education has been difficult due to hardware and network restrictions in an out-of-classroom environment. In this research we propose using smartphones for sports education to improve the learning curve of athletes. There has been previous research reported on using carrier specific cellular phone applications for sports education. While the previous approach reported effectiveness on using mobile devices for education assistance[1], the carrier specific cellular phone approach had functional and interface limitations due to the hardware restictions. For this research, we developed a Google Android application for sports education, namely track and field use, to support both the learner (athlete) and the educator (trainer). The developed application targets men's decathlon and female's heptathlon, and calculates the points achieved for each event, and displays the current total score. The decathlon and heptathlon event is a 2 day competition, with decathlon athletes competing in 10 different events, and heptathlon athletes competing in 8 different events. It is important for each athlete to manage how much energy and strength should be spent on each event, in order to complete the 2 day competition. The calculating program is used by the athlete to check current performance, but more importantly used to simulate target records for coming events, in order to set a goal for each individual event performance. The same use applies to the trainer, where the trainer will simulate possible performances and give advice to each athlete based on the simulation results.

Capability for managing multiple records was implemented, so that the learner can compare previous and current performance. The feature is also used by the educator to manage multiple students at the same time.

Effective user interface for sport education was taken in consideration. For the previous research using standard cellular phones, data input was through number buttons only. For the proposed application, we made use of the touch panel feature of Android hardware to facilitate data entry for the users.

Validity of the proposed system was verified through experiment.

2 SMARTPHONE PLATFORM

In order to promote the use of e-learning for sports education, there are several barriers that must be overcome. Firstly, e-learning for sports education requires that each participant has access to the e-learning system, so expensive hardware or limited hardware support will be against the motivation. Secondly, the e-learning system must be easily carried outdoors where sports education will take place, so the size of the hardware should be able to fit in a pocket. Thirdly, the hardware should have enough computing power and features to run complicated sport education support applications.

To clear the above requirements, smartphones were selected as the target hardware for this research. In particular, Google Android was selected for the smart phone platform. Android is a free and open source operating system for mobile devices, mainly smartphones and tablet computers. The first commercial version, Android 1.0, was released in September 2008. By the end of 2011, Android had grown to become the largest smartphone platform in many markets. In this light, Google Android was selected for the research platform to provide the large client base, and easy development environment.

Important features of Android utilized in this research are Java programming language development support, touch panel user interface support, sandbox memory access for application memory, and file read/write capability.

3 SPORTS EDUCATION APPLICATION

In this research, a sports education support application was developed with the following specifications.

Supported OS: Android

Supported version: 1.6 or newer

Supported screen size: HVGA or better

Supported installation: Download via Google Android Market

Android OS is currently the largest smartphone platform on the market, and while the latest Android version for smartphones is version 2.3, support for version 1.6 or newer was targeted to allow close to all of the current Android smartphones to be covered. For the same reason, minimum supported screen size is HVGA, in order to allow a large range of supported hardware.

Android applications can be distributed easily over the web, but for this research, the developed Android application was distributed through the Android Market, Google's official online software store for Android applications, to facilitate installation into client devices. The Android Market was also used to collect feedback and comments from users.

For this research, we developed a Google Android application for sports education, namely track and field use, to support both the learner (athlete) and the educator (trainer). The developed application supports the following 2 track and field events:

1) men's decathlon event and

2) female's heptathlon event.

The developed application calculates the points achieved for each event, and displays the current total score. Fig.1 shows a snapshot of the application running the men's decathlon score calculation.

Fig. 1. Decathlon score calculation application

For the calculation program for both events, the following supporting features were implemented.

1) Simultaneous score calculation during user record entry.

2) Multiple file support for saving record and score status.

Simultaneous score calculation during user record entry was implemented to minimize user operation. By this feature, users do not have to select a separate button to initiate calculation, and also does not require unnecessary zeros after the decimal point.

Multiple file support of score tables allows a single user to keep records of previous records of the same athlete, as well as keep records of multiple athletes for the same event. Fig.2 shows the multiple file selection for the developed application. Multiple file support enables athletes to compare their current record and progress with past records on previous decathlon/heptathlon events. Athletes can estimate their final score, and motivate themselves to improve their record, as well as allow the athlete to simulate how much effort must be put in the individual events still left, in order to keep ahead of the competition or improve personal records. For the coaches (or educators), multiple file support allows the coach to keep track and compare the individual scores for each athlete competing in the same event, including scores of the competition. The coach can compare the scores of each athlete and their previous records, to give more precise advice on strategy on which individual events to save stamina and which events to give extra tries.

Fig. 2. Multiple file selection screen

4 EXPERIMENT RESULTS

The developed Android application was registered in Google Android Market as "Track and Field Combined Event Calculation Tool" for public access, as a free application. Fig. 3 shows the registered application as seen on Android Market. The developed application was the first registered Android Market application for track and field combined event (decathlon and heptathlon) score calculation to support Japanese. We also asked the Tokyo University of Information Sciences track and field team coach to use the application and asked for feedback regarding the effectiveness of the application for sports education.

On the Android Market, as of November 30, 2011, there has been over 500 downloads of the developed application, and the overall rating of the application is 4.4 from a maximum 5.0 . There had been 1 report on a program error, which was immediately fixed and the fixed program uploaded. Another comment gave positive feedback on requested features for user interface.

From the track and field coach, positive comments on the effectiveness of the application on sports education were received. Further enhancements on the user interface were also requested, such as being able to show multiple athletes' records on 1 screen, or a 1-click feature for quickly switching multiple athletes' records.

Currently, the effectiveness of the developed application has not yet been evaluated statistically, but from user reviews on the Android Market and direct feedback from the track and field coach, the developed application running on a smartphone was shown to be effective in sports education support. Compared to previous reports using mobile phone applications, the developed application using smartphones enabled multiple file support as well as touch screen user interface, and greatly improved on accessibility and operability.

Fig. 3. Application registered in Android Market

5 CONCLUSION

In this research we propose using smartphones for sports education to improve the learning curve of athletes. In order to promote the use of e-learning for sports education, smartphones were selected as the target hardware for this research. In particular, Google Android was selected for the smart phone platform for the large client base and ease of development. We developed a Google Android application for sports education, namely track and field use, to support both the learner (athlete) and the educator (trainer). The developed application targets men's decathlon and female's heptathlon, and calculates the points achieved for each event, and displays the current total score. In the developed application, features for 1) simultaneous score calculation during user record entry, and 2) multiple file support for saving records and scores were implemented.

From user reviews and comments from an active track and field coach, positive feedback on the effectiveness of the proposed application for sports education were received.

For future works, improvements on user interface based on user requests will be implemented. Further, we plan to create a client-server model for sports education to allow data sharing between learners and trainers, and support real-time educational feedback from trainers to learners.

Abstract: When we learn our body motions with the physical exercises such as dances and sports, The learner, by him/herself, shall evaluate the correctness of the imitation in his/her movements. Therefore, we have developed a human-interface for instructing motions instead of instructors. The system was implemented with two functions. The first function is to evaluate the learner's movements. The second function is to correct the learner's motion using visual information. With these two functions, the learner can learn highly skilled motions in sports and dances by oneself. However, when instructing dynamic motions, we have to take into considerations not only postures but also speeds and accelerations. In this paper, aiming at providing a solution for the kind of motion speed instruction tasks, we proposed a vision-based system that is specifically designed for showing motion speed information to learner, and applied to an underarm ball throwing action. That is, while throwing before release, based on the online motion information, i.e., the velocity and position, the system predicts the after-release ball trajectory, and shows the trajectory to the learner in real-time. It is expected that, with the help of the predicted trajectory shown in real-time, the learner becomes to be able to adjust his/her motion in accelerative or declarative ways, and, thus, he/she masters the appropriate motion speed for hitting the reference. As a result of the instruction experiment, the proposed motion instruction system has feasibility as a practical tool for on-line motion speed

1. INTRODUCTION

How do we learn our body motions with the physical exercises such as dances and sports? While visually observing the expert's movements, we repeatedly practice in order to imitate expert's movements. Thus, vision-based motion learning methods, so-called, teach-by-showing, conversely learn-by-observing methods, would be typical ways of learning human boy motions. However, this process contains a fatal flaw in learning quality. It is that the learner, by him/herself, shall evaluate the correctness of the imitation in his/her movements. Even if the learner judged the movements correct, it may be actually incorrect movements. The misunderstanding may falls into a wrong motion acquirement. Thus, instructors who observe and correct the learners' movements are very important for learners to avoid such misleading. Therefore, we have developed a human-interface for instructing motions instead of instructors. The system was implemented with two functions. The first function is to evaluate the learner's movements. The second function is to correct the learner's motion using visual information. With these two functions, the learner can learn highly skilled motions in sports and dances by oneself.

In previous studies, we had developed a motion instructing system that visually teaches static postures using a motion-capturing suit and a head-mounted display. By using this system, we had instructed static poses of yoga [1] and pantomime [2].

However, when instructing dynamic motions, we have to take into considerations not only postures but also speeds and accelerations. For example, to enhance the correctness in ball throw toward a goal position (see Fig.1).Can you predict the trajectory of a ball from this picture? It must be impossible because, for the prediction, we need the ball velocity vector information together with the position at the release time.

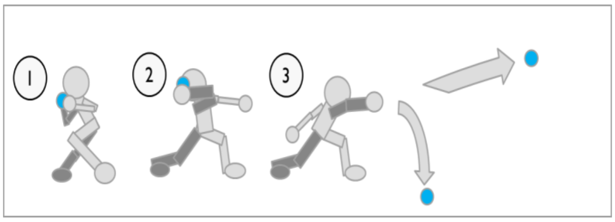

Figure 1 Ball throw toward a goal position

In previous studies, [3] and [4] utilized muscular power representation together with the postures . In this system, learners are assumed to align with the muscular power of reference motions. However, this system has a problem that we cannot perceive and control muscular powers quantitatively. In this sense, the muscular powers are not necessarily an effective way in motion monitoring.

Therefore, we recognized the importance of direct monitoring of the speed information. As for the speed information monitoring, there were various studies .

One of the systems has an off-line learning function that the learner can compare reference speed with his speed after operation [5]. Another system provides the motion correction information to learners so that learners adjust their motion speed either more or less faster in real-time [6]. However, there has not been seen any research on a systems that shows learners the difference of the present speed from the reference one. In this paper, aiming at providing a solution for the kind of motion speed instruction tasks, we proposed a vision-based system that is specifically designed for showing motion speed information to a learner. That is, while throwing before release, based on the online motion information, i.e., the velocity and position, the system predicts the after-release ball trajectory, and shows the trajectory to the learner in real-time. It is expected that, with the help of the predicted trajectory being shown in real-time, the learner becomes to be able to adjust his/her motion in accelerative or declarative ways, and, thus, he/she masters the appropriate motion speed for hitting the goal.

2. PROPOSED METHOD

2.1 Reference motion

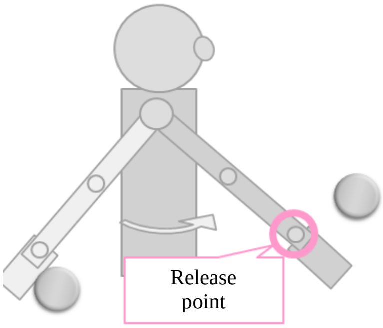

Figure 2 Example of a simple underarm throw motion

In this paper,, a simple underarm throw operation was examined. The underarm throw motion is a 1-DOF shoulder joint inward rotation, i.e., the flexion, where both an elbow and wrist joints were fixed so as not to bend.

2.2 Proposed display systems

Next, we considered the ways of presenting the velocity differential to a learner. We took the following points into considerations.

・The learner can react in real time.
・The learner can perceive the velocity differential.

Then, we thought up the following four presentation methods.

a. Ghost display
b. Speed meter display
c. Color display
d. Trajectory display

For all the display systems, the velocity difference is calculated by the following formulas, and is represented in either a desktop-PC monitor or a HMD by the ways to be described in the followings.

$$v_{e(t)} = v_{l(t)} - v_{r(t)} \dots\dots\dots\dots (1)$$

v_e : Velocity difference
v_r: Reference velocity
v_l: Learner's velocity
t : Present time ($t = 0$ at the motion start time)

a. Ghost display

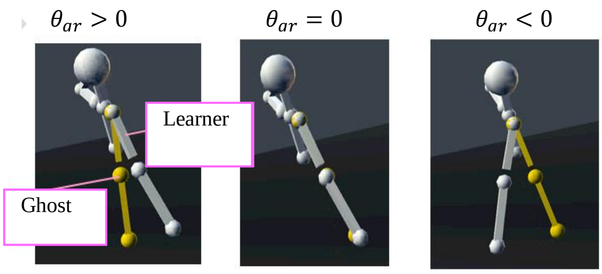

Figure 3 Ghost display system

While the learner's arm graphic being displayed, a ghost arm graphic is additionally displayed in proportion to the velocity difference of a ghost representing the reference motion, from a learner. The displayed ghost's shoulder joint rotation angle, θ_{gr}, is given by

$$\theta_{gr(t+1)} = \theta_{l(t)} - k_g e_{v(t)} \dots\dots\dots\dots\dots\dots (2)$$

θ_{gr} : Ghost's shoulder joint rotation angle (reference)
θ_l : Learner's shoulder joint rotation angle
k_g : Feedback gain for ghost display

The learner can learn a reference velocity by controlling his/her muscles so that the learner's arm graphic may lie on top of a ghost one.

b. Speed meter display

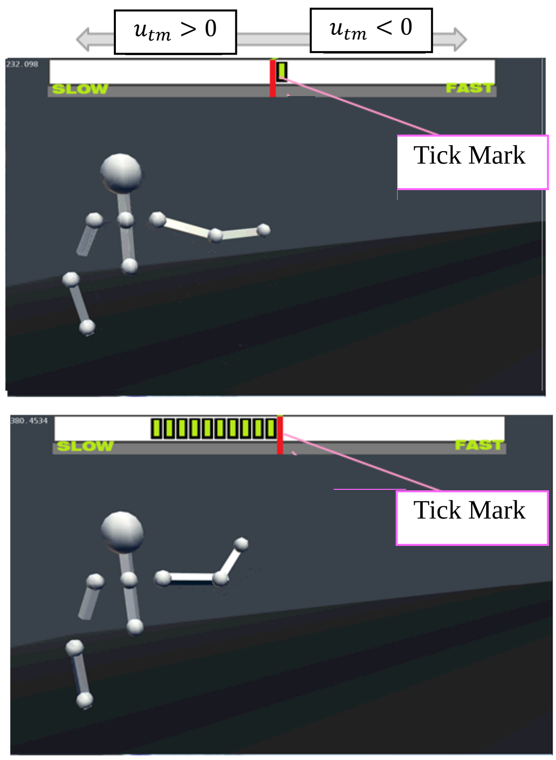

Figure 4 Speed meter display system

In the meter display system, a velocity differential is represented in the quantity of the tick marks. The quantity of the tick marks, u_{tm}, is given by

If the learner's motion is too fast, the tick marks increase to the right, which suggests the learner to move his/her arm more slowly., On the contrary, if, vice versa, the tick marks increase to the left, this system suggests the learner to move his/her arm faster.

c. Color display system

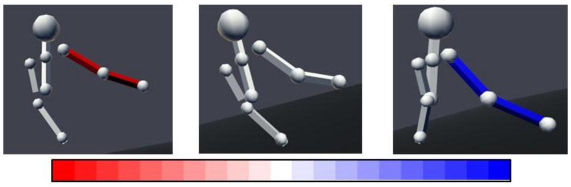

Figure 5 Color display system

The color display system represents the velocity difference by color. If the brightness of the color shows deep, the velocity difference is large. The RGB color intensites, *r*, *g*, *b*, are given by

If $v_{e(t)} > 0$

$$\begin{cases} r_{(t+1)} = 255 \\ g_{(t+1),} b_{(t+1),} = 255 - k_c v_{e(t)} \end{cases} \cdots\cdots\cdots(4)$$

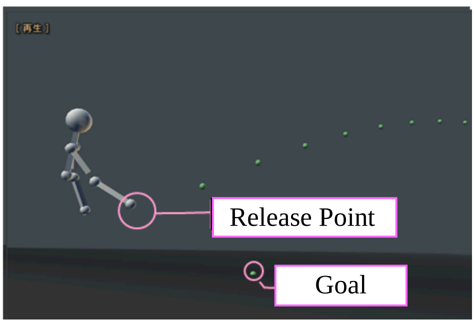
If $v_{e(t)} < 0$

$$\begin{cases} b_{(t+1)} = 255 \\ r_{(t+1),} g_{(t+1),} = 255 - k_c v_{e(t)} \end{cases} \cdots\cdots\cdots(5)$$

k_c
: Feedback gain for color dispay
r, g, b : RGB intensity values

If model's arm changes its color to red, this system informs the learner to move his/her arm faster. While, if the model's arm color is blue, this system inform learner to move his/her arm more slowly.

d. Trajectory display system



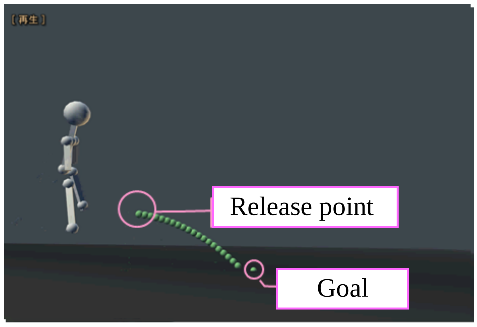


Figure 6 Trajectory display system

While throwing before release, based on the online motion information, i.e., the velocity $v_{l(t)}$ and position$\theta_{l(t)}$, the velocity vector $\vec{v}_{(t_{RP})}$ at the release point t_{RP} is assumed: in this paper, the magnitude of the velocity vector $\vec{v}_{(t_{RP})}$ at the release point t_{RP} is assumed to be identical to the present velocity $v_{l(t)}$, and the throwing direction is assumed to be given as a known unit vector $\vec{n}_{(t_{RP})}$. That is,

$$\vec{v}_{(t_{RP})} = \vec{n}_{(t_{RP})} v_{l(t)} \quad \cdots\cdots\cdots\cdots\cdots\cdots\cdots(6)$$

Next, assuming a free-fall motion with the initial velocity $\vec{v}_{(t_{RP})}$, the trajectory display system calculates the after-release ball trajectory and shows the trajectory to the learner in real-time.

It is expected that, with the help of the predicted trajectory shown in real-time. The learner becomes to be able to adjust his/her motion in accelerative or declarative ways, and, thus, he/she masters the appropriate motion speed for hitting the goal.

3. EXPERIMENTS

3.1 Discussing issues

We carried out some psychophysical experiments to evaluate the effectiveness of the proposed display systems. In this experiment, we ask for examinees to answer their subjective rating values with respect to the following issues.

1. Has the presentation been easy to perceive how much your motion velocities are deviated from the reference ones?
2. Have you enjoyed yourself when using the displaying method?
3. Haven't you felt stress?

3.2 Experimental devices

We used a binocular-type 3-D range finder, i.e., XtionPro which was made by Asus Corp (see Fig.7).

Figure 7 Xtion Pro: appearance (left), a captured range image (right)

3.3 Visual presentation program

An example of the visual presentation is shown in Fig.8. In the experiments, the upper-half- body model was employed.

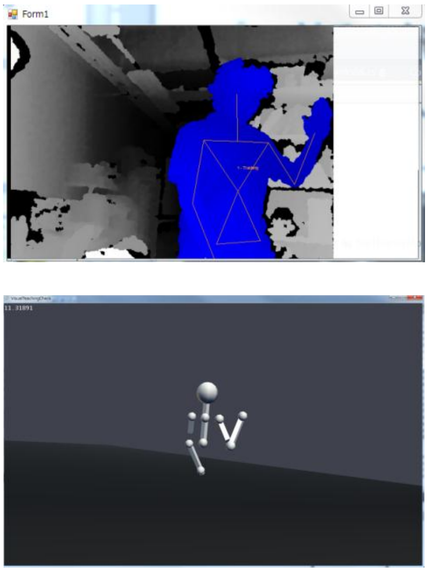

Figure 8 Visual presentation: an extracted human skeleton (top), created CG image based on the extracted human skeleton 3-D information (bottom)

3.4 Experimental result

The comments answered by the subjects with respect to the display systems were as follows.

Ghost display

・The CG images were just shown by the rectangular parallelepiped, and, therefore, I felt unclear in the discrimination of whether ghost model has overlapped or not.

. I felt disturbed in deciding an action of either acceleration or deceleration because the ghost responded to learner's motion too sensitively.

Speed meter display

・I felt disturbed in deciding an action of either acceleration or deceleration because the scale either increased or decreased too frequency.

・I suffered much stress in decreasing the quantity of the tick marks, i.e., in adjusting my arm velocity to the reference one .

Color display

・It was hard to notice the color change.

・I didn't feel much fun in this system because the color representation was too low-keyed.

・I feel tired in my eye when trying to detect the change in color.

Trajectory display

・ It was easy to perceive the appropriateness of my arm-motion speed by observing the predicted after-release trajectory.

・I felt fun in aiming at the goal position while changing trajectory.

As a result, almost all the people approved the trajectory display system among the four display systems. Two reasons are considered for the approval as in the followings. One reason is that the learners were able to learn as if they played a game. The other reason is that the learners were able to know in advance about what is going to happen.

4. CONCLUSIONS

We had thought up four kinds of motion display systems. Next, we had evaluated their performance through some psychophysical experiments, and confirmed that the trajectory display system was best performing among them, and it is considered to have a potential ability to meet our objective.

In the future, we are directed to evaluate the display system in learning under throw motion

Abstract: In these days, many production systems are consist of several factories. Such factories are dispersed in wide area and form "production networks". In such networks, each factory produces intermediate materials for other factories. In order to operate production networks efficiently, some rational and sound operational strategy is needed for realizing cooperative operation. In the previous work, "Behavior Model" of scheduling activities in decentralized production networks was developed and the validity was confirmed. Also, an attempt was made to obtain proper scheduling rules by means of reinforcement learning. Concretely, Profit Sharing was adopted in order to obtain rules for selecting suppliers of intermediate materials under the proposed operational model. In this work, improvement of the representation of states used in the rule learning was attempted. A series of experiments was carried out in order to examine the performances of the rules obtained under the new representations.

Keywords: Production System, Supply Chain, Reinforcement Learning

1 INTRODUCTION

In these days, many production systems are composed of several factories. Such factories are dispersed in wide area and form "production networks". In such networks each factory produces intermediate materials for other factories. In such networks, decision-making in each factory is currently carried out independently of other factories, and this causes low performance of the whole system. In order to operate production networks efficiently, some rational and sound operational strategy is needed for realizing cooperative operation among such networks. In order to manage such a production network soundly, negotiations among factories are very important. In the previous work, "Behavior Model" of scheduling activities in decentralized production networks was developed (Yamaba [1]). Also, an attempt was made to obtain proper scheduling rules by means of reinforcement learning (Yamaba [2]). Concretely, Profit Sharing was adopted in order to obtain rules for selecting suppliers of intermediate materials under the proposed operational model.

In this work, improvement of the representation of states used in the rule learning was attempted. A series of experiments was carried out in order to examine the performances of the rules obtained under the new representations.

2 CHARACTERISTICS OF TARGET PRODUCTION SYSTEM NETWORK

The target production system network in this work is composed of a single business department and several factories. Locations of them are widely dispersed.

Each order from customers is completed through multi-stage manufacturing processes. For example, plastic film manufacturing companies with an upper process of raw plastic film creation and several lower processes of chemical treatment of plastic films are assumed. Each stage of manufacturing of an order is allowed to be performed at different factories. Some factories have facilities only to create raw plastic film, some factories have facilities to perform chemical treatment of plastic film, and others have both of the facilities.

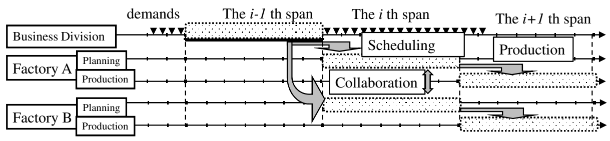

Fig. 1. An example of a timetable of the target production system

Orders from customers are concentrated to the single business department. The business department selects a factory for manufacturing processes of each order periodically (e.g., every one month). Each factory makes out production schedules of given orders together with procurement plans of intermediate materials at the same time. "Procurement plans" mean selection of factories for each intermediate material.

An example of a timetable of the production system is shown in Fig. 1. In general, schedules of orders given in the i 1 th span are made in the i th span and bases produce them in the $i+1$ th span.

In such a production network, if "Factory A" makes an order of its intermediate material needed to produce an order given in i 1 th span to "Factory B" in the i the span, "Factory A" cannot finish making out its schedule until it will be determined that "Factory B" will accept the order or not. Since "Factory B" makes out its own schedule for orders given in i 1 th span in the same span, "Factory B" cannot reply whether it can accept the order or not until the schedule is fixed. In general, "Factory B" also makes orders of its intermediate materials to other factories. This causes longer time until the whole scheduling process is finished. In particular, if "Factory B" also made an order to "Factory A", the scheduling process never finishes because of a deadlock. So it is indispensable to realize a scheduling algorithm which is equipped collaboration mechanism among factories.

3 BEHAVIOR MODEL OF DECENTRALIZED SCHEDULING

In order to realize the sound scheduling method, the concept of "behavior model" was introduced (Yamaba [1]).

Receiving orders of intermediate materials from other factories, each factory create several schedule candidates. However, it could be happened that no schedule candidate can satisfy all of the limitations of production (due date) of the given requirements in case that much workload which exceeds the productive ability of the factory is given. In this work, it is assumed that factories are allowed to reject some requirements on such occasions. But factories have to reply to the orderer that the requirements are rejected within the designated time span.

Receiving a reply of rejection ("reject messages"), production bases select another factory and make an order to the selected factory again. It is assumed that there is a limitation for the number of attempts of re-selection of factories. When the number of the re-selecton for the N 1th process exceeds the limitation, the orderer factory abandon the request of N th process given to the factory itself. Such factories reply the "reject message" to the orderer factory of the N th process.

4 LEARNING OF SUPPLIER SELECTION RULES

4.1 Supplier Selection Rules

There are several factors affecting the performance of schedules of production networks discussed here. In Yamaba [2], an acquisition method of rules for selecting proper factories for intermediate materials was proposed. Reinforcement learning was adopted in the method. Profit Sharing is one of the most promising methods of reinforcement learning. The method was used in order to obtain operational rules of engineering systems (Arai[3], Yamaba [4], Yamaba [5]).

The target production systems are plastic films factories. It is assumed that there are three processes in the production system: the film creation and two stages of chemical treatment of film processes (Fig. **??**.). Also, there are 3 types of factories in the target production system.

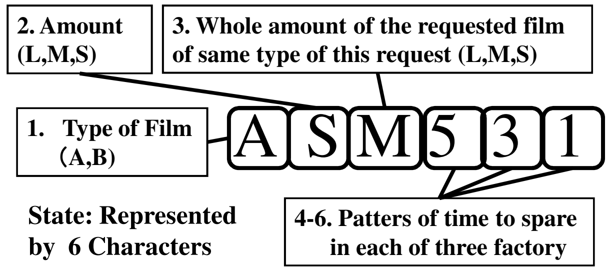

Fig. 2. Representation of states of an intermediate material requirement

Type 1: factories which has facilities for film creation processes only.

Type 2: factories which has facilities for chemical treatment processes only.

Type 3: factories which has all facilities.

It is assumed that there is one factory of Type 1 (factory 1), two factories of Type 2 (factory 2 and 5) and two factories of Type 3 (factory 3 and 4).

The target production systems deal with two types of films α and β. Each type of films is produced by fixed type of machines: machine type A and B. And in this work, it is assumed that requests of intermediate materials are limited to be required from Type 2 to Type 1 and 3. As for the factories of Type 3, intermediate materials required for the final products are processed the factory itself.

4.2 States of a production system

In this work, proper selection of factory for each of intermediate material requirement according to the conditions of the whole production network and the feature of the requirements is intended. Basically, next two points are concerned in representation of the states.

1. Vacant time in the current schedule (This means a time to spare for new requirements.)
2. Whole amount of requests

Concretely, a state of each intermediate material requirement is described as a string composed of six characters (See Fig. 2.).

1 The first character is one of "A" or "B". It represents the type of machine for film creation.

Table 1. The concrete values of L, M, S

	2	3 (α)	3 (β)	4-6
L	25	90	70	40
M	15 – 25	50 - 90	40 - 70	20 - 40
S	< 15	< 50	< 40	< 20

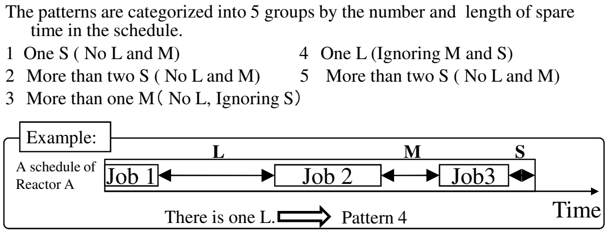

Fig. 3. Representation of vacant time in schedules

2 The second character is one of "S", "M" or "L". It represents the amount of the requested film. The first column in TABLE 1 shows the correspondence of an concrete amount and the three characters.

3 The third character is one of "S", "M" or "L". It represents the whole amount of the requested film which is the same type with the requests. Besides, requirements which are accepted already by some factory are ignored. The second and the third column in TABLE 1 shows the correspondence of an amount and the three characters.

4 – 6 Each of the 4 th , 5 th and 6th characters is one of "1", "2", "3", "4" or "5". They represent the pattern of vacant time in the factory 1, 3, and 4.

The 5 patterns used in from 4th to 6th characters are categorized by the number and the length of vacant time in the schedule of the corresponding factory (Fig. 3.). The length of vacant time is represented by "S", "M" or "L". The 4th column in TABLE 1 shows the correspondence of amounts and the three characters. Patterns are categorized by the number of each type of vacant time:

Pattern 1 There is only one S. (No M ,L).

Pattern 2 There are more than two S. (No M, L).

Pattern 3 There are more than one M. (No L).

Pattern 4 There is one L.

Pattern 5 There are more than two L.

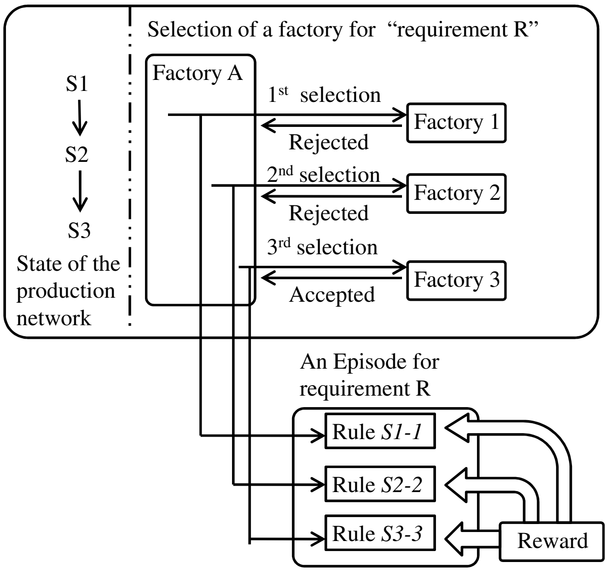

Fig. 4. The process of learning of rules

4.3 Process of Learning Rules

There are three actions (selection of factory 1, 3 or 4) for each state. A combination of each of the three actions and a state form "rules". The module of reinforcement learning observes the target production system and obtains data about current condition of the system. Next, the reinforcement learning module identifies the state of each intermediate material requirement. Then, the module selects a rule from three rules of the identified state.

Episodes of Profit Sharing start when requirement of intermediate materials are generated (See Fig.4.). A rule is selected from rules which are corresponding to the state of the requirement and the production network at that time. The selected rules are added to the episode of the requirement. The request of intermediate material is sent to the factory which is indicated by the selected rule. If the selected factory accepts the requests, a reward is given to the rules in the episode. On the other hand, in case that the request is not accepted, another factory is selected and the request is sent to the new factory. Since some requirements may be accepted, the state of each intermediate will be changed at each "re-scheduling".

5 IMPROVEMENT OF STATES REPRESENTATION

5.1 Introduction of new representation

First, preliminary experiments were carried out in order to examine the performance of the original representation. From the results of the experiments, several problems below were found.

- There are 2250 states under the proposed "6 characters"

Table 2. New ranges of spare times

Set No.	original	1	New 2
L	> 40	> 3000	> 5000
M	20 40	1500 3000	3000 3000
S	< 20	< 1500	< 3000

Table 3. Appearance of states

Set No.	original	1	2
Appeared states	307	1301	1349

representation, but the number of states which appeared frequently was almost 300 in the experiments.

- Appearance of states with Type 3 (including M size spare time) was very rare.
- 95% of appearedd states were type 4 or 5 (including L size spare time).

These results show that the ranges of a spare time used in the previous work did not match time length of production jobs. Concretely, the ranges of L and M have to be expanded.

So, new several candidates of ranges to represent spare time of machines were introduced. Table 2 shows two examples of the range sets used in the experiments below.

5.2 Experiments

A series of experiments was carried out in order to confirm that factory selection rules obtained under the new spare time ranges had ability to separate states of production networks properly keeping a performance of the rules. Since the model production network are same with the one used in the previous work (Yamaba [2]), the details is omitted here.

The numbers of appeared states are shown in Table 3. This result shows that the new ranges seems separate states of a production network more adequet then original one.

Table 4 shows the number of whole orders and rejected orders in the simulation experiments operated using the supplier selection rules obtained under the each spare time ranges. The column of "random" is the result of the experiment under the condition that supplier selection was carried out at random. Percentages of a rejected order ratio to the one when random selection was used are also shown in Table 4. The percentages show that the obtained rules can select proper factories.

6 CONCLUSION

An attempt was made to obtain operation rules by reinforcement learning in order to manage production network effectively.

Table 4. Comparison of performance

Set No.	original	1	2	random
Whole orders	170098	171556	172070	171234
Rejected orders	22216	22907	23327	26192
Rejected ratio	13.06	13.35	13.56	15.30
Percentage to random	85.39	87.29	88.63	100

The new candidates of ranges were proposed and it was confirmed that the new ranges separated the sates of the target production networks more adequate keeping the performance of the obtained supplier selection rules.

Abstract: In this paper, equations of motion of a manipulator are derived in consideration of characteristics of driving source. By considering impact force absorption between a link and an object, trajectories for saving energy are calculated by the iterative dynamic programming (IDP) method. And, the dynamic characteristics of manipulator controlled based on the trajectory for saving energy are analyzed theoretically and investigated experimentally.

Keywords: Manipulator, Trajectory, Dynamic Programming, Impact force, Minimum Energy.

1 Introduction

For the purpose of enlarging the work space in carriage work, it is necessary to study the throwing motion of a manipulator. In a previous report [1], a casting manipulator is introduced, and it has large work space compared with its simple mechanism. However, considerations of energy consumption are not enough. Evaluations of robotic mechanisms subjected to impact load are investigated [2], but energy consumption is not considered.

In previous report [3], trajectories for saving energy about the throwing motion of manipulator were easily calculated by IDP method. And, dynamic characteristics of the system were analyzed. In previous report [4], considering the collision between the link and the object, and considering the active motion which absorbs kinetic energy from the object, the trajectories for saving energy are calculated by the IDP method.

In this paper, equations of motion of a manipulator are derived in consideration of the characteristics of DC servomotors, and a performance criterion for saving energy is defined in consideration of energy consumption of the driving source. When the manipulator is operated in a vertical plane, the system is highly non-linear due to gravity, and an analytical solution can not be found. Then, a numerical approach is necessary. By considering impact force absorption between a link and an object, trajectories for saving energy are calculated by IDP method. The dynamic characteristics of manipulator controlled based on above-mentioned trajectory are analyzed theoretically and investigated experimentally.

2 Modeling of manipulator

The dynamic equations of the manipulator with two degrees of freedom, as shown in Fig. 1, which is able to move in a vertical plane, are as follows.

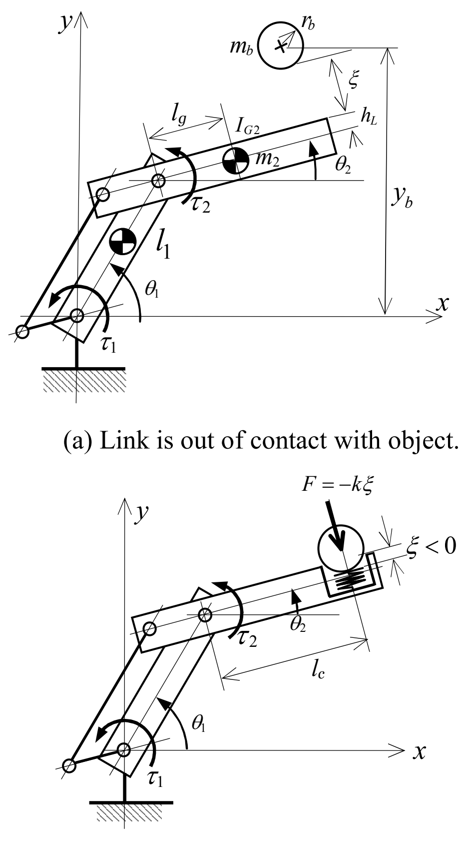
$$\begin{bmatrix} A_{11} & A_{12} \\ A_{21} & A_{22} \end{bmatrix} \begin{bmatrix} \ddot{\theta}_1 \\ \ddot{\theta}_2 \end{bmatrix} = \begin{bmatrix} A_{13} \\ A_{23} \end{bmatrix} \tag{1}$$

where

$$A_{11} = a_1 \,, A_{12} = a_3 \cos(\theta_1 - \theta_2) \,, A_{21} = A_{12} \,, A_{22} = a_2$$

$$A_{13} = \tau_1 - a_3 \dot{\theta}_2^2 \sin(\theta_1 - \theta_2) - a_4 \cos\theta_1 - F l_1 \cos\theta_1$$

$$A_{23} = \tau_2 + a_3 \dot{\theta}_1^2 \sin(\theta_1 - \theta_2) - a_5 \cos\theta_2 - F l_c$$



(a) Link is out of contact with object.

(b) Link is in contact with object.

Fig.1 Mechanism of manipulator

$$a_1 = m_1 l_{g1}{}^2 + I_{G1} + m_2 l_1^2 \ , a_2 = I_{G2} + m_2 l_{g2}{}^2$$
$$a_3 = m_2 l_1 l_{g2} \ , a_4 = \left(m_1 l_{g1} + m_2 l_1\right) g \ , a_5 = m_2 g l_{g2} \ .$$

When the link is in contact with an object, the contact force is

$$F = -k\xi \quad , \quad (\xi < 0) \quad . \tag{2}$$

Where ξ is displacement of spring, and

$$\xi = \frac{y_b - (l_1 \sin\theta_1 + l_c \sin\theta_2)}{\cos\theta_2} - (h_L + r_b) \quad . \tag{3}$$

The applied voltage of the servomotor is

$$e_j = b_{1j}\dot{\theta}_j + b_{2j}\ddot{\theta}_j + b_{3j}\tau_j + b_{3j}\tau_{f_j}\ \mathrm{sign}(\dot{\theta}_j) \tag{4}$$
$$(j = 1, 2) \quad ,$$

where

$b_{1j} = k_{vj} + (R_{aj}/k_{tj})D_{mj}$, $b_{2j} = (R_{aj}/k_{tj})\mathrm{I}_{mj}$, $b_{3j} = R_{aj}/k_{tj}$,

i_{aj} : electric current of the armature ,

R_{aj} : resistance of armature ,

I_{mj} : moment of inertia of armature,

D_{mj} : coefficient of viscous damping.

Then, the electric current is

$$i_{aj} = (e_j - k_{vj}\dot{\theta}_j)/R_{aj} \ . \tag{5}$$

And, the consumed energy is

$$E_j = \int (e_j \cdot i_{aj}) dt \ . \tag{6}$$

3 Simulation of the manipulator

We shall take the parameters of the system as shown in Table 1.

Figure 2 shows a flow chart for iterative dynamic programming method. In frame (A), the trajectory for saving energy is searched by IDP method [3]. In frame (B), the searching region is shifted to minimize the consumed energy, and width of the region is changed smaller.

Figure 3 shows the trajectory for searching, and initial trajectory for searching is expressed as

$$\theta_j = \theta_{ji} + \frac{(\theta_{jf} - \theta_{ji})}{2}\left\{1 - \cos\left(\frac{\pi}{t_f} t\right)\right\} \quad . \tag{7}$$

The performance criterion is

$$E' = \int (e \cdot i_a) dt + C_1 \int |F| \cdot dt + C_2 |y_b'| \quad . \tag{8}$$

The simulations of the system are done as follows.

Figure 4 and 5 show the response of the manipulator. The motion of an object is free-fall from initial height y_b=0.18(m). When t=0.206(s), the object is in contact with the link. And then, position and velocity are y_b'=0.03 (m), $\dot{y}_b$=–1.75 (m/s). Under the condition that $\theta_{2i} = \theta_{2f}$ =0, an optimal trajectory is calculated by IDP method.

Table 1 Parameters of the manipulator

Parameter	Value	Parameter	Value
l_2 (m)	0.10	I_{G2} (kgm^2)	4.8×10^{-5}
l_{g2} (m)	0.057	I_{m2} (kgm^2)	8.5×10^{-5}
m_2 (kg)	0.045	D_{m2} (Nms/rad)	7.9×10^{-5}
m_b (kg)	0.017	k_{t2} (Nm/A)	0.046
R_{a2} (Ω)	3.5	k_{v2} (Vs/rad)	0.046
k (N/m)	9000	τ_{f2} (Nm)	0.013
c (Ns/m)	2.0		

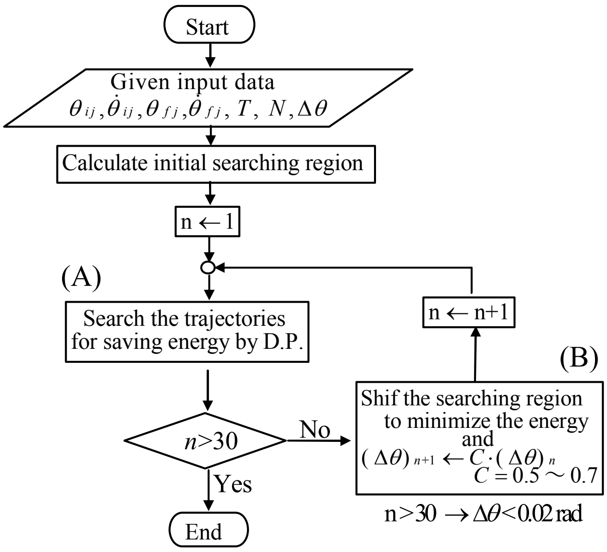


Fig.2 Flow chart for simulation

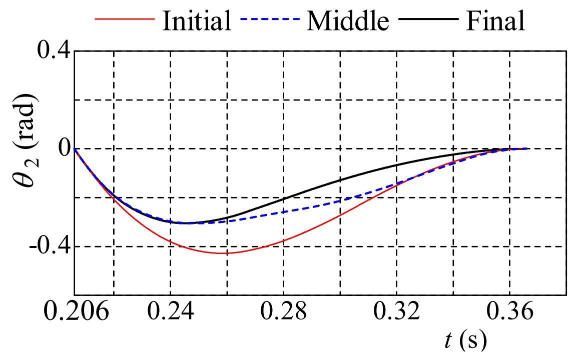

Fig.3 Trajectory for searching

In Figure 4, under the condition that $\dot{\theta}_{1i}$ =0, $\dot{\theta}_{2i}$ =–17.5 (rad/s), the solid lines show the response of manipulator which is actuated along the optimal trajectory. And broken lines show the response of manipulator which is fixed at the initial position. Impact force F about actuated case (solid line) becomes smaller than one of fixed case (broken line). And, consumed energy of motor is increases gradually.

In Figure 5, under the condition that $\dot{\theta}_{1i} = \dot{\theta}_{2i}$ =0, the solid lines show the response of manipulator which is actuated along the optimal trajectory. But, the impact force is not reduced.

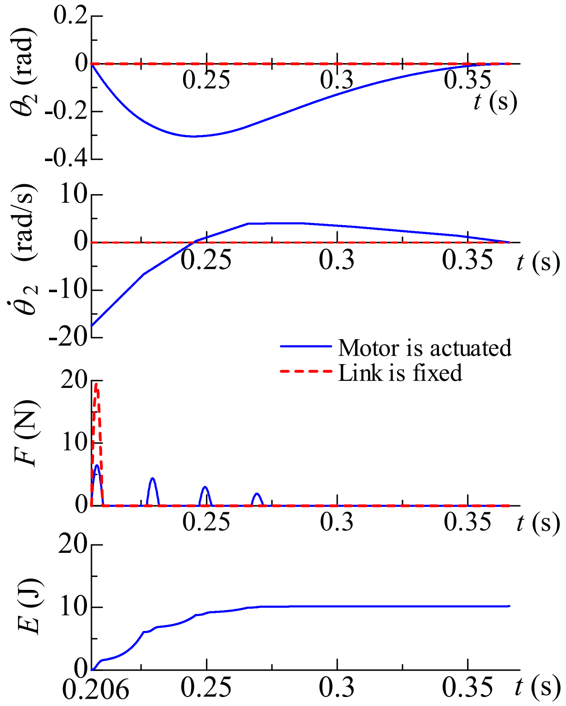

Fig.4 Theoretical results ($\dot{\theta}_{2i} = -17.5$ rad/s)

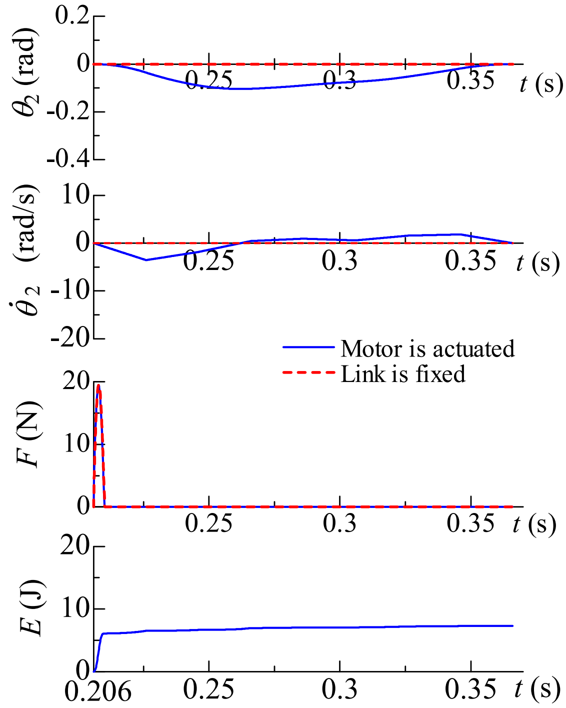

Fig.5 Theoretical results ($\dot{\theta}_{2i} = 0$)

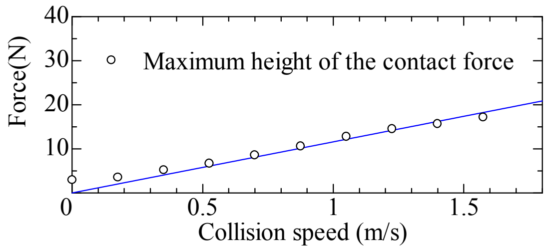
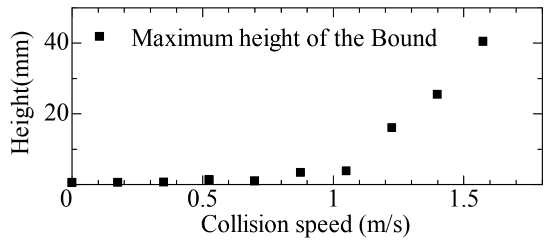
5 Experimental results

In this section, the results of fundamental experiment are shown to examine the effectiveness of modeling for the simulations.

Figure 7 shows an experimental apparatus. Slide board is tilted ($\pi/3$) measured from the level surface. And, two Laser displacement meters are installed for measuring the passing time of the object.

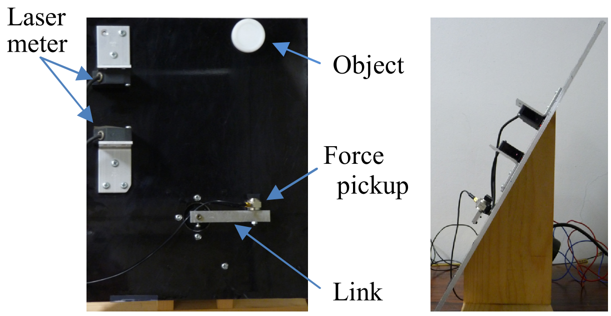


(a) Relation between collision speed and impact force



(b)Relation between collision speed and height of bound

Fig.6 Impact force and height of bound



(a) Front view (b) Side view

Fig.7 Experimental apparatus

The parameter of the link and the motor are shown in Table 1, and the motor (rated 24 V, 60W) are on the frame, and sampling time of the control is 0.002 s. The feedback gain for angular displacement is 100 V/rad, and the feedback gain for angular velocity is 1.0 Vs/rad.

Figure 8 (a) and (b) show experimental results about motion of the link and object. In Figure (a), the link is fixed at initial position, and the object bounds high. In Figure (b), the link is actuated along the trajectory calculated by IDP method, and the object bounds low.

Figure 9 shows the experimental results about the response of the link and motor after the passing time of Laser meter. Impact force F about optimal case (b) becomes smaller than one of supported case (a). The experimental results (solid line) are similar to the theoretical results (broken line).

From these results, it is considered that modeling for simulation is effective.

6 Conclusions

The results obtained in this paper are summarized as follows.

(1) It is considered that the active motion to absorb the impact force is possible by analyzing the relative motion about the collision between the link and object.

(2) From experimental results, it is considered that modeling for simulation is effective.

An application of guaranteed cost control to a 3-DOF model helicopter

Erwin Susanto*, Tatsuhiro Tamura, Mitsuaki Ishitobi and Sadaaki Kunimatsu

Department of Mechanical Systems Engineering, Kumamoto University, Kumamoto 850-8555, Japan
(Tel: +81-96-342-3866, *e-mail: 095d9213@st.kumamoto-u.ac.jp)

Abstract: This paper deals with guaranteed cost control for a model helicopter which has 3-DOF (degree of freedom): the elevation, pitch, and travel angles. One of main difficulties in designing a feedback controller for the helicopter is that the model includes nonlinearities. In this paper, these nonlinearities are considered as the uncertainty terms. Guaranteed cost control is applied not only to achieve the closed-loop stability but also to guarantee an adequate level of performance of the nonlinear 3-DOF model helicopter. A numerical example is shown to illustrate the effectiveness of the proposed method.

Keywords: guaranteed cost control, 3-DOF model helicopter, LMI

1 INTRODUCTION

This paper deals with guaranteed cost control for a model helicopter which has 3-DOF (degree of freedom): the elevation, pitch, and travel angles [1], [2]. One of main difficulties in designing a feedback controller for the helicopter is that the dynamics include nonlinearities.

Although single-input single-output approaches have advantages in simple structure, straightforward and so on, these methods are difficult to consider uncertainties. Therefore, development of multi-input multi-output control approaches are widely applied, see e.g. [3], [4]. Moreover, avoiding difficulties in measurement of system state due to uncertainties, an observer can be applied to reconstruct the system dynamics [5].

In this paper, these nonlinearities are considered as the uncertainty terms. By using Taylor's expansion, the state equation of a nonlinear 3-DOF model helicopter is changed to the form of a continuous-time uncertain system. Because the presence of the uncertainties may cause instability and bad performance on a controlled system, then guaranteed cost control method is applied.

The objective of this paper is to propose a design method of guaranteed cost control with a minimal order observer for a 3-DOF model helicopter via linear matrix inequalities (LMIs) feasible solutions.

Finally, a numerical example is given to illustrate the effectiveness of the proposed method and it is shown that a 3-DOF nonlinear model helicopter can be stabilized by the guaranteed cost control method.

2 MODEL HELICOPTER

The dynamics of a 3-DOF model helicopter shown in Fig. 1. are described [1] as

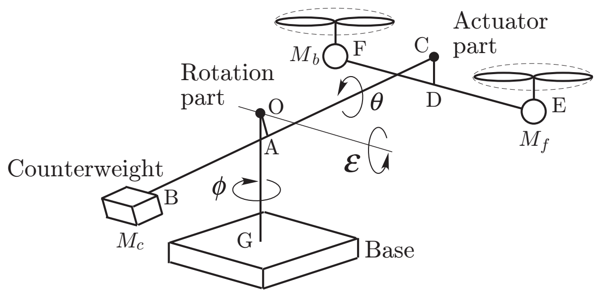

Fig. 1. A 3-DOF model helicopter

$$\dot{\boldsymbol{x}}_p = \begin{bmatrix} p_1\cos\varepsilon + p_2\sin\varepsilon + p_3\dot{\varepsilon} + p_4\cos\theta v_1 \\ p_5\cos\theta + p_6\sin\theta + p_7\dot{\theta} + p_8 v_2 \\ p_9\dot{\phi} + p_{10}\sin\theta v_1 \\ \dot{\varepsilon} \\ \dot{\theta} \\ \dot{\phi} \end{bmatrix} \tag{1}$$

where p_i, (i=1,...,10) are model helicopter constants; ε, θ, ϕ are the elevation, pitch and travel angles and

$$\boldsymbol{x}_p = \begin{bmatrix} \dot{\varepsilon}, \dot{\theta}, \dot{\phi}, \varepsilon, \theta, \phi \end{bmatrix}^T,$$
$$v_1 = V_f + V_b,\ v_2 = V_f - V_b,$$

V_f and V_b are voltages applied to the front and rear motor, respectively.

3 PROBLEM STATEMENT

By using Taylor's expansion, a 3-DOF nonlinear model helicopter (1) can be expressed by the form

$$\dot{\boldsymbol{x}}(t) = (A + \Delta A(t))\boldsymbol{x}(t) + (B + \Delta B(t))\boldsymbol{u}(t) \tag{2}$$
$$\boldsymbol{y}(t) = C\boldsymbol{x}(t),\ C = [O \ \ I_3] \tag{3}$$

$$\boldsymbol{u}(t) = \begin{bmatrix} u_1 \\ u_2 \end{bmatrix},\ u_1 = v_1 + \frac{p_1}{p_4},\ u_2 = v_2 + \frac{p_5}{p_8} \tag{4}$$

where

$$\begin{aligned}
A &= [a_{ij}],\ (i,j = 1,...,6),\\
a_{11} &= p_3,\ a_{14} = p_2,\ a_{22} = p_7,\ a_{25} = p_6,\\
a_{33} &= -\frac{p_1 p_{10}}{p_4},\ a_{41} = a_{52} = a_{63} = 1,\\
B &= [b_{ij}],\ (i = 1,...,6,\ j = 1,2),\\
b_{11} &= p_4,\ b_{21} = p_8,\\
\Delta A &= [\delta a_{ij}],\ (i,j = 1,...,6),\\
\delta a_{11} &= \Delta A_{11},\ \delta a_{14} = \Delta A_{14},\ \delta a_{15} = \Delta A_{15},\\
\delta a_{22} &= \Delta A_{22},\ \delta a_{25} = \Delta A_{25},\ \delta a_{33} = \Delta A_{33},\\
\delta a_{35} &= \Delta A_{35},\\
\Delta B &= [\delta b_{ij}],\ (i = 1,...,6,\ j = 1,2),\\
\delta b_{11} &= \Delta B_{11},\ \delta b_{22} = \Delta B_{22},\ \delta b_{31} = \Delta B_{31},\\
\Delta A_{11} &= \Delta p_3,\\
\Delta A_{14} &= p_2(-\frac{1}{3!}x_4^2 + O(x_4^4)) + p_1(-\frac{1}{2}x_4 + O(x_4^3)) + \Delta p_2,\\
\Delta A_{15} &= p_1(-\frac{1}{2}x_5 + O(x_5^3)),\ \Delta A_{22} = \Delta p_7,\\
\Delta A_{25} &= p_5(-\frac{1}{2}x_5 + O(x_5^3)) + p_6(-\frac{1}{3!}x_6^2 + O(x_6^4)) + \Delta p_6,\\
\Delta A_{33} &= \Delta p_9,\\
\Delta A_{35} &= -\frac{p_1 p_{10}}{p_4}(-\frac{1}{3!}x_5^2 + O(x_5^4)) - \Delta(p_1 p_{10}/p_4),\\
\Delta B_{11} &= p_4(-\frac{1}{2}x_5 + O(x_5^4)) + \Delta p_4,\\
\Delta B_{22} &= \Delta p_8,\ \Delta B_{31} = p_{10}(x_5 - \frac{1}{3!}x_5^3 + O(x_5^5)),
\end{aligned}$$

while other elements are zero, and $\boldsymbol{x}(t) \in \Re^n$ is the state vector, $\boldsymbol{u}(t) \in \Re^r$ is the control input vector, $\boldsymbol{y}(t) \in \Re^m$ is the measured output vector, Δp_i denote uncertain terms of p_i, A, B, C are known constant real-valued matrices with appropriate dimensions. Due to the system constraint, we have the bounds of $|\varepsilon|$, $|\theta|$ and $|\phi|$ as $\varepsilon_{max}(= 0.3)$, $\theta_{max}(= 0.3)$ and $\phi_{max}(= 0.8)$.

Under the limitations of $|\varepsilon|$, $|\theta|$ and $|\phi|$, matrices $\Delta A(t)$ and $\Delta B(t)$ can be represented as

$$\Delta A(t) = D_A F_A(t) E_A,\ \Delta B(t) = D_B F_B(t) E_B \tag{5}$$

with

$$F_A^T(t) F_A(t) \leq I,\ F_B^T(t) F_B(t) \leq I$$

where D_A, D_B, E_A, E_B are constant real-valued known matrices with appropriate dimensions, and $F_A(t)$ and $F_B(t)$ are real time-varying unknown continuous and deterministic matrices.

We assume that the initial state variable $\boldsymbol{x}(0)$ is unknown, but their mean and covariance are known

$$E[\boldsymbol{x}(0)] = \boldsymbol{m}_0 \tag{6}$$

$$E\left[(\boldsymbol{x}(0) - \boldsymbol{m}_0)(\boldsymbol{x}(0) - \boldsymbol{m}_0)^T\right] = \Sigma_0 > O \tag{7}$$

where $E[\cdot]$ denotes the expected value operator.

The problem considered here is to design a guaranteed cost controller with a minimal order observer so as to achieve an upper bound on the following quadratic performance index

$$E[J] = E\left[\int_0^\infty (\boldsymbol{x}^T(t) Q \boldsymbol{x}(t) + \boldsymbol{u}^T(t) R \boldsymbol{u}(t)) dt\right] < E[J^*] \tag{8}$$

associated with the uncertain system (2) where Q and R are given symmetric positive-definite matrices.

4 GUARANTEED COST CONTROLLER DESIGN

Design of a guaranteed cost controller is described in the following equations. Here, a minimal order observer is given by

$$\dot{\boldsymbol{z}}(t) = D\boldsymbol{z}(t) + E\boldsymbol{y}(t) + F\boldsymbol{u}(t) \tag{9}$$

$$\hat{\boldsymbol{x}}(t) = P\boldsymbol{z}(t) + W\boldsymbol{y}(t) \tag{10}$$

with

$$\begin{aligned}
&D = A_{11} + LA_{21},\ PT + WC = I_6,\\
&F = TB,\ TA - DT = EC,\ A = \left[\begin{array}{c|c} A_{11} & A_{12} \\ \hline A_{21} & A_{22} \end{array}\right],\\
&P = \begin{bmatrix} I_3 & \boldsymbol{0} \end{bmatrix}^T,\ T = \begin{bmatrix} I_3 & L \end{bmatrix}
\end{aligned}$$

and a controller is assumed to have a form of

$$\boldsymbol{u}(t) = K\hat{\boldsymbol{x}}(t),\ K = -R^{-1}B^T S_1 \tag{11}$$

where S_1 is a symmetric positive definite matrix.

Then, the following Theorem gives a design method of guaranteed cost control to the 3-DOF model helicopter (2)-(3).

Theorem 1. If the following matrix inequalities optimization problem; $\min\{\gamma_0 + \gamma_1 + \gamma_2 + \gamma_3 + \gamma_4\}$ subject to

$$\begin{bmatrix} \Lambda_0 & X^T & XE_A & XE_A \\ * & -Q^{-1} & 0 & 0 \\ * & 0 & -\alpha_1 I & 0 \\ * & 0 & 0 & -\alpha_4 I \end{bmatrix} < 0 \tag{12}$$

$$\begin{bmatrix} \bar{\Lambda}_0 & G_1 & G_2 & G_2 & G_3 & G_3 & G_4 \\ * & -R & 0 & 0 & 0 & 0 & 0 \\ * & 0 & -\alpha_{5,inv}I & 0 & 0 & 0 & 0 \\ * & 0 & 0 & -\alpha_{6,inv}I & 0 & 0 & 0 \\ * & 0 & 0 & 0 & -\alpha_3 I & 0 & 0 \\ * & 0 & 0 & 0 & 0 & -\alpha_6 I & 0 \\ * & 0 & 0 & 0 & 0 & 0 & -\alpha_{4,inv}I \end{bmatrix} < 0 \tag{13}$$

$$\sum_{k=1}^{6} \boldsymbol{e}_{6k}^T \Theta_0 \boldsymbol{e}_{6k} < \gamma_0,\ \sum_{k=1}^{3} \boldsymbol{e}_{3k}^T \Theta_1 \boldsymbol{e}_{3k} < \gamma_1,$$
$$\sum_{k=1}^{3} \boldsymbol{e}_{3k}^T \Theta_2 \boldsymbol{e}_{3k} < \gamma_2,\ \sum_{k=1}^{3} \boldsymbol{e}_{3k}^T \Theta_3 \boldsymbol{e}_{3k} < \gamma_3 \tag{14}$$

$$\begin{bmatrix} -\gamma_4 & \boldsymbol{v}_1^T Y^T & \boldsymbol{v}_2^T Y^T & \boldsymbol{v}_3^T Y^T \\ Y\boldsymbol{v}_1 & -S_2 & & \\ Y\boldsymbol{v}_2 & & -S_2 & \\ Y\boldsymbol{v}_3 & & & -S_2 \end{bmatrix} < 0 \tag{15}$$

where

$$\begin{aligned}
\Lambda_0 &= AX + XA^T - BR^{-1}B^T + (\alpha_2+\alpha_3)D_B D_B^T \\
&\quad + \alpha_1 D_A D_A^T + (\alpha_{2,inv}+\alpha_{5,inv})BR^{-1}E_B^T E_B R^{-1}B^T, \\
\bar{\Lambda}_0 &= S_2 A_{11} + A_{11}^T S_2 + YA_{21} + A_{21}^T Y^T, \\
Y &= S_2 L,\ Z = [S_2\ \ Y],\ G_1 = P^T S_1 B, \\
G_2 &= ZD_B,\ G_3 = P^T S_1 B R^{-1} E_B^T,\ G_4 = ZD_A, \\
\Theta_0 &= \frac{1}{2}(S_1(\Sigma_0 + \boldsymbol{m}_0\boldsymbol{m}_0^T) + (\Sigma_0 + \boldsymbol{m}_0\boldsymbol{m}_0^T)^T S_1), \\
\Theta_1 &= \frac{1}{2}(S_2\Sigma_{11} + \Sigma_{11}S_2),\ \Theta_2 = \frac{1}{2}(Y\Sigma_{21} + \Sigma_{21}^T Y^T), \\
\Theta_3 &= \frac{1}{2}(Y^T\Sigma_{12} + \Sigma_{12}^T Y),\ \boldsymbol{e}_{ik} = \ \ \mathbf{0}_{k-1}^T\ 1\ \mathbf{0}_{i-k}^T\ \ ^T, \\
\Sigma_0 &= \begin{bmatrix} \Sigma_{11} & \Sigma_{12} \\ \Sigma_{21} & \Sigma_{22} \end{bmatrix},\ \Sigma_{22}^{1/2} = [\boldsymbol{v}_1, \boldsymbol{v}_2, \boldsymbol{v}_3]
\end{aligned}$$

has a solution $S_1 > 0$, $S_2 > 0$, $X > 0$, Y, Z, $\alpha_1 > 0$, $\alpha_2 > 0$, $\alpha_{2,inv} > 0$, $\alpha_3 > 0$, $\alpha_4 > 0$, $\alpha_{4,inv} > 0$, $\alpha_{5,inv} > 0$, $\alpha_6 > 0$, $\alpha_{6,inv} > 0$, γ_0, γ_1, γ_2, γ_3, γ_4 which satisfy the relation $\alpha_2^{-1} = \alpha_{2,inv}$, $\alpha_4^{-1} = \alpha_{4,inv}$, $\alpha_6^{-1} = \alpha_{6,inv}$ and $S_1^{-1} = X$, then the minimal order observer-based control law (9)-(11) is a guaranteed cost controller which gives the minimum expected value of the guaranteed cost

$$E[J^*] = E\left[\boldsymbol{x}^T(0)S_1\boldsymbol{x}(0) + \boldsymbol{\xi}^T(0)S_2\boldsymbol{\xi}(0)\right] \tag{16}$$

where $\boldsymbol{\xi}(t) = \boldsymbol{z}(t) - T\boldsymbol{x}(t)$ is the estimated error of the minimal order observer.

Remark 1: Since inequalities in (12) and (13) contain scalars and matrices that satisfy inverse relations $S_1^{-1} = X$, $\alpha_2^{-1} = \alpha_{2,inv}$, $\alpha_4^{-1} = \alpha_{4,inv}$, and $\alpha_6^{-1} = \alpha_{6,inv}$. then an iterative LMI algorithm is adopted to solve [6],[7].

5 A NUMERICAL EXAMPLE

The nominal values of the model helicopter are as follows:

$$\begin{aligned}
p_1 &= [-(M_f + M_b)gL_a + M_c g L_c]/J_\varepsilon, \\
p_2 &= [-(M_f + M_b)gL_a \tan\delta_a + M_c g L_c \tan\delta_c]/J_\varepsilon, \\
p_3 &= \eta_\varepsilon/J_\varepsilon,\ p_4 = K_m L_a/J_\varepsilon,\ p_5 = (-M_f + M_b)gL_h/J_\theta, \\
p_6 &= -(M_f + M_b)gL_h \tan\delta_h/J_\theta,\ p_7 = -\eta_\theta/J_\theta, \\
p_8 &= K_m L_h/J_\theta,\ \ p_9 = -\eta_\phi/J_\phi, p_{10} = -K_m L_a/J_\phi, \\

6 CONCLUSION

This paper discusses a design method of guaranteed cost control with a minimal order observer for a 3-DOF nonlinear model helicopter via linear matrix inequalities (LMIs). The results show the effectiveness of the proposed method.

Abstract: In this paper, we propose a modeling method for an uncertain system of a three-link RRR manipulator. We consider that each rotation joint of this manipulator consists a nominal joint angle and uncertain joint angle. Though, the uncertainty is treated as disturbance in the system that is maximum possible value of the uncertain joint angle. A relationship between disturbance and the system structure in a state equation is clarified. Through the numerical example, we show the effectiveness of our proposed method. It can apply our result to the general method of the robust control with structured uncertainty, such as guaranteed cost control.

Keywords: Linear control system, Robust control, Guaranteed cost control

1 INTRODUCTION

In the framework of the linear control system theory, the design procedure for the controller is archived by a model based method. But the numerical model only contains a nominal characteristic of the plant. Thus, it is important problem to obtain the representation of the effect of the uncertainty, and use this information for the design of robust controller. Chang et al. proposed the design method to guarantee the existence of upper bound of performance index, which called guaranteed cost control (GCC) [1]. Sato et al. consider the trajectory generation problem for energy saving of the manipulator [2, 3]. Authors proposed a modeling method of a linear time invariant system which includes an uncertainty of the plant [4, 5]. And apply the uncertain system to GCC problem. In [6], authors consider GCC problem in the case with the system includes parameter variation in an output matrix. The parameter setting of the free variable $_i$ in the linear upper bound is available for adjustment of the closed-loop system's characteristic. In [7], authors consider a two-link RR manipulator model case. Such a higher-dimensional system, the effect of uncertainty to the disturbance becomes larger bad influence than smaller dimension one, so that it is not a negligible problem. The observer based method is effective to reduce the effects of disturbance.

In this paper, we apply our modeling method to the three-link RRR manipulator. In such a high dimensional system, the effect of nonlinear element is larger than the lower dimensional system. It is important the robustness of the controller.

2 DERIVATION OF THE UNCERTAIN SYSTEM

The dynamics of a three-link RRR manipulator is illustrated as a following second ordinary differential equation.

$$H(\boldsymbol{\theta})\boldsymbol{\theta} + D\dot{\boldsymbol{\theta}} + \boldsymbol{\eta}(\dot{\boldsymbol{\theta}},\boldsymbol{\theta}) + g\boldsymbol{\gamma}(\boldsymbol{\theta}) = \qquad (1)$$

where the inertia term is

$$H(\boldsymbol{\theta}) = \begin{bmatrix} h_{11}(\boldsymbol{\theta}) & h_{12}(\boldsymbol{\theta}) & h_{13}(\boldsymbol{\theta}) \\ h_{12}(\boldsymbol{\theta}) & h_{22}(\boldsymbol{\theta}) & h_{23}(\boldsymbol{\theta}) \\ h_{13}(\boldsymbol{\theta}) & h_{23}(\boldsymbol{\theta}) & h_{33}(\boldsymbol{\theta}) \end{bmatrix},$$

the nonlinear term is

$$\boldsymbol{\eta}(\boldsymbol{\theta},\dot{\boldsymbol{\theta}}) = \begin{bmatrix} & {}_{11}(\dot{\boldsymbol{\theta}},\boldsymbol{\theta}) & \\ {}_{21}(\dot{\boldsymbol{\theta}},\boldsymbol{\theta}) & & {}_{22}(\dot{\boldsymbol{\theta}},\boldsymbol{\theta}) \\ {}_{31}(\dot{\boldsymbol{\theta}},\boldsymbol{\theta}) & & {}_{32}(\dot{\boldsymbol{\theta}},\boldsymbol{\theta}) \end{bmatrix},$$

the dumping term is

$$D = \mathrm{diag}(d_1, d_2, d_3),$$

the gravity term and the input term are

$$\boldsymbol{\gamma}(\boldsymbol{\theta}) = \begin{bmatrix} {}_{1}(\boldsymbol{\theta}) \\ {}_{2}(\boldsymbol{\theta}) \\ {}_{3}(\boldsymbol{\theta}) \end{bmatrix}, \quad = \begin{bmatrix} {}_{1} \\ {}_{2} \\ {}_{3} \end{bmatrix}.$$

Here we derive the LTI system with structured uncertainty for the above dynamics. In this system, the relationship between an uncertainty of the system and system structure is expressed in the additional system matrix. Let us assume that the each rotation joints include an angle of the nominal element and an uncertain element. The possible value of the uncertain joint angle is unknown, therefore we use the maximum value of the uncertain angle as a disturbance of the system to derive an uncertain system. The nominal system structure is derived from the nominal joint angle, and the uncertain system structure is derived corresponding to the uncertain joint angle. The system uncertainty is only used to derive the uncertain system, though in the later section of numerical example, the simulation result is calculated by using nominal LTI system.

2.1 Introduce of uncertainty

In this section, we introduce an uncertain angle in the each joint to express the effect to the system structure. Here we consider that the rotation angle $\bar{\ }_i(t)$ of joint$_i$, $(i = 1, 2, 3)$ is constructed from an nominal joint angle $\ _i(t)$ and uncertain joint angle $\Delta\ _i$.

$$\bar{\ }_i \;=\; \ _i + \Delta\ _i, \quad (i = 1, 2, 3) \tag{2}$$

where the uncertain joint angle $\Delta\ _i$ takes very small value, it can be approximate sinusoidal functions $\sin, \cos$ as

$$\begin{aligned} \sin\Delta\ _i &\rightarrow 0 \\ \cos\Delta\ _i &\rightarrow \varDelta c_i \end{aligned}$$

Then, from the consideration of uncertainty of $\bar{\ }_i$, from the sinusoidal fundamental formulae, we have

$$\begin{aligned} \sin\bar{\ }_i &= \sin\ _i\cos\Delta\ _i + \cos\ _i\sin\Delta\ _i \\ & \quad \varDelta c_i\sin\ _i \end{aligned} \tag{3}$$

$$\begin{aligned} \cos\bar{\ }_i &= \cos\ _i\cos\Delta\ _i \quad \sin\ _i\sin\Delta\ _i \\ & \quad \varDelta c_i\cos\ _i \end{aligned} \tag{4}$$

In the term of $\bar{\ }_1 + \bar{\ }_2$, sin is becomes:

$$\begin{aligned} \sin(\bar{\ }_1 + \bar{\ }_2) &= \sin\bar{\ }_1\cos\bar{\ }_2 + \cos\bar{\ }_1\sin\bar{\ }_2 \\ & \quad \varDelta c_1\varDelta c_2(\sin\ _1\cos\ _2 + \cos\ _1\sin\ _2) \end{aligned} \tag{5}$$

We consider the approximation of cos as follows

$$\cos(\bar{\ }_1 + \bar{\ }_2) \quad \frac{1}{2}(\varDelta c_1 + \varDelta c_2)\cos(\ _1 + \ _2) \tag{6}$$

Then, the term of $\bar{\ }_1(t) + \bar{\ }_2(t) + \bar{\ }_3(t)$ becomes

$$\begin{aligned} &\sin(\bar{\ }_1 + \bar{\ }_2 + \bar{\ }_3) \\ &\quad \varDelta c_1\varDelta c_2\varDelta c_3(\sin\ _1\cos\ _2 + \cos\ _1\sin\ _2)\cos\ _3 \\ &\quad + \frac{1}{2}(\varDelta c_1 + \varDelta c_2)\varDelta c_3\cos(\ _1 + \ _2)\sin\ _3 \end{aligned} \tag{7}$$

The Taylor series expansion of Eqs. (3), (4), (5), (6) and (7) near $\ _i(t) = 0$, $(i = 1, 2, 3)$ up to the first-order are express as follows:

$$\begin{aligned} \sin\bar{\ }_1 &\quad \varDelta c_1\ _1 \\ \cos\bar{\ }_1 &\quad \varDelta c_1 \\ \sin\bar{\ }_2 &\quad \varDelta c_2\ _2 \\ \cos\bar{\ }_2 &\quad \varDelta c_2 \\ \sin\bar{\ }_3 &\quad \varDelta c_3\ _3 \\ \cos\bar{\ }_3 &\quad \varDelta c_3 \\ \sin(\bar{\ }_1 + \bar{\ }_2) &\quad \varDelta c_1\varDelta c_2(\ _1 + \ _2) \\ \cos(\bar{\ }_1 + \bar{\ }_2) &\quad \frac{1}{2}(\varDelta c_1 + \varDelta c_2) \\ \sin(\bar{\ }_1 + \bar{\ }_2 + \bar{\ }_3) &\quad \varDelta c_1\varDelta c_2\varDelta c_3(\ _1 + \ _2) \\ &\quad + \frac{1}{2}(\varDelta c_1 + \varDelta c_2)\varDelta c_3\ _3 \end{aligned}$$

By substituting these approximation terms into each elements h_{ij}, $(i = 1, 2, 3,\ j = 1, 2, 3)$ of the inertia term $H(\boldsymbol{\theta})$, The first row elements are:

$$\begin{aligned} \tilde{h}_{11} &= I_1 + m_1 l_{G1}^2 + I_2 + m_2(l_1^2 + l_{G2}^2 + 2\varDelta c_2 l_1 l_{G2}) \\ &\quad + I_3 + m_3\big(l_1^2 + l_{G2}^2 + l_{G3}^2 + 2\varDelta c_2 l_1 l_2 \\ &\quad + 2\varDelta c_3 l_2 l_{G3} + (\varDelta c_2 + \varDelta c_3) l_1 l_{G3}\big) \\ \tilde{h}_{12} &= I_2 + m_2\big(l_{G2}^2 + \varDelta c_2 l_1 l_{G2}\big) \\ &\quad + I_3 + m_3\big(l_2^2 + l_{G3}^2 + \varDelta c_2 l_1 l_2 + 2\varDelta c_3 l_2 l_{G3} \\ &\quad + \frac{1}{2}(\varDelta c_2 + \varDelta c_3) l_1 l_{G3}\big) \\ \tilde{h}_{13} &= I_3 + m_3\big(l_{G3}^2 + \varDelta c_3 l_2 l_{G3} + \frac{1}{2}(\varDelta c_2 + \varDelta c_3) l_1 l_{G3}\big) \end{aligned}$$

The second-row elements are:

$$\begin{aligned} \tilde{h}_{21} &= \tilde{h}_{12} \\ \tilde{h}_{22} &= I_2 + m_2 l_{G2}^2 + I_3 + m_3(l_2^2 + l_{G3}^2 + 2\varDelta c_3 l_2 l_{G3}) \\ \tilde{h}_{23} &= I_3 + m_3(l_{G3}^2 + \varDelta c_3 l_2 l_{G3}) \end{aligned}$$

The third-row elements are:

$$\begin{aligned} \tilde{h}_{31} &= \tilde{h}_{13} \\ \tilde{h}_{32} &= \tilde{h}_{23} \\ \tilde{h}_{33} &= I_3 + m_3 l_{G3}^2 \end{aligned}$$

As these results, the inertia term $H(\boldsymbol{\theta})$ is described as symmetric matrix with constant elements.

Table 1. Parameters of the Manipulator

Parameter	**Mean** [unit]
m_i	Mass of Link [kg]
I_i	Inertia moment of Link [kg·m^2]
l_i	length of Link [m]
l_{Gi}	Distance from the Joint to the center of gravity of the Link [m]
g	Gravity [m/sec^2]

$$H(\boldsymbol{\theta}) \quad \tilde{H} = \begin{bmatrix} \tilde{h}_{11} & \tilde{h}_{12} & \tilde{h}_{13} \\ \tilde{h}_{21} & \tilde{h}_{22} & \tilde{h}_{23} \\ \tilde{h}_{31} & \tilde{h}_{32} & \tilde{h}_{33} \end{bmatrix} \tag{8}$$

Next, we shall consider of the linearization of the gravity term. The elements in the first-row are:

$$\begin{aligned}\tilde{}_1 &= \Delta c_1\Big(m_1 l_{G1} + m_2(l_1 + \Delta c_2 l_{G2}) \\ &\quad + m_3(l_1 + \Delta c_2 l_2 + \Delta c_2\Delta c_3 l_{G3})\Big)\ {}_1 \\ &\quad \Delta c_1\Delta c_2\Big(m_2 l_{G2} + m_3(l_2 + \Delta c_3 l_{G3})\Big)\ {}_2 \\ &\quad \frac{1}{2}(\Delta c_1 + \Delta c_2)\Delta c_3 m_3 l_{G3}\ {}_3 \\ &= \Big[\ \tilde{}_{11}\ \ \tilde{}_{12}\ \ \tilde{}_{13}\Big]\boldsymbol{\theta} \qquad (9)\end{aligned}$$

where

$$\begin{aligned}\tilde{}_{11} &= \Delta c_1\big(m_1 l_{G1} + m_2(l_1 + \Delta c_2 l_{G2}) \\ &\quad + m_3(l_1 + \Delta c_2 l_2 + \Delta c_2\Delta c_3 l_{G3})\big) \\ \tilde{}_{12} &= \Delta c_1\Delta c_2\big(m_2 l_{G2} + m_3(l_2 + \Delta c_3 l_{G3})\big) \\ \tilde{}_{13} &= \frac{1}{2}(\Delta c_1 + \Delta c_2)\Delta c_3 m_3 l_{G3}\end{aligned}$$

The second-row elements are:

$$\begin{aligned}\tilde{}_2 &= \Delta c_1\Delta c_2\Big((m_2 l_{G2} + m_3 l_2) + \Delta c_3 m_3 l_{G3}\Big)\ {}_1 \\ &\quad \Delta c_1\Delta c_2\Big((m_2 l_{G2} + m_3 l_2) + \Delta c_3 m_3 l_{G3}\Big)\ {}_2 \\ &\quad \frac{1}{2}(\Delta c_1 + \Delta c_2)\Delta c_3 m_3 l_{G3}\ {}_3 \\ &= \Big[\ \tilde{}_{21}\ \ \tilde{}_{22}\ \ \tilde{}_{23}\Big]\boldsymbol{\theta} \qquad (10)\end{aligned}$$

where

$$\begin{aligned}\tilde{}_{21} &= \Delta c_1\Delta c_2\big(m_2 l_{G2} + m_3(l_2 + \Delta c_3 l_{G3})\big) \\ \tilde{}_{22} &= \Delta c_1\Delta c_2\big(m_2 l_{G2} + m_3(l_2 + \Delta c_3 l_{G3})\big) \\ \tilde{}_{23} &= \frac{1}{2}(\Delta c_1 + \Delta c_2)\Delta c_3 m_3 l_{G3}\end{aligned}$$

The third-row elements are:

$$\begin{aligned}\tilde{}_3 &= \Delta c_1\Delta c_2\Delta c_3 m_3 l_{G3}\ {}_1 \\ &\quad \Delta c_1\Delta c_2\Delta c_3 m_3 l_{G3}\ {}_2 \\ &\quad \frac{1}{2}(\Delta c_1 + \Delta c_2)\Delta c_3 m_3 l_{G3}\ {}_3 \\ &= \Big[\ \tilde{}_{31}\ \ \tilde{}_{32}\ \ \tilde{}_{33}\Big]\boldsymbol{\theta} \qquad (11)\end{aligned}$$

where

$$\begin{aligned}\tilde{}_{31} &= \Delta c_1\Delta c_2\Delta c_3 m_3 l_{G3} \\ \tilde{}_{32} &= \Delta c_1\Delta c_2\Delta c_3 m_3 l_{G3} = \tilde{}_{31} \\ \tilde{}_{33} &= \frac{1}{2}(\Delta c_1 + \Delta c_2)\Delta c_3 m_3 l_{G3} = \tilde{}_{13}\end{aligned}$$

From Eqs. (9), (10) and (11), the linearized gravity term is obtained as:

$$g\gamma(\boldsymbol{\theta}) \quad \tilde{\Gamma}\boldsymbol{\theta}(t),\ \ \tilde{\Gamma} = g\begin{bmatrix}\tilde{}_{11} & \tilde{}_{12} & \tilde{}_{13} \\ \tilde{}_{21} & \tilde{}_{22} & \tilde{}_{23} \\ \tilde{}_{31} & \tilde{}_{32} & \tilde{}_{33}\end{bmatrix}$$

2.2 Formulation of the uncertain system

Here we us assume that the derivative of the angle $\dot{}_i$ takes vary small value, the product term becomes $\dot{}_i\dot{}_j \to 0,\ (i = 1,2,3,\ j = 1,2,3)$. Thus, it can ignore the nonlinear term in Eq. (1). Let $\boldsymbol{\eta}(\boldsymbol{\theta},\dot{\boldsymbol{\theta}}) = \mathbf{0}$

$$H(\boldsymbol{\theta})\boldsymbol{\theta}(t) + D\dot{\boldsymbol{\theta}}(t) + g\boldsymbol{\gamma}(\boldsymbol{\theta}) = \qquad (12)$$

Let us substitute Eqs. (8), (12), then

$$\tilde{H}\boldsymbol{\theta}(t) + D\dot{\boldsymbol{\theta}}(t) + \tilde{\Gamma}\boldsymbol{\theta}(t) = \qquad (13)$$

By multiplying $\tilde{H}\ ^1$ from the left side to Eq.(13),

$$\boldsymbol{\theta}(t) = \ \tilde{H}\ ^1 D\dot{\boldsymbol{\theta}}(t)\ \ \ \tilde{H}\ ^1\tilde{\Gamma}\boldsymbol{\theta}(t) + \tilde{H}\ ^1 \qquad (14)$$

From the above equation, we can compose the augmented system as:

$$\begin{matrix}\dot{\boldsymbol{\theta}}(t) \\ \boldsymbol{\theta}(t)\end{matrix} = \begin{matrix}\mathrm{O} & \mathrm{I} \\ \tilde{H}\ ^1\tilde{\Gamma} & \tilde{H}\ ^1 D\end{matrix}\ \begin{matrix}\boldsymbol{\theta}(t) \\ \dot{\boldsymbol{\theta}}(t)\end{matrix} + \begin{matrix}\mathrm{O} \\ \tilde{H}\ ^1\end{matrix}$$

By the definition of the state vector $\boldsymbol{x}(t)$ and the input vector $\boldsymbol{u}(t)$ as:

$$\boldsymbol{x}(t) = \begin{matrix}\boldsymbol{\theta}(t) \\ \dot{\boldsymbol{\theta}}(t)\end{matrix} = \begin{bmatrix}{}_1(t) \\ {}_2(t) \\ {}_3(t) \\ \dot{}_1(t) \\ \dot{}_2(t) \\ \dot{}_3(t)\end{bmatrix},\ \boldsymbol{u}(t) = \begin{bmatrix}{}_1(t) \\ {}_2(t) \\ {}_3(t)\end{bmatrix}$$

We can obtain the uncertain LTI system.

$$\dot{\boldsymbol{x}}(t) = A(\boldsymbol{\xi})\boldsymbol{x}(t) + B(\boldsymbol{\zeta})\boldsymbol{u}(t)$$

where state matrix $A(\ )$ and intput matrix $B(\ )$ are:

$$A(\boldsymbol{\xi}) = \begin{matrix}\mathrm{O} & \mathrm{I} \\ \tilde{H}\ ^1\tilde{\Gamma} & \tilde{H}\ ^1 D\end{matrix},\ B(\boldsymbol{\zeta}) = \begin{matrix}\mathrm{O} \\ \tilde{H}\ ^1\end{matrix}$$

The uncertain system is express as $A(\boldsymbol{\xi})$ and $B(\boldsymbol{\zeta})$. This matrix is separates to a nominal elements A_0, B_0 and an uncertain elements $\Delta A, \Delta B$.

$$\begin{aligned}A(\boldsymbol{\xi}) &= A_0 + \Delta A \qquad (15) \\ B(\boldsymbol{\zeta}) &= B_0 + \Delta B \qquad (16)\end{aligned}$$

The structure of the nominal elements is express as A_0, B_0. The structure of the uncertain elements A_i and B_i is defined by uncertainty $\Delta\ \ _i$ where $i = 1,2,3$.

$$\Delta A = \sum_{i=1}^{3}\ {}_i A_i,\ |\ {}_i|\ \ 1 \qquad (17)$$

$$\Delta B = \sum_{j=1}^{3}\zeta_j B_j,\ |\zeta_j|\ \ 1 \qquad (18)$$

where $\ _i$ and ζ_j are scalar values which express a scale of uncertainty. A_i and B_j are matrices which expressed a structure of the uncertainty.

3 NUMERICAL RESULT

In this section, we show the numerical example that is modeling method of the state and input matrix with structured uncertainty in the state equation. Each parameters takes as in the table 2. The nominal system structure is obtained as follows:

Table 2. Parameters ($i = 1, 2, 3$)

Parameter	value	Parameter	value
m_i	1.00	l_{Gi}	0.15
I_i	0.30	g	9.80
Δc_i	0.03	d_i	0.03

$$A_0 = \begin{bmatrix} 0.00 & 0.00 & 0.00 & 1.00 & 0.00 & 0.00 \\ 0.00 & 0.00 & 0.00 & 0.00 & 1.00 & 0.00 \\ 0.00 & 0.00 & 0.00 & 0.00 & 0.00 & 1.00 \\ 74.34 & 81.94 & 14.42 & 0.64 & 1.10 & 0.16 \\ 104.35 & 164.46 & 24.81 & 1.10 & 2.05 & 0.44 \\ 10.77 & 29.62 & 11.35 & 0.16 & 0.44 & 0.51 \end{bmatrix}$$

$$B_0 = \begin{bmatrix} 0.00 & 0.00 & 0.00 & 21.26 & 36.57 & 5.50 \end{bmatrix}^{\mathrm{T}}$$

State matrix and input matrix of the structured uncertainty are:

$$A_1 = 10^{\ 7} \begin{bmatrix} 0.00 & 0.00 & 0.00 & 0.00 & 0.00 & 0.00 \\ 0.00 & 0.00 & 0.00 & 0.00 & 0.00 & 0.00 \\ 0.00 & 0.00 & 0.00 & 0.00 & 0.00 & 0.00 \\ 3.72 & 4.09 & 0.36 & 0.00 & 0.00 & 0.00 \\ 5.22 & 8.22 & 0.62 & 0.00 & 0.00 & 0.00 \\ 0.54 & 1.48 & 0.28 & 0.00 & 0.00 & 0.00 \end{bmatrix}$$

$$A_2 = 10^{\ 7} \begin{bmatrix} 0.00 & 0.00 & 0.00 & 0.00 & 0.00 & 0.00 \\ 0.00 & 0.00 & 0.00 & 0.00 & 0.00 & 0.00 \\ 0.00 & 0.00 & 0.00 & 0.00 & 0.00 & 0.00 \\ 9.1726 & 26.54 & 4.02 & 0.15 & 0.27 & 0.06 \\ 17.277 & 49.84 & 7.44 & 0.27 & 0.51 & 0.10 \\ 3.7671 & 9.30 & 1.02 & 0.05 & 0.10 & 0.02 \end{bmatrix}$$

$$A_3 = 10^{\ 7} \begin{bmatrix} 0.00 & 0.00 & 0.00 & 0.00 & 0.00 & 0.00 \\ 0.00 & 0.00 & 0.00 & 0.00 & 0.00 & 0.00 \\ 0.00 & 0.00 & 0.00 & 0.00 & 0.00 & 0.00 \\ 0.90 & 1.12 & 0.56 & 0.01 & 0.02 & 0.01 \\ 1.91 & 2.92 & 0.84 & 0.02 & 0.05 & 0.02 \\ 0.25 & 1.76 & 0.40 & 0.01 & 0.02 & 0.01 \end{bmatrix}$$

$$\begin{aligned} B_1 &= \mathbf{0}_{6\times 1} \\ B_2 &= 10^{\ 7} \begin{bmatrix} 0.00 & 0.00 & 0.00 & 4.86 & 9.13 & 1.78 \end{bmatrix}^{\mathrm{T}} \\ B_3 &= 10^{\ 7} \begin{bmatrix} 0.00 & 0.00 & 0.00 & 0.27 & 0.66 & 0.27 \end{bmatrix}^{\mathrm{T}} \end{aligned}$$

4 CONCLUSION

In this paper, we proposed the design method of uncertain system of three-link RRR manipulator with parameter variation in each joint angle. The relationship between an uncertainty and system structure is clarified in the structured uncertainty in the state matrix and input matrix of the state differential equation. The numerical example will be shown that the effectiveness of our method. Future study is to apply GCC to our method to design a robust controller.

Abstract: In this paper, we propose an obstacle avoidance strategy for the autonomous locomotion control of a snake robot with passive wheels. By using a general pass planning method for the head position control, it will be a complicated problem and the robot will have to take a circuitous path because any parts of the robot (from head to tail) must avoid contact with the obstacle. Our strategy is transformation of a periodic undulate gliding form for the robot to keep go straight without any collision with the obstacle. It is actualized by switching a control constraint imposed on the head of the robot. In this paper, we denote the detail of our strategy and investigate the effectiveness of our strategy by numerical simulations.

Keywords: snake-like robot, obstacle avoidance, control constraint

1 INTRODUCTION

As a control strategy of the n-link snake robot with passive wheel, Mita and Prautsch et al [1] proposed an autonomous locomotion control of the head's position based on Lyapnov function method. They also proposed another control strategy which restricts the motion of the snake robot to some kind of a serpenoid curve to minimize the energy needed for motion of the snake robot. The serpenoid curve has proposed by Hirose [2], he is a pioneer of the field of the snake robot, to describe the undulation of natural snakes. This is based on an assumption that natural snakes have developed an efficient way of creeping. As other approaches, Hoshi et al [3] proposed an autonomous control strategy with consideration of the dynamic manipulability. Sato et al [4] proposed a method that they removed passive wheels of some links, and introduce the shape controllable points in the snake robot's body.

Considering the autonomous locomotion control of the snake-like robot in real environment, obstacle avoidance is one of the important tasks. However, there are few reports about it. Therefore, in this paper, the obstacle avoidance is considered under following assumptions; a snake robot is going straight, this robot consists of some rigid links with passive wheels, there is one obstacle in the direction of forward movement of the robot, and the length of robot is long enough for the width and depth of the obstacle. For above assumption, a general path planning method for the head position control will be figured out immediately. However, the path must be designed to that any parts of the robot (from head to tail) avoid contact with the obstacle. Therefore, the path planning will be complicated problem and robot will have to take a circuitous path. Moreover, if the robot must go straight through the area where is narrow width, enclosed with walls (for example, pipe line or air duct) and assigned one obstacle, the robot might not be able to pass the area without any touch with the obstacle or walls.

For these problems, we propose a different approach of the obstacle avoidance. Note that the robot moves with periodic undulant gliding form. If the length of robot is long enough for the width and depth of the obstacle, and the amplitude and cycle length of the gliding form can be chosen appropriately when the snake robot closes the distance from the obstacle, the robot will be able to keep go straight without any collision with the obstacle. To control the snake locomotion with an arbitrary gliding form, we introduce zeroing method [1]. It constrains the motion of the snake robot to an arbitrary serpenoid curve. This constraint is imposed on the first link of the robot. The serpenoid curve can be calculated by numerical integration and the snake robot traces the curve exactly. Therefore, switching the control constraint, the gliding form is transformed and the snake robot traces the changed serpenoid curve. In this paper, we denote the detail of our strategy and investigate the effectiveness of our strategy by numerical simulations.

2 Dynamic model of the Snake Robot

In this research, we deal with the dynamical model of the snake-like robot consisting of n-links as shown in Figure 1. Length $2l$ and weight m are the same for each link and distribution of the weight is assumed to be uniform. Therefore, the COM (center of mass) of each link is placed at the middle of the link. (x, y) is the position of the head in $x-y$ coordinates on a ground. For each link, (x_i, y_i) and θ_i $(i=1,\ldots,n)$ represent the position of its COM and absolute angle measured clockwise from y axis. $p_i\,(i=1,\ldots,n-1)$ is the relative angle which is controlled by input torques $u \in R^{n-1}$.

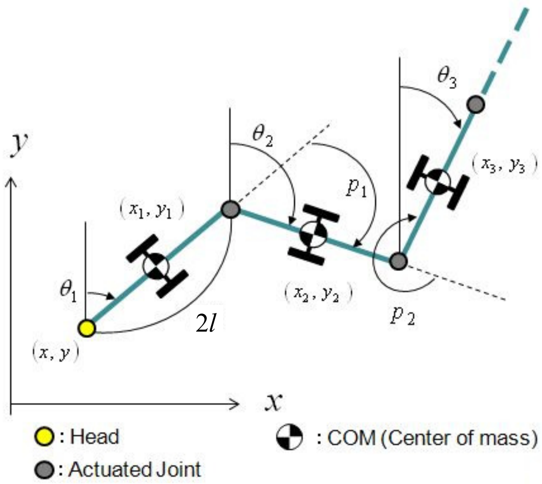

Fig. 1. n-link model of the snake robot

Each link has a passive wheel at the middle which does not slip in direction perpendicular to the body. From the condition, the equation of motion of the snake-like robot can be written as

$$\tilde{M}(\theta)\ddot{w} + \tilde{C}(\theta,\dot{\theta})\dot{w} + \tilde{D}(\theta)\dot{w} = F^T(\theta)Eu$$

$$w = \begin{bmatrix} x \\ y \end{bmatrix}, \theta = \begin{bmatrix} \theta_1 \\ \vdots \\ \theta_n \end{bmatrix} \qquad (1)$$

where $\tilde{M}$, $\tilde{C}$ and $\tilde{D}$ are matrices which are relevant to inertia, centrifugal force and friction, respectively. $E \in R^{n \times n-1}$ is a matrix satisfying $\theta = Ep$. F is a matrix which expresses the velocity constraint of each links is as $\dot{\theta} = F(\theta)\dot{w}$. In our research, we use another reduced order model using a different set of coordinate in order to control the robot motion with an arbitrary gliding form. Rewriting Eq.(1) with respect to the absolute angle of the 1st link θ_1 and the length of the trace of the 1st link η_1, the following system is obtained.

$$\bar{M}\begin{bmatrix} l\ddot{\theta}_1 \\ \ddot{\eta}_1 \end{bmatrix} + \bar{C}\begin{bmatrix} l\dot{\theta}_1 \\ \dot{\eta}_1 \end{bmatrix} + \bar{D}\begin{bmatrix} l\dot{\theta}_1 \\ \dot{\eta}_1 \end{bmatrix} = GF^T Eu \qquad (2)$$

Where, G is a transformation matrix, and $\bar{M}$, $\bar{C}$ and $\bar{D}$ are transformed matrices from $\tilde{M}$, $\tilde{C}$ and $\tilde{D}$ by the change of coordinate, respectively. The detail of the derivation of Eq. (1) or Eq (2) is introduced in [1].

3 Obstacle avoidance strategy

Here, let consider an obstacle avoidance problem for the snake robot modeled as Fig.1 under following assumptions; a snake robot is going straight, there is one obstacle in the direction of forward movement of the robot, and the length of robot is long enough for the width and depth of the obstacle. In the case, a general path planning method for the head position control will be figured out immediately. However, the path must be designed to that any parts of the robot (from head to tail) avoid contact with the obstacle as shown in Figure 2. Therefore, the path planning will be complicated problem and robot will have to take a circuitous path.

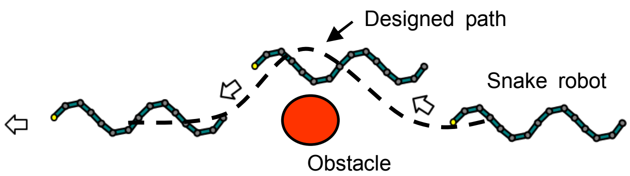

Fig. 2. Obstacle avoidance by the path planning

Moreover, as shown in Figure 3, the robot must go straight through the area where is narrow width, enclosed with walls (for example, pipe line or air duct) and assigned one obstacle, the robot might not be able to pass the area without any touch with the obstacle or walls.

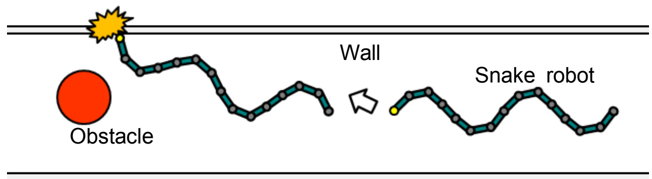

Fig. 3. Obstacle avoidance in the narrow width space

For these problems, if the robot can move with a periodic undulate gliding form, and the amplitude and cycle length of the gliding form can be chosen appropriately when the snake robot closes the distance from the obstacle, the robot will be able to keep go straight without any collision with the obstacle. Furthermore the robot will be able to pass the narrow width space without any touch with the obstacle or walls (See Figure 4).

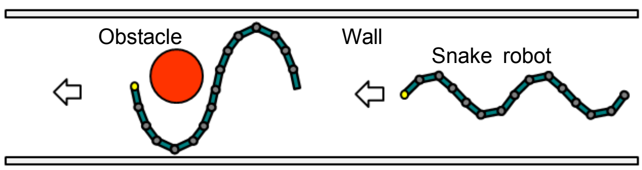

Fig. 4. Obstacle avoidance changing the gliding form

To control the snake locomotion with an arbitrary gliding form, we introduce zeroing method [1]. It constrains the motion of the snake robot to an arbitrary serpenoid curve.

3.1 Serpenoid Curve

The serpenoid curve has proposed by Hirose [2] to describe the undulation of natural snakes. An arbitrary curve can be described by its length η and the direction angle $\theta(\eta)$, as shown in Fig.5.

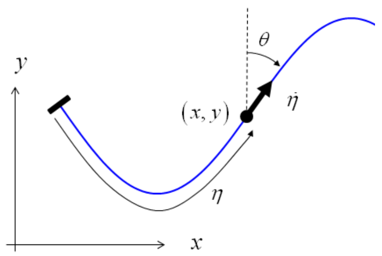

Fig. 5. Length and direction angle of a curve

Following Hirose[2], the serpenoid curve is defined as

$$\frac{dx}{d\eta} = \sin\left(w\sin(k\eta)\right), \frac{dy}{d\eta} = \cos\left(w\sin(k\eta)\right) \tag{3}$$

From this definition and relations $dx = \sin\theta d\eta$, $dy = \cos\theta d\eta$, it can be see that

$$\theta = w\sin\left(k\eta\right) = w\sin\left(\frac{\pi}{2L}\eta\right). \tag{4}$$

Therefore, the serpenoid function is a curve whose direction angle varies sinusoidally along the distance and shape of the curve depends on the w or k . Where, w is a maximum angle of gliding form and L is body length of 1/4 cycle of gliding form. The position of any point on the curve is obtained by integrating (3).

3.2 Restrict motion to the serpenoid curve

To restrict the motion of the robot to an arbitrary serpenoid curve, we use zeroing method [1]. For the control constraint to the serpenoid curve (4) and distance control with a reference distance along the curve γ expressed as

$$\begin{aligned} F_1 &= l\theta_1 - lw\sin(k\eta_1) = 0 \\ F_2 &= \eta_1 - \gamma = 0 \end{aligned} , \tag{5}$$

following differential equations are defined.

$$\begin{aligned} &\ddot{F}_1 + \alpha\dot{F}_1 + \beta F_1 = 0 \\ &\ddot{\eta}_1 + \vartheta\dot{\eta}_1 + \xi\left(\eta_1 - \gamma\right) = 0 \end{aligned} \tag{6}$$

where,

$$\begin{aligned} &\dot{F}_1 = l\dot{\theta}_1 - lwk\cos\left(k\eta_1\right)\dot{\eta}_1 \\ &\ddot{F}_2 = l\ddot{\theta}_1 - lwk\cos\left(k\eta_1\right)\ddot{\eta}_1 + lwk^2\sin\left(k\eta_1\right)\dot{\eta}_1^2 \end{aligned} \tag{7}$$

and $\alpha, \beta, \vartheta, \xi$ are positive coefficients. Define a nonsingular transformation matrix

$$P = \begin{bmatrix} 1 & -lwk\cos\left(k\eta_1\right) \\ 0 & 1 \end{bmatrix} \tag{8}$$

and multiply the vector $\begin{bmatrix} l\ddot{\theta}_1 \\ \ddot{\eta}_1 \end{bmatrix}$ by P from the left to get

$$P\begin{bmatrix} l\ddot{\theta}_1 \\ \ddot{\eta}_1 \end{bmatrix} = \begin{bmatrix} l\ddot{\theta}_1 - lwk\cos\left(k\eta_1\right)\ddot{\eta}_1 \\ \ddot{\eta}_1 \end{bmatrix} := K. \tag{9}$$

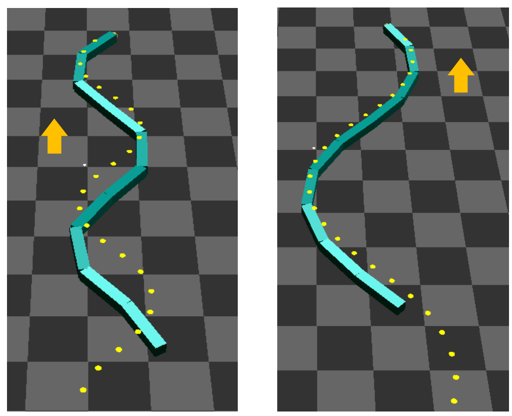
Substituting from (7) and (6) into (9) yields

$$\begin{bmatrix} l\ddot{\theta}_1 \\ \ddot{\eta}_1 \end{bmatrix} = P^{-1}\begin{bmatrix} -lwk^2\sin\left(k\eta_1\right)\dot{\eta}_1^2 - \alpha\dot{F}_1 - \beta F_1 \\ -\vartheta\dot{\eta}_1 - \xi\left(\eta_1 - \gamma\right) \end{bmatrix} \tag{10}$$

And then, substituting (10) into the system (2), the controller

$$\mathbf{u} = \left(GF^T E\right)^{\dagger}\left[\left(\bar{C} + \bar{D}\right)\begin{bmatrix} l\dot{\theta}_1 \\ \dot{\eta}_1 \end{bmatrix} + \bar{M}P^{-1}K\right] \tag{11}$$

are obtained. This ensure that $F_1 \to 0, F_2 \to 0$.



(a) $4L = 5.0[m]$ (b) $4L = 10.0[m]$

Fig. 6. Simulation of motion of a 10 link snake robot

Figure 6 shows two motions of the snake robot. These simulations are applied the controller (11) to the system (2). The robot has 10 links and each length is 1.0[m], yellow dot-lines denote the serpenoid trace, and the robot go straight to the upper direction. In the left figure (a), parameter w is set $\pi/4$ [rad] and $4L = 5.0[m]$ (It means that the robot moves with two cycle undulate motion). As a result, the robot shows a periodic undulate gliding form. However, the gap between the Serpenoid curve and link position is increased as the distance from the head. On the other hand, in the right figure (b), parameter w is set $\pi/4$ [rad] and $4L = 10.0[m]$. In this case, the gap is very small compared to (a). We simulated various patterns changing w, $4L$, the link length or the number of links. As a result, we confirmed that the number of links is larger or the cycle length of the serpenoid curve is longer, the gap tends to be decreased. Therefore, this control method is useful for the obstacle avoidance if the length of robot is long enough and has appropriate amount of links for the width and depth of the obstacle.

3.3 Switching control constraint

For the snake locomotion, there is an energy-efficient gliding form. Therefore, it is reasonable that under normal conditions, the robot moves with the energy-efficient gliding form, and when the robot confronts the obstacle, the gliding form is transformed to avoid collision with the obstacle. The transformation of the gliding form is actualized by switching the control constraint. Namely, change the values of w or k. However, at the switching point, the angle of the changed serpenoid curve must be coincided with the angle of the former serpenoid curve. If it is omitted, the trace of the 1st link strays far from the serpenoid trace after the switching point as shown in Fig.7.

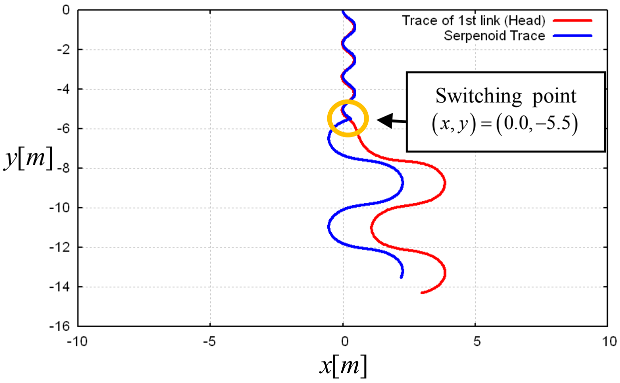


Fig. 7. Simulation result of switching control constraint

Moreover, about the connection of serpenoid functions, two cases are considered as shown in Fig.8. In Case1, the curve is non-smooth and it cause rapid variations of input torques. Therefore, Case2 should be chosen. To achieve the connection as Case2, the serpenoid function after the switching is designed as follows.

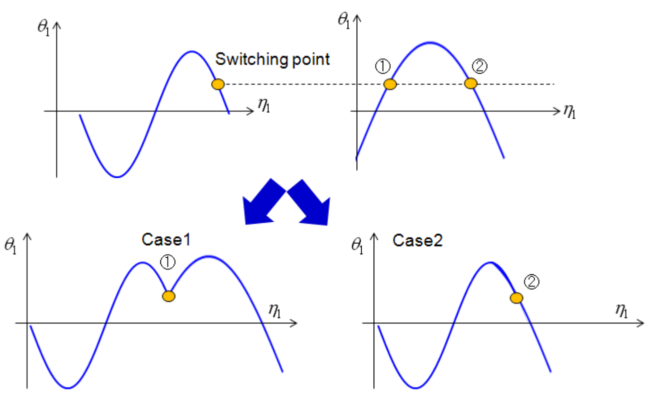

Fig. 8. Connection of the serpenoid function

$$\theta_1(\eta_1)=\begin{cases} w_\beta \sin\left(k_\beta \eta_1+\phi\right) & \dot{\theta}_1(\eta_{sw})\ge 0 \\ w_\beta \sin\left(k_\beta \eta_1+\pi-\phi\right) & \dot{\theta}_1(\eta_{sw})<0 \end{cases}, \qquad (12)$$
$$\phi = k_\beta \eta_{sw}+\sin^{-1}\left(\frac{\theta_1(\eta_{sw})}{w_\beta}\right)$$

where $w_\beta, k_\beta, L_\beta$ are parameters of the serpenoid function after the switching and η_{sw} is a constant of the length of the trace of the 1st link at the switching point. In Fig.9, it is shown that the trace of the1st link is well coincided with the serpenoid trace after the switching point.

From the result, it is known that designing a serpenoid curve to avoid an obstacle with the proposed technique, the snake robot achieve the obstacle avoidance because the robot can trace the designed trace exactly.

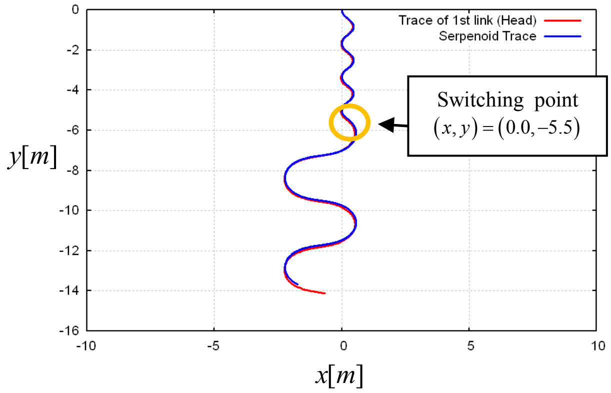

Fig. 9. Simulation result (using serpenoid function (12))

4 CONCLUSION

In this paper, we detailed the obstacle avoidance strategy for the snake robot. By the results of the numerical simulations, we were convinced that the design of the serpenoid curve with the switching control constraint is effective to the obstacle avoidance of the snake robot.

In our future works, we will construct an algorism which designs a serpenoid trace to avoid an obstacle automatically.

Abstract: Robust controllers have feature of corresponding to the model error and the disturbance. However, obtained controller is generally high-order. The controller order is desirable in small from a standpoint of cost and reliability. The purpose of our work is to propose of effective controller order reduction method. In this paper, we propose a controller order reduction method using alternative Gramian. We were applied this method to conventional methods. Further, we confirmed effect using the numerical example. As a result, our proposed method found some efficacy in stability and performance degradation of a closed loop system. However, when applied to other controlled objects, these was relatively-ineffective. Therefore, this method admit of improvement. As one of these improvements, we are thinking that to use Genetic Algorithm (GA) for optimal solution derivation of the riccati inequality.

Keywords: controller order reduction, gramian, H_∞ controller

1 INTRODUCTION

Traditional modern control theory had a gap by between theory and reality, because it was not considering the model error. For resolve this problem, the robust control theory was corresponding to the model error and disturbance. However, the robust controller such as H_∞ controller is generally high-order. Generally, the controller order is desirable in small from a standpoint of cost and reliability. Therefore, it is necessary obtaining low-order controller that could be suppress to performance degradation. In this paper, we focus attention on the balanced realization truncation method.

The balanced realization truncation method is one of the controller reduction. In addition, the blocked balanced realization truncation method is also one of the controller reduction method, this method is considering the characteristics of the closed-loop system input-output. In these methods, we obtain controllability Gramian and observability Gramian from Lyapunov equations. When the Gramian replaced by a solution of stringent condition, we think that could effective coordinate transformation. We replaced the Gramian by the solution of stringent condition, it will be referred to as "Alternative Gramian".

In this paper, we propose a controller order reduction method using Alternative Gramian. Alternative Gramians were used a solution of three kinds, Lyapunov inequations, Riccati equations and Riccati inequations. Moreover, controller order reduction methods were applied to the balanced realization truncation method and the block balanced realization truncation method. We confirmed the effectiveness of the proposed method by numerical examples.

2 METHOD

2.1 Controllability and Observability Gramian

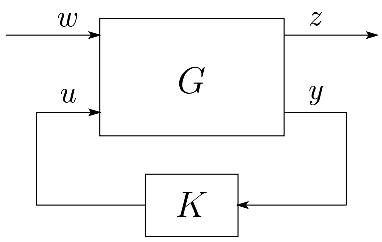

Fig. 1. The closed-loop system

Consider the closed-loop system shown in Fig.1. In the figure, w has shown the external input, z has shown the controlled output, u has shown the control input, and y has shown the measured input. Let, system G is the generalized plant, and K is the controller. G and K are represented as following.

$$G = \left[\begin{array}{c|c} A & B \\ \hline C & D \end{array}\right] = C(sI - A)^{-1}B + D \tag{1}$$

$$K = \left[\begin{array}{c|c} A_k & B_k \\ \hline C_k & D_k \end{array}\right] \tag{2}$$

where, the matrix A_k assumed to be stable. Solution Q of the following Lyapunov equation is called the "observability Gramian".

$$A_k^T Q + Q A_k + C_k^T C_k = 0 \tag{3}$$

In the same way, solution P of the following Lyapunov equation is called the "controllability Gramian".

$$A_kP + PA_k^T + B_kB_k^T = 0 \tag{4}$$

The eigenvalues size of the controllability Gramian and observability Gramian shows ease of the control and observation for corresponding states. However, the Gramian of alone cannot accurately assess effect of input-output relation. In order to solve this problem, we introduce a special realization of the controllability Gramian and observability Gramian.

2.2 Balanced realization truncation method

When controller K, controllability Gramian P and observability Gramian Q are shown in equation (2)-(4), we assume $P \geq 0$ and $Q \geq 0$. Here, we convert to $\hat{y} = Ty$ using the nonsingular matrix T. At this time, K is

$$K = \left[\begin{array}{c|c} \hat{A}_k & \hat{B}_k \\ \hline \hat{C}_k & \hat{D}_k \end{array}\right] = \left[\begin{array}{c|c} TA_kT^{-1} & TB_k \\ \hline C_kT^{-1} & D_k \end{array}\right] \tag{5}$$

Furthermore, Gramians will change as follows:

$$\hat{P} = TPT^T \tag{6}$$

$$\hat{Q} = (T^{-1})^T QT^{-1} \tag{7}$$

In particular, when these are the minimal realization, can be the following:

$$TPT^T = (T^{-1})^T QT^{-1} = \Sigma \tag{8}$$

$$\Sigma = \mathrm{diag}(\sigma_1, \sigma_2, \dots, \sigma_n) \tag{9}$$

This is called a balanced realization. And, $\sigma_1 \geq \sigma_2 \geq \cdots \geq \sigma_n \geq 0$ are called Hankel singular values. Corresponding state to the zero eigenvalue of P and Q can eliminate from the transfer function matrix. When the new realization of K is split as follows

$$K = \left[\begin{array}{c|c} TA_kT^{-1} & TB_k \\ \hline C_kT^{-1} & D_k \end{array}\right] = \left[\begin{array}{ccc|c} A_{11} & \cdots & A_{1j} & B_1 \\ \vdots & & \vdots & \vdots \\ A_{i1} & \cdots & A_{ij} & B_i \\ \hline C_1 & \cdots & C_j & D \end{array}\right] \tag{10}$$

We obtain the low-order system K_r by truncation of low-impact parts from the high-order system K. The obtained low-order system K_r is following.

$$K_r = \left[\begin{array}{c|c} A_{11} & B_1 \\ \hline C_1 & D \end{array}\right] \tag{11}$$

This method called the balanced realization truncation method. This is one of the famous model reduction method. The controller order reduction methods had been proposed various methods such as proposed of the frequency weight based on the balanced realization method. When using the balanced realization method to the controller order reduction, it is considering the input-output characteristics. However, it was not consider stability of the closed-loop system. Wherein, the blocked balanced realization was proposed for considering the input-output characteristics of the closed-loop system. The blocked balanced realization has been considered by the input-output characteristics of the closed-loop system by to think about overall the closed-loop system.

2.3 Proposed Method 1

As previously explained, controllability and observability Gramian are solution of Lyapunov equations (2) and (3). The balanced realization using these gramians have been considered for the mutual similarity with the original system. However, it has not considered for the performance degradation of low-order system. In addition, the traditional balanced realization was not consider stability of the closed-loop system. Here, in order to consider the H_∞ characteristics, we propose to use Riccati equations as alternative of controllability and observability Gramian. For example, when this method is applied by the block balanced realization, used Riccati equations are as following.

$$\begin{aligned}(A + BR^{-1}D^TC)^TQ + Q(A + BR^{-1}D^TC) \\ + QBR^{-1}B^TQ + C^T(I + DR^{-1}D^T)C = 0\end{aligned} \tag{12}$$

$$\begin{aligned}(A + BR^{-1}D^TC)P + P(A + BR^{-1}D^TC)^T \\ + PC^TR^{-1}CP + B(I + D^TR^{-1}D)B^T = 0\end{aligned} \tag{13}$$

Where, R is

$$R = \gamma^2 I - D^TD$$

or

$$R = \gamma^2 I - DD^T$$

To exist solutions of equation (12) ,(13) and to be less than γ to the H_∞ norm of the system are equivalent. Therefore, when the block balanced realization is applied by these solution,the H_∞ norm of the closed-loop system will can be expected to less than γ.

2.4 Proposed Method 2

Secondly, to further reduce the performance degradation, we propose to use solution of the Lyapunov inequality on alternative of gramian. For example, when this method is applied by the block balanced realization, used Lyapunov inequality are as following.

$$AP + PA^T + BB^T \leq 0 \tag{14}$$

$$A^TQ + QA + C^TC \leq 0 \tag{15}$$

Lyapunov equation has a unique solution exists, but there is no unique solution in the Lyapunov inequality. We give the guidepost for minimization of solution. When make the Trace(P) and Trace(Q) smaller, it is expected that truncation part of the Hankel singular values can be smaller. Therefore, when we find P and Q to minimize Trace(P) and Trace(Q) , the closed-loop system performance degradation will can reduce.

2.5 Proposed Method 3

Section 2.3 proposed that we use solution of the Riccati equation as alternative for the controllability and observability Gramian for to consider of the H_∞ characteristic. Moreover, Section 2.4 proposed also that we use solution of the Lyapunov inequality for to reduce the performance degradation of the closed-loop system used the low-order controller. In this section, we propose that we use solution of Riccati inequality for to reduce the performance degradation and to consider of the H_∞ characteristic. For example, when this method is applied by the block balanced realization, used Riccati inequality are as following.

$$\begin{bmatrix} AP+PA^T & PC^T & B \\ CP & -\gamma I & D \\ B^T & D^T & -\gamma I \end{bmatrix} < 0 \qquad (16)$$

$$\begin{bmatrix} A^TQ+QA & QB & C^T \\ B^TQ & -\gamma I & D^T \\ C & D & -\gamma I \end{bmatrix} < 0 \qquad (17)$$

To exist solutions of equation (16) ,(17) and to be less than γ to the H_∞ norm of the system are equivalent. Therefore, when this solutions are applied to the block balanced realization, the H_∞ norm of the closed-loop system will can be expected to less than γ. Also, the closed-loop system performance degradation will can reduce.

3 RESULT

As a numerical example, we treat the four-disk controller system. The state-space realization of generalized plant is at the left. In this paper, we design the H_∞ controller set at design specification γ=1.2. The obtained controller is the 8th-order, and this controller meets the specifications as follows:

$$\begin{aligned}\|F_l(G,K)\|_\infty &= \|G_{11}+G_{12}K(I-G_{22}K)^{-1}G_{21}\|_\infty \\ &= 1.1963 < 1.2\end{aligned}$$

We reduce order of this controller from 7th-order to 1st-order. We showing in Table 1-3 the H_∞ norm of the closed-loop system that is including by reduced-order controller. Where, in Table 1-3, "BT" has shown the balanced realization truncation method, "WBT" has shown the balanced realization truncation method with frequency weight($W = G(I+KG)^{-1}$), "BBT" has shown the block balanced realization truncation method. Moreover, "no mark" has shown a method using Lyapunov equations (conventionally method), "Ric(eq)" has shown a method using Riccati equations (Proposed method 1), "Lyap (ineq)" has shown a method using Lyapunov inequalities(Proposed method 2), "Ric(ineq)" has shown a method using Riccati inequalities(Proposed method 3). "U" has shown unstable system.

From the Table 1, the method using Lyapunov inequality can be the most reduced order. However, the H_∞ norm of 2nd order by Lyapunov inequality is over 20, system performance degradation can not reduced in this method. In addition, when it used the balanced realization truncation method by alternative gramian that is solution of Riccati equations or Ricacati inequality, those are almost no variation by original balanced realization. Therefore, an alternative gramian unfitted for the balanced realization truncation method.

Next, from the Tabale 2, the method using Riccati inequality can be the most reduced order. Especially, when it was used Riccati inequality in 6th order, the H_∞ norm of the closed-loop system including the low-order controller is under γ. From this, we find that performance degradation is suppressed.

Finally, from the Table 3, the method using Riccati inequality can be the most reduced order. When the controller order is 7th, 6th and 4th, the H_∞ norm is under γ. In addition, In the 2nd order, closed-loop is stable, and performance degradation is most small. Therefore, we found significant effect by applying the solution of Riccati inequality to the block balanced realization from these results.

4 CONCLUSION

In this paper, we have proposed the controller order reduction method which used solution of the Riccati inequality etc. as substitute for the controllability grammian and the observability grammian. Moreover, this paper applied a proposed method to the block balanced realization etc, and looked at an effect of a proposed method by numerical examples. As a result, We were found that our proposed method obtained some efficacy in stability and performance degradation of a closed loop system. However, when applied to other controlled objects, these was relatively-ineffective. Therefore, this method admit of improvement. As one of these improvements, we are thinking that to use Genetic Algorithm (GA) for optimal solution derivation of the Riccati inequality.

Abstract: In this paper we investigate higher order systems of linear difference equations where the associated characteristic matrix polynomial is self-inversive. We consider classes of equations with bounded solutions. It is known that stability properties of higher order systems of linear difference equations are determined by the characteristic values of the corresponding matrix polynomials. All solutions are bounded (in both time directions) if the spectrum of the corresponding matrix polynomial lies on the unit circle, and moreover if the characteristic values of modulus one are semisimple. If the corresponding matrix polynomial is self-inversive then one can use the inner radius of the numerical range to obtain a criterion for boundedness of solutions. We show that all solutions are bounded if the inner radius is greater than 1. In the case of matrix polynomials with positve definite coefficient matrices we derive a computable lower bound for the inner radius.

Keywords: linear difference equations, matrix polynomials, bounded solutions, self-inversive, inner radius, numerical range

1 INTRODUCTION

In this paper we investigate higher order systems of linear difference equations where the associated characteristic matrix polynomial is self-inversive. We consider classes of equations with bounded solutions.

Self-inversive polynomials and matrix polynomials have been studied in the literature under various names including reciprocal, self-reciprocal, palindromic and conjugate-symmetric (see [1], [3], [8], [12]). There are applications in numerous areas of engineering, for example, optimal design of problems governed by hyperbolic field equations [12], the study of line spectral pairs in speech coding [11], and kernel representations of time-reversible systems [9]. Moreover, such polynomials are used in applied mathematics to deal with stability of periodic orbits of autonomous Hamiltonian systems [10], and to investigate Lie algebras for semisimple hypersurface singularities [7].

Only recently self-inversive matrix polynomials and corresponding linear differential and difference equations appeared in the solution of discrete time linear quadratic optimal control problems [2], in the study of discretization schemes for cubic Schrödinger equations [4] and in vibration analysis of railway tracks for high-speed trains [5].

It is known that stability properties of higher order systems of linear difference equations are determined by the characteristic values of the corresponding matrix polynomials.

All solutions are bounded (in both time directions) if the spectrum of the corresponding matrix polynomial lies on the unit circle, and moreover if the characteristic values of modulus one are semisimple (that is the corresponding elementary divisors are linear). If the corresponding matrix polynomial is self-inversive then one can use the inner radius of the numerical range to obtain a criterion for boundedness of solutions. We show that all solutions are bounded if the inner radius is greater than 1. In the case of matrix polynomials with positve definite coefficient matrices we derive a computable lower bound for the inner radius. We illustrate our results by examples.

2 PRELIMINARIES

Let γ be complex number with $|\gamma| = 1$ and $F_0, F_1, \ldots, F_m$ complex hermitian $n \times n$ matrices satisfying

$$F_j^* = \gamma F_{m-j},\ j = 0, 1, \ldots, m, \qquad \det F_0 \neq 0,\ \det F_m \neq 0. \quad (1)$$

Consider the following higher order systems of linear difference equation:

$$F_m x(t+m) + F_{m-1} x(t+m-1) + \cdots + F_0 x(t) = 0, \quad (2)$$

where $\{x(t)\}_{t=-\infty}^{\infty}$ is a sequence of vectors in $\mathbb{C}^n$ to be determined. The associated characteristic matrix polynomial is as follows:

$$F(z) = F_0 + F_1 z + \cdots + F_m z^m \in \mathbb{C}^{n \times n}[z]. \quad (3)$$

The conjugate-reverse matrix polynomial of $F(z)$ in (3) is defined by

$$\hat{F}(z) = F_m^* + \cdots + F_1^* z^{m-1} + F_0^* z^m.$$

Then it follows form (1) that $F(z) = \gamma \hat{F}(z)$ and thus $F(z)$ is γ-self-inversive.

We use the following notation. If $P(z) \in \mathbb{C}^{n\times n}[z]$ then the set of characteristic values of $P(z)$ is denoted by $\sigma(P) = \{\lambda \in \mathbb{C}; \det P(z) = 0\}$. A characteristic value λ of $P(z)$ is said to be normal if for any $v \in \mathbb{C}^n$,

$$P(\lambda)v = 0 \Longleftrightarrow v^* P(\lambda) = 0.$$

A characteristic value λ of $P(z)$ is said to be semisimple if the corresponding elementary divisors are linear.

Let $W(P) = \{\lambda \in \mathbb{C}; v^* P(\lambda)v = 0 \text{ for some } v \in \mathbb{C}^n, v \neq 0\}$ be the numerical range of $P(z)$. It is obvious that $\sigma(P) \subset W(P)$. We call $r_i(P) = \min\{|\lambda|; \lambda \in W(P)\}$ the inner radius of $P(z)$. If H is hermitian then $\lambda_{\min}(H)$ and $\lambda_{\max}(H)$ shall denote the smallest and the largest eigenvalue of H, respectively. Let $\|H\|$ be the spectral norm of H. Then $\|H\| = \max\{|\lambda_{\min}(H)|, |\lambda_{\max}(H)|\}$ and

$$\|H\| \geq -|\lambda_{\min}(H)|.$$

3 BOUNDEDNESS

In this section we deal with the boundedness for the difference equation (2). The equation (2) is said to be bounded if any solution $x(t)$ of (2) with initial conditions $x(0) = x_0, x(1) = x_1, \ldots, x(m-1) = x_{m-1}$ is bounded for $t \to \infty$ and $t \to -\infty$.

In the rest of this paper we assume that the associated characteristic matrix polynomial $F(z)$ to (2) has the form

$$F(z) = P(z) + \gamma z^r \hat{P}(z) \tag{4}$$

for some $r \geq 0$ and some $P(z) = \sum_{j=0}^{k} A_j z^j \in \mathbb{C}^{n\times n}[z]$. Then $F(z)$ is γ-self-inversive. Note that for any $P(z) = \sum_{j=0}^{k} A_j z^j \in \mathbb{C}^{n\times n}[z]$ and any $r \in \mathbb{Z}, r \geq 0$, $P(z) + \gamma z^r \hat{P}(z)$ is γ-self-inversive.

We have the following fact (see [6]).

Proposition 1. *Let $F(z)$ be a self-inversive matrix polynomial of the form* (4) *and suppose $r_i(P) > 1$. Then the characteristic values of $F(z)$ lie on the unit circle, and they are normal and semisimple.*

An immediate consequence of the preceding proposition is the following.

Theorem 2. *Let $F(z)$ be a self-inversive matrix polynomial of the form* (4) *and suppose $r_i(P) > 1$. Then, the difference equation* (2) *is bounded.*

The following theorem provides a computable lower bound for the inner radius.

Theorem 3. *Let the coefficients A_j, $j = 0, \ldots, k$, of $P(z) = \sum_{j=0}^{k} A_j z^j$ be hermitian and positive definite. Set*

$$\mu(P) = \min\left\{\lambda_{\min}(A_j A_{j+1}^{-1});\ j = 0, \ldots, k-1\right\}.$$

Then $r_i(P) \geq \mu(P)$.

Corollary 4. *If $A_0 > A_1 > \cdots > A_k > 0$ then $\mu(P) > 1$.*

4 ROBUST BOUNDEDNESS

The difference equation (2) is said to be robustly bounded if there exists $\varepsilon > 0$ such that for any hermitian matrices $\tilde{F}_0, \tilde{F}_1, \ldots, \tilde{F}_m$ satisfying

$$\|\tilde{F}_j - F_j\| < \varepsilon,\ F_j^* = \gamma F_{m-j},\ j = 0, 1, \ldots, m,$$

and for any initial conditions $x(0) = x_0, x(1) = x_1, \ldots, x(m-1) = x_{m-1} \in \mathbb{C}^n$, the solution of the difference equation

$$\tilde{F}_m x(t+m) + \tilde{F}_{m-1} x(t+m-1) + \cdots + \tilde{F}_0 x(t) = 0$$

is bounded for $t \to \infty$ and $t \to -\infty$.

First, we consider the following difference equation in the case of $n = 1$:

$$\begin{aligned} a_0 x(t+m) &+ a_1 x(t+m-1) + \cdots \\ &+ a_k x(t+m-k) + a_k x(t+k) + \cdots \\ &+ a_1 x(t+1) + a_0 x(t) = 0,\ m > 2k, \end{aligned} \tag{5}$$

where $a_0, a_1, \ldots, a_k \in \mathbb{R}$ $(a_0 \neq 0)$ are given and $\{x(t)\}_{t=0}^{\infty}$ is a sequence in $\mathbb{R}$ to be determined.

Assume $a_0 > a_1 > \cdots > a_k > 0$. Set

$$\varepsilon = \min\{a_i - a_{i+1} \mid 0 \leq i \leq k-1\}. \tag{6}$$

Suppose that $\tilde{a}_0, \tilde{a}_1, \ldots, \tilde{a}_k \in \mathbb{R}$ satisfy

$$|\tilde{a}_i - a_i| < \frac{1}{2}\varepsilon,\ i = 0, 1, \ldots, k, \tag{7}$$

and consider the difference equation

$$\begin{aligned} \tilde{a}_0 x(t+m) &+ \tilde{a}_1 x(t+m-1) + \cdots + \\ &\tilde{a}_k x(t+m-k) + \tilde{a}_k x(t+k) + \cdots + \\ &\tilde{a}_1 x(t+1) + \tilde{a}_0 x(t) = 0 \end{aligned} \tag{8}$$

and the associated characteristic matrix polynomial

$$\begin{aligned} f(z) = \tilde{a}_0 &+ \tilde{a}_1 z + \cdots + \tilde{a}_k z^k + \\ &\tilde{a}_k z^{m-k} + \cdots + \tilde{a}_1 z^{m-1} + \tilde{a}_0 z^m. \end{aligned} \tag{9}$$

The condition (7) implies $\tilde{a}_0 > \tilde{a}_1 > \cdots > \tilde{a}_k$. Thus by Theorem 3.2 in [6] all zeros of f in (9) lie on the unit circle and simple, and hence for any initial conditions $x(0) = x_0, x(1) = x_1, \ldots, x(m-1) = x_{m-1} \in \mathbb{R}$ the solution of the equation (8) is bounded. Therefore the equation (5) is robustly bounded.

Next, we consider the equation (2) with $n \times n$ matrices. Suppose the matrices $M_i = A_{i-1} - A_i$, $i = 1, 2, \ldots, k$, are positive definite. Set $\mu_i = \lambda_{\min}(M_i)$, $i = 1, 2, \ldots, k$ and define $\mu = \min\{\mu_i; i = 1, 2, \ldots, k\}$. Then $M_i \geq \mu I > 0$, $i = 1, 2, \ldots, k$.

Lemma 5. *Suppose $A_0 > A_1 > \cdots > A_k > 0$. Let $\tilde{A}_0, \tilde{A}_1, \ldots, \tilde{A}_k$ be hermitian $n \times n$ matrices satisfying*

$$\|\tilde{A}_i - A_i\| < \frac{\mu}{2},\ i = 0, 1, \ldots, k.$$

Set $\tilde{A}_{k+1} = 0$. Then

$$\tilde{A}_{i-1} > \tilde{A}_i,\ i = 0, 1, \ldots, k+1.$$

Proof. Set $\Delta_i = \tilde{A}_i - A_i$. Then

$$\begin{aligned}\tilde{A}_{i-1} - \tilde{A}_i &= (A_{i-1} - A_i) + (\Delta_{i-1} - \Delta_i)\\ &\geq \mu I + (\Delta_{i-1} - \Delta_i).\end{aligned}$$

We have

$$(\Delta_{i-1} - \Delta_i) \geq \lambda_{\min}(\Delta_{i-1} - \Delta_i) I \geq -\|\Delta_{i-1} - \Delta_i\| I.$$

Moreover,

$$\|\Delta_{i-1} - \Delta_i\| \leq \|\Delta_{i-1}\| + \|\Delta_i\| < \mu.$$

Hence

$$(\Delta_{i-1} - \Delta_i) > \mu I,$$

and we obtain $\tilde{A}_{i-1} - \tilde{A}_i > 0$. □

Using the preceding lemma and Proposition 2 we obtain the following result.

Theorem 6. *Let $F(z)$ be a self-inversive matrix polynomial of the form* (4) *and suppose that $A_0, A_1, \ldots, A_k$ are hermitian with*

$$A_0 > A_1 > \cdots > A_k > 0. \quad (10)$$

Then the difference equation (2) *is robustly bounded.*

5 EXAMPLE

Example 1. Consider the following difference equation with $n = 2$:

$$\begin{aligned}&\begin{pmatrix} 2 & i \\ -i & 3 \end{pmatrix} x(t+3) + \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix} x(t+2)\\ &\quad + \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix} x(t+1) + \begin{pmatrix} 2 & i \\ -i & 3 \end{pmatrix} x(t) = 0 \quad (11)\end{aligned}$$

The associated characteristic matrix polynomial $F(z)$ is as follows:

$$\begin{aligned}F(z) = &\begin{pmatrix} 2 & i \\ -i & 3 \end{pmatrix} + \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix} z\\ &+ \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix} z^2 + \begin{pmatrix} 2 & i \\ -i & 3 \end{pmatrix} z^3 \quad (12)\end{aligned}$$

Setting

$$P(z) = \begin{pmatrix} 2 & i \\ -i & 3 \end{pmatrix} + \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix} z,$$

$F(z)$ has the form (4) with $\gamma = 1$ and $r = 2$. Thus $F(z)$ is self-inversive. It is easy to see that the coefficients of $F(z)$ are hermitian matrices satisfying

$$\begin{pmatrix} 2 & i \\ -i & 3 \end{pmatrix} > \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix} > 0.$$

Therefore, it follows from Theorem 6 that the equation (11) is robustly bounded.

We obtain that the spectrum of $F(z)$ lies on the unit circle and all characteristic values of $F(z)$ are normal and semisimple. In fact, one has

$$\begin{aligned}\det F(z) = (z+1)^2 &\left(z^2 - \left(\frac{1}{2} - \frac{\sqrt{5}}{10}\right) z + 1\right)\\ &\left(z^2 - \left(\frac{1}{2} + \frac{\sqrt{5}}{10}\right) z + 1\right)\end{aligned}$$

and all zeros of $\det F(z)$ lie on the unit circle (see Fig.1).

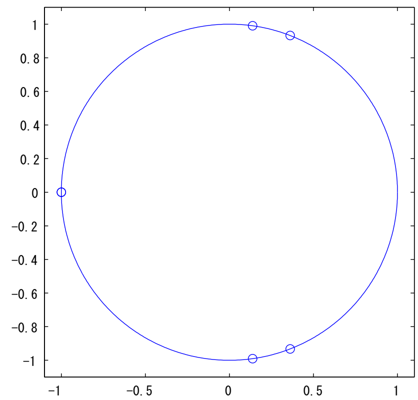

Fig. 1. Characteristic values of (12)

Computing the Smith form $S(z)$ of $F(z)$, we obtain

$$S(z) = \begin{pmatrix} z+1 & 0 \\ 0 & (z+1)p(z) \end{pmatrix}$$

where

$$\begin{aligned}p(z) = &\left(z^2 - \left(\frac{1}{2} - \frac{\sqrt{5}}{10}\right) z + 1\right)\\ &\left(z^2 - \left(\frac{1}{2} + \frac{\sqrt{5}}{10}\right) z + 1\right).\end{aligned}$$

Hence, it can be seen that all characteristic values of $F(z)$ are normal and semisimple.

Example 2. Consider the following diffrence equation with $n = 3$:

$$\begin{aligned}&A_0 x(t+3) + A_1 x(t+2)\\ &\quad + A_1 x(t+1) + A_0 x(t) = 0 \quad (13)\end{aligned}$$

where

$$A_0 = \begin{pmatrix} 2 & i & -i \\ -i & 3 & 0 \\ i & 0 & 3 \end{pmatrix}, \ A_1 = \begin{pmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{pmatrix}.$$

The associated characteristic matrix polynomial $F(z)$ is given by

$$F(z) = P(z) + z^2 \hat{P}(z), \ P(z) = A_0 + A_1 z. \qquad (14)$$

Then, it is easy to see that A_0 and A_1 are positive definite hermitian matrices. Moreover, one has $A_0 \not> A_1$, but $A_0 \geq A_1$ because of $\det(zI - (A_0 - A_1)) = z(z-2)(z-3)$.

We compute the inner radius $r_i(P)$. To do so, set $v \in \mathbb{C}, v \neq 0$. Then,

$$v^* P(\lambda) v = \begin{pmatrix} \bar{a} & \bar{b} & \bar{c} \end{pmatrix} P(\lambda) \begin{pmatrix} a \\ b \\ c \end{pmatrix} = \lambda |v|^2 + v^* A_0 v.$$

Thus $r_i(P) = 1$ because of $\det(zI - A_0) = (z-1)(z-3)(z-4)$.

We obtain

$$\begin{aligned} \det F(z) &= 12 + 19z + 27z^2 + 53z^3 + 49z^4 \\ &\qquad + 49z^5 + 53z^6 + 27z^7 + 19z^8 + 12z^9 \\ &= (z+1)^3 (z^2+1) \\ &\qquad (3z^2 - 2z + 3)(4z^2 - 3z + 4) \end{aligned}$$

and thus it can be seen that all zeros of $\det F(z)$ lie on the unit circle (see Fig.2).

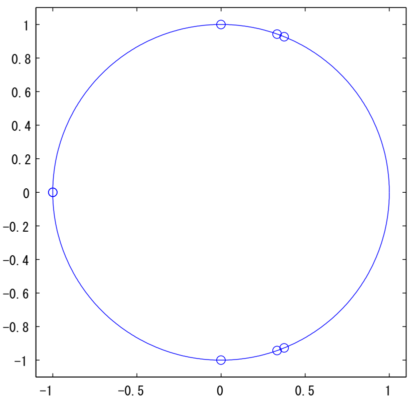

Fig. 2. Characteristic values of (14)

Computing the Smith form $S(z)$ of $F(z)$, we obtain

$$S(z) = \begin{pmatrix} z+1 & 0 & 0 \\ 0 & (z+1) & 0 \\ 0 & 0 & \frac{1}{12}(z+1)p(z) \end{pmatrix}$$

where $p(z) = (z^2+1)(3z^2-2z+3)(4z^2-3z+4)$. Hence, the spectrum of $F(z)$ lies on the unit circle and all characteristic values of $F(z)$ are normal and semisimple. Therefore, (10) is not nessesary for robust boundedness.

Abstract: This paper proposes a reactive control method for mobile robots in the presence of moving obstacles. The method is based on the dynamic window algorithm and extends it in order to avoid moving obstacles efficiently. Firstly, the future collision is detected based on the generalized velocity obstacles. Secondly, input value can be varied within the prediction horizon. This means that better input can be selected such that the robot starts passing maneuver ealier. However, this causes the dimension of the search space larger. In order to reduce the computation time, GDS (gradually dense-sparse) discretization and randomized sampling method similar to RRT is adopted. By means of these extensions, the robot can avoid moving obstacles with simpler cost function and reasonable computation time. Performance of the proposed method is evaluated by numerical simulations.

Keywords: Dynamic Window, Receding Horizon Control, Randomized MPC GDS discretization

1 INTRODUCTION

The problems of path-planning and collision avoidance are computing a collision-free path for a robot moving among obstacles and are crucial tasks for mobile robots. The application area has been spread to wide areas such as, automated transportation systems, automated factories, and robot human interactions. In many cases, the environment is uncertain and dynamic, thus, the path-planning and obstacle avoidance system should perform in such environments. When restricted to the collision avoidance, there have been proposed many reactive approaches in the last thirty years. Originally, these approaches have been applied to the static environment, then, some of them have been extended to the dynamic case recently.

The dynamic window approach, which was originally proposed by Fox et al in [1], is one of the most popular reactive collision avoidance methods. The original algorithm was extended by Brock and Kathib [2] such that the global path planning such as A* is integrated in the cost function. Furthermore, Seder and Petrović [4] applied the FD* search algorithm in order to consider the dynamically changing environment. However, in the case where the obstacles are moving, the planning should be time-dependent especially in the predicting phase, thus, more complicated computation for path planning is needed.

On the other hand, because of its *look ahead* nature, the dynamic window approach can be thought as one of the *Receding Horizon Control* problem (RHC, for short) in the model predicted control. This point has been pointed out by Ogren and Leonard [3]. In the general RHC problem, it is assumed that the input may change within the predicting horizon when the optimal input is searched.

But, in many works on the dynamic window approach, the use of constant input value is assumed in order to reduce the dimension of search space and decrease the computation time. Recently, Kiss and Tecesz [7] applied the RHC approach to dynamic window and they permitted piecewise constant input in the prediction phase, however, they did not show the concrete method to compute the optimal input sequence and, in addition, considered only static problem.

In this paper, the authors propose a method to extend the dynamic window approach to the moving obstacle avoidance with piecewise constant input. In the proposed method, the obstacles are divided to two classes; static and dynamic. The goal-intended term in the cost function is calculated by path planning method only for static obstacles. The collision to the dynamic obstacles are evaluated by computing the generalized velocity obstacles which is proposed by Wilkie et al [5]. In order to reduce the computation time, a randomized planning method with the gradually dense-sparse discretization is applied. The randomized planning method used in this work is proposed by Brooks et al [9] for the static path planning problem and the authors modify it in order to fit to the dynamic obstacle avoidance. The gradually dense-sparse discretization [10] is one of the methods to discritize the time horizon in the RHC problem and can reduce the search space without the loss of control performance. By applying these methods, the robot can avoid the obstacles with better behavior and with admissible computation time. The effectiveness of the proposed approach is evaluated by numerical simulations.

2 PRELIMINARIES

In this paper, it is supposed that the robot moves on a horizontal plane and its kinematics is nonholonomic differential-drive type. The shape of the robot and the obstacles are assumed to be approximated by circles. The state vector of the robot is given by $p(t) := (x(t), y(t), \theta(t))^T$, where $q := (x, y)$ and θ are the position and the orientation of the robot. The continuous time kinematics of the robot is described as

$$\begin{aligned} \dot{x} &= \cos(\theta)v \\ \dot{y} &= \sin(\theta)v \\ \dot{\theta} &= w \end{aligned} \tag{1}$$

where the input $u = (v, w)$ consists of the translational and the angular velocities. The solution of (1) for $p(t_0) = p_0$ and $u(t); t \in [t_0, t_1]$ is denoted as $p(t_1; t_0, p_0, u)$. Furthermore, it is assumed that the values and instantaneous variations of these inputs are limited. It is also supposed that the static map of the environment and the movement of the temporally obstacles is known.

2.1 Dynamic Window Approach

The dynamic window approach, proposed by Fox et al. [1] is a velocity space based local reactive avoidance technique where the optimal control command is searched in the subspace of the velocity space. The search space is reduced by kinematic and dynamic constraint of the robot and the constraint that the robot with the input does not collide with the obstacles, and the reduced search space is called *Dynamic Window* and denoted as V.

Suppose that the time is discretized at equal intervals Δt and the input is constant within each interval. In addition, the predicting time horizon T is set as $T = n\Delta t$ for some integer $n > 1$ and it is assumed that the input is constant with in the predicting horizon in evaluating the input.

the cost function in [1] is defined as a linear combination of *heading* term, *distance* term, and *velocity* term. If the position trajectory by the input is directed towards the goal, then the heading term takes high value. The distance term is the smallest distance to the obstacles within the horizon, and the velocity term is simply the value of v.

2.2 Extensions of Dynamic Window

Using the original dynamic window approach proposed in [1], robust obstacle avoidance is achieved in many cases, but there exist several shortcomings. These are summarized as :

- The heading function may cause local minima when the shape of the free space is complicated .
- It does not consider the dynamic environment.

To overcome the first problem, Brock and Khatib modified the cost function such that the free space connectivity information is taken into account [2]. They used a navigating function (NF) which is a local minima-free function defined on the discretized configuration space. NF is computed by the global path planning algorithm such as A* or wavefront propagation, so their approach is called *global* dynamic window (GDW, for short). Suppose that NF is denoted as $N(q)$ and the current state p_0, input $u \in V$, and the corresponding trajectory $p(t; t_0, p_0, u)$, $t \in [t_0 : t_0 + T]$ is given. Then, the modified cost function in [2] has the following form:

$$\begin{aligned} \Omega_g(p, u) &= \alpha \cdot n_1(p, u) + \beta \cdot vel(u) \\ &\quad + \gamma \cdot goal(p, u) + \delta \cdot n_2(p, u), \end{aligned} \tag{2}$$

where n_1 takes high value when the difference between $\theta(t_0 + T; t_0, p_0, u)$ and the direction of $\nabla N(q(t_0 + T; t_0, p_0, u))$ is large, *goal* is a binary function (1 if the trajectory $q(t; t_0, p_0, u)$ pass through the goal area), and

$$n_2(p, u) = N(q_0) - N(q(t_0 + T; t_0, p_0, u)).$$

Because the original heading term is replaced with NF, the resulting maneuvers can avoid local minima so that the robot can move along the optimal path.

It should be noted that, in (2), the *distance* term is deleted. This is because the local minima may caused by the trade-off between *heading* term and this term.

The second problem is more serious. The framework in [1] can be easily extended to the dynamic environment by means of the velocity obstacles[8], or its generalizations [5]. However, if the moving obstacles is not considered in the path planning phase, trade-off problem may occurs. On the other hand, the method in [2] needs the global free-space information. this means, for all time instances, the position and shape of all obstacles should be known. When the environment is static, it is sufficient that the path planning is made at the first phase only. However, when the environment is dynamic, on-line re-planning is needed. Furthermore, when the obstacles move, the path planning problem should be time-dependent, such that, the search space is extended to $\mathscr{C}\mathscr{T}$-space[6].

In [4], FD* algorithm is applied to GDW and its effectiveness are shown. But, even if the FD* is used, the replanning needs large computation time, thus it is not easy to apply this method to the case where the moving obstacles are large, or when the obstacles move fast.

2.3 Optimality issue

Many of the previous researches about DW assume that through the predicting time horizon, the input should be constant. As mentioned above, this is because the search space can be reduced so that the computation time becomes small. In the case where the environment is static and where GDW is used, this yields satisfactory results in many cases because the optimal path is already given by path planning phase, thus the time horizon can be made rather short. However, especially in the dynamic environment without re-planning, this assumption causes not only non-optimal but also dangerous behaviors.

3 EXTENSION TO PIECEWISE CONSTANT INPUTS

Based on the discussions in the previous section, it is preferred to use piecewise constant inputs for search instead of constant input throughout the predicting time horizon. As mentioned above, this extension causes the increase of the dimension of the search space such that the computation time increases exponentially. Therefore, some kind of computationally efficient solver is required.

It has been reported in [3], DW can be regarded as a special kind of *Receding Horizon Control* approach in the model predictive control (MPC), and several real-time solvers has been proposed for some problems including the trajectory generation problem for mobile robots. In this paper, Randomized MPC approach in [9] and GDS (Gradual Dense-Sparse) discretization are applied to DW for moving obstacle avoidance.

The randomized MPC is a kind of input space-based tree search for RHC, which is similar to RRT for path planning problem. For a system

$$\dot{x} = f(x,u) \tag{3}$$

with state variable $x \in X \subset \Re^n$ and input $u \in U \subset \Re^m$.

For given time horizon $[t_0 : t_0 + t']$, suppose that its discretization

$$t_0, t_1, t_2, \ldots, t_{r-1}, t_r = t_0 + t'$$

is given. We suppose that the input is piecewise constant and let $u_{t_0:t_r} = \{u_0, u_1, \ldots, u_{r-1}\}$ denotes a input sequence. Let $c(x(t_0), u_{t_0:t_r})$ denotes a cost function for initial condition and control sequence. The task is to find the control sequence $u^*_{t_0:t_r}$ which maximize (minimize) $c(x(t_0), u^*_{t_0:t_r})$. The basic ideas of the randomized MPC is similar to an RRT. A tree T is grown in which each node q consists of the tuple $< x_q, t_i, u_q >$: a state, a time, and a control input. This means, for the parent node $q' =< x_{q'}, t_{i-1}, u_{q'} >$, x_q is a solution of (3) at $t = t_i$ whose initial position is $x_{q'}$, and to which input u_q is applied. Thus, algorithm iteratively expands the tree by selecting an existing node q' and a control input u_q, then adding new nodes by integrating (3) forwards in time until t_q. Let $c_T(q_f)$ denotes a cost of the control input $u_{t_0:t_r}$ from the root node to a final leaf q_f at $t = t_0 + t'$. The basic procedure in [9] is summarized in Algorithm 1. Furthermore, in the next time, the previous optimal control sequence is used for the initial tree for effective search.

In the Algorithm 1, some subroutines should be specified. The usual RRT implementations of **SELECT_NODE** and **SELECT_CONTROL** sample a point in state space at first, select the nearest node as parent, then select the control which grows the tree from the node toward the sampled point. By means of these procedures, uniformly sampling or exploring the state space is achieved, however, these requires high computational time especially when the nearest neighbor node is found. In [9], parent node is selected uniformly from the existing nodes, and input is also selected uniformly from U. In addition, the method to discritize the time horizon is not addressed. These simplifications yields the low computational cost, but, may causes biased search in the state space. In order to achieve wider searching region with small number of node, Gradual Dense-Sparse discretization (GDS discretization) for predicting time horizon [10] is effective. In GDS discretization, the discretization time interval is made short in the early phase, and is made larger incrementally.

Algorithm 1 Tree Expansion for Randomized MPC

4 SIMULATION RESULTS

The proposed algorithms have been implemented in *Player/Stage* software tools. In order to illustrate the effectiveness of the proposed algorithm, a result of a test is presented in Fig. 1. In Fig. 1 red rectangle is the controlled

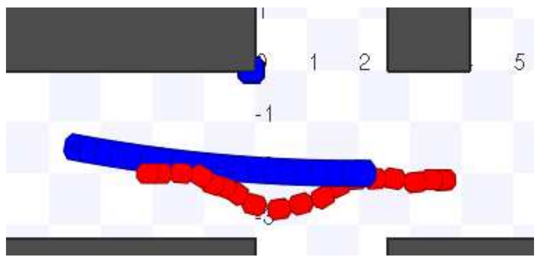

Fig. 1. Trajectories of the robot and the obstacle.

robot and blue one is the obstacle. The obstacle is also governed by the kinematic model (1) and the input is supposed to be constant $(v,w) = (0.3(m/s), -0.01(rad/s))$. The sampling interval and the prediction horizon are set to 0.1(s) and 3.2(s), respectively. The discretization intervals for GDS are set to 0.2, 0.2, 0.2, 0.2, 0.8, 1.6(s) and the number of nodes for randomized MPC is set to 4,200. In this case, the average computation time for about 16(s) execution was 0.012(s) by core i5 2.3GHz processor. The navigating function $N(q)$ for static environment was a L_1-based distance to the goal point, which was obtained by wavefront propagation algorithm a priori. It should be noted that, in the situation depicted in Fig. 1, the navigating function for the static map is the same as the simple L_1 distance. The cost function used at simulation is

$$\Omega_g(p,u) = \alpha \cdot n_1(p,u) + \gamma \cdot goal(p,u) + \delta \cdot n_2(p,u),$$

that is. less terms than (2) are used. This means that the parameter tuning becomes easier than GDW. In addition, the result is compared with those that the constant inputs are selected in Fig. 2, where additional *distance* term is added to the cost function. In Fig. 2, the line "single T=2" means

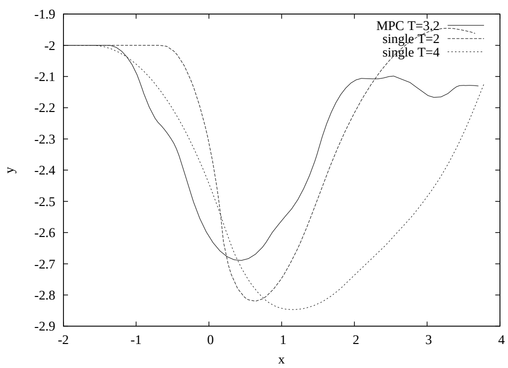

Fig. 2. Trajectories of the robot and the obstacle.

that the optimal constant input is searched in each time with prediction horizon $T = 2$. From the Fig. 2, the robot based on the proposed method starts avoiding maneuver as early as $T = 4$, and pass the obstacle more quickly than others.

5 CONCLUSIONS

In this paper, an extension of Dynamic Window approach is proposed for dynamic environment, and its effectiveness is examind by numerical simulations. By admitting piecewise constant input in the predicting and searching step, better performances are obtained. In addition, by means of randomized searching with GDS discretization, real-time calculation is also possible. However, the obtained trajectory seems to be nonsmooth and its modification is one of the future issues.

Abstract: Recently, particle filter has been applied to many visual tracking problems and it has been modified in order to reduce the computation time or memory usage. The one of them is the Mean-Shift embedded particle filter (MSEPF, for short) and Randomized MSEPF. These methods can decrease the number of the particles without the loss of tracking accuracy. However, the accuracy may depend on the definition of the likelihood function (observation model) and of the prediction model. In this paper, the authors propose an extension of these models in order to increase the tracking accuracy. Furthermore, the expansion resetting method, which was proposed for mobile robot localization, and the changing the size of the window in Mean-Shift search are also selectively applied in order to treat the occlusion or rapid change of the movement.

Keywords: Expansion Resetting, Mean-Shift, Multiple Model, Particle Filter, and Visual Tracking.

1 INTRODUCTION

Visual tracking is the process of locating a moving object (or multiple objects) over time using a camera. It has a variety of application areas, such as robot vision, human-computer interaction, security and surveillance, video communication, and so on. Visual tracking requires high accuracy tracking and real-time processing. To achieve high accuracy tracking, many approaches have been studied. Particle filter [1-3] is one of the robust tracking approaches in visual tracking, which has recently been developed. It performs a random search guided by a stochastic motion model to obtain an estimate of the posterior distribution describing the object's configuration. However, it is known that the degeneracy is one of the difficult problems inherent in particle filter. The degeneracy problem is a phenomenon of the tracking accuracy's decreasing because most particles may have very low likelihood. One of approaches that deal with it is to use very large number of particles, but it is hard to implement it to real-time systems because it requires a lot of computation times and resources. Shan and coworkers proposed the Mean-Shift embedded particle filter (MSEPF) in order to keep the accuracy with small number of particles [4]. In their approach, the state of each particle moves to the point in the window with the highest likelihood value.

In general, MSEPF overcomes the degeneration problem because each particle has higher likelihood. In addition, the accuracy of estimation depends on the size of the window, but the larger window size makes the computation slower. In the previous work [5], the authors modified the mean value calculation part of MSEPF by Monte-Carlo approximation and the likelihood function by adding the term about frame difference. It was shown that the computation time can be reduced without the loss of tracking accuracy.

In this paper, the authors extend the method in [5] such that the tracking accuracy can be improved. The first is application of the multiple prediction models for the case where the precise model for the movement of the tracked object cannot be obtained. The second is adaptation to the case where the tracked object is occluded or its velocity changes suddenly. In order to track the object robustly, two methods are switched according to the mean value of the likelihood function. The effectiveness of the proposed approach is examined by real video examples.

2 MEAN-SHIFT EMBEDDED PARTICLE FILT ER

2.1 Particle Filter

Particle filter is an approach for Bayes Estimation by Random Sampling. A continuous state vector of a target object and the observed feature vector at time step t are denoted by x_t and z_t, respectively. The dynamic model is assumed to be represented as a temporal Markov chain

$$p(x_t|x_1,\dots,x_t) = p(x_t|x_{t-1}), \qquad (1)$$

and the observation model is denoted as

$$p(z_1,\dots,z_t|x_1,\dots,x_t) = \prod_{i=1}^{t} p(z_i|x_i). \qquad (2)$$

Particle filter aims to estimate the sequence of hidden parameters x_t based only on the observed data $\{z_1,\dots,z_t\}$. According to the Bayes rule, the prior and the posterior are given by

$$p(x_t|z_1,\dots,z_{t-1}) = \int p(x_t|x_{t-1})p(x_{t-1}|z_1,\dots,z_{t-1})dx_{t-1} \quad (3)$$

$$p(x_t|z_1,\dots,z_t) = k_t p(x_t|z_1,\dots,z_{t-1}), \quad (4)$$

where k_t is the normalization term.

In the particle filter, by using a set of samples and the corresponding weights $S_t \coloneqq \{(s_t^n,\pi_t^n)\}_{n=1}^N$ at time step t (where N is the number of particles), the posterior is approximated as

$$p(x_t|z_1,\dots,z_t) \approx \sum_{n=1}^N \pi_t^n \delta(x_t - s_t^n), \quad (5)$$

where $\delta(\cdot)$ is the Dirac's delta function. Then, the prior can be approximated as

$$p(x_t|z_1,\dots,z_{t-1}) \approx \sum_{n=1}^N \pi_{t-1}^n p(x_t|s_{t-1}^n). \quad (6)$$

The weights π_t^n are determined such that $\pi_t^n \propto p(z_t|s_t^n) =: w_t^n$ (this probability is called as *likelihood*) and $\sum_{n=1}^N \pi_t^n = 1$. If sufficiently large number of particles can be prepared, Eq. (5) and (6) are accurate. In reality, however, using an infinite number of particles is not allowed, especially for real-time processing.

2.2 MSEPF

MSEPF is proposed in [4] which incorporates Mean-Shift into particle filter. Mean-Shift is another approach for visual tracking that climbs the gradient of a probability distribution to find the nearest dominant mode (peak). In the search window, the mean position of the target object is computed and the search window is centered at that position. Position of the target object is tracked by iterating this mean position calculation until the shift length converges.

In MSEPF, Mean-Shift analysis is applied to each particle based on observation density, after each particle was measured by likelihood function. MSEPF can keep the accuracy using fewer particles because particles converge to the local maximum. Therefore, MSEPF can reduce particles than particle filter. It is known that the accuracy of estimation depends on the size of the window. However, the larger window size requires additional computation time.

It was pointed out in [6] that the computational cost for mean value calculation is $O(n^2)$, where n denotes the window size. This shortcoming can be improved by replacing the mean value calculation by its Monte-Carlo approximation [5]. It is called as Randomized MSEPF (RMSEPF, for short). By means of this approximation, it was shown that the cost can be reduced to $O(n)$. Furthermore, in [5], the likelihood function for MSEPF was also modified using the edge detection and the frame difference.

3. EXTENSION OF RMSEPF

3.1 Multiple prediction models

In the particle filter-based state estimation, the state of each particle is updated by the prediction model Eq. (1). This is based on the property of the kinematics of the object to be tracked. However, many objects in the real world may not obey a simple kinematics, so precise modeling by single model is difficult. If insufficient prediction model is used, the tracking accuracy may decrease. Thus, in this paper, multiple prediction models are used in order to adapt to the various movement of the object.

3.1.1 Three types of prediction models

In this paper, three types of prediction models are adopted. They are *Static model*, *Drift model*, and *Statistical model*. The state of each model is (x, y) coordinates of the object on the image plane. These models are defined as follows:

1. Static model

$$\begin{aligned} x_t &= x_{t-1} + l_u \cos\theta_u, \\ y_t &= y_{t-1} + l_u \sin\theta_u. \end{aligned} \quad (7)$$

2. Drift model

$$\begin{aligned} x_t &= x_{t-1} + (x_{t-1} - x_{t-2}) + l_u \cos\theta_u, \\ y_t &= y_{t-1} + (y_{t-1} - y_{t-2}) + l_u \sin\theta_u. \end{aligned} \quad (8)$$

3. Statistical model

$$\begin{aligned} x_t &= x_{t-1} + \hat{x}_{t-1}, \\ y_t &= y_{t-1} + \rho_{t-1}\hat{x}_{t-1} + \sqrt{1-\rho_{t-1}^2}\,\hat{y}_{t-1}, \end{aligned} \quad (9)$$

where $\hat{x}_t \sim N(\mu_t^x, (\sigma_t^x)^2)$ and $\hat{y}_t \sim N(\mu_{t-1}^y, (\sigma_{t-1}^y)^2)$.In Eq. (7), $l_u \sim \mathcal{U}(0, l_{max})$ and $\theta_u \sim \mathcal{U}(0, 2\pi)$ are random variables with some positive l_{max}. In Eq. (9), μ_t^x and $(\sigma_t^x)^2$denote the median and the variation of the estimated velocity of the object in the x-direction up to time t. In addition, ρ_{t-1} denotes the correlation efficient of estimated velocity in the image plane.

The static model is based on the random walk movement. This model corresponds to the case where the object suddenly changes the direction. The drift model is used to describe the movement of the object with linear velocity. Finally, the statistical model predicts the nonlinear movement of the object by learning the change of the velocity and the direction from the sequence of the estimated state.

3.1.2 Model selection

One approach to use the multiple prediction model for the particle filter is applying the interacting multiple models (IMM, for short) [7, 8]. In this approach, each particle possesses additional information about which model is applied to it. However, the transition probability between models should be determined in advance. In this paper, a simple adaptive model selection algorithm is proposed. In this algorithm, the probability that each model is selected is proportional to their median of likelihood function. Suppose that the number of the models and the particles are $M > 0$ and $N > 0$ respectively. Furthermore, the models are denoted as $F^1, \ldots, F^M$. For any particle, the probability that it adopts the prediction model F^i at time t is denoted as n_t^i. The algorithm is summarized as follows:

0. Initialize the time as $t = 0$ and the model selection probabilities $\mathcal{N}_t := \{n_t^1, \ldots, n_t^M\}$ such that $\forall i \in \{1, \ldots, M\}, n_t^i > 0$, $\sum_{i=1}^{M} n_t^i = 1$.
1. For each particle, select a model according to $\mathcal{N}_t$ and update its state. For each model, define the group of particles X_t^i whose elements use F^i.
2. Compute the likelihood for all particles and obtain the median of likelihood $\widehat{W}_t^i =: med_{s_t^n \in X_t^i}(w_t^n)$.
3. For each group X_t^i. For some small positive constant ε, define $W_t^i := \widehat{W}_t^i + \varepsilon$.
4. Resample the particles and calculate each n_{t+1}^i such as $n_{t+1}^i = W_t^i / \sum_{j=1}^{M} W_t^j$.
5. Set $t \leftarrow t + 1$ and back to Step 1.

In the above algorithm, small constant ε should be added in order to avoid the case where certain models are not selected.

3.2 Escape from the Kidnapped state

Particle filters can approximate the probability of the existence of the object by means of many particles. However, if the particles lost the object by some reasons, the accuracy becomes very low. In this paper, the authors call such a situation as *kidnapped state*. The kidnapped state may occur when the object moves with very large velocity or the object is occluded by other objects (Fig. 1).

Fig. 1. Example of kidnapped state.

In this paper, two methods are selectively used in order to escape the particles from kidnapped state. The former is Expansion Resetting method [9] (ER method, for short) which was proposed for mobile robot localization problem. The latter is making the window size in the Mean-Shift search variable.

3.2.1 ER method

In the ER method, the particles are re-configured when they lost the object to be tracked. If the target was lost again, the particles are diffused to larger region (see Fig. 2). The decision whether particles lost the target or not is based on the mean $\bar{W}_t$ of likelihood. Suppose that the estimate of the position of the object by particles S_t is given by $\tilde{s}_t$. In addition, a PDF $p_0(x; \mu_x, \sigma_i^2)$ on the image plane, whose increasing variances are given by $\sigma_i^2, \forall j > i, \sigma_j^2 > \sigma_i^2$, is

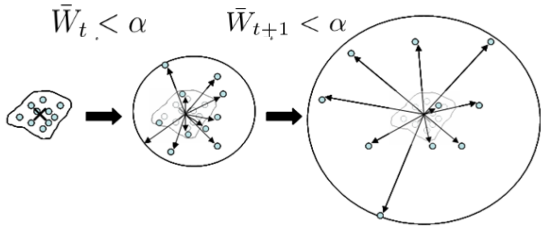

Fig. 2. Expansion resetting in 2D space.

also given. If $\bar{W}_t$ is smaller than a pre-defined threshold $\alpha > 0$ at certain time step t, then the particles are resampled based on $p_0(x; \tilde{s}_t, \sigma_0^2)$. Next, if $\bar{W}_{t+1}$ is also smaller than α, the particles are resampled again based on $p_0(x; \tilde{s}_{t+1}, \beta\sigma_1^2)$.

3.2.2 Changing the window size for Mean-Shift

In the visual tracking by only Mean-Shift search, large size of searching window is preferred because it is possible to robustly track the object even if it moves rapidly. However, in MSEPF, if large window in Mean-Shift search step is used, the particles may gather in local maxima. This weakens the variety of the particles, which is one of the important features of particle filter. Thus, small size of search window should be used, and we can see that there exists a trade-off.

To overcome this difficulty, the variable size of search window is adopted. When tracking is succeeded, it is made small. On the other and, if the object is lost, it becomes large.

3.2.3 Switching two methods

The ER method described in 3.2.1 can re-capture the object even if the object is occluded temporary. However, while this method is being used, tracking accuracy decreases. In contrast, changing the window size for Mean-Shift cannot track the object when the object is occluded, but it can track accurately, if the kidnapped state is rather weak. Thus, in this paper, two methods are switched according to the severity of the kidnapped state.

At first, two thresholds $0 < \alpha_0 < \gamma$ and the minimal (maximal) window sizes $W_{min}(W_{max})$ should be chosen. If $\bar{W}_t < \alpha_0$, then ER method is applied. Else if $\alpha_0 \leq \bar{W}_t < \gamma$, change the window size for Mean-Shift as

$$\frac{W_{min} - W_{max}}{\alpha_0 - \gamma}(\bar{W}_t - \alpha_0) + W_{max}.$$

4. EXPERIMENTS

This section illustrates the performance of proposed algorithm by real video sequences in lab environment. Tracked object is a pink toy shown in the left of Fig. 4 and the environment is shown in the left of Fig. 3.

Fig. 3. Tracked object (left) and lab environme nt with an occluding object

In Fig. 3 (left), there exists an object (yellow bottle) by which the tracked object may be occluded. Furthermore, there exists another object (tree) in the left side of image, which has decollations with several colors. In each video sequence, the object moves from the left to the right in the image plane. The image size is 320x240 (pixel) and the flame rate is 15(fps).

In the ER method, the particles are resampled on circle region whose center is $\tilde{s}_t$ and the radius is $5.18m + 0.5$, where m denotes how many times the heavily kidnapped state has been continue. The window size foe Mean-Shift varies in the range $[10 \times 10 : 30 \times 30]$. The threshold values are set as $(\alpha_0,\ \gamma) = (2.8, 20.6)$. On each experiment, the number of the particles is set to 50, and that of the samples in Mean-Shift search is also set to 50.

Fig. 4. Escape from the occluded state.

Fig. 5. Escape from the light kidnapped state (top: fixed window size; bottom: variable window size).

At first, Fig. 4 shows the results for the case where the object is occluded and this case corresponds to the heavily kidnapped state. We can see that,after diffusing, the particles can catch the object, and then track it.

Next, Fig. 5 shows results for the case where the object moves rapidly. When the constant (small) size of search window is used (top), the particles lose the object and they are caught by decollated tree which has similar color feature. On the other hand, the proposed method can track the object successfully.

5. CONCLUSIONS

In this paper, some extensions for Mean-Shift embedded particle filter are proposed. In order to improve the tracking performance when the tracked object changes the velocity rapidly or is occluded, two methods are selectively applied. In addition, multiple prediction models are used to take the complex and unpredictable movement of the object into account. Their effectiveness was examined by experiment with real video sequence and it was shown that the filter does not lose the object even when the object was occluded.

Evaluating the validity of the prediction models and finding more suitable models for each application are some of the future issues.

Abstract: In the natural world, cooperative behavior emerges and assumes the crucial roles. Cooperative behavior means altruistic behavior and non-cooperative behavior (defection) means selfish behavior. Although cooperators emerge in the society, cooperation has not any advantage as compared to defection in rational terms. Earlier studies proposed many mechanisms to fill a gap between theoretical prediction and experimental evidence. As previous works, the authors studied the SPD that is spatial-temporal version of the Prisoner's Dilemma to investigate the maintenance mechanisms of cooperators. Then we observed a membrane formation as a mechanism that protects cooperation from invasion of defectors. The authors consider the effects of the interaction distance on the game payoff. In the present model, interacting with distant individuals pays a higher cost than interacting with adjacent individuals. In the SPD simulation, this paper shows that cooperators emerge easier by considering the effects of the interaction distance.

Keywords: cooperation, membrane formation, spatial generosity, spatial prisoner's dilemma

1 INTRODUCTION

In the natural world, cooperative behavior emerges and assumes the crucial roles. Cooperative behavior means altruistic behavior and non-cooperative behavior (defection) means selfish behavior. A cooperator pays a cost for someone's benefit. On the other hand, a defector does not pay a cost. Although cooperators emerge in the society, cooperation has not any advantage as compared to defection in rational terms. Instead of cooperating, each individual or player should defect pursing their benefit. Natural selection obviously favors defection over cooperation and prevents evolution of cooperation unless it has mechanisms. Earlier researchers proposed many mechanisms to fill a gap between theoretical prediction and experimental evidence. Some of them are based on the game theory, especially the Prisoner's Dilemma (PD) game.

The PD has been widely studied not only in international politics but also in the evolutionary biology [1]. Nowak and May invented a spatiotemporal version of the PD named Spatial Prisoner's Dilemma (SPD) [2, 3]. The SPD also is the model as to discuss cooperative behavior. In the SPD, the effects of a spatial structure that protects cooperators and sustains are well-known results. After the invention of the SPD, many types of the SPD that are more realistic than the conventional model have engendered. They have considered the realistic factors such as Tit-for-tat (direct reciprocity), indirect reciprocity, random graph networks, scale-free networks, heredity effects and social generosity effects [4 - 6].

As previous works, we studied the SPD that treats the spatial generosity, to investigate the effects of the social generosity on cooperation. Then the authors observed a membrane formation as a mechanism that protects cooperation from invasion of defectors and maintains cooperators in the SPD model with the spatial generosity.

The membrane works as a mechanism for protects cooperators from invasion from defectors. Moreover the membrane emerges even if the lattice structure (e.g., square lattice, hexagonal lattice) and neighborhood radius change.

The robustness of the membrane for the lattice topology and the neighborhood is already shown [7]. This investigation, however, was conducted on the SPD under the ideal conditions in which all of the neighbors have equivalent value. In the realistic interaction between individuals, to interact with distant individuals has a higher cost than adjacent individuals.

In the present work, we use the SPD model that takes into account the interaction distance and the spatial generosity to investigate the effects of the distance between individuals. In the previous studies, the interaction distance has not considered. Thus, the player profits whether it is playing with the adjacent players or the distant players. In the real situation, however, playing with the distant players requires the high costs than the adjacent players. We assume that the payoffs which the players receive by playing mutual interaction are affected and discounted as the interaction distance increases.

This paper shows that cooperators emerge easier by considering the effects of the interaction distance.

This paper is organized as follows. In the next section, we explain the games models. In the section 3, we describe the membrane formation. Subsequently, we show the main results of our simulations. In the last section, we conclude and summarize this paper.

2 MODEL

2.1 Prisoner's Dilemma

The Prisoner's Dilemma (PD) is a one of fundamental models of the game theory. It is played just once by two players with two actions (Cooperation, C, or Defection, D). The players decide action simultaneously whether to cooperate or to defect. If both players cooperate, players receive payoff *R* (Reward), whereas if both players defect, players receive payoff *P* (Punishment). If one player cooperates and one player defects, the cooperator receives payoff *S* (Sucker) and the defector receives payoff *T* (Temptation). In the PD game, the payoffs must satisfy the equation $T > R > P > S$. In this model, whatever the opponent player chooses, the defection is the optimal choice for individuals clearly.

Therefore, both players always choose defection and receive payoff *P*, which is lower than that received when both choose cooperation.

The Iterated Prisoner's Dilemma (IPD) is temporal extension of the PD. In IPD, the PD is carried out repeatedly where $2R > T + S$. For IPD, some earlier researches proposed the temporal strategy. Axelrod reported a tit-for-tat (TFT) strategy is the best strategy among other temporal strategies [1]. The TFT strategy consists of playing C in the first round and from then on copying the opponent's action of the previous round. The TFT strategy contains temporal generosity as an element.

2.2 Spatial Prisoner's Dilemma

The Spatial Prisoner's Dilemma (SPD) is a spatio-temporal version of the PD. Our model generalized SPD by introducing a spatial strategy. Each player takes over the each site of a two-dimensional lattice. There have an action and a spatial strategy, and receive a score. The spatial strategy determines the next action according to the spatial pattern of action of their neighbor. A player plays the PD game with its neighbors (eight adjacent players when *Moore* neighborhood and neighborhood radius is one), and changes its strategy to the strategy that earns the highest total score among the neighbors'. Table 1 shows the payoff matrix of the PD. In our simulations, *R*, *S*, *T* and *P* are set to 1, 0, *b* and 0, respectively, below following the Nowak-May's simulations.

Table 1. The Payoff Matrix of the Prisoner's Dilemma Game. *R*, *S*, *T* and *P* are payoff for the player 1. A single parameter *b* is used following the Nowak-May's simulation.

		Player 2	
		C	D
Player 1	C	*R*(1)	*S*(0)
	D	*T*(*b*)	*P*(0)

The SPD is conducted in the following way with *N* players simultaneously.

1. Initial arrangement phase: an action and a strategy of each player are determined randomly with equal probability.
2. Action renewal phase: the next action of player will be determined by its strategy based on the neighbors' action (excluding the player itself).
3. Interaction phase: the players play the PD game with the neighbors and player itself, and then receive the payoff according to the payoff matrix in Table 1. However, the receiving payoff is discounted by an effect of the interaction distance. The score for each player is calculated by summing up all the scores and add the sum to the current score of the player.
4. Strategy renewal phase: after (2-3) is repeated *q* (strategy update cycle) times, the strategy will be chosen from the strategy with the highest score among the neighbors and the player itself.

2.2.1 Weight of the Interaction Distance

We weight the payoff that the player receives from the PD game to incorporate the effects of the interaction distance. The weight *w* ($0 < w \leqq 1$) discounts the player's payoff according to the decreasing function of the interaction distance. Hence, as distance between players increases, the weight decreases and a discount factor increases. The net payoffs of player *x* is given by

$$P_x = w \times \textit{game payoffs}.$$

In this paper, we proposed the two types of the decreasing function of the interaction distance. One is,

$$w = -\frac{d}{r+1} + 1, \tag{1}$$

where *d* is a interaction distance and *r* is a neighborhood radius. The other one is,

$$w = \frac{1}{(d+1)^2}. \tag{2}$$

For both definitions, the payoff's weight is one, when only the player plays the PD game with itself.

2.2.2 Spatial Strategy and Spatial Generosity

We conduct the SPD simulation with the spatial strategy and spatial generosity. The player decides next action according to its strategy and the pattern of the neighbors' action.

The spatial strategy determines player's action only based on the pattern of the neighbors' action. However, the patterns of the neighbors' action make an enormous amount. For example, in *Moore* neighborhood and its radius is 1, the patterns of the neighbors' action amount to 2^9 patterns. Hence, the 2^9 rules are required. For simplicity, we consider only "totalistic spatial strategy" that depends on the number of defectors in the neighbors, not on their positions. To represent a strategy, let l be number of the D actions of the neighbors excluding the player itself.

As a typical totalistic spatial strategy, we define k-D strategy. The player chooses D if $l \geqq k$, otherwise chooses C (Fig. 1). For instance, All-C (always cooperate) corresponds to the 9-D strategy, whereas All-D (always defect) corresponds to the 0-D strategy.

The k-D strategy can be regarded as a spatial version of the TFT where k indicates the spatial version of generosity.

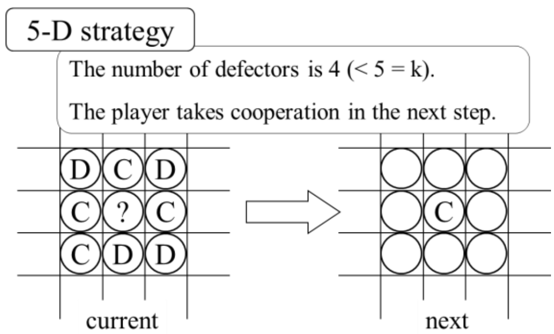

Fig. 1. An example of the spatial strategy. When k (spatial generosity) is five, the player tolerates to four defectors in the neighbors. Therefore, the center player will be cooperator in this situation.

3 MEMBRANE FORMATION

We already simulated the interaction between All-D (always D) vs. k-D instead of All-D vs. All-C (Nowak-May's simulation). In All-D vs. k-D interaction, we already observed the membrane as a mechanism for protects cooperation from invasion of defectors of All-D.

The membrane is composed of only the k-D defectors. Fig 2 shows an example of the membrane formation in *Moore* neighborhood.

In this paper, we also argue the effects of the weight of the interaction distance on the membrane formation.

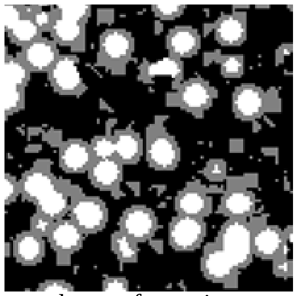

Fig. 2. The membrane formation generated by SPD simulation. *Black cells* indicate All-D players. *White and gray cells* indicate C and D players of k-D. In this snapshot, k is 6. The cooperators are covered by the membrane (*gray*).

4 SIMULATION

We carried out a SPD simulation in order to investigate the effects of the incorporating of the interaction distance with the parameter list in Table 2.

Table 2. Parameter list for the simulations

Parameter name	Description	Value		
$L \times L$	Size of lattice	700×700		
N	Number of players	490,000		
T	Number of steps	1,000		
r	Neighborhood radius	1	2	3
b	Bias of defectors of the payoff matrix in Table 1	1.8001, 2.0001	1.5625, 2.0001	1.4849, 2.0001

In a certain neighborhood radius, we carried out the two types of the simulation. In these simulations, we set a different parameter b (bias for defectors of the parameter matrix in Table 1).

1. The parameter b is set to be a minimum value that allows All-D to expand in the sea of cooperators from a single All-D player following the earlier study
2. The parameter b is set to be 2.0001. It does not satisfy the condition of the IPD ($2R > T + S$). This value favors a situation that defectors drive out cooperators in the IPD. Thus, it is favorable situation for the defector.

As a result, we observed the membrane formation whether the payoff is weighted (Fig. 3). Fig. 4 plots the time evolution of the cooperators when r = 1 and (1). In 6-D simulation, most players cooperate. This is because the All-D player could not invade and take over the cooperators

(Fig. 5). The cooperators receive higher payoff than defectors by an impact of self-interaction increasing.

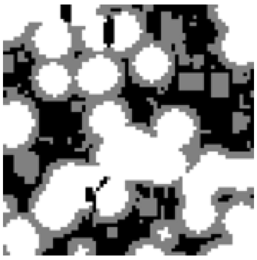

Fig. 3. The membrane formations emerge when k = 6, step t = 10, and the expression (1).

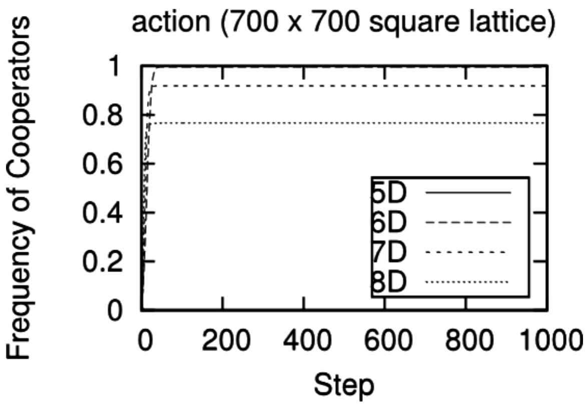

Fig. 4. The time evolution of the frequency of the cooperators. In the 6-D simulation, most players cooperate.

Fig. 5. This snapshots show step t = 100 of Fig. 3 simulation. The color code is same as in Fig. 3. The cooperators are not invaded by the defectors and remain.

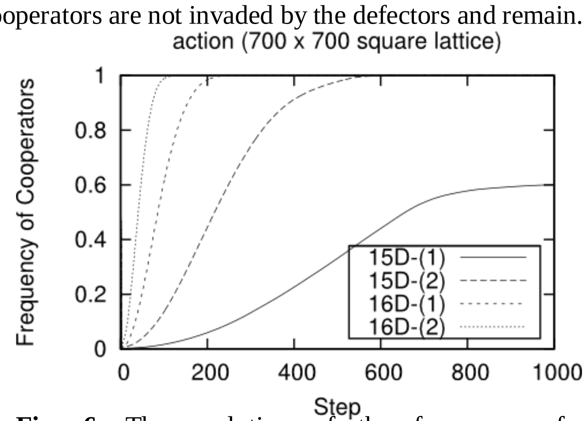

Fig. 6. The evolution of the frequency of the cooperators when r = 2. as the effect of the interaction distance increasing, the promotion of cooperation is preferred to defection.

Fig. 6 shows the time evolution of the cooperators when neighborhood radius r = 2. The cooperators easily emerge when (2). The interaction distance strongly influences a payoff weight when (2) than (1). Thus, as the effect of the interaction distance increasing, the promotion of cooperation is preferred to defection.

4 CONCLUSION

In conclusion, we have investigated the effect of the interaction distance on cooperation. In order to investigate this effect, we assumed that interacting with the distant individuals requires the high costs than the adjacent individuals. The payoff is discounted as the interaction distance increases.

In our model, cooperation easily emerges by incorporating the payoff's weight. The impact of the self-interaction increases by the introducing the payoff weight.

Moreover, we observed the membrane formation whether the payoff weight is introduced.

Identifying Cellular Automata Rules Using Local Rule Network From Spatiotemporal Patterns

Takuya Ueda[1], Yoshiteru Ishida[1]

Abstract: There are some methods of Identifying rules of cellular automata (CA) from their spatiotemporal patterns. But these methods do not consider relations of local rules. The relations include spatial ones and temporal ones. For example, a rule which satisfy the mass conservation law has spatial constraints for how to apply local rules to each cells. A local rule network represents spatial or temporal associations between local rules which are identified from spatiotemporal patterns. This paper address to construct local rule networks from spatiotemporal pattern and propose rule identification methods using the networks.

Keywords: Cellular Automata (CA), Rule Identification, Graphical Model

1 INTRODUCTION

Visualizations are used extensively for understanding behaviors of various phenomena. For example, Bayesian networks which are visualized causal associations by graphs (networks), apply to various area such as image recognition [1, 2]. Meanwhile, Wolfram classified 256 elemental rule of one dimensional cellular automata (CA) [3] into four classes by their behaviors [4]. Wolfram found differences between global behaviors of 256 rules by constructing directed graphs. The graphs represent transitions between possible configurations in certain space size. A Wolfram's graph can represent global behaviors of a rule but we cannot know local behaviors from the graph. Therefore we propose *local rule network* which consists of local rules as nodes and their transitions as arcs. A local rule network can represent associations between local rules. A rule of CA consists of local rules and each cell changes own state by applying a local rule. A local rule describes local a behavior which determine next state of a cell in a certain neighborhood pattern.

CA are known as which can generate various complex patterns from simple rules and uses for modeling of phenomena which generate spatiotemporal patterns. For example, ASEP[5] which is known as a traffic model is one of the one dimensional probabilistic cellular automata (PCA).

On the other hand, some researches deal with identifying cellular automata rules from analyzing their spatiotemporal patterns[6, 7]. Ichise proposed a method which identify a one dimensional deterministic and probabilistic cellular automaton rule from a spatiotemporal pattern generated by a computer simulation. Authors also applied the identifying method to actual phenomena and spatial prisoner's dilemma[8, 9]. The identifying method is simple which identifies local rules by scanning spatiotemporal patterns. The method can identify rules when spatiotemporal patterns are sufficiently big and simple such as patterns of Wolfram's 256 elemental rules. But the method cannot completely identify some rules which have hidden (embedded) rule such as ASEP's mass conservation law[10]. Because the method does not consider association between local rules. Therefore this paper propose local rules network which are constructed from spatiotemporal patterns and visualize local behaviors of these spatiotemporal patterns.

Section 2 explains cellular automata. Then local rule network is defined in section 3. Section 4 shows a example of patterns which the method cannot completely identify rules and discusses using local rule network.

2 CELLULAR AUTOMATA

Cellular automaton (CA) consists of cells which arranged on a lattice. Each cell has certain states and changes next own state following current neighborhood pattern. In this paper we restrict ourselves a case of one dimensional cellular automata. A time evolution of a cell is described by formula (1). Where n_i^t is a neighborhood pattern of cell i and r is neighborhood radius. When $r = 1$ current left, right and own three neighborhood determine the next state. A mapping $f : N \to S$ is a rule of CA where S is space of possible states and $N(= S^{r+1})$ is a set of possible neighborhood patterns. In a elemental CA (ECA) which is two states, three neighborhood and one dimensional CA has eight local rules because the number of possible neighborhood patterns is 2^3. Then there are $2^8 = 256$ rules in ECA.

$$\begin{array}{rcl} s_{i+1}^t & = & f(n_i^t) \\ n_i^t & = & s_{i-r}^t, \cdots, s_i^t, \cdots, s_{i+r}^t \end{array} \qquad (1)$$

Wolfram numbered these 256 ECA rules. The numbers are defined by formula (2). Where $c_j (\in S)$ is a state after applying local rule j such as table 1. The formula (2) also can consider that below of table 1 is binary string. Table 2 shows an example of rule 90.

$$R = \sum_{j=0}^{8} c_j 2^j \tag{2}$$

Table 1. A rule of 2-states,3-neighbors,one dimensional cellular automata (ECA). The rule consists of eight local rules.

n_i^t	111	110	101	100	011	010	001	000
s_i^{t+1}	c_7	c_6	c_5	c_4	c_3	c_2	c_1	c_0

Table 2. An example of rule90. When we consider the bottom column to binary number, it corresponds to $(01011010)_2 = 90$

n_i^t	111	110	101	100	011	010	001	000
s_i^{t+1}	0	1	0	1	1	0	1	0

Fig. 1 shows a spatiotemporal pattern generated by computer simulation of rule 90. Where white cells indicate 0 and black are 1. Space size is 100 and simulation time steps are 100. Initial condition is given by random.

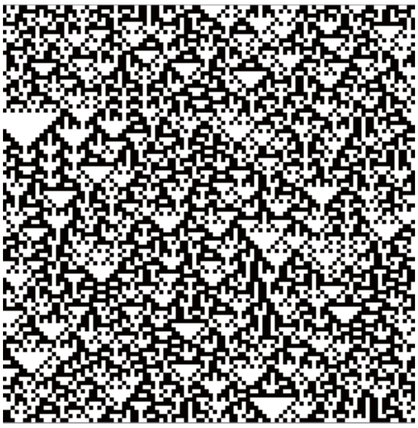

Fig. 1. A spatiotemporal pattern which is generated by rule90. White cells indicate 0 and black is 1. Space size is 100 and simulation time steps are 100. Initial condition is given by random.

3 LOCAL RULE NETWORK

Formula (3) defines a local rule network $G = (V, E)$. Fig. 2 shows a small example of local rule network. V is a set of nodes which are local rules and E is a set of arcs which are transitions (l_j, l_k) from local rule l_j to l_k. Where n_j is jth neighborhood pattern. For example, n_7 corresponds to $(1, 1, 1)$ in Table 1. When the neighborhood pattern of cell i at time step t is $(0, 0, 0)$, time step $t + 1$ is $(0, 1, 0)$ and the state of cell i at time step $t + 2$ is 0, there is a transition from local rule $((0, 0, 0), 1)$ to $((0, 1, 0), 0)$. Each arc has transition frequency $w(j, k)$ as weight. Then transition frequencies satisfy condition (4).

$$\begin{aligned} V &= \{l_j | l = (n_j, c_j), n_j \in N\} \\ E &= \{(l_j, l_k) | l_j, l_k \in V\} \end{aligned} \tag{3}$$

$$\sum_{l_k \in V} w(l_j, l_k) = 1 \quad \forall l_j \in V \tag{4}$$

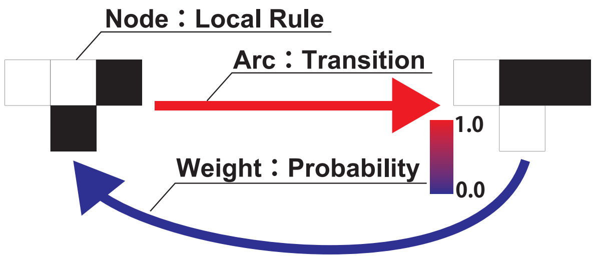

Fig. 2. An example of local rule network. Nodes correspond to local rules and arcs correspond to transitions between local rules. Each arc has transition frequency as a weight.

A local rule network is generated by scanning given a spatiotemporal pattern and finding local rules and their transitions. Then a transition frequency is obtained from the number of appearance. Fig. 3 shows a local rule network generated by a spatiotemporal pattern of rule 90 when space size is 1000, simulation time steps is 1000 and initial condition is random. Rule 90 is classified as class 3 which behaves chaos by Wolfram. Therefore rule 90 generates complex fractal patterns. Then the local rule network visualizes that there are many transitions and the rule is complex. Meanwhile, Fig. 4 shows a local rule generated by rule 5. This network has some hub local rules and it shows rule 5 is simple rule. Actually a spatiotemporal pattern of rule 5 is monotonous such as Fig. 5.

4 APPLICATION TO ASEP

ASEP is a traffic model and two states, three neighbors and one dimensional probabilistic CA. Each cell has a state, existing a car on the cell $(= 1)$or not existing $(= 0)$. Each car on the cell moves to front cell in probability p when front cell is empty. The number of cars is constant. Thus cars suddenly appears or disappears. It means that ASEP satisfies the mass

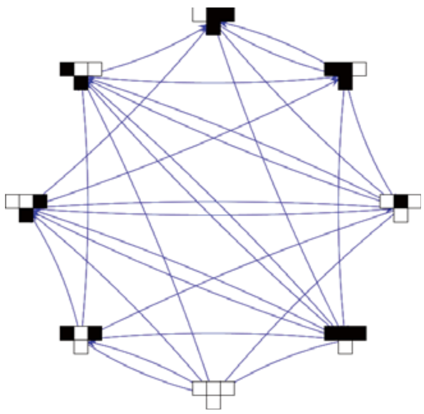

Fig. 3. A local rule generated from a spatiotemporal pattern of rule90. Each node indicates a two states and three neighbors local rule. White cells indicate 0 and black is 1.

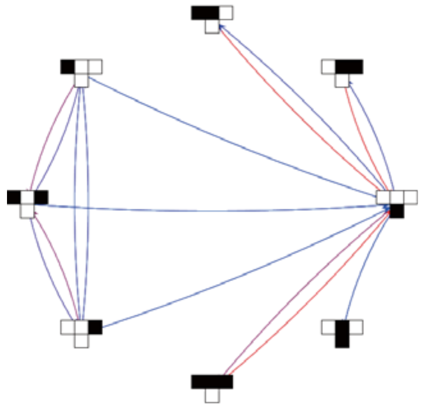

Fig. 4. A local rule generated from a spatiotemporal pattern of rule5. Each node indicates a two states and three neighbors local rule. White cells indicate 0 and black is 1. A spatiotemporal pattern is generated with 1000 space size and 1000 simulation time steps.

conservation law. But the mass conservation law cannot find a identified rule by the identifying method. While the method identify same rules from a pattern of satisfying the mass conservation law and not satisfying one [10]. Therefore we estimate whether spatiotemporal patterns satisfy the mass conservation law using local rule networks. Fig. 6 is generated by ASEP simulation and Fig. 7 is generated by a similar rule to ASEP but it does not satisfy the mass conservation law. These patterns shows major differences by comparison.

Fig. 8 is a local rule network generated from Fig. 6 and Fig. 9 is generated from Fig. 7. Fig. 9 shows that it has some transitions which do not appear in Fig. 8. These transitions break the mass conservation law. Thus local rule network can bring out differences between rules which identified as same rules by the identifying method.

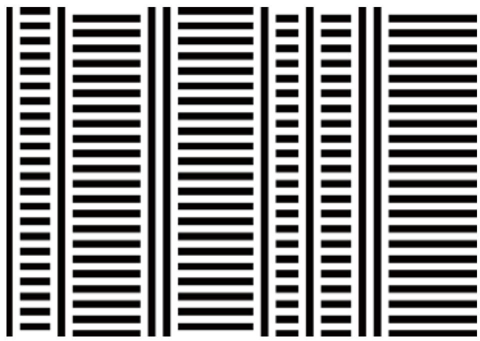

Fig. 5. A part of spatiotemporal pattern which is used for generating Fig. 4. White cells indicate 0 and black is 1.

5 CONCLUSIONS

This paper proposed a visualization of cellular automata rules from spatiotemporal patterns. A local rule network visualizes associations between local rules. Then we also shows an example of analysis in ASEP using local rule networks. Local rule network can bring out differences between rules which identified as same rules by the identifying method.

Abstract: This paper studies a relationship between an adaptive strategy and its payoff. In a recent study, the adaptive strategy has already proposed to evaluate how much the strategy obtains a payoff on average against not only itself but also other strategies. We study the adaptive strategy in two examples: a prisoner's dilemma and self-repairing network. We study the prisoner's dilemma by focusing on two parameters: benefit and cost. We reveal a condition when the strategy gets the highest adaptive measure against other strategies in the prisoner's dilemma game. Further, we apply the analysis to the self-repairing network with spatial strategies. We investigate the adaptive strategy in the self-repairing network by simulations. We revealed that the adaptive strategies get the high payoff which minimize the standard deviations in the simulations.

Keywords: self-repairing network, adaptive strategies, spatial strategies, game theory, dynamic environments

1 INTRODUCTION

Autonomous distributed systems composed of agents need to adapt changes of environments. In the autonomous distributed systems, the agents pursue their own profits to achieve assigned their own goals. The agents need to change their behavior to adapt conditions in the dynamic environments. The agents determine next actions based on their own strategies. However, decision makings of the agents will affect each other. The policy of the agent behavior is represented as a strategy in game theory. The agents need to choose the strategy that earns the high profits as much as possible and determine their next actions based on their strategies.

There are various kinds of agents in information networks. The agents, connected each other with a network structure, interact with other agents based on their own strategies. The agents will encounter other ones having not only same strategies but also different strategies. For the agents, to choose the strategies earning the high payoff to specific strategies is risky, since, the agents face with a lot kind of the other agents selecting different strategies. The neighbor agents of the agent also will affect itself as the environment. The environments dynamically change according to interactions among them. Therefore, the agents need to have the strategies that obtain the high profits on average against other strategies.

An earlier study has already proposed a concept of an adaptive strategy [1] of which how well the strategies perform against other strategies. The performance of the strategies is evaluated as adaptive measures based on interaction results of the payoffs. In the study, the authors introduced two models as calculation examples: prisoner's dilemma [2] and self-repairing network [3, 1]. The evaluation results of the strategies from the viewpoint of the adaptive strategy showed that the strategies earning the highest payoff do not correspond to that ones getting the highest adaptive measures. The study has reported that the adaptive strategies would perform well against other strategies although they do not obtain the highest payoffs.

The related works on the adaptive strategies are fault-tolerant strategies [4] and evolutionary stable strategies [5, 6]. However, both notions aim to investigate robust strategies against other strategies. Other related studies aim to construct a good strategy (strong strategy) than other strategies. Further, they compared with the proposed and other strategies by simulations [7, 8, 9, 10]. However, the focus of the adaptive strategies is to investigate adaptiveness of the strategies that earn the high payoff on average against other strategies.

An aim of this paper is to investigate two issues on the adaptive strategies. Firstly, we analyze the iterated prisoner's dilemma game as a typical example. We reveal a certain condition in which an adaptive measure of a trigger strategy exceeds that one of always defection strategy. Secondly, we study relationships between the adaptive measures and variances of the payoffs earned by the strategies. The earlier study [1] showed the strategies earning the highest adaptive measures obtains the high payoffs on average against other strategies. For this issue, we consider a self-repairing network as another example in the autonomous distributed systems. We study the self-repairing network composed of the agents choosing spatial strategies by numerical simulations.

In Section 2, we give a formal definition of adaptive strategies, and we consider parameter conditions on the adaptive strategies in the iterated prisoner's dilemma with three simple strategies. In Section 3, we introduce and define the self-repairing network for simulations. In Section 4, we evaluate the self-repairing network from the viewpoint of the adaptive strategies by simulations. In Section 5, we discuss the significance of the adaptive strategies on the basis of the simulation results. In Section 6, finally, we state our conclusions in this paper.

2 ADAPTIVE STRATEGY

2.1 Definition

The concept of adaptive strategies and its formal definition has already introduced in the former paper [1]. The concept of the adaptive strategies is proposed in order to construct the autonomous distributed systems which work well on average in uncertain environments. The concept of the adaptive strategies incorporates fundamental two factors: (a) cooperative and (b) self-tolerance. Cooperative means that the strategies need to behave cooperative to maintain their performance against the opponents because the agents would encounter various kinds of strategies in information networks. Self-tolerance means that the agents need to cooperate with their neighboring agents because if they defect from others who have the same strategies, they would lose future opportunities to get a higher payoff. These two fundamental factors require agents to cooperate with not only themselves but also other agents.

For designing the strategies, performance of the strategies how much they behave well agains other strategies is evaluated as an adaptive measure. This measurement is defined by payoffs and strategies. Let S denote a set of strategies. Let N denote the cardinality of the strategy set S. Let i, j, and k denote natural numbers used for numbering the strategies in the strategy set. Strategy s_i is expressed as one strategy in the set S numbered as i. Let $E_p[s_i|s_j]$ denote the expected payoff of strategy s_i against s_j. Let $E_m[s_i]$ be the expected payoff of the strategy s_i for all strategies.

Let denote the adaptive measure $E[s_i]$ of a strategy s_i its strength. The adaptive measure is represented as follows:

$$E[s_i] = \frac{1}{NM} \sum_{s_j \in S} E_p[s_i|s_j] E_m[s_j] \tag{1}$$

$E_m[s_j]$ is expressed as follows:

$$E_m[s_j] = \frac{1}{NM} \sum_{s_k \in S} E_p[s_j|s_k] \tag{2}$$

The symbol M represents the maximum total payoff in the payoff matrix of the game. Formula (2) represents the averaged performance of strategy s_j for all strategies. The adaptive measure in Formula (1) is expressed as the product of $E_p[s_i|s_j]$ and $E_m[s_j]$ to evaluate whether strategy s_i achieves the higher payoff against strategy s_j even if s_j achieves a high payoff for other strategies. The adaptive measure will decrease when strategy s_i achieves the smaller payoff and even if strategy s_j achieves the higher averaged payoff. In contrast, the adaptive measure will increase when strategy s_i gets the larger payoff and strategy s_j obtains the higher averaged payoff. The range of the measure can be normalized from zero to one. The strategy is adaptive if the measure is close to one, and it is not adaptive if the measure is close to zero. The adaptiveness of the strategies can be evaluated by comparing with the measures.

2.2 Example of adaptive strategy analysis

We present a calculation example of the adaptive measures of the adaptive strategies in the iterated prisoner's dilemma (IPD). This example uses simple three strategies: All-C (always cooperate), All-D (alway defect) and Trigger (it cooperates until an opponent defects in a previous round, otherwise defects). We reveal a condition in which the adaptive measure of Trigger strategy exceeds All-D strategy's one where a discount rate is a variable parameter. The IPD is a temporal extension of the prisoner's dilemma. The prisoner's dilemma [2] is a one-shot game whereas the IPD is a repeated game. We consider a two-player game in the infinite IPD. The players determine their actions of cooperation or defection simultaneously without prior consultation before the game. The payoff for each player is determined by combinations of moves among the players.

The payoff matrix is shown in Table 1. The payoff matrix is defined with two parameters b (benefit) and c (cost). Each symbolic value in the table satisfies the conditions $T > R > P > S$ and $2R > T + S$. We assume a discount rate w of the payoff for every round. The discount rate can be used for calculating the discounted payoff regarded as the future payoff.

The expected payoffs of the infinite IPD for the three strategies can be calculated theoretically [2]. The theoretical results shown in Table 2 are calculated from the payoff matrix shown in Table 1.

Table 1. Payoff matrix for the proponent in the prisoner's dilemma with two parameters

		Player 2	
		C	D
Player 1	C	$R = b \quad c$	$S = \quad c$
	D	$T = b$	$P = 0$

Table 2. Expected payoff for the proponent in the infinite IPD with two parameters

		Opponent		
		All-D	Trigger	All-C
Proponent	All-D	0	b	$\frac{b}{1-w}$
	Trigger	c	$\frac{b-c}{1-w}$	$\frac{b-c}{1-w}$
	All-C	$\frac{-c}{1-w}$	$\frac{b-c}{1-w}$	$\frac{b-c}{1-w}$

From Table 2, we simply obtain the averaged payoffs for all strategies.

$$E_m[All \quad D] = \frac{2b \quad 3c}{3b} \tag{3}$$

$$E_m[Trigger] = \frac{1 \quad w}{3b}\left(\quad c + \frac{2(b \quad c)}{1 \quad w}\right) \tag{4}$$

$$E_m[All \quad C] = \frac{2 \quad w}{3} \tag{5}$$

We focus on the two strategies of Trigger and All-D. The adaptive measures of these two strategies can be calculated by the definitions. Therefore, we obtain adaptive measures of both strategies as follows:

$$E[All \quad D] = \frac{1}{9b}\Big(\quad cw^2 + 4cw \quad 2bw \quad 6c + 4b\Big) \tag{6}$$

$$E[Trigger] = \frac{1}{9b}\Big(\quad bcw^2 + (4bc \quad c^2)w + 6c^2 \quad 12bc + 4b^2\Big) \tag{7}$$

We calculate the condition of the discount rate which leads the adaptive measure of Trigger to be the highest value.

$$\begin{aligned} E[Trigger] &> E[All \quad D] \\ 2b^2w + c^2w &> 6c^2 \quad 6bc \end{aligned} \tag{8}$$

We replace the term c/b with r. Then, we obtain

$$w > \frac{6r(r \quad 1)}{(\sqrt{2} \quad r)(\sqrt{2} + r)} \tag{9}$$

According to the above result, the adaptive measure of Trigger exceeds the adaptive measure of All-D when the discount rate exceeds the threshold. Fig. 1 shows a curve of discount rate against the cost-benefit ratio calculated by Formula

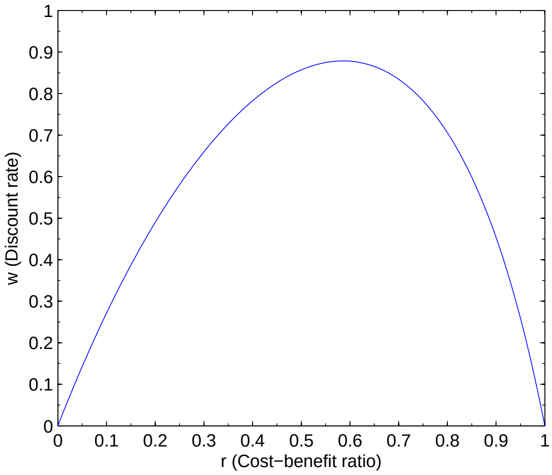

Fig. 1. Discount rate curve against cost-benefit ratio in Eq. (9).

(9). The highest discount rate is 0.88 when the cost-benefit ratio is 0.69. The discount rate increases as the cost-benefit ratio grows because the defective strategy dominates the cooperative strategies where the the discount rate is smaller than its highest value. On the other hand, the discount rate decreases as the cost-benefit ratio grows to be larger than 0.69 because the benefit is small due to the cost to be large.

3 SELF-REPAIRING NETWORK

In order to consider the relationship between the highest adaptive measures and the payoffs, we apply the adaptive strategy analysis to the self-repairing network with spatial strategies [11]. The self-repairing network is a network model in which agents repair other agents by copying their contents mutually. We consider the self-repairing network by game-theoretic approach model [3, 12]. We adopt the proposed former model defined by replicator dynamics and master equations.

For simplicity, we assume the network large, well-mixed population. Each agent has a state either normal or abnormal. We denote the frequency of normal agents (abnormal agents) by ρ_N (ρ_A). Each agent determines the next action: *repair* (C, cooperation) or *not repair* (D, defection). We denote the frequency of repair agents (not repair agents) in the network by ρ_C (ρ_D). The agents determine their actions based on their strategies.

The repairing is done between the two agents. The two agents are randomly chosen from the network, then they repair each other based on their decisions. The repair success rate is different by the state of the agent. We denote the repair success rate of the normal and abnormal agents by α and β respectively. We assume to simplify the model that the repair by the normal agents is always successful ($\alpha = 1$). The repaired agent becomes normal if the repairing is successful, otherwise the repaired agent becomes abnormal. We assume that the normal agents become abnormal by spontaneous failure. We denote the failure rate by λ.

From above definitions, the repairing dynamics is expressed as follows:

$$\begin{aligned}\frac{d\rho_N}{dt} &= \alpha\rho_N\rho_A\rho_C + \beta\rho_A^2\rho_C \quad (1 \quad \alpha)\rho_N^2\rho_C \\ &\quad (1 \quad \beta)\rho_A\rho_N\rho_C \quad \lambda\rho_N \end{aligned} \tag{10}$$

Each term represents the repair interactions between the two agents. The first and second terms express the increase of normal agents while the third and forth terms represent the decrease of the abnormal agents.

The agents have their own resources consumed by repairing. The normal agents (abnormal agents) have the maximum resources b_N (b_A). If the normal agents (abnormal agents) do the repairing, then the agents consume their resources only c_N (c_A). The agents deal with the remained resources as the available resources. The resources of the agents are filled in the beginning of the step.

The agents determine their next actions based on the strategies. We introduce spatial strategies [11] to the agents. The spatial strategies determine the actions involving the effects of neighborhood decision making. Especially, kC strategy of the spatial strategies is introduced into the agents. In an original definition of kC strategy, it determines the next action *repair* if the number of defeaters exceed the threshold k. We modify the strategy from the original one to the strategy one that determine the next actions based on the frequency of silent agents ρ_D in the previous step. The range of the threshold k is from 0 to 1. We denote the frequency of the kC strategy by ρ_k.

For calculating the payoff of each strategy, we define a function $\rho_C^k(\rho_C^p)$ that returns a binary value 0 or 1 according to the frequency ρ_C^p of the repair agents in the previous step. The function $\rho_C^k(\rho_C^p)$ is defined as follows:

$$\rho_C^k(\rho_C^p) = \begin{cases} 0 & (\rho_C^p > k) \\ 1 & (\rho_C^p \quad k) \end{cases} \tag{11}$$

Let denote $W(kC)$ the expected payoff of the strategy kC. The $W(kC)$ is expressed as follows:

$$\begin{aligned} W(kC) &= \rho_k(\rho_N((b_n \quad c_n)\rho_C^k(\rho_C^p) + b_n(1 \quad \rho_C^k(\rho_C^p))) \\ &\quad + \rho_A((b_a \quad c_a)\rho_C^k(\rho_C^p) \\ &\quad + b_a(1 \quad \rho_C^k(\rho_C^p)))) \end{aligned} \tag{12}$$

Let denote $\overline{W}$ expected payoff of the whole network. The expected payoff $\overline{W}$ is expressed as follows:

$$\overline{W} = \rho_{k_1}W(k_1C) + \rho_{k_2}W(k_2C) \tag{13}$$

We consider the self-repairing network with the agents implementing two different strategies. The strategies are denoted as k_1C and k_2C. Therefore, the dynamics of the competition among the strategies is expressed as follows:

$$\frac{d\rho_{k_1}}{dt} = (W(k_1C) \quad \overline{W})\rho_{k_1} \tag{14}$$

Therefore, the dynamics of the self-repairing network with the spatial strategies are expressed by the two equations (10) and (14) are expressed.

4 SIMULATIONS

We make a round-robin tournament of the self-repairing network with spatial strategies. We evaluate the spatial strategies in the self-repairing network from the viewpoint of the adaptive strategy. We choose two strategies from the strategy set and run the simulations with the two strategies. Parameters for simulations are shown in Table 3. After simulations, we calculate the adaptive measure for each strategy.

Table 4 shows the round-robin tournament results for the failure rate $\lambda = 0.01$. According to the result, the $0.6C$ strategy obtains the highest averaged payoff among the strategies, while the $1C$ strategy gets the highest adaptive measure and smallest standard deviation. The $0.6C$ strategy gets the high payoff against other strategies except the $1C$ strategy. The $1C$ strategy obtains the high payoff against not only itself but also other strategies although $1C$ strategy agents are repaired by other strategy agents. This difference makes the $1C$ strategy get the highest adaptive measure.

Table 5 shows the round-robin tournament result for the failure rate $\lambda = 0.04$. According to the result, the $0.6C$ strategy obtains the highest averaged payoff among the strategies, while the $0.6C$ strategy gets the highest adaptive measure and smallest standard deviation. This result is contrary to the round-robin tournament one where the failure rate $\lambda = 0.01$. For both cases, 0.6 strategy obtains the higher payoff than $0.6C$. Unfortunately, the $0.6C$ strategy causes the decrease of the payoff when it repairs itself. The $1C$ strategy makes its standard deviation the smallest. In other words, the strategy obtaining the highest adaptive measure also gets the smallest standard deviation.

According to two cases, the standard deviations of the adaptive strategies become the smallest values. The adaptive strategies earn the high payoff on average and make the standard deviations he smallest.

5 DISCUSSION

In the previous section, we compared the two results where the different failure rates are used. The round-robin

Table 3. Parameters for numerical simulations

Parameter	Name	Value
T	Step	500
α	Repair success rate by normal agents	1.0
β	Repair success rate by abnormal agents	0.1

tournaments demonstrated the considerable results. The standard deviations of the strategy obtaining the highest adaptive measure are the smallest values among the strategies. In one of the two cases, the strategy does not correspond to that one obtaining the highest averaged payoff. On the other hand, the strategy obtaining the highest adaptive measure correspond to that one obtaining the highest averaged payoff. However, the adaptive strategies could get the high payoff on average against given strategies set and make its standard deviation the smallest in them.

In information network, the agents encounter various kinds of agents implementing different strategies. The agents need to adapt behavior of the other agents in order to pursue their goals. According to the simulation results, the adaptive strategies could obtain high payoffs on average against other strategies. Further, their lack of the payoffs compared with the averaged payoffs would be the smallest or small values. The neighborhood of the one agent can be regarded as its environment. For the agents, to adapt for a specific environment is not reasonable because of they would face and need to follow the changes of the environments. The adaptive strategies would adapt to different environments by the simulation results.

6 CONCLUSIONS

We studied a relationship between an adaptive strategy and its payoff in both examples of a prisoner's dilemma and self-repairing network. In the prisoner's dilemma, we considered on the adaptive strategies what conditions make the strategies get the highest adaptive measure. We analyze the adaptive strategies in the prisoner's dilemma game with simple three strategies and certain parameters. For the analysis, this paper focused on the two parameters: benefit and cost. We revealed the condition of which the strategy gets the highest adaptive measure against other strategies in the prisoner's dilemma.

Further, we considered the adaptive strategies in the self-repairing network with spatial strategies. The dynamics of the self-repairing network involve interactions on a mutual repairing and strategy update. We investigated the adaptive strategy in the self-repairing network by numerical simulations. In the results, we showed that the standard deviations of the strategies obtaining the highest adaptive measures are the smallest values among the strategies even the strategies do not earn the highest averaged payoffs. We revealed that the adaptive strategies would get the high payoff which minimize the standard deviations.

matsuka@sys.cs.tut.ac.jp

Abstract: Solar insolation influences important factors such as the indoor sunshine and room temperature. For a smart house, the amount of power generation of a photovoltaic generation depend on the solar insolation. However, knowledge required to evaluate the influences may not be readily available. We aim to build a solar insolation simulator that can be used without professional knowledge and detailed information. The simulator has simplicity and flexibility of a computational model of cellular automata. The advantage of this simulator is in an easy setup. Since this simulator needs only a floor plan diagram, its detailed knowledge is unnecessary. Moreover, the merit of the application by having created by the cellular automaton is also an advantage of this simulator.

Keywords: cellular automata, living climate, insolation

1 INTRODUCTION

Solar insolation influences important factors in designing a smart home such as the indoor sunshine, room temperature and the amount of power generated by a photovoltaic generation for the house installed. Many simulators of solar insolation have been already developed [1][2].

However, professional knowledge such as architectonics is required for those simulators, and it would be difficult to use those simulators for novices. For example, when Daysim [1] performs a simulation, it requires the three-dimensional model by CAD (Computer Aided Design). Therefore, a simulation cannot be performed without the knowledge of CAD. Further, information required to use those simulators described above (such as the quality of the material of a wall, the form of a roof, and information on the surrounding residence) may not readily be available.

We aim to develop a simulator which requires a floor plan diagram but neither professional knowledge nor detailed information. By performing a simulation only from a floor plan diagram, the time and effort for model creation is reduced.

Section 2 explains a definition of cellular automaton modified to simulate a light ray.

Section 3 presents the outline of the simulator.

Section 4 deals with the application of the simulator. The function and simulation result are also presented.

2 CELLULAR AUTOMATON MODEL

2.1 Cellular Automata

Cellular automata are a computational model composed of homogeneous cells each of which has the same number of states and the same set of rules to change the state. These cells are arranged in a regular lattice such as a square lattice and a hexagonal lattice. We use a two dimensional square lattice. In discrete time progresses, each cell determines the own state by an interaction from the state of itself and its neighborhood [3].

The cellular automaton can express a complicated phenomenon easily only by applying the same transition rule as all the cells. Moreover, it also has the pliability which can express another new phenomenon by adding a transition rule. For simplicity we used cellular automata to build solar insolation simulator.

2.2 Cellular Automata for the Simulation of Solar Insolation

The outline of cellular automata for the simulation of solar insolation is shown below.

The state s of a cell is a collection of states (as in the formula (1)): c is a type of a cell; a is the degree of incidence angle; x and y are the movements to the direction of x and y from an incidence position, respectively; and d is a direction of movement.

$$s = (c, a, x, y, d) \tag{1}$$

The type of a cell c is air, a wall, or light. Furthermore, when c is light, a cell has the information on the degree of incidence angle a, the amount of movements x and y, and a direction of movement d.

The degree of incidence angle a is the degree of incidence angle of sunlight. The position of the sun changes with time. Therefore, it is necessary to change the degree of incidence angle according to the date and time.

The amount of movements x and y are value used when determining a direction of movement, and x and y takes both of positive.

A direction of movement d is a direction where light actually progresses, and there are eight directions as shown in Fig.1. There is the degree of incidence angle to a range of 0 to 360 degrees, but the light cannot move to the direction of this angle correctly on grid-like space. Therefore, by choosing a direction of movement appropriately, light moves the degree of incidence angle approximately.

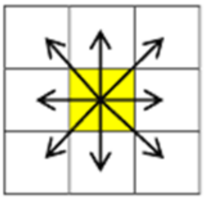

Fig. 1. The direction of movement of light

Each cell determines the next state by applying the transition rule f to determine the next state $s_{i,j}^{t+1}$ based on the state of the own cell and neighbor cell as in the following update rule (2). The symbol $s_{i,j}^{t}$ indicates the state of the cell in the coordinate (i, j) at the time t.

$$s_{i,j}^{t+1} = f(s_{i-1,j-1}^{t}, s_{i-1,j}^{t}, \cdots, s_{i,j}^{t}, \cdots, s_{i+1,j+1}^{t}) \qquad (2)$$

3 THE OUTLINE OF THE SIMULATOR

3.1 The Outline of the Simulator

A floor plan diagram is used for a simulation, and 1 pixel is set up as one cell. The state of each cell is distinguished by the color of a pixel when a floor plan diagram is read.

There are three kinds of sunlight: direct sunlight, skylight and catoptric light from the ground. But, for simplification of a setup, only direct sunlight with the largest amount of solar insolation is considered in this simulator.

The simulation is performed in two dimensions. And a floor plan top is set up north.

3.2 The Procedure of the Simulation

Operation of the simulator consists of arrangement of light, movements of light, and those repetitions. The details of three operations are shown below.

3.2.1 Arrangement of Light

If the type of a cell is air and the cell is on the edge of the screen, the type of the cell is made to change light. For example, sunlight is incident from the right and under of the screen at 9:00 (refer to Fig. 2). Moreover, light sets up the degree of incidence angle which suits at time (refer to Fig. 3).

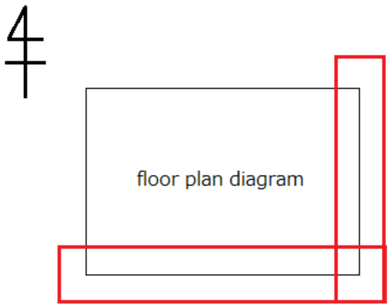

Fig. 2. The incidence position of light at 9:00

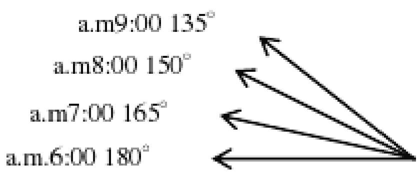

Fig. 3. The degree of incidence angle

3.2.2 Movements of Light

If there is the light whose the direction of movement turned to the own cell at neighborhood and the type of own cell is air, the type of the own cell changes to light. Moreover, if a type of a cell is light, the cell changes to air. And other cells do not change. This transition rule expresses movement of light.

Further, when changing in light, the degree of incidence angle a succeeds the same angle and the amount of movements increases according to a direction of movement.

A direction of movement is determined by the following formula (3).

$$d^{t+1} = \begin{Bmatrix} d_p : if \ |a - \theta_p| < |a - \theta_q| \ then \\ d_q : if \ |a - \theta_p| > |a - \theta_q| \ then \end{Bmatrix} \qquad (3)$$

The direction of movement of light is chosen from two directions of movement assumed, d_p and d_q (If it is 180 degrees to 135 degrees, they are the left or the upper left: refer to Fig.4). Angles θ_p and θ_q are calculated and the angle θ near the degree of incidence angle is chosen as a direction of movement. θ is determined by the formula (4).

$$\theta = sin^{-1} \frac{y}{\sqrt{x^2+y^2}} \tag{4}$$

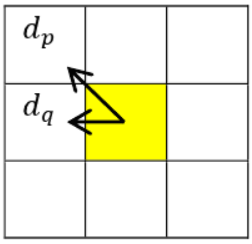

Fig. 4. The example of a direction of movement

3.2.2 Repetitions

If the cell which exists in the move direction of light is a wall or the edge of the screen, another cell is made to change to light and light is moved.

When changing and moving a cell of all the incidence positions to light, the degree of incidence angle is reduced by 1 degree and the simulation is repeated till finish time.

4 APPLICATION OF THE SIMULATOR

4.1 Simulation of Daylight of a Residence

Fig. 5 shows a simulation result of the snapshot daylight at 9:00 a.m. A dark portion expresses a wall and a bright portion expresses a sunshine portion. If a cell has changed to light at the time, the simulator expresses the cell as a sunshine portion.

Moreover, Fig. 6 shows daylight through the daytime. A cell with long time of type of light is expressed more brightly.

These two simulation result (Fig. 5 and Fig. 6) demonstrate that the simulator can be used to evaluate the indoor condition of daylight both at a specific time and during a daytime.

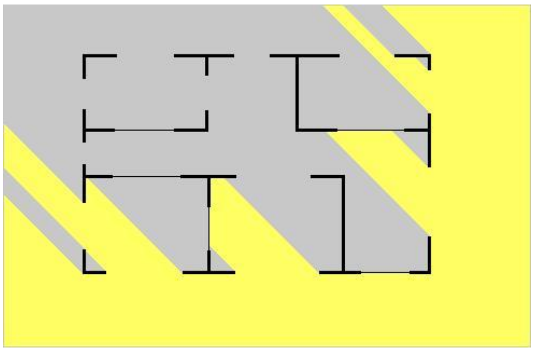

Fig. 5. Daylight of a residence at 9:00

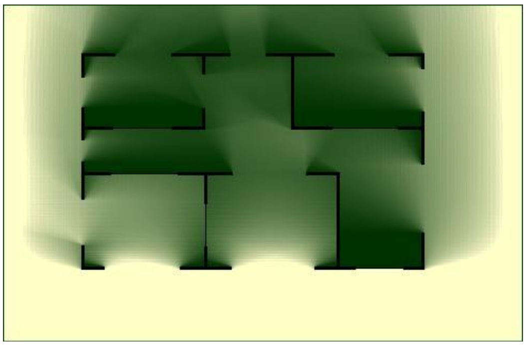

Fig. 6. Daylight of a residence through the daytime

4.2 Simulation of Daylight of a Roof

The amount of insolation of a roof can be checked by applying this simulator.

A roof and the hip of a roof are newly added to the type of a cell. Furthermore, the information on an amount of insolation is added to the state of a cell. The amount of insolation refers to METPV-3 [4].

METPV-3 is a database of insolation in Japan. It has data of various amounts of insolation (such as amount of global solar radiation (the sum of direct sunlight and skylight), the amount of insolation which enters into a slope) in each area.

Fig.7 is the example of a roof used for the simulation. Since an amount of insolation changes with the angles of direction of a roof, it changes a color. The roof on which a color is different is considered that the type of a cell is also different.

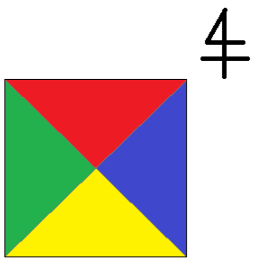

Fig. 7. The example of a roof

Light goes straight on until it strikes upon the hip of a roof. In the roof through which light passed, the amount of global solar radiation is added to the cell which light passed. Moreover, the amount of insolation of skylight is added to the roof through which light did not pass.

Fig. 8 is the simulation result of the amount of insolation of a roof. Table 1 is a setup of a simulation. This figure shows the place with many amounts of insolation more brightly.

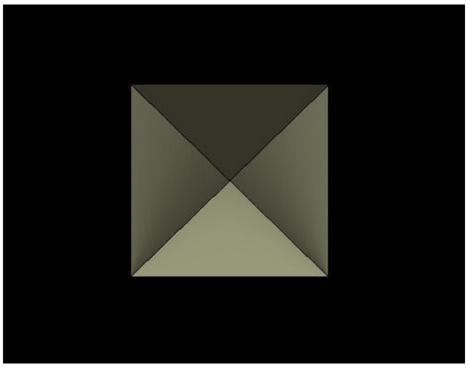

Fig. 8. The amount of insolation of a roof

Table 1. Setup of a simulation

Area	Tokyo
Date	Mid-March
Weather	Shine
A Cell Size	0.01 [m^2]
The angle of gradient of a roof	30°

The fault of this simulation is that the amount of insolation of the top of a roof is smaller than the actual condition. It is necessary to improve by setting up the information such as height.

Fig. 9 is a calculation result of the amount of insolation of the roof of each time. Since the amount of insolation of the roof facing east and west become the maximum around 10:00 and 14:00, respectively, that influence appears in this graph.

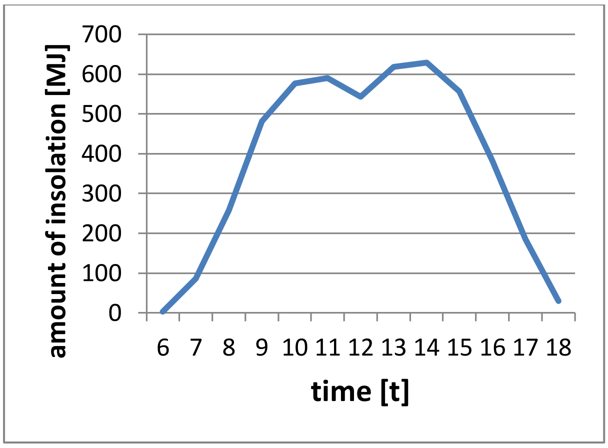

Fig. 9. The amount of insolation of each time

If a part with many amounts of insolation is known, it will be made to reference when performing the simulation such as a photovoltaic generation.

5 DISCUSSIONS

A conventional simulator needs the detailed information on a residence to calculate internal brightness. However, this simulator requires only a floor plan diagram because it does not calculate brightness.

Additional advantage of the simulator comes from the cellular automata model. Because cellular automata can express another new phenomenon easily by adding a new transition rule, the simulator in principle could estimate the room temperature. Since the current simulator could not involve air circulation, it cannot estimate the temperature.

We consider the simulation of a photovoltaic generation as an application of this simulator. The electricity generated of photovoltaic generation is calculable if an amount of insolation is known. If the electricity generated can be predicted only from one image, the advantage of not needing special knowledge will be made. Moreover, a simulation including an atmospheric state (for example, the simulation in the situation where snow lies on the roof) is also considered by using cellular automata.

6 CONCLUSION

A solar insolation simulator is introduced incorporating cellular automata. Simulations demonstrated that the simulator can estimate daylight of a residence using a floor plan diagram.

The simulator could also estimate the amount of insolation of a roof.

Abstract: The present study examines a possibility of new AIDS treatment without using anti-HIV-1 drugs to avoid drug resistance. Our idea originated in Eigen [1] is by inducing excess mutations to HIV-1 genome, to drive HIV-1 population to destruction. Namely, we use the high mutation rate of HIV-1 as an underhanded way.

Our study proposes a novel HIV-1 mathematical model considered viral kinetic processes such as mutation, replication, infection and an action of a mutagen to control HIV-1 mutation rate. Through some model simulations by computer it reports to drive HIV-1 population to the error catastrophe by increasing HIV-1 mutation rate.

Keywords: HIV-1, AIDS, Mathematical model, Error catastrophe, Mutagen

1 INTRODUCTION

HIV-1 is the causal virus for AIDS (Acquired Immune Deficiency Syndrome). AIDS treatment mainly depends on drug therapy and now four different types of drugs are used for the therapy. However troublingly all types of drugs easily develop drug resistance if they are used as the sole regimen. In order not to evolve drug resistance, highly active antiretroviral therapy (HAART) based on the administration of at least three different drugs has been executing. However HAART also is somewhat less than perfect in terms of drug adherence because AIDS patients suffer in adverse effects with long-term use. From these reasons, the present study examines a possibility of new AIDS treatment without using drugs. Our idea is by inducing excess mutations to HIV-1 genome, to lead HIV-1 population to destruction. Namely, this study uses the high mutation rate of HIV-1 as an underhanded way.

There were some experimental studies which reported that destruction of a viral population by inducing excess of mutations was achieved. Crotty's group demonstrated inducing excess mutations to poliovirus population by mutagenic action of ribavirin drives poliovirus to error catastrophe, thereby turning a productive infection into an abortive one [2]. Domingo's group reported a similar result on foot-and-mouth disease virus (FMDV) [3].

Meanwhile in the theoretical point of view, quasispecies theory built by Eigen provided a motivation for our study. A viral population structured and maintained by various mutants transiting each other through mutations is called quasispecies [4]. Quasispecies theory suggests when viral mutation rate is crossed a threshold value (called error threshold), viral population formed by the wild type as the primary member changes drastically into a different population dominated by only low fitness mutants This change means that wild type disappears and viral population loses its identity. In terms of HIV-1, it was reported that an estimated HIV-1 mutation rate is near the error threshold value predicted by quasispecies theory, thus HIV-1 barely might keep its identity [5].

Taking the above mentioned background into consideration, the present study proposes a HIV-1 mathematical model considered viral kinetic processes such as mutation, replication, infection and an action of a mutagen to control HIV-1 mutation rate. Through some model simulations by computer it reports it is possible to drive HIV-1 population to the error catastrophe by increasing HIV-1 mutation rate.

2 MODEL

This section proposes a mathematical model to simulate HIV-1 reproduction process. The reproduction process is divided into two phases: (1) replication and mutation process in infected CD4+Tcells and (2) budding and infectious process. First, we introduce a model to simulate HIV-1 replication and mutation process. We consider a quasi-species of HIV-1 population classified into four types: fast or low replication type and viable or defective type referring to [6]. We assume the viable type maintain an ability to permit replication and infection; the defective one can permit replication but has a deficiency of an ability for infection. In the viable (defective) type, we denote fast replicators to *V** (*D**); slow ones *v** (*d**) where infected state be denoted by an asterisk. The fast replicators have an average of *R* (greater than one) offspring; slow ones have *r* (less than one).

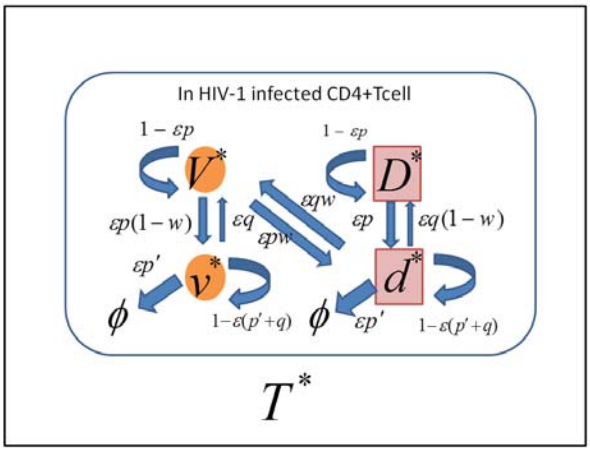

Fig. 1: HIV-1 kinetic processes of viral replication and mutation in HIV-1 infected CD4+T cell.

We assume mutational events occur between the four types. Fig. 1 is a schematic representation of possible mutations between them. This model assumes that (1) a fast replicator mutates a slow one with a mutation rate *p*; the inverse mutation which is called "backward mutation" occurs with a rate *q*, whose value is known very small and (2) small ratio (*w*) of mutated viable HIV-1 population mutates the defective type; the inverse mutation occurs at the same ratio. The replication and mutation process in Fig. 1 is formulated as a population dynamics:

$$\frac{dP_{V^*}}{dt} = F_{V^*}(P_{V^*}, P_{v^*}, P_{d^*}) \equiv R(1-\varepsilon p)P_{V^*} + r\varepsilon qP_{v^*} + r\varepsilon qwP_{d^*}$$

$$\frac{dP_{v^*}}{dt} = F_{v^*}(P_{V^*}, P_{v^*}) \equiv R\varepsilon(1-w)P_{V^*} + r(1-\varepsilon(p'+q))P_{v^*}$$

$$\frac{dP_{D^*}}{dt} = F_{D^*}(P_{D^*}, P_{d^*}) \equiv R(1-\varepsilon p)P_{D^*} + r\varepsilon q(1-w)P_{d^*}$$

$$\frac{dP_{d^*}}{dt} = F_{d^*}(P_{V^*}, P_{d^*}) \equiv R\varepsilon pwP_{V^*} + r(1-\varepsilon(p'+q))P_{d^*}$$

We next formulate HIV-1 infection and budding process represented schematically in Fig. 2. A role model of the process was proposed by Perelson[7] and Wei[8]. Our formulation is based on the role model. *T* and *T** denote uninfected and infected CD+4 T cells respectively. The four types of "free" HIV-1 are denoted by the previously given symbol without asterisk which means infected state. Uninfected CD+4 T cells are recruited at a birth rate λ and killed at a death rate *d*; infected ones are killed at δ. Viable and defective HIV-1 is released at a rate γ and s respectively from infected CD4+Tcells.

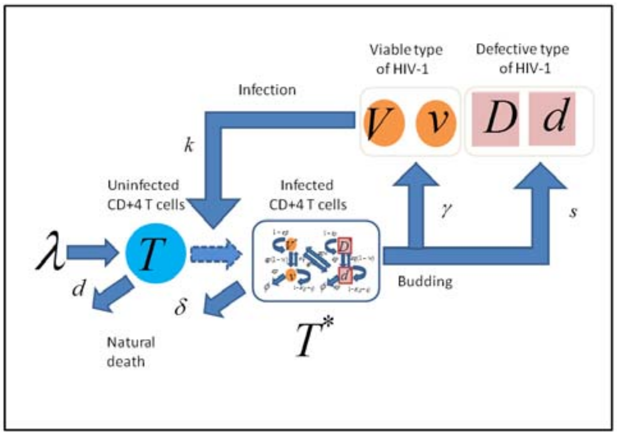

Fig. 2: HIV-1 infection and budding processes

The mutation and replication process of HIV-1 in infected CD4+Tcells and an infection and budding process of free HIV-1 are described by the following equations:

$$\frac{dP_T}{dt} = \lambda - dP_T - k(P_V + P_v)P_T$$

$$\frac{dP_{T^*}}{dt} = k(P_V + P_v)P_T - \delta P_{T^*}$$

$$\frac{dP_{V^*}}{dt} = F_{V^*}(P_{V^*}, P_{v^*}, P_{d^*}) + kvP_T - \delta P_{V^*} - \gamma P_{V^*}$$

$$\frac{dP_{v^*}}{dt} = F_{v^*}(P_{V^*}, P_{v^*}) + kvP_T - \delta P_{T^*} - sP_{d^*}$$

$$\frac{dP_{D^*}}{dt} = F_{D^*}(P_{D^*}, P_{d^*}) - \delta P_{T^*} - sP_{D^*}$$

$$\frac{dP_{d^*}}{dt} = F_{d^*}(P_{V^*}, P_{d^*}) - \delta P_{T^*} - sP_{d^*}$$

$$\frac{dP_V}{dt} = \gamma P_{V^*} - cP_V$$

$$\frac{dP_v}{dt} = \gamma P_{v^*} - cP_v$$

$$\frac{dP_D}{dt} = \gamma P_{D^*} - cP_D$$

$$\frac{dP_d}{dt} = \gamma P_{d^*} - cP_d$$

3 RESULTS AND DISCUSSIONS

3.1 A Mutagen's Action

Our scenario for AIDS treatment is to drive HIV-1 population to destruction due to the increase of the viral mutation rate by a mutagen. We examined feasibility of the scenario in simulations by controlling the parameter ε representing mutagen's action. Fig. 3 shows time series of viral load of free HIV-1 (V) when ε is 0.3, 0.6 and 0.9. The values of parameters except ε are $\lambda=10^4$ ml/day k=8x10^{-7} ml/day c=13 day^{-1} δ=0.7 day^{-1}, d=0.01 day^{-1}, R=1.3, r=0.1, p=0.5, q=0.09, w=0.2, p'=0.8 [9]. When a mutagen's action is relatively weak (ε=0.3), after a viral load once decreases, it continues to increase and finally leads to developing AIDS; when the mutagen's action is relatively strong (ε=0.9), a viral load continue to decrease slowly and viral eradication is achieved. This case indicates our scenario is feasible. Fig. 3 also clarifies the threshold value of ε of when the downward trend of the viral load changes into the upward trend is 0.8.

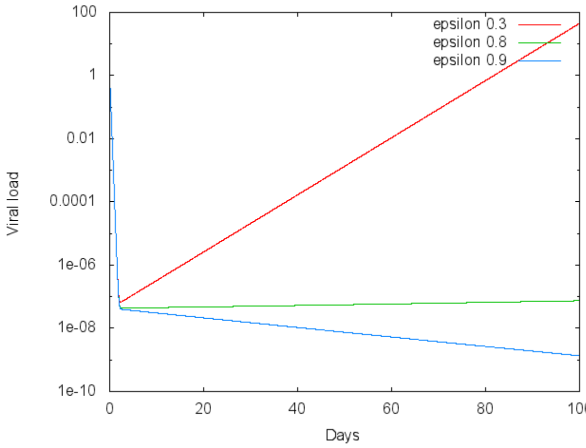

Fig. 3: The changes of time series of viral load over three cases of epsilon value

3.2 The Relationship between the Threshold Value of ε and a Replication Rate, R

We estimated threshold values of ε over the change of the parameter R. Fig. 4 shows the result. The figure indicates the threshold value of ε monotonically increases as parameter R increases. This means that if HIV-1 produces more offspring per replication, destructing HIV-1 population requires intensifying the mutagen's action ε.

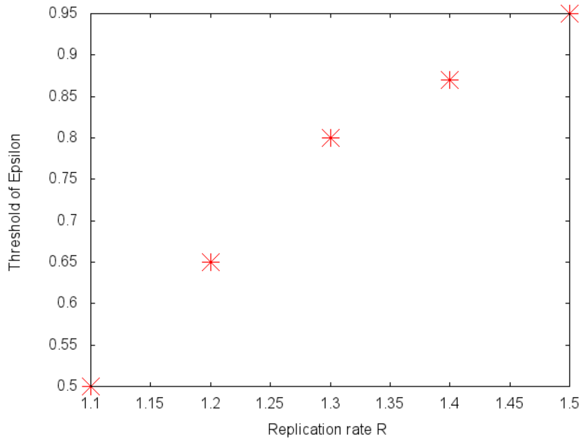

Fig.4: Threshold of the parameter ε versus viral replication rate R

3.3 Mutational Meltdown

The quasi-species theory proposes one scenario of viral extinction that when viral mutation rate is over the threshold value, the wild type disappears from the population and low fitness mutants dominate the population. This type of viral extinction means to lose the identity of the population.

This scenario in the case of our model is interpreted as the following condition:

$$P_V, P_{V*} = 0;\ P_v, P_{v*}, P_D, P_{D*}, P_d, P_{d*} \neq 0 (t \to +\infty).$$

Now we are studying whether this type of viral extinction occurs.

As another scenario of viral extinction, "mutational meltdown" is known. This scenario mentions all genotypes in the quasi-species disappear simultaneously. In the case of our model, this scenario is described as the followings:

$$P_V, P_{V*}, P_v, P_{v*}, P_D, P_{D*}, P_d, P_{d*} = 0\ (t \to +\infty).$$

The viral extinction observed in Fig. 3 corresponds to this type of extinction because the sum of four types of HIV-1 population decreases toward zero as displayed in Fig. 5

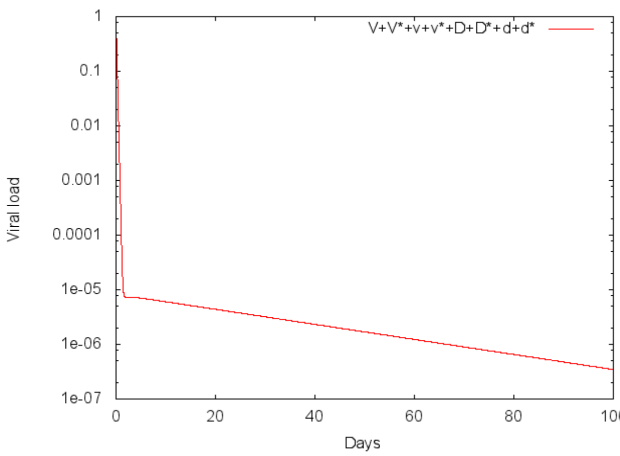

Fig. 5: A time series of the total viral population.

ACKNOWLEGEMENTS

This study was supported by Grant-in-Aid for Scientific Research(C) No.22500273 of Japan Society for the Promotion of Science (JSPS) from 2010 to 2011. We are grateful for their support.

Abstract: The present study has an interest on complexity produced by removing the original boundary between different classes of concepts and it removes a boundary between a state variable and its dynamics by interacting them circularly on a two dimensional cellular automaton. It clarifies that removing the boundary creates the complexity of changing simple periodic orbits into attractive ones and proves a theorem about a period which characterizes periodic behaviors observed in simulations.

Keywords: Cellular automaton, Boundary, Complexity, Periodic attractor

1 INTRODUCTION

The cellular automaton is a computation model driven by a simple rule which describes the time evolution of a state of each cell on a lattice space. Despite its simplicity, it is much applied to simulating from life phenomena to physical ones such as crystal growth, turbulence and so on. As a typical example of cellular automaton, "life game" invented by Conway is very popular [1]. His model is thought to be able to simulate various growth patterns of living systems therefore it is called Life game. Life game's rule is quiet simple: a state of a cell at the next time is determined by the total number of active cells in its neighborhood. Namely the future states are directly determined by the past ones (the state is driven by itself); the dynamics is invariant on time. Namely there is a boundary to discriminate the state variable and its dynamics. Most of the cellular automata are modeled by the same formulation.

Meanwhile, the present study has an interest on complexity produced by removing the boundary between different class of concepts. In immunology, Jerne removed the discrimination between antibody (recognizer) and antigen (recognized entity) whereby built a new immunological theory called idiotype network theory [2]. In computer science, Lisp computer language opened a possibility of new calculation called λ calculation by removing the boundary between function (rulers) and dummy arguments (subject) [3]. In game theory, we tried to remove a boundary between player's move and its strategy by introducing a meta-rule to interact them circularly [4][5]. Masumoto and Ikegami achieved openness of a strategy space by rebuilding a framework of the game by λ calculus [6].

This study focuses on removing a boundary between a state variable and its dynamics by introducing a circular interaction between them.

This paper is composed of six sections. The second section proposes a standard two dimensional cellular automaton driven by a basic rule without interaction between state variables and its dynamics and discusses its behaviors. This standard model provides a control against a new model considered the interaction. The third section proposes new two dimensional cellular automaton, which introduces a reciprocal determination process between a state variable and its dynamics. The firth section discusses an analogous relationship between the new model and a spatial game model. In the fifth section, considering the fact that the space-temporal patterns of the new model has some 1-,3-,6- and 9-period attractors, it proves two lemma and one theorem about a period of these attractors. The last section discusses how difference introducing the reciprocal determination process makes on the dynamical behaviors.

2 ONE WAY DETERMINATION FROM A DYAMICS TO ITS VARIABLES

We consider a two dimensional square lattice with a size of its side, N. To designate a site of each cell, we prepare a horizontal and vertical axis with a suffix *i*, *j* respectively and place the origin at the top left of the lattice. The suffixes *i* and *j* take an integer value from 0 to *N*-1. We let a symbol $A^r_{i,j}$ to denote a state variable of a lattice cell (*i*, *j*) at the time *r* and the variable takes which of the two states:0 and 1. As a dynamical system of state variable $A^r_{i,j}$, we consider a linear system as the followings:

$$A^{r+1}_{i,j} = F(\vec{b}, \vec{A}^r_{i,j}) \equiv \vec{b} \cdot \vec{A}^r_{i,j}, \tag{1}$$

where $\vec{b}$ is a vector of coefficient parameters and is defined as $\vec{b} = (b_0, b_1, b_2, b_3, b_4, b_5, b_6, b_7, b_8)$ but $b_k = 1, b_i = 0 (i \neq k)$; $\vec{A}^{r+1}_{i,j}$ is defined as $(A^r_{i-1,j-1}, A^r_{i,j-1}, A^r_{i+1,j-1}, A^r_{i+1,j}, A^r_{i+1,j+1}, A^r_{i,j+1}, A^r_{i-1,j+1}, A^r_{i,j})$. As shown in Fig. 1, each component of the vector $\vec{A}^r_{i,j}$ arranges in a clockwise fashion from the upper left of the site (*i*,*j*)

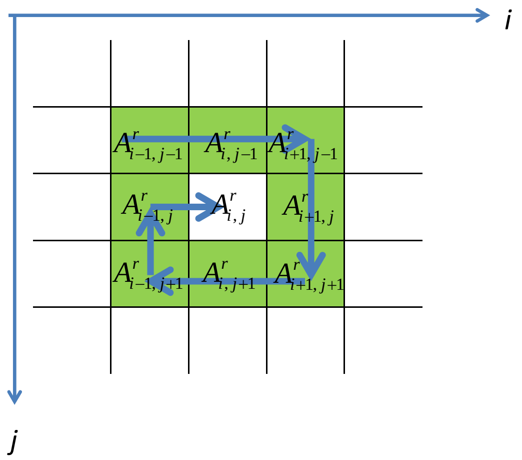

Fig.1. Arrangement of each component of the vector $\vec{A}^r_{i,j}$

2.2 Dynamic behaviors

Assuming the periodic boundary, a time evolution of spatial-temporal pattern of state variables is easily imagined from the model's definition. Only periodic motions in one direction which is determined by the vector $\vec{b}$ are observed. For example, when *k* is one, any spatial-temporal pattern moves downwards. In another case of *k* is three, any pattern moves leftwards. A period *T* is determined by *N* and is given as divisor of *N*. For example, *N* is four, *T* is one, two and four.

3 RECIPROCAL DETERMINATION BETWEEN VARIABLES AND ITS DYNAMICS

This study interests a reciprocal determination process between the state variables and its dynamics thus considers to update the parameter $\vec{b}$ through the time evolution of the state variables $\vec{A}^r_{i,j}$.We define a function $g(\vec{A}^r_{i,j})$ to calculate the sum of all cells' state in the Moore neighborhood of the cell (*i*,*j*) as

$$g(\vec{A}^r_{i,j}) = \sum_{i'=i-1}^{i+1} \sum_{j'=j-1}^{j+1} A^r_{i',j'} \quad . \tag{2}$$

Then through the value of $g(\vec{A}^r_{i,j})$ we update the parameter $\vec{b}$ as following:

When $g(\vec{A}^r_{i,j})$ is equal with *k*,

$$b^r_i = \begin{cases} 1 & (i = k) \\ 0 & (i \neq k) \end{cases} \tag{3}$$

After all, Eq.(1) results in

$$A^{r+1}_{i,j} = F(\vec{b}^r, \vec{A}^r_{i,j}) \equiv \vec{b}^r \cdot \vec{A}^r_{i,j}. \tag{4}$$

Fig.2 shows a situation that the state variable and its dynamics determine circularly.

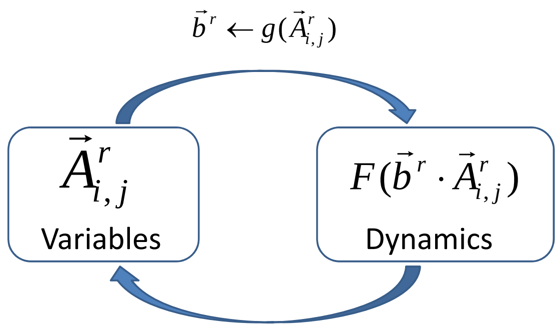

Fig.2 Reciprocal determination process between variables and its dynamics

4 A VIEW FROM SPATIAL GAME MODELS

Our proposed model is a particular kind of spatial game systems. In the common spatial games, a player has a game with each of its neighborhood players and in the next round uses the move of the highest scoring player among them.

We mention the correspondence relationship between the common spatial game model and our proposed model. We let the state variable $A^r_{i,j}$ to represent a move of a player at the site (*i*,*j*) at a certain time *r* thus a player's move is 0 or 1.

When the player (*i*,*j*) has a game with each of its Moore neighborhood players, our model determines the highest scoring player by the function $g(\vec{A}^{r}_{i,j})$. Concretely speaking, when the value of g is k, our model let the highest scoring player to be the one in the k-th site in the clockwise fashion from the top-left of the site (i,j). Fig. 3 shows a case of k is 4. Meanwhile, we can construe determining $A^{r+1}_{i,j}$ by Eq. (4) as for the player (i,j) to copy the highest scoring player's move as its own move at the next round, which is known as the copy strategy in the common spatial games.

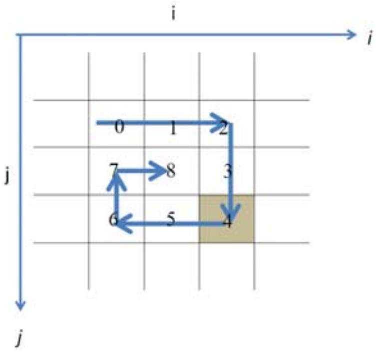

Fig. 3 A rule to assign k to each site. When k is 4, gray colored cell is selected as the highest scoring player's site.

In the present game, what sort of game situation must be established for a player to win? Only when not only the player but also all of the neighborhood players choose the same move 1, the player can be the winner.

The uniform state of all players taking the specific move 0 or 1 is unstable. Because when one player takes a opposite move in the uniform state, the system unable to return the original state.

5 THEOREMS ABOUT PERIODIC BEHAVIORS

We examined all of spatial temporal patterns observed in the case of the system size is 3 and clarified the emerged patterns are periodic and they are classified into 1, 3, 6 and 9 period. Fig. 4 is a typical example of the observed periodic behaviors. This section discusses why the observed period is limited to multiples of 3. We first mention a lemma on determination of the period. For the proof, we define two symbols: P^r and $S_{L,L'}$. Let P^r to be a configuration pattern of all players' action at the round r. Let $S_{L,L'}$ to be a translation to shift a configuration pattern P by L and L' in a vertical and horizontal direction respectively.

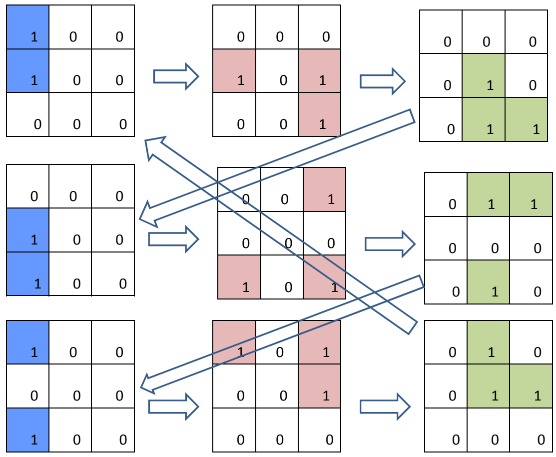

Fig. 3 Period-9 behavior

Lemma 1

Assume L, L' and n such that $S_{L,L'}P^1 = P^{n+1}$ exist, then $S_{L,L'}P^r = P^{n+r}$ for any r succeeds.

Proof

The assumption $S_{L,L'}P^1 = P^{n+1}$ succeeds thus for any i, j,

$$A^1_{i,j} = A^{n+1}_{i+L,j+L'}. \tag{5}$$

Eq. (5) leads to

$$\vec{A}^1_{i,j} = \vec{A}^{n+1}_{i+L,j+L'}. \tag{6}$$

And from Eq. (6),

$$g(\vec{A}^1_{i,j}) = g(\vec{A}^{n+1}_{i+L,j+L'}) \tag{7}$$

Due to Eqs. (6) and (7), for any i, j

$$A^2_{i,j} = A^{n+2}_{i+L,j+L'} \tag{8}$$

Therefore,

$$S_{L,L'}P^2 = P^{n+2} \tag{9}$$

Through the same discussions, for any r,

$$S_{L,L'}P^r = P^{n+r} \tag{10}$$

On the basis of lemma 1, we prove a theorem on the period of the dynamics.

Theorem

Assume $S_{L,L'}P^k = P^{n+k}$ and $S^r_{L,L'}P^1 = P^1$ then the period T is given as $n \times r$.

Proof

By the first assumption,

$$P^{2n+1} = S_{L,L'}P^{n+1} = S^2_{L,L'}P^1 \tag{11}$$

Applying S to Eq. (11) for r-2 times,

$$P^{r\times n+1} = S^r_{L,L'}P^1 \tag{12}$$

By the second assamption and Eq. (1),

$$P^{r\times n+1} = P^1 \tag{13}$$

So that

$$T = r \times n. \tag{14}$$

The following lemma answers how r is determined.

Lemma 2

Assume $S^{r}_{L,L'}P^{1} = P^{1}$, $L \neq 0$ and $L' \neq 0$ then

$$r = L.C.M\left(L.C.M(N,|L|)/|L|,\ L.C.M(N,|L'|)/|L'|\right).$$

But if $L(L') = 0$ then

$$r = L.C.M(N,|L|)/|L| \ \ (L.C.M(N,|L'|)/|L'|)$$

where $L.C.M(x,y)$ represents least common multiple of x and y.

Referring to lemma 2, we try to answer why the period is the multiple of 3 when the system size N=3.

All possibilities of (L,L') on the parallel translation $S^{r}_{L,L'}$ is (1,0),(0,1),(1,1),(2,0),(0,2),(2,1),(1,2) and (2,2).

1. $(L,L') = (1{,}0),(01)$
   $r = L.C.M(3{,}1) = 3.$
2. $(L,L') = (1{,}1)$
   $r = L.C.M\left(L.C.M(3{,}1), L.C.M(3{,}1)\right)$
   $= L.C.M(3{,}3) = 3$
3. $(L,L') = (2{,}0),(0{,}2)$
   $r = L.C.M(3{,}2)/2 = 6/2 = 3.$
4. $(L,L') = (2{,}1),(1{,}2)$
   $r = L.C.M\left(L.C.M(3{,}2)/2, L.C.M(3{,}1)/1\right)$
   $= L.C.M(3{,}3) = 3$
5. $(L,L') = (2{,}2)$
   $r = L.C.M\left(L.C.M(3{,}2)/2, L.C.M(3{,}2)/2\right)$
   $= L.C.M(3{,}3) = 3$

In all the cases, r is 3 thus based on the theorem the period is limited to the multiple of 3. This result is consistent with the fact that the observed period is 3, 6 and 9.

6 DISCUSSIONS

The main interest of the present study is what is the characteristic behaviors created by the reciprocal determination process between the variable and its dynamics. To clarify this question, we prepared two models: the former is not taken the reciprocal determination process between the variable and its dynamics into consideration and the latter is done, and examined the difference of behaviors between the former and the latter. The both models have periodic orbits but only the latter's periodic orbit is "attractive". Fig. 5 displays 3-period attractor and some part of its basin structure and shows the process of 6 different spatial patterns suctioned into the 3-periodic orbit.

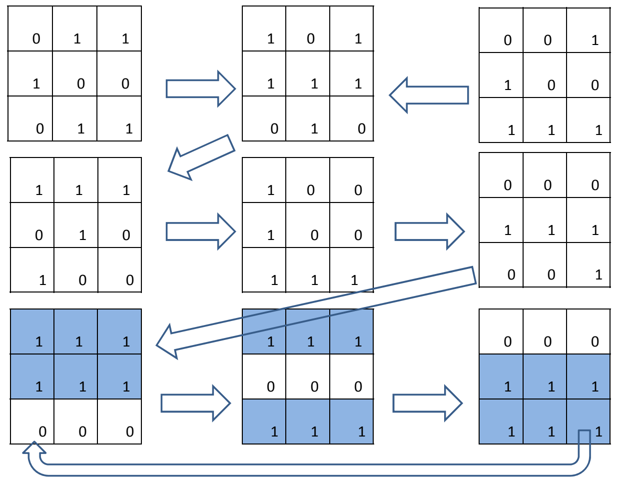

Fig. 5 3-periodic attractor

As a future work, we will clarify why non attractive periodic orbits transmutes into attractive ones by introducing the reciprocal determination process between the variable and its dynamics.

ACKNOWLEGEMENTS

This study was supported by Grant-in-Aid for Scientific Research(C) No.22500273 of Japan Society for the Promotion of Science (JSPS) from 2010 to 2011. We are grateful for their support.

Abstract: Among self-action networks: self-recognition network and self-repairing networks, the self-repairing network allows the state change of nodes as a result of action (repair). The self-repair network is extended to allow network change as a result of action (rewire). Self-rewiring algorithm is also extended from the self-repairing algorithm. The extended algorithm can be applied to several problems such as stable marriage problem and distance adjustment problem. Comparison between node repair and link rewire as well as further extension will be discussed.

Keywords: Network rewiring, self-action network, self-repairing network, probabilistic algorithm.

1 INTRODUCTION

Dynamic network has been attracting attention for large-scale systems such as genetic network, collaboration network. Preferential attachment of link has been studied extensively after pioneering work by Barabási, Albert and Jeong [1]. In contrast to such dynamic and growing networks, rewiring networks, which assumes preferential rewiring (of existing links) [2] rather than attachment also have been studied. The model and algorithm proposed here belongs to the latter class: network rewiring models. The self-rewiring algorithm proposed can also be understood as a generalization of Gale-Shapley algorithm [3, 4].

We have been studying self-action networks where the actions by nodes through arcs mutually affect the state of nodes, and the state of nodes in turn affects the result of the actions. As self-action networks, two networks (i.e., self-recognition network [5, 6, 7] and self-repairing network [8]) has already been proposed. The remarkable feature of self-action networks is that each agent (expressed as a node in the network) not only acts on other agents that are connected (expressed by an arc in the network) but also being acted from other agents connected. This paper proposes yet another self-action network: a self-rewiring network as an extension of self-repairing network. In the self-rewiring network, each agent indirectly acts on other agents through reconfiguration of arcs (or edges).

Self-recognition network assumes recognition of other agents as the self-action. Expressed by a graph, agents correspond to nodes; recognition to arcs; and results of the recognition to sign associated to the arc.

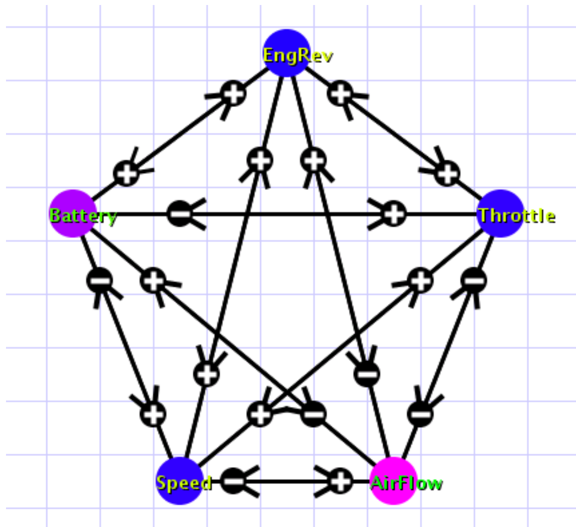

Fig.1 An example of self-recognition netwo rk for automobile engine diagnosis.
EngRev: Engine revolutions; Battery: Batt ery voltage. Gray level in the nodes indicat es credibility. Dark nodes correspond to hig h credibility, while light nodes to low credi bility (i.e. evaluated as faulty) [6].

Fig. 1 shows an example of self-recognition network expressed by a graph. The self-recognition network and technology to build the network have been extensively studied to apply to automobile engine [6], home security [9], motherboard [10], and information security [11]. The self-recognition network can be technique to recon ciliate and unify the observed data and inference, similarly to data reconciliation and can be related to data assimilation [12]. The self-recognition network where the recognition is based on the physical relation is also comparable to on-line simulation [13] where missing data will be inter- or extrapolated based on the observed data.

Self-repairing network, on the other hand, assumes repairing on other agents as the self-action. It can be expressed by a graph similarly to the self-recognition network. However, to derive significant results such as critical phenomena for a network cleaning problem [6], regular graph (as is often the case in cellular automata) is often assumed. While the self-recognition network assumes sensor networks as a potential application area, the self-repairing network assumes actuator network for applications. Both self-recognition and self-repairing network can be applied to a computer network where recognition as well as (software) repair are possible.

Section 2 briefly reviews the self-repairing network. Section 3 proposes a self-rewiring network and self-rewiring algorithm based on the self-repairing network. Section 4 presents possible applications to stable marriage problem and distance adjustment problem that intrinsically require network rewiring.

2 SELF-REPAIRING NETWORKS

A self-repairing network consists of agents capable of repairing other agents connected. In this study, each agent is placed at each node of one-dimensional lattice (Fig. 1) with a periodic boundary condition (leftmost

Fig.2 Cellular automaton with one-dimensional lattice and two states: normal (0) and abnormal (1) [6]

agent and rightmost agent are connected). Each agent has two states: normal (0) and abnormal (1).

Each agent tries to repair its neighbor agents. However, since the repairing is done possibly by abnormal agents, the repair could damage the neighbor agents rather than repair. Frequency of the repair trial is controlled by a parameter: repair rate ***Pr***. As shown in Fig. 3, the repair will be successful with a rate ***Prn*** (the repair success rate by normal agents) when the repair is done by a normal agent, and with a rate ***Pra*** (the repair success rate by abnormal agents) when it is done by an abnormal agent.

Self-repairing network consists of three elements (***U***, ***T***, ***R***) where ***U*** is a set of nodes, ***T*** is a topology connecting the nodes, and ***R*** is a set of rules of the interaction among nodes. A set of nodes is a finite set with ***N*** nodes, and the topology could be n-dimensional

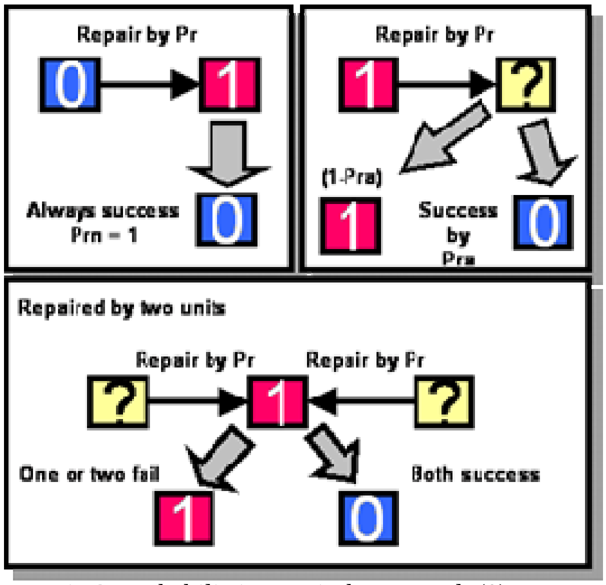

Fig.3 Probabilistic repair by normal (0) agents (*above left*) and by abnormal (1) agents (*above right*). Repair by two agents (*below*) [6].

array, complete graph, random graph, or even scale-free network where each node could have *S* neighbors for each nodes with a boundary condition, i.e. the structure of the array is a ring with node 1 adjacent to the node *N*. Also, we restrict the case where each node has a binary state: normal (0) and abnormal (1). Each node tries to repair the adjacent nodes in a synchronous fashion with a probability $\boldsymbol{P_r}$. The repairing will be successful with the probability $\boldsymbol{P_{rn}}$ when it is done by a normal node, but with the probability $\boldsymbol{P_{ra}}$ when by an abnormal node ($\boldsymbol{P_{ra}} < \boldsymbol{P_{rn}}$). The repaired nodes will be normal when all the repairing is successful. Thus, when repairing is done by the two adjacent nodes, all these two repairing must be successful in order for the repaired node to be normal.

3 SELF-REWIRING NETWORKS

Self-repairing network and its probabilistic repairing algorithm have been extended to include not only node repair but also link rewiring. The extended model and algorithm can deal with a wide variety of problems that require link rewiring to be solved. Such problems range from a naïve matching problem of Stable Marriage Problem (that requires link rewiring in bipartite graph) to a practical adjustment problem of inter satellites distance in the system of autonomous networked satellites.

In the extension, each node will evaluate the current link and rewire it from the current target node to other target node by conditions specific to the problem. Since

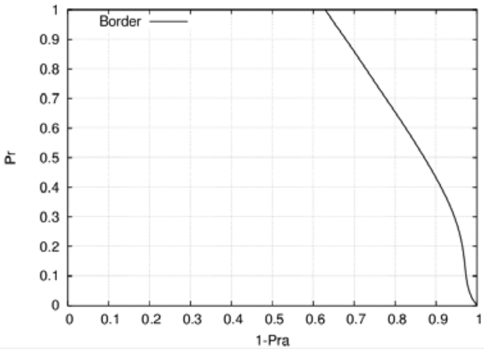

Fig.4 Frozen Phase (*left region* where all the agents are normal) and Active Phase (*right region* where some units remain to be abnormal) [6].

the evaluation will be done by a node with limited information, the evaluation could be wrong, hence the "double edged sward" would take place similarly to the original self-repairing network.

Self-repairing network with the probabilistic repairing algorithm is known to have a specific threshold in model parameters to eradicate all the abnormal nodes. This paper investigates if such specific threshold exists for the extended Self-repairing network in the network rewiring. If the threshold exists, engineering should be carried out in the close vicinity of the threshold, for the phase may be critically changed across the threshold, while the parameter regions far from the threshold need not be carefully managed.

Although the self-repairing networks assume a fixed network, the self-rewiring networks allow the network to change the connection. The state of nodes: normal or abnormal depends on the connection of the node. Normal state should be understood as the state that the agent cannot be better by changing the links incident to the node, while abnormal state as the state that agent can improve by changing the links. The self-rewiring algorithm can be similarly defined to the self-repairing algorithm.

[Step 1] Each agent will be activated with a probability *Pr*.

[Step 2] For the activated agent, try to activate the link with a probability proportional to the preference.

[Step 3] The other agent connected by the activated agent will accept the connection, if the connection improves the agent.

With this algorithm, all the agents become normal state, and this all normal state is a probabilistically stable. That is, once all nodes become normal state with a certain configuration, then transition probability to other configuration is smaller than the transition probability to the attained configuration.

4 APPLICATIONS OF THE SELF-REWIRING NETWORK

4.1 Stable Marriage Problem

The Stable Marriage Problem (SMP) assumes n women and n men each of them has an ordered preference list (or a rank) without tie to the opposite sex. As in the example shown in Fig. 5, the men m_2 has an ordered preference list (w_2, w_3, w_1) or a rank (2, 3, 1), which means m_2 likes w_2 best, and he prefers w_3 to w_1.

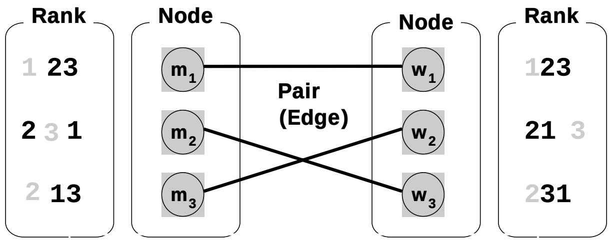

Fig. 5. An illustration of Stable Marriage Problem with size three.

Under the above assumptions, SMP seeks for the complete matching between n women and n men, which satisfies stability. The stability requires the concept of blocking pair. Two pairs (m_i, w_p) and (m_j, w_q) are blocked by the pair (m_i, w_q) if m_i, prefers w_q to w_p and w_q prefers m_i to m_j. For example, a pair (m_2, w_3) and (m_3, w_2) will be blocked by the pair (m_2,w_2). A complete matching without being blocked is called *stable* matching.

Self-rewiring algorithm applied to SMP may be summarized as follows:

[Step 1] For each agent, activate the agent with a probability *Pr*.

[Step 2] For the activated agent, try to find a higher rank with a probability proportional to the preference.

[Step 3] For the new partner agent being proposed in the previous step, accept the proposal if the new partner agent does not have the current partner, or the new partner agent has a higher rank on the proposing agent than the current partner.

In selecting agent in the step 1, the agents can be selected from male (female, or don't care) agent if the algorithm assumes male (female-optimal, or gender does not matter) as the proposing side (Fig. 6).

4.2 Simulation Result

We consider an instance of SMP with size 3 where every man has a fixed ordered preference list (w_0, w_1,

w_2) and every woman also has a fixed ordered preference list (m_0, m_1, m_2). In the simulation below, male is set to be the proposing side. In the Gale-Shapley algorithm, male-optimal solution will be obtained when the proposing side is fixed to the male side. In the self-rewiring algorithm, however, female side can attain optimal solution with a certain probability (Fig. 6).

In each plots of Fig. 6, horizontal axis is time step and vertical axis the rank attained for each individual shown line type. Figures left are the attained rank for male; and those right are the rank for female. Upper figures are when *Pr* =0.3 and those lower are when *Pr* =0.9. As *Pr* increases, female side attains happier matching (closer to female-optimal). This is because higher *Pr* would lead to more simultaneous proposals to a woman, which will give the woman a chance to select her preferred proposal.

Additional difference from the Gale-Shapley algorithm is on the concept of stability. Although Gale-Shapley algorithm obtain a stable matching, the network rewiring algorithm would obtain the distribution of matchings including all the stable matchings as well as the unstable ones with blocking pairs with a smaller probability than the ones for stable matchings (Fig. 6).

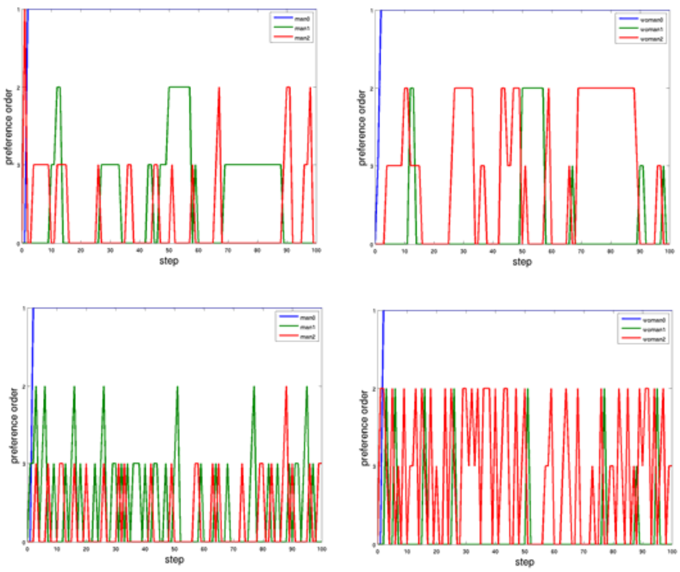

Fig. 6 Probabilistic rewiring applied to the Stable Marriage Problem with size three.

5 DISCUSSIONS

Since the self-rewiring network and algorithm are extension of the self-repairing network and algorithm, they share some commonalities. If we regard the normal state of agents as favorable state of agents (as in the Stable Marriage Problem above) defined similarly to the Nash equilibrium that any rewiring would not improve the satisfaction of agents, then self-rewiring algorithm also allows the normal state to spread.

Although simple and naïve problem of Stable Marriage Problem is used for illustrative purpose, the self-rewiring algorithm could be used for many other problems such as a distance adjustment problem (agents placed in a space will adjust their relative positions to meet a given constraint); and dynamic reconfiguration for embedded systems.

Abstract: In our previous studies, we have proposed an immunity-based statistical en-route filtering (ImSEF) to not only eliminate false data injection attack in wireless sensor networks but also identify compromised nodes which are injecting false data. Some simulation results showed that ImSEF outperformed the original SEF. However, ImSEF does not deal with false negative attack where a compromised node can block legitimate reports from forwarding through it. In addition, ImSEF mistakenly filter out legitimate reports en-route with low probability (mistaken filter). In this paper, we propose a multipath immunity-based statistical en-route filtering (ImMEF) to combat both the false negative attack and the mistaken filter. Like a multipath en-route filtering method (MEF) proposed by Kim and Cho, ImMEF exploits a multipath routing technique and a random key pre-distribution scheme for key assignment. We carry out some simulations to evaluate the performance of ImMEF.

Keywords: Wireless sensor networks, Statistical en-route filtering, Immunity-based approach, Multipath routing

1 INTRODUCTION

Wireless sensor networks consisting of many small and cheap sensor nodes may be deployed in a potentially adverse environment where an attacker can launch various kinds of threats. *False data injection attack*, which is also called *false positive attack*, is that sensor nodes compromised by an attacker can inject false reports of non-existing or bogus events. The attack may cause not only false alarms but also the waste of the limited energy of the nodes forwarding these reports. A *statistical en-route filtering* (SEF) [1] and several revised schemes [2-4] have been proposed to combat the attack.

In our previous studies [5-7], we also have proposed an *immunity-based statistical en-route filtering* (ImSEF) to identify compromised nodes and achieve earlier detection of false reports. In ImSEF, each node assigns *credibility* to its neighboring nodes and updates the credibility based on the success or failure of filtering and transmission. And then each node uses the updated credibility as the probability of the next communication. Both simulation results and mathematical analyses [6,7] showed that ImSEF outperformed the original SEF. However, SEF and ImSEF do not deal with *false negative attack* where a compromised node can block legitimate reports from forwarding through it. As a result, users cannot receive the legitimate reports and cannot take appropriate countermeasures. In addition, ImSEF mistakenly filters out legitimate reports en-route with low probability (*mistaken filter*) in the environment where both legitimate and fake reports exist.

In this paper, we propose a *multipath immunity-based statistical en-route filtering* (ImMEF) to deal with not only false negative attack but also mistaken filter. Like a *multipath en-route filtering method* (MEF) proposed by Kim and Cho [3], ImMEF also exploits a multipath routing technique and a random key pre-distribution scheme for key assignment. We carry out some preliminary simulations to evaluate the performance of ImMEF.

2 SENSOR NETWORK MODEL

Following the previous studies on SEF, we consider a large-sized sensor network composed of a lot of sensor nodes and a base station (BS) which is a data collection center. We further assume that the nodes are deployed at a high density, so that an event (sensing target) can be detected by multiple surrounding nodes. It is unnecessary for each of the detecting nodes to send the event report (e.g., the location, the time, and the type of event) to the BS, so that one of them is elected as cluster head (CH). The CH collects all the event reports from all the detecting nodes and forwards a synthesized report to the BS. The report potentially traverses a large number of hops.

We assume that an attacker can compromise some nodes to obtain the security information installed in the nodes. Once compromised, the nodes can be used to inject false data reports of bogus events. Such an attack is called a *false data injection attack* (*false positive attack*). This paper also focuses on *false negative attacks* where a compromised node can block legitimate reports from forwarding through it. However, we consider that the attacker cannot defeat the BS because the BS has powerful security.

3 IMMUNITY-BASED STATISTICAL EN-ROUTE FILTERING (ImSEF) [5-7]

SEF and ImSEF can probabilistically filter out false reports en-route. They exploit collective decision-making by multiple detecting nodes and collective false detection by multiple forwarding nodes. They consist of three major components: (1) key assignment and report generation, (2) en-route filtering, and (3) base station verification. In addition, ImSEF has the credibility update and the communication based on the updated credibility.

3.1 Key Assignment and Report Generation

The process of key assignment and report generation in ImSEF is as follows.

1) The BS maintains a global key pool of N secret keys $\{K_i, 0 \leq i \leq N-1\}$, divided into n non-overlapping partitions $\{P_j, 0 \leq j \leq n-1\}$. Each partition has m keys (i.e., $N = m\ n$). A simple way to partition the key pool is $P_j = \{K_i | jm \leq i \leq (j+1)m - 1\}$.
2) Before each sensor node is deployed, it stores randomly chosen k ($k < m$) keys from a randomly selected partition in the key pool.
3) After all the nodes are deployed, they broadcast their indexes to their neighboring nodes within one-hop distance. Every node receives the message from each of its neighbors, establishes a list of neighboring nodes, and then assigns a state variable $R(t) \in [0, 1]$ indicating the *credibility of neighbor* to each neighboring node. The initial value of credibility $R(0)$ is set to 1.
4) When an event appears, multiple surrounding nodes can detect the event. A CH is elected from the detecting nodes for creating the synthesized event report.
5) Each of the nodes that detected the event generates a keyed message authentication code (MAC) M_i using the event report E and a randomly selected K_i, one of its k stored keys. Each detecting node then sends the key index and the MAC, $\{i, M_i\}$, to the CH. K_i is secret while M_i is public.
6) The CH collects all the $\{i, M_i\}$s from the detecting nodes and randomly chooses T MACs from distinct partitions. This set of multiple MACs acts as the proof that the report is legitimate. Then the CH sends the final report with T attached key indices and T MACs, e.g. $\{E, i_1, M_{i1}, i_2, M_{i2}, \ldots, i_T, M_{iT}\}$, toward the BS.

Fig. 1 depicts an example of the key assignment and report generation in ImSEF. In this figure, the BS has a global key pool of N = 12 keys divided into n = 4 partitions, each of which has m = 3 keys. Each node randomly picks k = 2 secret keys from one partition of the key pool. After each detecting node endorses the event report by producing a keyed MAC using one of its 2 stored keys, the CH collects all the MACs from the detecting nodes and attaches randomly selected T = 3 MACs, that is, M_2, M_9, and M_{10}, to the event report E.

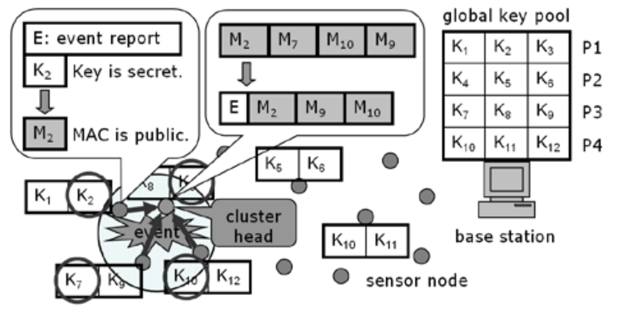

Fig. 1. An example of the key assignment and report generation in ImSEF [5].

3.2 En-Route Filtering and Credibility Update

In the en-route filtering component of SEF and ImSEF, intermediate forwarding nodes verify the correctness of the MACs probabilistically, and drop a report with forged MACs en-route. ImSEF also performs the credibility update and the communication based on the updated credibility. The process of en-route filtering in ImSEF is as follows.

1) Forwarding node j receives a report from the previous neighboring node i in proportion to the credibility $R_{ji}(t)$ of node i. In other words, node j drops a report from node i with the probability (1 - $R_{ji}(t)$) unconditionally and finishes the filtering process.
2) Since a legitimate report carries exactly T MACs produced by T keys of distinct partitions, a report with fewer than T MACs or more than one MAC in the same partition is dropped. Node j decreases the credibility $R_{ji}(t)$ of the previous node i and finishes the filtering process.
3) For the randomized key assignment, node j has a certain probability of possessing one of the keys that are used to produce the T MACs. If node j finds out that it has one of the T keys in the report, then it reproduces the MAC using its stored key and compares the result with the corresponding MAC attached to the report. If the reproduced MAC is different from the attached one, then the report is

dropped, the credibility $R_{ji}(t)$ of the previous node i decreases, and the filtering process is finished.

4) If node j verifies the reproduced MAC is the same as the attached one or if node j does not have any of the T keys, then it forwards the report to the next neighboring node k and replies an acceptance message to the previous node i to inform that the validation of the report is successful. Note that node j does not reply to node i if it discards the report.

5) Node j waits a reply from the next node k for a certain time. If node j can receive the reply from the next node k, it increases the credibility $R_{ji}(t)$ of the previous node i. Otherwise it decreases $R_{ji}(t)$.

To sum up the credibility update, node j updates the credibility $R_{ji}(t)$ of the previous node i based on its filtering result or the reply from the next node k as follows:

$$R_{ji}(t+1) = \begin{cases} R_{ji}(t) + \Delta_s & \text{if node } j \text{ receives the reply from next node } k \\ R_{ji}(t) - \Delta_f & \text{if node } j \text{ does not receives the reply from next node } k \\ R_{ji}(t) - \Delta_d & \text{if node } j \text{ drops the report} \end{cases}$$

For example, in Fig. 2, node i increases the credibility R_{ih} of the previous node h because the reply from the next node j can be received. However, node j decreases the credibility R_{ji} of the previous node i because the next node k drops the report and does not reply to node j. Since node k discards the report by itself, the credibility R_{kj} of the previous node j also decreases. To achieve the identification of compromised nodes, ImSEF not only updates the credibility but also uses the updated credibility as the receiving probability as mentioned in process 1) of the en-route filtering. In the same example, assuming that node h is compromised. Node i has an adversely higher probability of receiving the report from compromised node h because of the increase in the credibility R_{ih}. However, since node j has a lower probability of receiving a report from node i, node i may fail to send a next report to node j, and then the credibility R_{ih} of the previous node h in the neighborhood list of node i decreases. Although the credibility R_{kj} of the previous node j in the neighborhood list of node k decreases at first, if node j sends legitimate reports received from other previous nodes to node k, the credibility R_{kj} can be recovered. By iterating the credibility update and the communication based on the updated credibility, ImSEF is expected to inhibit neighboring nodes of compromised nodes from forwarding false reports.

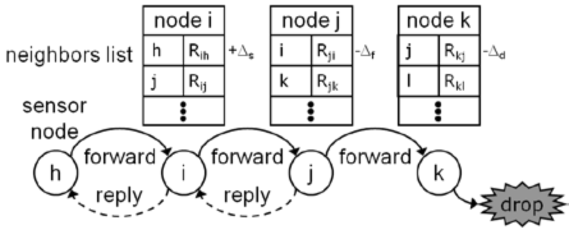

Fig. 2. An example of the credibility update in the en-route filtering process of ImSEF [5].

3.3 Base Station Verification

Owing to the statistical nature of the detection mechanism, a few bogus reports with invalid MACs may escape en-route filtering and reach the BS. In the base station verification process, the BS further verifies the correctness of all MACs and eliminates false reports that elude en-route filtering.

4 PROPOSED MULTIPATH ImSEF (ImMEF)

SEF and ImSEF do not address *false negative attacks* such as blocking legitimate reports or selective forwarding attacks by a compromised intermediate node. Furthermore, ImSEF may mistakenly drop legitimate reports in process 1) of the en-route filtering with low probability (*mistaken filter*). Kim and Cho [3] have proposed a *multipath en-route filtering method* (MEF) to tackle false negative attacks, and shown that MEF is more resilient to the attacks up to a certain number of compromised nodes than SEF.

In this paper, we propose a *multipath immunity-based statistical en-route filtering* (ImMEF) to deal with not only false negative attack but also mistaken filter. Like MEF, ImMEF exploits a multipath routing technique and a random key pre-distribution scheme for key assignment. Specifically speaking, the process 6) of report generation is changed as follows:

6') The CH collects all the $\{i, M_i\}$s from the detecting nodes and classifies the MACs into P separate groups, hashed as a function of key partition number, j of P_j. The CH allocates each of P different hash groups onto each path toward the BS. From each hash group, the CH randomly chooses S MACs and attaches them to the event report on the path. The CH sends P event reports of different hash group to the BS via multiple disjoint paths. The number of transmitted MACs per path is S ($S \leq T$) because the CH aggregates as least T MACs. The BS previously sets values for T and S.

The en-route filtering component in ImMEF is also slightly changed from T MACs to S MACs. In addition, a forwarding node verifies the group of received reports in process 2) of the en-route filtering. If a key index does not belong to the key group in the report, the report is dropped.

Fig. 3 shows an example of event reports of different hash group on multiple disjoint paths where $P = 2$ and $S = 2$. There are 2 event reports which have 2 MACs, M_6 and M_{10} and M_2 and M_9, of the hash group for "group 0 mod 2" and for "group 1 mod 2", respectively. Even if a compromised node can stall forwarding a legitimate report on a path as shown in Fig. 3, or a normal forwarding node mistakenly drops a report, the BS can receive the other reports.

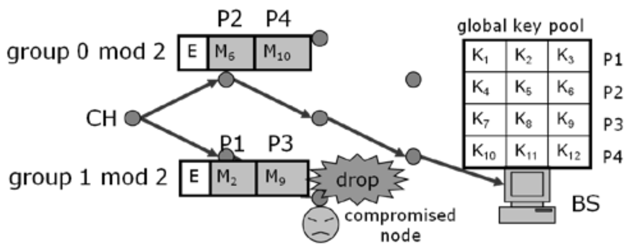

Fig. 3. An example of event reports of different hash group on multiple disjoint paths where $P = 2$ and $S = 2$.

5 SIMULATION

We perform some preliminary simulations to evaluate the performance of ImMEF on the following conditions: 9×100 sensor nodes are located in a two-dimensional lattice field. 9 source nodes sit at the left side of the field, and a base station is at opposite ends, with 100 hops between the sources and the base station. One of the source nodes is compromised and sends 1000 bogus reports, while the remaining sources transmit 1000 legitimate reports. A global key pool consists of $N = 1000$ keys, divided into $n = 10$ partitions, each of which has $m = 100$ keys. Each node has $k = 50$ keys. When $T = 5$, the number of transmitted MACs S per path and the number of disjoint paths P are varied as satisfying the inequality $P \cdot S \leq T$. All the values of the parameters Δ_s, Δ_f, and Δ_d are set to 0.02.

Fig. 4 illustrates the percentage of mistakenly dropped legitimate reports as a function of the number of paths P for ImMEF. ImSEF corresponds to ImMEF where $P = 0$. The result shows that as the number of paths increases, the percentage of mistakenly dropped legitimate reports decreases. By using multiple disjoint paths, ImMEF has been shown to deal with mistaken filter. We are now carrying out additional simulations for false negative attacks comparing with MEF, so that we will show the results at conference site.

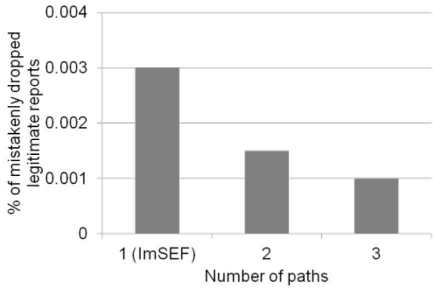

Fig. 4. Percentage of mistakenly dropped legitimate reports as a function of the number of paths P for ImMEF.

6 CONCLUSION

In this paper, we proposed a multipath immunity-based statistical en-route filtering (ImMEF) to deal with not only false negative attack but also mistaken filter. We performed some preliminary simulation to evaluate the performance of ImMEF. In future, the proposed scheme will be combined with the other revised SEFs for a higher security level.

Abstract: A smart phone has a large amount of private information, so that user authentication and identification are important to prevent attacks by illegal users who are not the owner of the smart phone. Both password authentication and biometrics can be applied only at the beginning of use. After the authentication is passed, not only the legal owner but also illegal users freely use the phone. For the second protection, the behavior-based user identification can continuously check the user activities after login. In this paper, we investigate operational behaviors at the first stage for user identification on smart phone. We make a text browsing application to record fingers history on smart phone. From the recorded fingers history, we extract and compare characteristic operational behaviors, for instance, the speed and the acceleration of fingers, the distance between fingers, and the distribution of touched region.

Keywords: Smart phone, Behavior-based user identification, Operational behavior, Security

1 INTRODUCTION

In recent years, smart phones have been exponentially popularized for many convenient applications. Because a smart phone has as a large amount of private information as a personal computer, user authentication and/or user identification are important to prevent attacks by illegal users who are not the owner of the smart phone. At first, user authentication can be classified into two types, namely *password authentication* and *biometrics*. Although the password authentication requires that the owner only memorizes a short password and inputs the password for login, the password is probably lost or forgotten and then it is illegally shared and used by attackers. On the other hand, the biometrics verifies the owner based on the intrinsic physiological characteristics, for example, fingerprint, face and voice [1]. The biometric characteristics cannot be lost or forgotten, so that it is hard to copy and share them. However, the user authentication of both password authentication and biometrics can be applied only at the beginning of use. After the authentication is passed, not only the legal owner but also illegal users freely use the computer or the phone.

For the second protection, many user identification systems based on *user behavior* have been proposed since the 1990s in personal computer environment. As user behavior which is difficult to be imitated, commands sequence [2-4], keystroke pattern [5-9], or mouse operation [10] has been employed. The identification systems initially create normal profiles of a legitimate user behavior. If the systems observe the remarkable difference between the profiles and the current user activities, then they give an alarm. The behavior-based user identification can continuously check the user activities after login.

Isohara et al [11] have proposed a simple and easy-to-use user identification system on mobile phone environment for the first time. The system records keystrokes in the background process, calculates the frequency of keys or key groups from the recorded keystrokes to make a normal user profile, and then estimates a similarity score by comparing the frequency-based profile with the latest keystrokes to detect illegal users. A prototype system was implemented on the BREW emulator and error rates were evaluated. Because the system was proposed for mobile phone with severely limited calculation resources, it used only the key frequency for user identification. However, since smart phone has more powerful calculation resources than mobile phone, identification systems based on other complicated characteristics such intervals of time between keys can be applied on smart phone. In addition, unlike mobile phone where only key buttons are pushed, there are also operational behaviors peculiar to smart phone with touch-screen panel, for example, *swipe*, *tap*, *flick*, and *pinch*.

In this paper, we investigate operational behaviors at the first stage for user identification on smart phone. We make a simple text browsing application to record fingers history on smart phone, that is, iPhone, iPod touch and iPad. From the recorded fingers history, we extract and compare characteristic operational behaviors, for instance, the speed and the acceleration of fingers, the distance between fingers, and the distribution of touched region. From the experiment results, the distribution of region touched by fingers for each subject is interestingly different.

2 HISTORY RECORD APPLICATION

2.1 Platform for Development

To create an application to record fingers history on smart phone, we should firstly select a platform for developing the application. Although Google's Android became the world's leading smart phone platform in the last quarter of 2010 [12] (also in Japan [13]), we have developed some applications on iOS for a year (as a matter of course we start to develop on Android OS). iOS is Apple's mobile operating system for iPhone, iPod touch, iPad and Apple TV [14]. The user interface of iOS is based on the concept of direct manipulation, using multi-touch gestures. As interface control elements, there are sliders, switches, and buttons. Interaction with the OS includes gestures such as *swipe*, *tap*, *flick*, and *pinch*, all of which have specific definitions within the context of iOS and its multi-touch interface.

The iOS SDK (Software Development Kit) allows developers to make native applications for iPhone, iPod touch and iPad, as well as test them in an iPhone simulator. Xcode is the integrated development environment for the iOS SDK. Like iOS and Mac OS X, iPhone applications are written in Objective-C. iOS has four abstraction layers: the Core OS layer, the Core Services layer, the Media layer, and the Cocoa Touch layer. The developers mainly use the Cocoa Touch layer at the highest level because many sophisticated services and technologies can be implemented easily. However, lower level layers may still be accessed by the developer when needed.

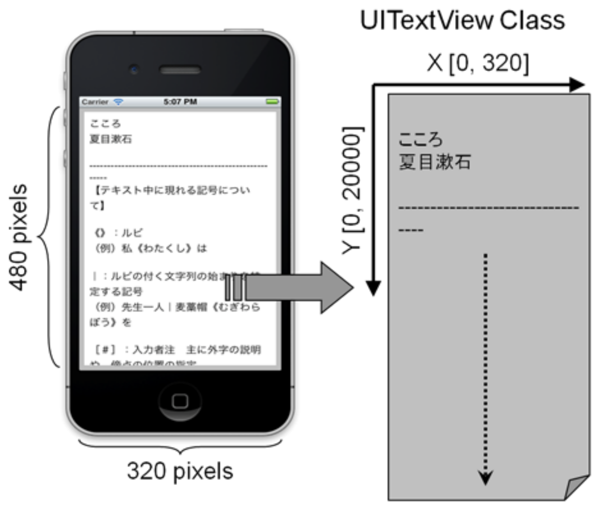
2.2 Text Browsing Application

Like the previous studies on behavior-based user identification such as mouse operation [10] and mobile phone keystrokes [11], it is preferable that user behavior is recorded in the background process. Because multitasking is supported for iOS through only seven background APIs: background audio, voice over IP, background location, push notifications, local notifications, task completion, and fast app switching [14], it is difficult to store operational behaviors in the background process on iOS.

Because browsing is one of basic functions equipped with many applications on smart phone, as the first stage for user identification on smart phone, we make a simple text browsing application to record fingers history on iPhone and iPod touch as shown in Fig.1 (a). The display size is 480 pixels high by 320 pixels wide (iPhone 4 and 4th generation iPod touch has 960 x 640 pixels, and iPad has 1024 x 768 pixels). So the text browser has only vertical scroll. A text is scrolled by the following fingers operations.

- *Flick*: users place a finger on the screen and quickly swipe it in the desired direction.
- *Drag*: users place a finger on the screen and move it in the desired direction without lifting it from the screen.

Fig. 1 (b) illustrates that the origin is located at the top left corner of the screen, and the X and Y coordinates are specified. The UITextView Class which implements the behavior for a scrollable, multiline text region is used to display multiple lines of text, such as when displaying the body of a large text document. The class can get touched points not on screen but on text, so that the range of Y varies depending on the text document while the range of X is from 0 to 320. The Japanese text document in Fig. 1 (b) has Y ranging from 0 to 20000.



(a) (b)

Fig. 1. (a) screenshot of the simple text browsing appli cation to record fingers history on iPhone and iPod to uch. (b) the origin and the X and Y coordinates on U ITextView Class

2.3 Characteristic Operational Behaviors

The fingers history continuously recorded by the text browsing application is in the form of $\{(x, y), t, event\}$, where (x, y) is the coordinates of point touched by fingers, t is the touch event time. And *event* means one of 3 touch events as follows.

1. A finger is placed on the text.
2. The finger is moving without lifting from the text.
3. The finger is released.

From the recorded fingers history, we should extract characteristic operational behaviors suitable for user identification. This study is propably closer to the previous research on mouse operation [10] than on mobile phone keystrokes [11]. The research on mouse operation [10] has checked the following features and then used the last one for user identification.

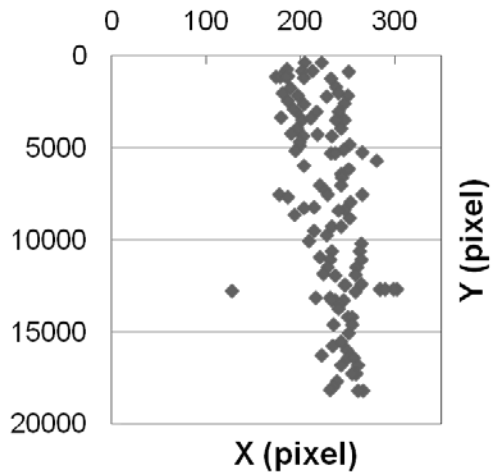
1. The region of mouse used by each user
2. The moving route of mouse from the starting point to the ending point
3. The velocity of mouse
4. The acceleration of mouse
5. The movement direction near the starting point and the ending point
6. The pattern of mouse movement

We also extract the same features, that is, the distribution of region touched by fingers, the speed and the acceleration of fingers, the movement direction, and the operations pattern of fingers.

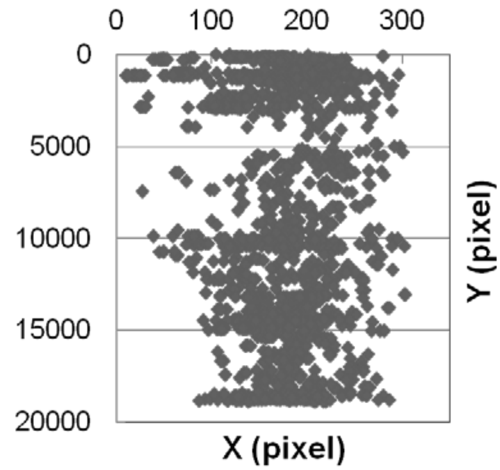
3 EXPERIMENTAL RESULTS

We carried out experiments using the text browsing application on iPod touch to extract characteristic operational behaviors. 5 subjects participated in this experiment. After the subjects were explained how to use iPod touch and the application, they were free to read the text document. When they finished reading, they returned iPod touch. We can get each recorded fingers history through iTunes.

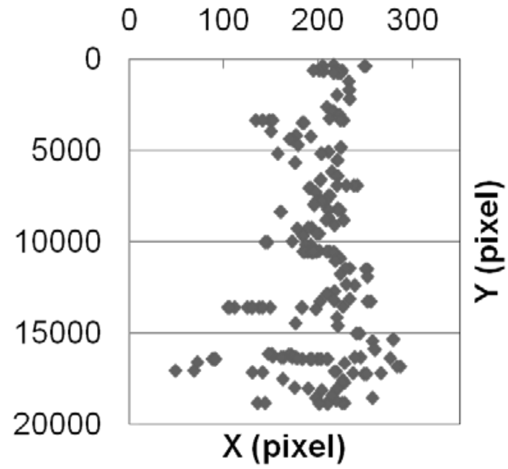
Fig. 2 shows the distribution of region touched by fingers for 3 subjects, A, B, and C. From the results, subject A and C are accustomed to operation on smart phone while subject B may be not used to reading the text document on smart phone. The distribution can be one of promising characteristic operational behaviors suitable for user identification. Table 3 depicts average, minimum and maximum speeds of fingers for 3 subjects. The speed is calculated by dividing the distance between *event* 1 and the corresponding *event* 3 by the taken time. Although subject C can manipulate smart phone more quickly than the others, the feature is invalid for user identification because the minimum and maximum speeds are overlapped. The acceleration of fingers is also inappropriate. We are now extracting the other features for all the subjects including the remaining subjects, so that we will show the results at conference site.



(a) subject A



(b) subject B



(c) subject C

Fig. 2. The distribution of region touched by fingers for 3 subjects

Table 1. Average, minimum and maximum speeds of fingers for 3 subjects

	A	B	C
Ave. speed	104.0	119.4	86.9
Min. speed	8.2	0	0
Max. speed	307.7	9749.3	608

4 CONCLUSION

In this paper, we made a text browsing application to record fingers history on smart phone and then extracted characteristic operational behaviors for user identification on smart phone. From the experiment results, the distribution of region touched by fingers for each subject was interestingly different. In future work, we will continue to extract and compare characteristic operational behaviors. We then plan to construct user identification system on smart phone based operational behavior.

Continuous review model of mutual support supply system for disaster responses

Nur Budi Mulyono[1], Yoshiteru Ishida[2]

[1 2]Toyohashi University of Technology, Toyohashi 441-8580, Japan
[1]nurbudi@gmail.com

Abstract: Mutual support of supply is needed to leverage number of stock between shelters during disaster response time. The goal of this research is to develop reactive lateral stock transshipment between shelters based on traditional continuous review inventory model in which demand and delivery lead time information are greatly biased. This paper presents self-repair framework that provide an emergency relief strategy after natural disaster events. In addition, supply system buffer analysis also presented to enrich model development. A case study focused on volcanic eruption disaster at Merapi Mountain Indonesia, illustrate application of the model.

Keywords: Mutual support supply network, continuous order review model, lateral transshipment, disaster relief supply, self-repair network, buffer analysis.

1 INTRODUCTION

Due to increasing number of natural disaster occurrence recently, disaster relief is extremely important activity today (EMDAT, 2010) [1]. The need to respond to human need in the event of disaster is not diminishing and may even be increasing. Government, NGO, and other related parties should provide life support items such as food, clothes, and medicine; in timely manner.

Planning and management of logistic and inventory activities is needed for better relief supplies. Inventory or supply system play critical role in this emergency situation, in which they system has to manage all the needed items, store it, and provide it to the victim whenever they need.

The role of logistic and inventory for famine relief is explicitly mentioned by (Long & Wood, 1995) [2] that describe complex environment in which disaster relief logistic and inventory system must operate.

The traditional design of an inventory system is hierarchical where transportation flows from one echelon to the next, i.e. from suppliers to manufacturers, from manufacturers to retailers, and from retailers to customers. This inventory system tends to have less flexibility since each supply point cannot communicate or help each other to get a better performance. The more flexible inventory system allows lateral transshipment within same or adjacent echelon, i.e. between wholesalers or retailers (Paterson, et al, 2010) [3].

At disaster recovery situation, lateral transshipments between inventories at each shelter points are allowed to minimize number of run out stock or stock out in each shelter point. Lateral transshipment is one of the alternative ways to leverage number of stock between shelter points and reduce stock out.

Simple lateral transshipment inventory system for a disaster situation is graphically illustrated in Figure 1 with single central warehouse supplies three inventory shelter points. Lateral transshipment in an inventory system is stock movements between locations of the same echelon (Paterson, et al, 2010) [3]. These transshipments can be conducted periodically at predetermined points in time to proactively redistribute stock, or they can be used reactively as a method of meeting demand, which cannot be satisfied from stock on hand.

In proactive transshipment models, lateral transshipments are used to redistribute stock amongst all stocking points in an echelon at predetermined moments in time. Reactive transshipments respond to situations where one of the stocking points faces a stock out or risk of a stock out.

Lateral transshipment is suitable to use in disaster situation since cost consideration is less important than saving life. By stock transfer from one surplus location into needed location, average stock out of all location will significantly reduce.

After occurrence of disaster, needed item's demand is usually fluctuate drastically and arrive at extremely irregular time. In most disaster-relief practices, demand information for emergency resources is mainly collected at the operational level and then flow upward to the higher level (Turoff, 2004) [4]. In addition, transportation time for the item to each shelter point becomes extremely vary due to infrastructure damages.

Lateral transshipment is suitable to use in disaster situation since cost consideration is less important than saving life. By stock transfer from one surplus location into needed location, average stock out of all location will significantly reduce.

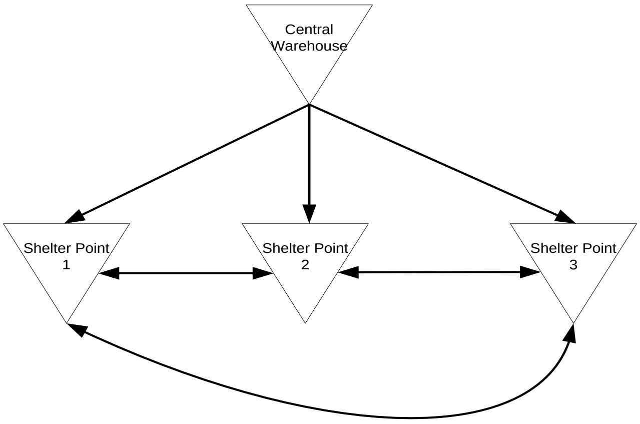

Fig. 1: Lateral transshipments between stock points

Self-repair network model in computer network application is one collaboration model of computer network where each computer tries to repair each other by mutual copying. Repairing process of self-repair network doesn't require resources while repairing process of lateral transshipment sacrifices resources.

This paper propose framework of lateral transshipment of supply system after occurrence of natural disaster with continuous review inventory model and self-repair network as reference model.

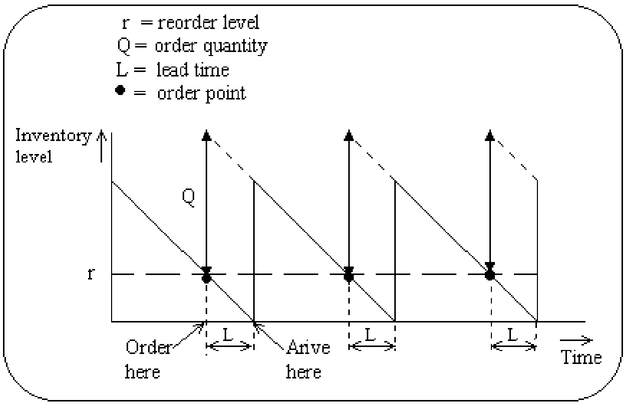

Fig. 2: Continuous review model of inventory

3 MUTUAL SUPPORT MODEL

There are differences between the enterprise and disaster-relief inventory models. These differences are found in the environment and characteristics of disaster-relief inventories in all area from acquisition through storage and distribution (Whybark,2007) [5]. Even though different, fundamental enterprise inventory model can be adopt for modeling inventory at disaster situation.

Continuous order review inventory model or known as economic order quantity (EOQ) model, state that there is optimum order quantity (Q) based on tradeoff between predetermined setup cost (SC) and holding cost (HC) (Heizer & Render, 2008) [6]. Figure 2 illustrate basic model of continuous order review inventory. Another variable necessary for calculating order quantity is overall demand along planning horizon (D). Equation 1 show the calculation of optimum order quantity based on this model.

$$\mathrm{Q} = \sqrt{\frac{2.D.SC}{HC}} \qquad (1)$$

This model used reorder point (R) formula which is derived from interaction of demand rate (d), delivery lead time (L), and safety stock (SS). Equation 2 shows calculation of reorder point while safety stock calculation of continuous order review is shown at equation 3.

$$R = d.L + SS \qquad (2)$$

$$\mathrm{SS} = z\sigma_{RP+L} \qquad (3)$$

We formulate the lateral transshipment problem into simple mathematical formulation. The model consists of three elements (U, T, R) where U is a set of shelter points, T is a topology connecting the units, and R is a set of rules of interaction among shelter points. A set of shelter point U is a finite set number of shelter points. The topology for the lateral transshipment inventory system is scale free network. We restrict the case where each shelter point has a state: normal (0), abnormal (1) and need help (-1). Each shelter point tries to help the other shelter points in a synchronous fashion with probability **Pr**. The helping will be successful with probability **Ps** and the shelter point states will increase if the current inventory level plus the proportion shared by another shelter point is greater than the standard normal threshold (N). Proportion shared by normal shelter point is Pn while the proportion shared by abnormal shelter point is Pa in which Pa<Pn. In this model, it is assume that *need help* shelter point cannot behave as helping unit. N and A is the proportion threshold of the normal and abnormal unit state, while I represent a proportion of current inventory level. There are several assumption used in this model

1. Only one shelter point can help another shelter point for one period of time.
2. Number of shelter point remains same during periodical review.
3. Each shelter point has dedicated transportation vehicle and common use transportation vehicle.

4. Logistic decision parameter such as vehicle capacity and route is neglected.

Our model has several similar characteristics with the self-repairing network model (SRN) where the network of computer repairs each other by mutual copying (Ishida, 2005) [7]. The following lists are characteristic of our model, which also exists in SRN model:

1. Set of units
2. Topology connecting the units
3. Set of rules of the interaction among units
4. Probability of repairing other units
5. There is possibility of disturbance occurs during interaction of the units

The definition of unit in both models is the smallest entity having an ability to interact, repair, and being repaired by other units. In SRN model, unit is a computer while in our model, unit is shelter points. Even though both models having a great number of similarity, there are also several differences between them as shown at Table 1

Table 1. Differences of SRN and our model

	SRN	Our Model
Repairing action	Mutual copying	Transfer stock
Sacrifices resource	No	Yes
Success rate	Probability (Prn, Pra)	Probability of success Ps and Proportion shared (Pn, Pa) and proportion of current inventory level (I)

Success rate of repairing is depending on the two factor ssuch as probability of success (Ps) and proportion shared (Pn and Pa). Probability Ps represents delivery success of items transported from one place to another during after occurrence of disaster event. Due to infrastructure damage, there is possibility transportation vehicle not able to reach destination or able to reach destination but the item carried has been damaged or deteriorated.

Transition rules for the state changes by helper unit are as followed:

$$0 \rightarrow 0 : (I\text{-}Pn) \geq N \tag{4}$$

$$0 \rightarrow 1 : A \leq (I\text{-}Pn) < N \tag{5}$$

$$0 \rightarrow \text{-}1 : (I\text{-}Pn) < A \tag{6}$$

$$1 \rightarrow 1 : A \leq (I\text{-}Pa) < N \tag{7}$$

$$1 \rightarrow \text{-}1 : (I\text{-}Pa) < A \tag{8}$$

Transition rules for the state changes by helped unit if help by normal unit are as followed:

$$0 \rightarrow 0 : (I+Pn) \geq N \tag{9}$$

$$1 \rightarrow 0 : (I+Pn) \geq N \tag{10}$$

$$1 \rightarrow 1 : A \leq (I+Pn) < N \tag{11}$$

$$\text{-}1 \rightarrow 1 : A \leq (I+Pn) < N \tag{12}$$

$$\text{-}1 \rightarrow 0 : (I+Pn) \geq N \tag{13}$$

Transition rules for the state changes by helped unit if help by abnormal unit are as followed:

$$0 \rightarrow 0 : (I+Pa) \geq N \tag{14}$$

$$1 \rightarrow 0 : (I+Pa) \geq N \tag{15}$$

$$1 \rightarrow 1 : A \leq (I+Pa) < N \tag{16}$$

$$\text{-}1 \rightarrow 1 : A \leq (I+Pa) < N \tag{17}$$

$$\text{-}1 \rightarrow 0 : (I+Pa) \geq N \tag{18}$$

4 NUMERICAL SIMULATION

Numerical simulation conducted using real disaster data of volcanic eruption in Indonesia. In November 2010, one of the active volcanoes in Indonesia, Merapi Mountain, located at Yogyakarta province erupted. During one month, government and other NGO trying to support their life at each shelter point, which spread all over the city. Data of evacuees and shelter points gathered from Indonesia National Disaster Management Agency for two provinces during one-month evaluation is shown at Table 2 (Indonesia National Disaster Management Agency, 2010) [8].

In numerical simulation, two options will be evaluated such as:

1. No transshipment
2. Transshipment

Table 2. Disaster evacuees and shelter point

Sub area	Areas (km2)	Evacuees	Shelter points	Evacuees/shelter	Shelter density
Sleman	574.82	109193	74	1476	7.77
Kulon Progo	586.28	4753	16	297	36.64
Yogyakarta city	32.5	5118	14	366	2.32
Bantul	506.85	20516	17	1207	29.81
Gunung Kidul	1485.35	12162	13	936	114.26
Total	*3185.8*	*151742*	*134*	*4282*	*190.8*

Table 3. Simulation setting

Simulation setting	
Evacuees/shelter	4282
Total demand	385380
Total period (hours)	720
demand rate (/hour)	535
Lead time (hours)	1
Safety stock	318
Order quantity (Q)	6207
Number of pool truck	268
Number of shelter truck/shelter	2
Pn	0.2
Pa	0.1
Pr	0.9
Ps	0.5
Normal threshold (N)	0.7
Abnormal threshold (A)	0.3

First option is the basic inventory model which not allowed any transfer items from any shelter points. This option made for performance reference of a transshipment system proposed. Second option allows transfer items between shelter points.

Number of truck for delivering item is assumed static throughout the time which is 268 trucks at pool or central warehouse and 2 trucks for each shelter. The other simulation setting can be seen at Table 3.

The result of numerical simulation as shown at Figure 3 that number of need help unit decreasing when success delivery rate is increasing and with transshipment option, number of need help unit decrease even bigger. Based on that fact, performance of transshipment system can be measured up to 60% as shown at Figure 4. In transshipment option, number of need help unit also sensitive to probability of helping where number of need help unit decrease significantly as probability of helping increase as shown at Figure 5.

5 BUFFER ANALYSIS

The purpose of buffer or safety stock is to reduce an effect of demand and lead time fluctuation. The prediction of the buffer is relied on the known distribution of the demand and lead time during a planning period.

We propose an analysis of buffer inventory for lateral transshipment system with the goal of getting percentage of expected reduce of stock out and also addition of expected over stock. The benefit of that action is reduction of stock out for certain amount but there is a side effect of increasing possibility of excessive stock.

Consider M as a percentage of additional buffers for current inventory level. Stock out occurs if a current level below abnormal threshold.

$$I \leq A \quad (19)$$

$$TI - d - Pr \cdot Pa \cdot TI \leq A \cdot TI \quad (20)$$

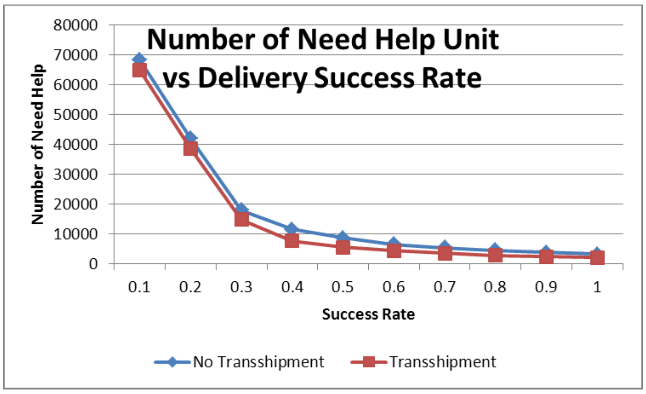

Fig 3. Number of need help unit vs delivery success rate

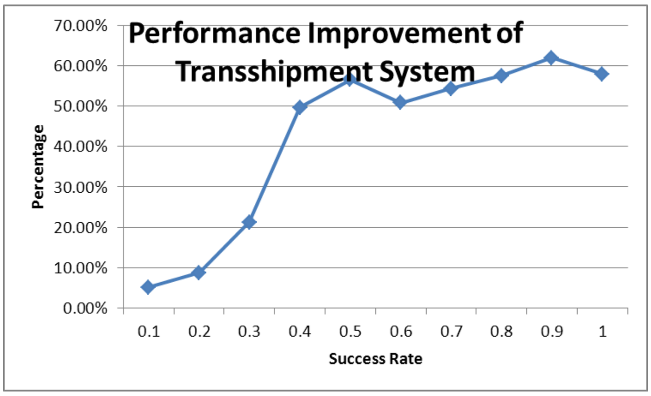

Fig 4. Performance improvement of transshipment

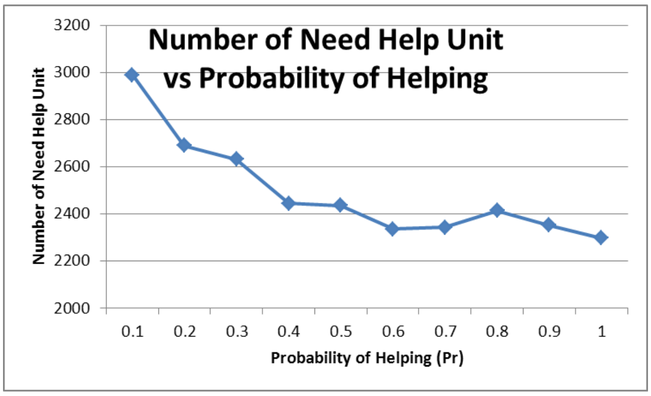

Fig 5. Number of need help unit vs probability of helping

If a proportion amount of M added to the current inventory stock the equation becomes as follows:

$$TI(1+M) \quad - d - Pr \cdot Pa \cdot TI(1+M) \le A \cdot TI \qquad (21)$$

$$TI - d - Pr \cdot Pa \cdot TI + M(1-Pr \cdot Pa) \le A \cdot TI \qquad (22)$$

From equation (22), we can conclude that buffer addition of M, cause the possibility of stock out reduced at maximum M(1 – Pr · Pa). On the other hand, if a proportion amount of M added to the current inventory stock, excess stock will add maximum as much as M(1 + Pr · Pn). The equation (25) shows the calculation of that excess stock.

$$I \quad \ge TI \qquad (23)$$

$$TI - d + Pr \cdot Pn \cdot TI \ge TI \qquad (24)$$

If a proportion amount of M added to the current inventory stock the equation become as follows:

$$TI(1+M) \quad - d + Pr \cdot Pn \cdot TI(1+M) \ge TI \qquad (25)$$

$$TI - d + Pr \cdot Pn \cdot TI + M(1+Pr \cdot Pn) \ge TI \qquad (26)$$

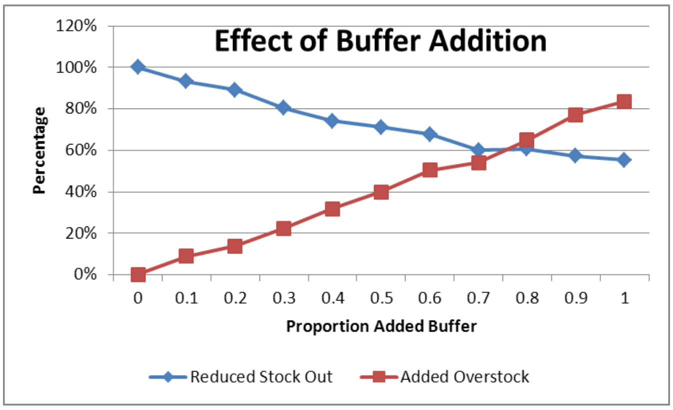

Fig 6. Effect of buffer addition

Based on numerical simulation data, if 10%, buffer is added to the current stock, then maximum stock out will be reduced as much as 9.1 % and maximum excess inventory will be added as much as 11.8 %. Figure 6 show the numerical simulation of proportion of need help unit after buffer M is added. Amount of stock out is reduced about 6.8% comparing the situation without buffer addition but expected maximum over stock increase as much as 8.7%. The result of numerical simulation is consistent with mathematical formulation where buffer addition will have greater effect to the expected over stock rather than expected stock out.

6 CONCLUSION

Lateral transshipment has demonstrated a positive impact to the performance improvement of the inventory system during a disaster where demand and lead time information are greatly biased. It can reduce number of stock out level for all shelter points. The performance of the system is greatly affected by success rate and probability of helping. Even with low delivery success rate and probability of helping, lateral transshipment supply system show significant improvement in inventory performance. It can be noted that the greater success rate and probability of helping the greater also inventory performance as measured by number of need help units.

Future research can be directed to the study on the dynamic of number of shelter points during planning horizon and also characteristic interaction between shelter points. Integration with logistic decision planning can also be one of the major concerns for future development such as truck capacity and routing problems.

Abstract: Collective intelligence of a group of intelligent robots can be realized as autonomous distributed robots with an advent of sensor network. Collective survivability can also be regarded as a subject of group problem solving, and realized by a framework of network rewiring (dynamic configuration) of systems. To realize the network rewiring, separation of physical systems and information systems is proposed to apply the self-rewiring network as well as self-repairing and self-recognition networks. Self-rewiring algorithm can be formalized as a matching automaton. An application to autonomous distributed satellites will be discussed.

Keywords: Network rewiring, rearrangement system, collective survivability, matching problem, dynamic configu ration.

1 INTRODUCTION

Network rewiring has been studied extensively in the new field of network science (e.g. [1, 2, 3]). Indeed, we can find network rewiring in many large-scale networks in nature: biological networks such as genetic networks; artificial networks such as the Internet; and social networks such as relation by birth or marriage.

On the other hand, current technology realizes highly reliable systems based on system reliability engineering using redundant components. However, the reliabilities of artificial systems are far behind from that of biological systems due to the different design principle. Biological systems involve rearrangement of similar and replaceable components when some important components fails or are missing.

As target areas for applications, group robotics where autonomous robots (agents) cooperate with each other in a framework of autonomous distributed network would be a potential area, since collective survivability is a sort of a group problem solving. The similar approach can be used for group satellite systems where small-sized but autonomous satellites cooperate with each other to increase the collective survivability for a given mission.

This paper proposes a design for autonomous distributed systems that allows rearrangement of autonomous components (agents) thus realizing high survivability rather than high reliability. The design incorporates network rewiring by matching automaton [4, 5].

Section 2 briefly surveys matching problems including stable marriage problem and stable roommate problems. Section 3 defines matching automaton based on the matching problems. Section 4 presents a design principle of separating physical and information systems to attain rearrangement system by network rewiring. A paradigm shift from unit reliability to group survivability will be discussed in several potential applications.

2 MATCHING PROBLEMS

The *Stable Roommates Problem* (*SRP*) [6] assumes 2*N* participants, each of whom has a strict (without tie) ordered preference over the other 2*N-1* participants. The *SRP* seeks complete matching consisting of *N* pairs without being blocked. A matching is said to be blocked if a participant A prefer the participant C to the current roommate B in the matching and that preferred participant C also prefers A to the current partner D in the matching. The pair A-C is called as blocking pair.

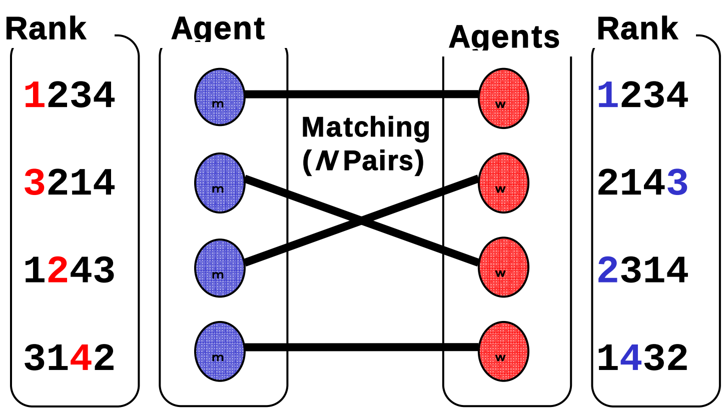

Fig. 1. An example of *SMP* instance specified by ordered preferences of men (left) and women (right) over the subscript of the member of the opposite sex. A bipartite graph shows a matching of *SMP* consisting of four pairs [9].

The *Stable Marriage Problem* (*SMP*) [7, 8, 9] assumes N women and N men, each of whom has a strict (without tie) ordered preference over the opposite sex. As in the example shown in Fig. 1, the man m_2 has a ranking (3, 2, 1, 4), which means that m_2 likes w_3 best, and prefers w_3 to w_2, w_2 to w_1, and w_1 to w_4.

The *SMP* seeks complete matching which satisfies *stability*. The stability requires the concept of *blocking pairs*. Two pairs (m_i, w_p) and (m_j, w_q) are blocked by the pair (m_i, w_q) if m_i prefers w_q to w_p and w_q prefers m_i to m_j. A complete matching without being blocked is called *stable* matching.

3 MATCHING AUTOMATON

Structure functions [10] to express the structure of system reliability and survival functions to evaluate a time to failure [11] have been used in system reliability theory for design and assessment of reliable systems. Similarly to the structural function used in system reliability, matching automaton [4, 5] will be used in collective survivability for design and assessment of survivable systems.

The matching automaton consists of two parts of N agents (automata) corresponding to men and women in the SMP. The preference is considered to be the input to the automata, and the resulting matching. In the interactive mode, the already determined pairs as well as the preference can be input to the agents whose pairs are to be determined, and that determined pair in turn can be the input to the rest of the agents, and so on.

The preference of each agent is expressed by a preference matrix $\{ a_{ij} \}$ where the element a_{ij} in the i^{th} row and j^{th} column is defined to be $R(m_i, w_j)/R(w_j, m_i)$ where $R(m_i, w_j)$ is the rank of m_i to w_j.

We will use the affinity matrix $\{A(m_i, w_j)/A(w_j, m_i)\}$ to specify the matching automaton. $A(m_i, w_j)$ is the man m_i's affinity for the woman w_j, and $A(w_j, m_i)$ is the woman w_j's affinity for the man m_i. The affinity is defined by the rank as: $A(m_i, w_j) = N + 1 - R(m_i, w_j)$, varying from N to 1 as the rank changes from 1 to N. In the following, the left matrix is the preference matrix and the right one is the affinity matrix of the example shown in Fig. 1. We will use the affinity matrix in the rest of the paper.

4/4,3/3,2/3,1/4	1/1,2/2,3/2,4/1
2/3,3/4,4/2,1/1	3/2,2/1,1/3,4/4
4/2,3/1,1/4,2/2	1/3,2/4,4/1,3/3
2/1,4/2,1/1,3/3	3/4,1/3,4/4,2/2

The cyclic preference can be generated by shifting one digit in the ordered list of 1, 2, 3, ..., N where N is the number of agents for one part.

For convenience of visualizing asymmetry and symmetry, the diagram is expressed on a coordinate system where women's satisfaction H_w and men's satisfaction H_m are defined as follows:

$$H_w(\mu) = \sum_{(w_j, m_i) \in \mu} A(w_j, m_i)$$

$$H_m(\mu) = \sum_{(w_j, m_i) \in \mu} A(m_i, w_j),$$

$A(w_j, m_i)$ is the woman w_j's affinity when the mating (w_j, m_i) is attained in a matching μ. All the possible matchings are plotted in the coordinate system of H_w on the vertical axis and H_m on the horizontal axis.

The matching automaton can be regarded as a discrete analog of a continuous dynamical model. In fact, Fig. 2 is called as *affinity space diagram*, and is similar to a *phase space diagram* which is often drawn for the continuous dynamical model where a stable matching (red node) corresponds to a stable equilibrium point (or an *attractor*) and the state proceeds to the stable matching as the exchange proceeds from an initial matching.

Since the matching automaton is a collection of automatons (similarly to cellular automatons) by identifying each agent as an automaton, the diagram of course can be regarded as a *state-transition diagram* where each node (corresponding to matching) represents a state and each edge represents a transition to and from by exchanging partners in two pairs.

As an illustration, let us explain the simplest matching automaton of a switching gate. The gate consists of two by two agents (*SMP* with size 2) and each agent in a set has a distinct preference to avoid symmetry; furthermore, each pair of agents has no first rank assignment (no *mutual infatuation*) to avoid fixation of the pair in matching. These restrictions lead to the following affinity matrix: 2/1, 1/2
1/2, 2/1.

With this preference as input, the behavior of the matching automaton is grasped by the affinity space diagram (Fig. 2). Note that only two matchings exist and both of them are stable. When the automaton seeks the women-optimal solution, then the matching will be the one on the upper left. On the other hand, if the automaton seeks the men-optimal solution, the matching will be switched to the one on the lower right.

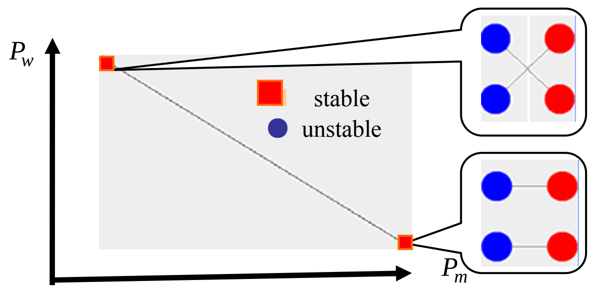

Fig. 2. An example of a switching gate realized by the matching automaton of 2 by 2 agents. Two squares indicate stable matchings. The matchings will be switched among one another by changing the mode of automaton, i.e., women-optimal or men-optimal [4].

4 NETWORK REWIRING BY MATCHING AUTOMATON

4.1 Separation of Physical Systems and Information Systems

Network-rewiring or rearrangement studied by matching automaton [4, 5] may be comparable to the network-rewiring by preferential rewiring in bipartite graph [12].

Network rewiring system by Matching Automaton can be applied to autonomous distributed systems such as a group of swarm robots and a group of networked satellites. Each robot (called $\boldsymbol{A_i}$, for the abbreviation of an agent i), for example, may be divided into two subsystems: physical system (called $\boldsymbol{P_i}$ for the agent i) including mechanical system, sensor system, and actuator system; and information system (called $\boldsymbol{I_i}$ for the agent i) including control and communication system from and to the sensor and actuator system.

Usually, in each agent $\boldsymbol{A_i}$, the information system $\boldsymbol{I_i}$ takes care of its own physical system $\boldsymbol{P_i}$, thus forming a disconnected independent nodes of $\boldsymbol{A_i}$. However, the remarkable feature of the network rewiring system is that $\boldsymbol{I_i}$ can take care of $\boldsymbol{P_j}$ ($i \neq j$), thus the network topology can be connected nodes of $\boldsymbol{A_i}$. In case of the failure of $\boldsymbol{P_i}$, $\boldsymbol{P_j}$ ($i \neq j$) can be used instead, and likewise in case of the failure of $\boldsymbol{I_i}$, $\boldsymbol{I_j}$ ($i \neq j$) can be used, thus attaining high survivability for the target tasks or the target missions. The rewiring can be used not only for collective survivability but also high robustness and high space/time resolution in sensory functions. The rewiring can be done by the Matching Automata if the preference between two sets $\{\boldsymbol{P_i}\}$ and $\{\boldsymbol{I_i}\}$ is determined considering the factors such as distances between the agents and the affinity among agents.

Matching automata is also used to evaluate the survivability of a given systems: two sets $\{\boldsymbol{P_i}\}$ and $\{\boldsymbol{I_i}\}$, and the preference between these two sets. If physical components $\boldsymbol{P_i}$ are equally important for the given mission, the preference (or affinity) from $\{\boldsymbol{I_i}\}$ should be distributed over all the $\boldsymbol{P_i}$ equally, otherwise (if the preference is biased toward one or few physical components) missing or malfunction of the preferred components would cause low preference (affinity) pair in any of rearrangements.

4.2 Application to Autonomous Networked Satellites

Recent advances in sensor network technology as well as collective intelligence robotics technology allows that these agents can be realized and used in the Space, that is "Sensor Net on the Space" and "Collective Intelligence on the Space" is technologically possible by small sized but ICT intensive satellites.

The framework of network rewiring by MA may be used in AntSat (AntSats, Autonomous Networked Tiny Satellites) project that aims a group of small satellites of mutually cooperative and controllable. Although sensing capability a single satellite may be limited, the space-time resolution of sensing will be greatly enhanced when a group of satellites cooperates with each other. Importantly, the survivability of a group of satellites will exceed that (reliability) of a single satellite when mutual repair and control are possible. This is true for a long term and a long distance mission demonstrated by Hayabusa [13]. Although CubeSat [14] also uses small size satellites, it does not assume Inter-satellites Corporation.

Whenever, some of the functions are disabled or failed, equal or similar functions will be enabled by rearrangement of the physical systems or the information systems. Again, the separation of physical systems and information systems will make the rearrangement possible.

Separation of physical systems and information systems allows not only rearrangement for collective survivability but also mutual repair and mutual recognition among autonomous satellites using a self-repairing network [15] and a self-recognition network [16]. For example, the self-recognition network formed by three sensors possibly from three satellites allows higher reliable prediction of High-energy Electron Flux at Geostationary Orbit [17] (Fig. 3).

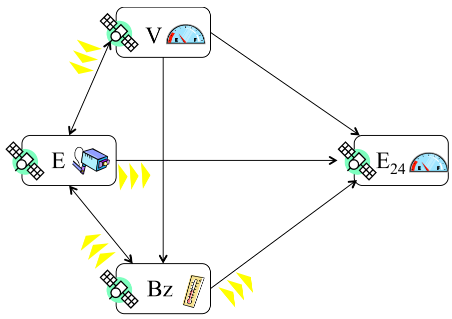

Fig.3. Mutual recognition network to predict High-energy Electron Flux at Geostationary Orbit [17]

The mutual recognition can be formed in a hierarchical system involving intra-satellite sensor systems as well as inter-satellite sensor systems (Fig. 4).

Similarly to the mutual recognition network, a mutual repair network can be formed among information systems (for the repair of information systems where repair may be carried out by mutual copying [14]) and among physical systems involving actuators that physically repair physical systems.

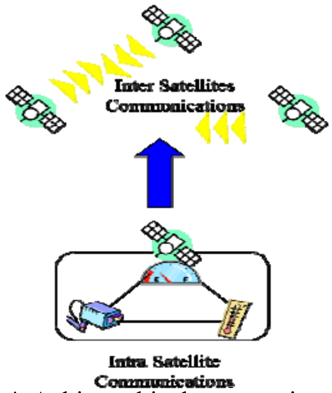

Fig. 4. A hierarchical system involving intra-satellite sensor systems as well as inter-satellite sensor systems.

4.3 Application to Formation of Sister Cities

As another avenue of network-rewiring application, disaster management may be worth mentioning. The following is basically a pairing, and matching automaton based on SRP as well as SMP can be used. First, we notice that the pairing of cities (or local governments) to provide mutual support in the case of natural disaster turned out to be effective as demonstrated after the Sichuan earthquake on 12 May, 2008 in China, and it is suggested that the policy could be implemented to support the recovery of the area damaged by the Tohoku earthquake on 11 March, 2011 in Japan. To set up the situation as a matching problem, preference may be carefully designed for disaster management and support. For, example, two cities close to each other would be damaged simultaneously by a large-scale natural disaster. To support and temporarily substitute the local industry specific to the city, the paired city should have a similar industrial structure. Thus, if we first want to separate cities that could be damaged by a disaster, we use MA of bipartite structure (as in SMP), as the west part and the east part in Japan. This is similar to separation of physical systems and information systems, but differs from it that a set of agents is divided into two, rather than dividing each agent.

If are separation is neither necessary nor inadequate, MA of single connected structure (as in SRM) may be used. The preference information required for each agent will be almost doubled though.

5 SUMMARY

Self-rewiring network is proposed to realize dynamic and functional rearrangement of components for collective survivability as well as collective sensing.

To realize self-active networks (self-rewiring, self-repairing, and self-recognition), a design principle of a separation of information systems from physical systems in each agent is adopted. Since the collective survivability may be applied to severe missions demonstrated by the Hayabusa project, an application to autonomous networked satellites has been briefly mentioned.

"Sensor network in the space" and "collective intelligence in the space" would be a technologically sound first step.

Abstract: We study the Input-Output table for East Asia as complex networks. The 50%~95% of sum of the off-diagonal elements is included in several percent of the big off-diagonal elements of the Input-Output table. This makes the network representation useful. We make the extracted networks with these big off-diagonal elements. The distributions of these off-diagonal elements (edge values) are power law shape with exponents of 2.56(money base), 2.07(EF base) and 2.00(CO2 emission base) on the average. EF base and CO2 base inter-dependences between industry sections are more unequal than money base, so from environmental point of view, a fewer inter-dependences are important. We can see the differences of the maximum 'degree', 'closeness' and 'the sum of elements (edge values)' in developed nations and in developing nations.

Keywords: Ecological Footprint, CO2 Emission, Input-Output table, Induced analysis, Complex Networks

I. INTRODUCTION

How production in each industry causes environmental impacts becomes more important for reducing these impacts and sustaining the earth for future. One of the methods to research this problem is to use environmental extension of Input-Output table. For decades, Input-Output table has been studied for analyzing the nation or regional economy on the basis of the inter-industry relations of how much production in one section is induced by the production in other sections. Generally, inter-industry relations are complicated, so it is not easy to extract the useful information to appeal to intuition. On the other hand, lots of studies on the topic of complex networks have been done recently and applied to various fields. Network representation is suitable to appeal to intuition and various analytical methods in this area help our deep understanding of the problems. And the Input-Output table can be thought as network matrix, but few studies of the complex networks have been applied to Input-Output table. [1][2][3] Moreover it is interesting to compare the economy (money) base inter-industry relations and the environmental impact base ones.

There are a lot of representations of environmental impact. One of them is Ecological Footprint (**EF**)[4] and other is CO2 emission. EF is one of the sustainable indexes, which converts nation's or regional basic consumption to the nation's or regional virtual area which is necessary to produce it. For example, we consume agricultural products to keep our life. These consumptions are converted to cropland area. Finally the virtual area caused by our total consumption is compared to bio capacity of the earth. The CO2 emission is most severe environmental impact which has to be reduced.

So in this paper, we compare inter-industry relations of money base , EF base and CO2 emission base.

II. INDUCED ANALYSIS OF ENVIRONMENTAL IMPACT

EF is represented by total area of six land types, "Cropland", "Forest", "Grazing land", "Fishing ground" , "Carbon uptake land" and "Built-up land". Each area is calculated to reproduce our final consumption as necessity area for "the supplies of crop", "the supplies of wood", "the supplies of livestock feed", "the supplies of fish", "absorption of CO2 emission" and "house, factory, road etc.". And it is compared to the real area (bio capacity) on the earth. Actually Japan needs 2.5 times as much area as real Japan area to keep our lifestyle. Whole world people need more area than whole area of the earth.

EF is calculated for an area on the basis of consumption in the area. That is, EF of the imported product does not belong to the nation in which the product is produced but it belongs to the nation in which the product is consumed.

$$EF_N = \sum_{\alpha,i,j\ldots k,\Omega} \frac{1}{y_{N,\alpha}} \varepsilon_{l(\alpha)} \psi_{N,l(\alpha)} \chi_{\alpha i} \chi_{ij} \cdots\cdots \chi_{k\Omega} C_\Omega \quad (1)$$

Here C_Ω is the weight of the consumed product Ω of which we want to know the effect, χ_{ij} is the weight of the product i to produce unit weight of product j, $\varepsilon_{l(\alpha)}$ is the equivalence factor of land type $l(\alpha)$ for the product α *, $\psi_{N,l(\alpha)}$ is yield factor of nation N and land type $l(\alpha)$, $y_{N,\alpha}$ is the average weight of the product from unit area in the nation N. And the sums are executed in all paths from product Ω to product α through intermediate products *i*, *j*... Using the matrix representation, $\{1+\chi+\chi\chi+\chi\chi\chi+\quad\}=[1-\chi]^{-1}$, and

$$EF = \vec{\lambda}[\mathbf{1}-\boldsymbol{\chi}]^{-1}\vec{C} \tag{2}$$

here $\vec{\lambda}$, $\vec{C}$ is vector representation of $\varepsilon_{l(\alpha)}\psi_{N,l(\alpha)} / y_{N,\alpha}$ and C_{Ω}, $\boldsymbol{\chi}$ is the matrix representation of χ_{ij} and $\mathbf{1}$ is unit matrix and we omit the nation's suffix N in *EF* and $\vec{\lambda}$.But usually it is difficult to know χ_{ij} of all products' pairs [*i*, *j*] without double counting. Sometimes we want to measure the effect of consumption toward other industrial sectors or toward other nations, not only on economic impact but also on environmental impact. Input-Output table enables us to calculate such impacts by induced analysis.

$$EF = \vec{\lambda}[\mathbf{1}-\boldsymbol{\chi}]^{-1}\vec{C} + \vec{\lambda}^{fuel}\vec{C} \tag{3}$$

In eq.(3), $\vec{C}$ is a demand vector of sectors expressed by amount of money, $\boldsymbol{\chi}$ is the coefficient matrix and $[\mathbf{1}-\boldsymbol{\chi}]^{-1}$ is the Leontief Inverse Matrix of the Input-Output table. $\vec{\lambda}$ is a kind of induced value added vector which shows environmental impacts. Additional term $\vec{\lambda}^{fuel}\vec{C}$ represents CO2 emission from the direct fuel use of final consumption. For example, in case of agriculture sector, $y_{N,\alpha}$ is the total amount of agricultural product divided by the total area of the Cropland of the considering region N. $\varepsilon_{l(\alpha)}$ is the equivalence factor of Cropland, $\psi_{N,l(\alpha)}$ is yield factor of the region N and Cropland .

There is another method to calculate the vector $\vec{\lambda}$. Global Footprint Network (GFN) calculates nation's EF_l of each land type l every year and these EF_l s represent the area after considering the productivity.

If EF_l s were distributed to each sector α (They are called direct EFs), $\vec{\lambda}$ is able to replace by them. The merit of this method is that induced EFs are able to compare to other nations' EFs through EFs calculated by GFN.

III. NETWORK REPRESENTATION

Our purpose of this paper is to study inter-industry relation on the economy (money) base and environmental impact base by network representation. So we rewrite the vectors $\vec{\lambda}$ and $\vec{C}$ to the diagonal matrix $\boldsymbol{\lambda}$ and $\mathbf{C}$. Then we get the basic matrix.

$$\mathbf{W} = [\mathbf{1}-\boldsymbol{\chi}]^{-1}\mathbf{C} \tag{4}$$

$$\mathbf{EF} = \boldsymbol{\lambda}[\mathbf{1}-\boldsymbol{\chi}]^{-1}\mathbf{C} + \boldsymbol{\lambda}^{fuel}\mathbf{C} \tag{5}$$

$$\mathbf{EF}_C = \boldsymbol{\lambda}_C[\mathbf{1}-\boldsymbol{\chi}]^{-1}\mathbf{C} + \boldsymbol{\lambda}_C^{fuel}\mathbf{C} \tag{6}$$

Here eq.(4), eq.(5) and eq.(6) are the matrix representations of normal induced analysis, of EF base (eq(3)) and of CO2 emission EF base. $\boldsymbol{\lambda}_C$ is one part of $\boldsymbol{\lambda}$ calculated by EF of Carbon uptake land.

$\mathbf{W}$, $\mathbf{EF}$ and $\mathbf{EF}_C$ are no symmetric matrix with diagonal elements, so they can be thought as the adjacency matrix of the directed multi-weighted networks.

IV. Input-Output Table for East Asia

We use "Input-Output table for East Asia" of 2000 [5]. This Input-Output table includes the data of 8 nations in East Asia (China, Indonesia, Japan, Korea, Malaysia, Philippines, Singapore, Thailand) and the data of USA. In this paper, we split this table into each nation's table with 76 industry sections.

1. To calculate the matrix $\boldsymbol{\lambda}, \boldsymbol{\lambda}^{fuel}, \boldsymbol{\lambda}_C, \boldsymbol{\lambda}_C^{fuel}$, we allocate the EF calculated by GFN to each sector of each nation. EFs are allocated in proportion to the total of each sector according to the Table 1. We reallocate the CO2 emission data provided by International Energy Agency(IEA) into the 76 sectors of Input-Output table. Next we allocate the Carbon uptake land EF into 76 sectors in proportion to these CO2 emission data.

Table 1. Land types and corresponding sectors

1	EF of Cropland	Agriculture sectors
2	EF of Forest	Forestry sectors
3	EF of Grazing land	Agriculture sectors
4	EF of Fishing ground	Fishery sectors
5	EF of Carbon uptake land	All sectors Final consumption
6	EF of Built-up land	All sectors

2. Using the Input-Output table, we calculate eq.(4), eq.(5) and eq.(6).
3. The networks represented by the adjacency matrixes $\mathbf{W}$, $\mathbf{EF}$ and $\mathbf{EF}_C$ are directed multi-weighted networks. But the analytical tools for directed multi-weighted networks have not been developed well, so in this paper we extract directed un-weighted networks as follows.

Extraction of the network

1. We make complete network of all industry sections as nodes being connected each other by edges.
2. We remove edges from the complete network in order from the smaller corresponding matrix elements until the number of nodes of largest connected network becomes 38(half of the number of all nodes).

V. RESULT

Figure 1 shows extracted network of **EF** in Japan, which includes 38 nodes. Figure 2 shows the distribution of off-diagonal elements (edge values) of the matrix **EF** of Japan. The edges (log(edge values) >

31, right side of the dotted line) remain in extracted network. Log-log plot of the cumulative distribution of extracted network is shown in Figure 3. It shows power law with exponent -2.12+1. For example in Japan, Table 2 shows that only 2.13%(money base), 1.83%(EF base) and 2.17%(CO2 base) of all edges remain in extracted network, but the sum of these edge values reaches 51.9% , 77.2% and 80.8% of the sum of all edge values. In EF base network, the smaller number of edges have more edge values than money base network. In CO2 base network, the smaller number of edges have more edge values than EF base network. The power law exponents in 27 extracted networks are summarized in Table 3. In Japan, power law exponents are 2.79, 2.12 and 2.08 on money, EF and CO2 base. Table 4 shows industry sections (nodes) of maximum degree, of maximum closeness and of maximum sum of elements (edge values), being calculated by out-edge and in-edge separately. In developed nations (USA, Japan, Korea, Singapore), on money base, Building construction sector has maximum connection and gives large influence to other sectors. On EF base and CO2 emission base, Wholesale and retail trade sector has maximum connection to inward direction. On money, EF and CO2 emission base, Other services sector has maximum connections to inward direction and gets large influence from other sections.

In developing nations (China, Malaysia, Philipines, Thailand, Indonesia), on money base, Wholesale and retail trade sector has maximum connection to inward direction from other sections. On EF base, Livestock and poultry/ Fishery/ Food crops have maximum connection to the outward direction to other sections. But on CO2 emission base, Wholesale and retail trade sector has maximum connection to the outward direction to other sections.

V. CONCLUSION

We study the Input-Output table for East Asia as complex networks. We show that 'the complex networks' is suitable method for these studies. We find the basic characteristics of the inter-connection between industry sections. Although we have not studied the international relations, it is expected that these studies will be able to make clear the way on which nations have developed with inter-nations connection if we study the Input-Output table of other years.

Acknowledgements

The study was supported by research project for a sustainable development of economic and social structure dependent on the environment of the eastern coast of Asia. We thank for not only financial support but also helpful discussion of the project members.

Abstract: As an emerging financial market, the trading value of Carbon emission trading Market are definitely increased in recent years. The carbon emission is not only trading in Carbon emitters but also become an important investment target. For reveal the mechanism of this growing market, we analyzed the EU allowances (EUA) price series in European Climate Exchange (ECX), that is the leading European emissions futures market. As other financial market, the absolute value of price change (volatility) in Carbon emission trading Market also shows long-term power-law correlations. Our analysis shows that definite cross correlations exist between EUA and many other markets. These cross correlation exist in wild-range fields, stock market index, futures of crude, sugar, cocoa, etc. it suggest that in this new carbon emission trading market the speculation behavior had already become a main factor that can affect the price change.

Keywords: carbon emission, emerging financial market, Minimal-spanning trees,long-term power-law correlations

1 INTRODUCTION

Many social systems are characterized by complex int eractions between a large numbers of individual compo nents, which manifest in power-law Correlations. For e xample, in financial field, several stylized facts have b een found for the equity price data in temporal field, s uch as 1, the distribution of the stock price changes (r eturn) has a power-law tail. 2, the absolute value of st ock price change (volatility) is long-term power-law co rrelated. 3. The spectral density of stock price is well described by power-law function. Such as 1, the distrib ution of the stock price changes (return) has a power-l aw tail. 2, the absolute value of stock price change (v olatility) is long-term power-law correlated. 3. The spe ctral density of stock price is well described by power -law function [3-5].

In the field of physics and economy, not only the c haracter of a single asset (time series) is important, bu t also the cross-correlations between pairs of assets pla y a key role in the financial analysis. The taxonomy a nalysis for a stock portfolio is considered as a useful method. The investigation of correlation distance of dif ferent stocks can extract economic information stored i n the stock-price time series, and define the metric of the relative distance between the stocks included in po rtfolio. In this study we investigate the relative distanc es based on daily price time series of EU allowances (EUA) and with other stock and futures markets. The Minimal-spanning trees (MST) are determined by the r elative distances.

2 TAXONOMY OF EUA AND SOME OTHER MARKET

A method of determining a distance between time seri es (usually stock price time series) i and j evolving in time in a synchronous fashion is the following.

$$\tilde{S} \equiv \frac{S_i - \langle S_i \rangle}{\sqrt{\langle S_i^2 \rangle - \langle S_i \rangle^2}} \qquad (1)$$

Where S_i the logarithmic price difference of time seri es i, is given by equation (2).

$$S_i \equiv \ln Y_i(t) - \ln Y_i(t-1) \qquad (2)$$

Here is the daily closure price of time series i at tim e t, and S_i is the daily change of the logarithm of t he price of stock i.

The Euclidean distance d_{ij} between vectors $\tilde{S}_i$ and $\tilde{S}_j$ is obtainable from the Pythagorean relation. If th ere have n time series of $\tilde{S}_i$ present in the same tim e interval. The distance of time series i and j can b e described as equation (3)

$$d_{ij} = \| \tilde{S}_i - \tilde{S}_j \|^2 = \sum_{k=1}^{n} (\tilde{S}_{ik} - \tilde{S}_{jk})^2 \qquad (3)$$

The d_{ij} can also be described by correlation coefficie nt ρ_{ij}, as following function, the correlation coefficien t assume values ranging from -1 to 1.[1]

$$d_{ij} = \sqrt{2(1-\rho_{ij})} \qquad (4)$$

Because Equation (3) defines a Euclidean distance the following three properties must hold:

$$d_{ij} = 0 \Leftrightarrow i = j$$

$$d_{ij} = d_{ji}$$

$$d_{ij} \le d_{ik} + d_{kj}$$

Thus the quantity d_{ij} fulfills all three properties that must be satisfied by a metric distance. In the presence of a metric space in which n objects are linked toget her, the subdominant ultrametric can be obtained by de termining the minimal spanning tree (MST) connecting n objects. The MST is a concept in graph theory [2]. In a connected weighted graph of n objects, the MST is a tree having n-1 edges that minimize the sum of the edge distances.

In our study, we select 22 worldwide financial price time series from 2007 to 2010, which include 6 stoc ks indicates and 16 future options that include EU all owances (EUA). The data are download from finance yahoo and European Climate Exchange ECX market. All financial daily price time series that used in our study are list in Table 1.

Table 1. The list of financial products used in our stu dy

Name	***Description***
NYdow	indicator of NYDOW stock excha nge
FTSE100	Financial Times Stock Exchange 1 00 Index
BSE30	Bombay Stock Exchange Sensitive Index
BVSP	indicator of Sao Paulo Stock Exch ange
Nikkei	indicator of Tokyo stock Exchange
SSEindex	indicator of Shanghai stock Excha nge
Treasury30	U.S. 30-year bonds
UKgilt_all	Average UK gilt
EUA	EU allowances future price
WTI	West Texas Intermediate
RIchard_bay_Coal	Future price of coal loading at Ri chards Bay in South Africa
EUR_Index	Index of Euro
UK_Nature_Gas	Future price of UK nature gas
UK_Base_Electrici ty	Future price of UK base Electricit y
Coffee_C	Future price of Coffee in ECX
Sugar_No_11	Future price of Sugar No. 11
FCOJ-A	Future price of FCOJ A
Cotton_No_2	Future price of Cotton No.2
US_Dollar_Index	Index of US Dollar
Western_Barley	Future price of Western Barley
Canola_Futures	Future price of Canola of Canada
RJ/CRB_Index	Reuters Jefferies/CRB Index, benc hmark indicator of overall commo dity price

We calculate the relative distance of each two price time series from 2007 to 2010 by using equation (3). Next the MST can be produced by these relative dista nces. It is shown in Figure 1.

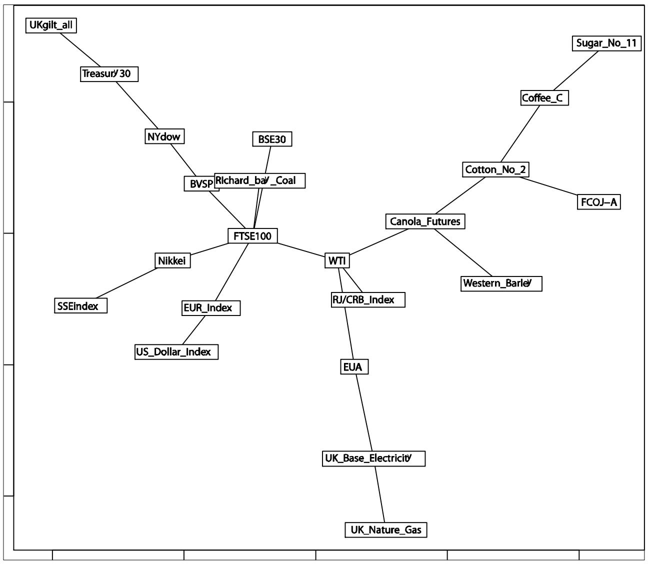

Fig. 1. The structure of minimal spanning tree (MST) for the time period 2007 to 2010.

From Figure 1, we can find that all stocks indicate b ecome a group, and EUA are strong correlated with ga s and electricity futures. In this graph we also find tha t WTI and FTSE100 are two key financial products, th e two connect the stocks and futures. Moreover, we fi nd that the same type financial productions are closer than different type. For example debt future Treasury30 and UKgilt are connected, EUR and Dollar futures ar e also connected.

3 STABILITY OF MST

In chapter 2, we investigate the relative distance of our selected worldwide financial products. Next we want to know how stable a minimal spanning tree structure can be. So we showed the minimal spanning tree obtained in the calendar years from 2007 to 2010 for the 22 financial products.

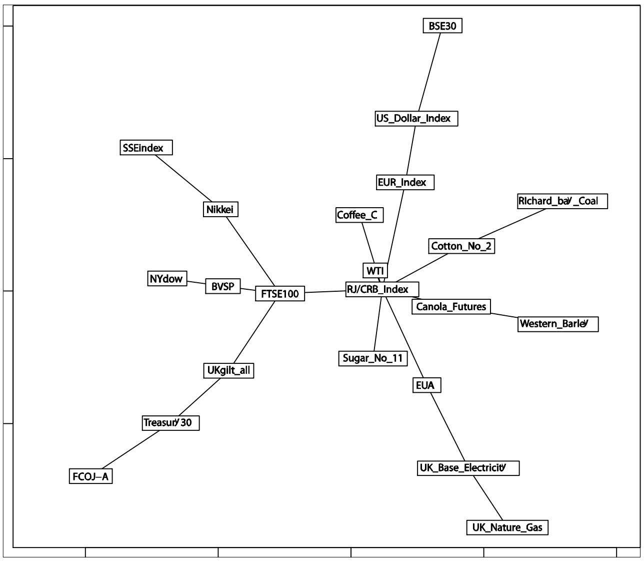

Fig. 2. The minimal spanning tree of 2007

In Figure 2, we show the MST during the calendar year 2007. From this graph we also find that the stock indicates and futures are grouped into two sides. The WTI and FTSE100 also show important characters. Different with figure 1, RJ/CRB index become Central node instead of WTI. Next, the FCOJ-A is moved to stock and debt side, BSE30 is connected with US dollar index. EUA are also correlated with nature gas and electricity futures.

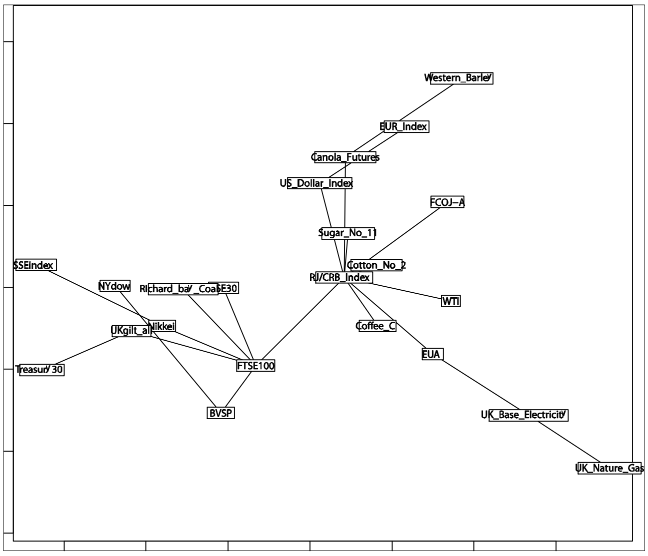

Fig. 3. The MST minimal spanning tree of 2008

Figure 3, shows the MST during the calendar year 2008. Compare with Figure 2 that is from 2007, the structure of MST is more similar with figure 1. The EUA connections with gas and electricity futures are still existed.

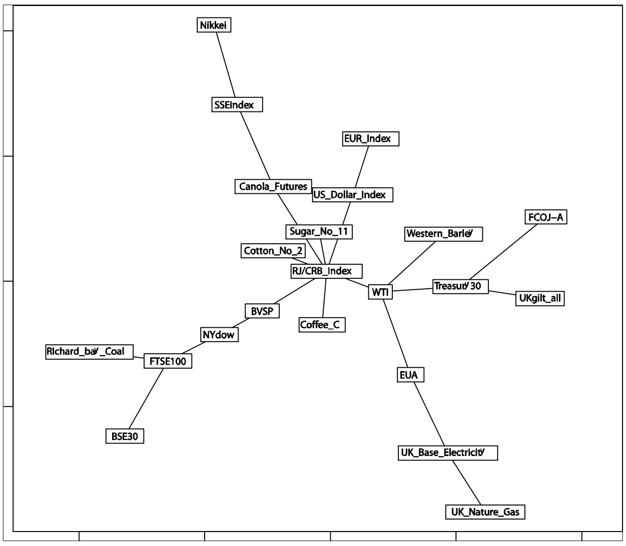

Fig. 4. The MST minimal spanning tree of 2009.

Figure 4, shows the MST during the calendar year 2009. The structure of MST is changed a lot, it look likes a one center tree, the center is RJ/CRB index. But the basic links are not changed, the stocks are connected as one group, debt future and currency index are connected too.

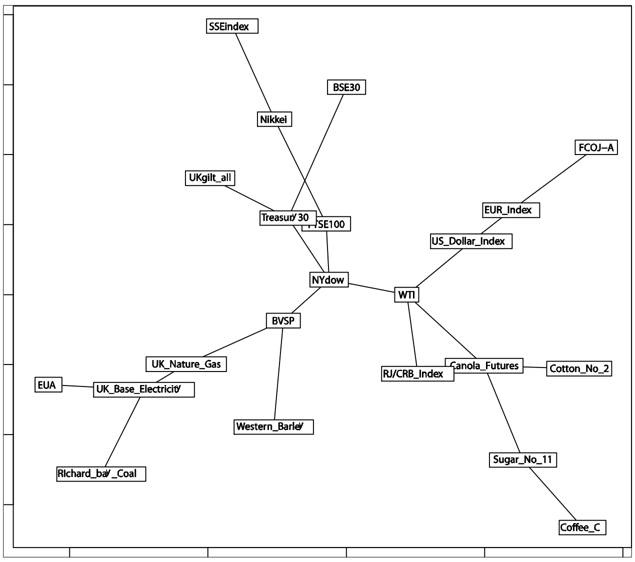

Fig. 5. The MST minimal spanning tree of 2010

Figure 5, shows the MST during the calendar year 2010. EUA are correlated with nature gas and electricity futures, and the base electricity future is connected with Coal. WTI and NYdow are two key financial products which connect the stocks and futures.

In these figures, the correlations of EUA and gas and electricity futures are observed in all years. It indicates that the stable correlation of EUA, nature gas and electricity futures. In all financial produces we may find that the center nodes of the structures are always included in next four products, WTI, RJ/CRB index, NYdow and FTSE100.

In summary, the Figure 2 to Figure 5 show that the MST is time dependent, but maintains on a time scale of years a basic structure that exhibits some meaningful economic correlations.

4 SUMMARY

In our study we have seen that is possible to devise strategies that allow us to obtain meaningful structure of taxonomies if we start from the synchronous analysis of more than one price time series. We find that compare with other links the links of EUA and Nature gas and base electricity price. It indicates d that the Carbon emission are more depended on nature gas and base electricity than other elements. Our study also show that the MST is time dependent, and it maintains on a long time scale a basic structure. The structure may exhibits some meaningful economic correlations.

5 ACKNOWLEDGEMENT

We thank JSPS for grant of "Research project for a s ustainable development of economic and social structur e dependent on the environment of the eastern coast o f Asia" that made it possible to complete this study.

Abstract: Tokyo University of Information Sciences receives MODIS (Moderate Resolution Imaging Spectroradiometer) data, one of the sensors equipped by NASA's Terra and Aqua satellites, and researches of the analysis on change of environment as part of the academic frontier project. For the information infrastructure of this frontier research, we are currently developing a satellite image data analysis system (SIDAS) implemented as a web system, with parallel distributed system configuration using multiple PC clusters, database for MODIS data, and applications to analyze the environmental changes. SIDAS is used to open the research results and MODIS data for public use. In this research, we are developing SIDAS 1.2 using the previously developed SIDAS 1.1 as the basic system. The main feature of SIDAS1.2 is the function of stream data processing, used to analyze the influence of the East Japan Earthquake and the monitor the regrowth of vegetation for the tsunami-stricken area in Tohoku region.This paper presents the overview of system configuration, the stream data processing and analysis functions of SIDAS 1.2.

Keywords: Satellite image data, MODIS, Stream Data Platform.

1 Introduction

Tokyo University of Information Sciences (TUIS) receives MODIS (Moderate Resolution Imaging Spectroradiometer) data, one of the sensors on NASA's Terra and Aqua satellites, and provides the processed data to universities and research institutes as part of the academic frontier project. The main research theme of this project is on “the sustainable development of economic and social structure dependent on the environment in eastern Asia”. One of the major fields of research using MODIS data is the analysis of change in the environment. In this research, we are developing satellite image data analysis system (SIDAS) to support the frontier research such as weather change and environmental changes. In order to improve the accuracy of the analysis, we have developed SIDAS 1.1 which is implemented as a web system, with a parallel distributed system configuration using multiple PC clusters and a database system. SIDAS 1.1 has already supported several applications to analyze the satellite data such as “search system for fire regions in forests and fields” and “search system for similar satellite image data”.

The purpose of our present study is to support the recovery from the East Japan Earthquake. In the research, we examined methods to observe the reconstruction of northeastern Japan after the East Japan Earthquake of March 11, 2011 by using the MODIS data. From these results, we are developing SIDAS 1.2 in order to provide the change of vegetation in time series of the north eastern regions, using the previously developed SIDAS 1.1 as the basic system. The main feature of the updated system is the addition of time series data processing to allow the analysis of the influence of the East Japan Earthquake and the revival of vegetation in the tsunami stricken area in north eastern regions. This paper presents the overview of system configuration, the stream data processing and analysis features of SIDAS V1.2 enhancements for the observation of the reconstruction from the East Japan Earthquake in the north eastern regions.

2 Overview of satellite data analysis system (SIDAS)

In this section, we describe the satellite data analysis system (SIDAS) to support the research environment and open the research results for public use. Figure 1 shows the overview of SIDAS 1.1. SIDAS 1.1 consists of a web server, an application server consisting of multiple PC clusters, and a database server. The application server schedules the execution of applications, manages the satellite data, and controls PC clusters which execute applications. The user can access the system, request data analysis and check the results over the network via a Web browser or other web applications, and the user can also download satellite image data through the system.

The processing flow of SIDAS1.1 is shown as follows.

(1) The Web server accepts request of the user and submits processing of the request to the application server.
(2) The application server transmits the MODIS data used by the processing from the MODIS database to the local disk in the application server.
(3) The application server executes application for the request and returns the results to Web server.

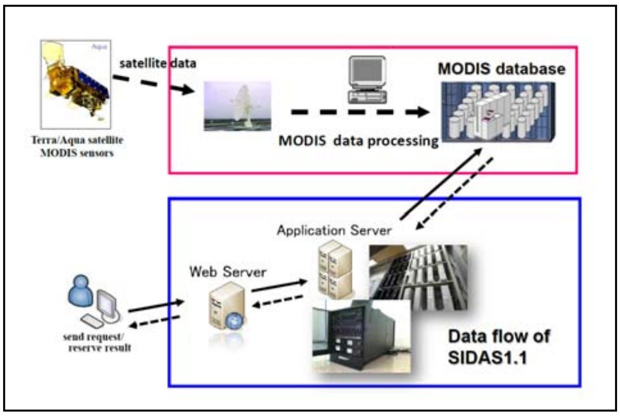

Fig. 1 Overview of SIDAS1.1

3 Overview of Satellite data analysis system 1.2

The purpose of our present study is to support the recovery from East Japan Earthquake. SIDAS 1.2 is being developed for this purpose, and the main feature of this updated system is the stream data processing, to enable the analysis of the influence of East Japan Earthquake and to monitor the regrowth of vegetation for the tsunami stricken area in Tohoku region. The analyzed results are automatically produced for open public access.

The information that we have planned to provide are the next 4 items to identify the reconstruction of land in the tsunami stricken area in the north eastern region from March 11, 2011.

(a) Image information from March, 2010 to the end of February, 2011 (Twice a month: In the first half and the latter half of each month).
(b) Image information after March 1, 2011 (Every day).
(c) Visible information of Normalized Difference Vegetation Index (NDVI), Sea Surface Temperature (SST) and Land Surface Temperature (LST) after March 1, 2011 (Every day).
(d) Visible information of difference between NDVI after March 1, 2011 and NDVI on the same day for one year ago (Every day).

Figure 2 shows the overview of SIDAS 1.2. SIDAS 1.2 executes the following processes every day.

(1) The application server receives the MODIS data stored in the MODIS database, and analyzes the information described in the above (a) ~ (d).
(2) The application server stores the analytical result in the database server.
(3) The Web server retrieves the analysis results from the database server and provides the data for open public access.

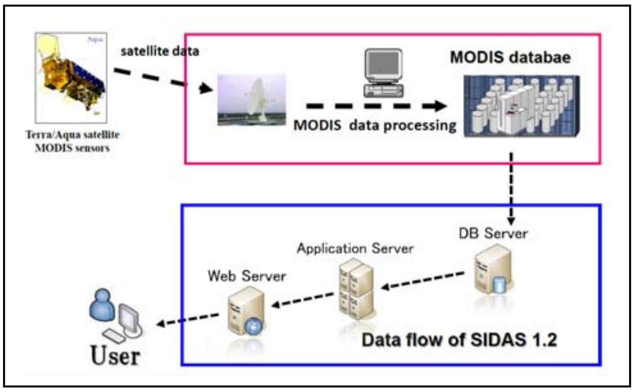

Fig. 2 Overview of SIDAS1.2

4 Summary of MODIS data in SIDAS

MODIS is a multiple band radiometric sensor instrument aboard Terra (NASA launched on December 18, 1999, at local time 10:30AM) and Aqua (NASA launched on May 4, 2002, at local time 1:30PM) satellites to monitor the environment of a large region of the earth covering a width of 2,330 km. It measures 36 spectral bands between 0.405 and 14.385 μm with three spatial resolutions (250m, 500m, 1,000m).

Tokyo University of Information Sciences (TUIS) is receiving MODIS data from three places in Hokkaido, Tokyo and Okinawa, and received the data 3 or 4 times in the daytime and 3 or 4 times in the nighttime from each place. The observing areas from the three places are from 100 degrees to 180 degrees of east longitude and from 10 degrees to 70 degrees of north latitude.

In this research, we use the following standard MODIS data products, MOD02 (MODIS calibrated radiances product: spatial resolution), MOD03 (geological location product), MOD11 (land surface temperature), MOD13 (vegetation index), MOD28 (Sea Surface Temperature), MOD35 (cloud mask) from MODIS products. Table 1 shows the band information of MODIS data.

Table 1 Relationship between the feature of the wavelength and the resolution of the bands

BAND	WAVELENGTH(nm)	SPATIAL RESOLUTIONS	KEY USE
1	620 ~ 670	250m	Absolute Land Cover change, Vegetation Chlorophyll
2	841 ~ 876	250m	Cloud Amount, Vegetation Land Cover change
3	459 ~ 479	500m	Soil/ Vegetation Differences
4	545 ~ 565	500m	Green Vegetation
5	1230 ~ 1250	500m	Leaf/Canopy Differences
6	1628 ~ 1652	500m	Snow/Cloud Differences
7	2105 ~ 2155	500m	Cloud Properties, Land Properties
21	3929 ~ 3989	1000m	Forest Fires & Volcanoes
22	3929 ~ 3989	1000m	Cloud Temperature, Surface Temperature
31	10780 ~ 11280	1000m	Cloud Temperature, Forest Fires & Volcanoes, Surface Temperature
32	11770 ~ 12270	1000m	Cloud High, Forest Fires & Volcanoes, Surface Temperature

5 Process of function in Stream Data Platform

In this research, we examined the observation method for the reconstruction of land in the Tohoku region from the East Japan Earthquake that had occurred on March 11, 2011 by using the MODIS data. The developed analysis functions of SIDAS1.1 is used to open the satellite data described in Chapter 3 for public retrieval. SIDAS1.1 that is base system of this research receives MODIS data, and this system executes application according the request of user such as "Search for fire regions in forests and fields" or "Search for similar image data" by using the MODIS data. Fig. 3 shows the configuration of SIDAS1.1.

In this research, we are examining stream data processing function that analyze reconstruction of the tsunami stricken areas in the Tohoku region, and are developing SIDAS1.2 to open the analytical result in real time by using the satellite data received every day.

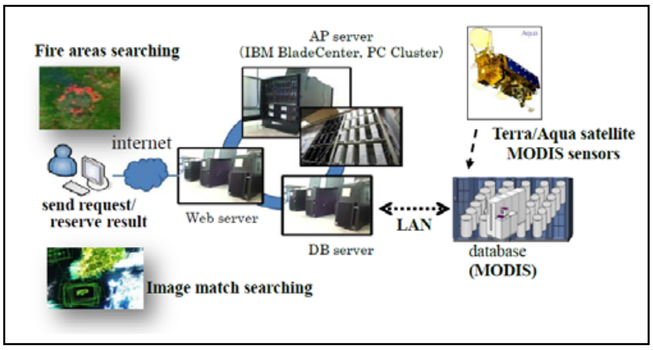

Fig. 3 Configuration of SIDAS1.1

Fig. 4 shows the configuration of SIDAS1.2. We used the stream data processing model for the data processing in SIDAS1.2. In this model, data processing scenarios are registered in the system beforehand, and the system receives and processes huge satellite data in real-time according to the predefined process scenario.

In the stream data processing function of SIDAS1.2, the analysis and web publishing function for the following item were implemented.

(a) Analysis from March in 2010 to the end of February in 2011

(b) Analysis after March 1, 2011

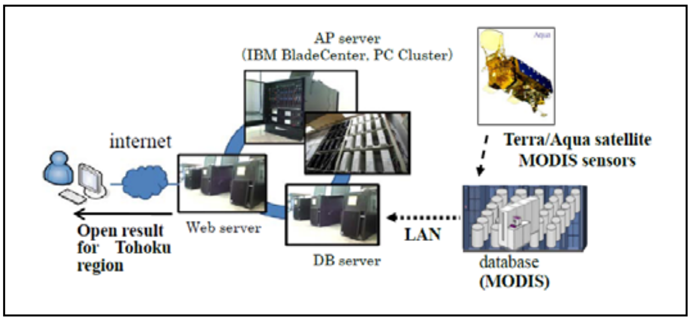

Fig. 4 Configuration of SIDAS1.2

MODIS data is analyzed beforehand and stored into the database for (a). We developed the data stream function to execute the reception, analysis and web data release of the satellite data in real time for (b). The process in the application server and Web server for (a) and (b) is shown as follows.

(a) Create analytical information from March, 2010 to the end of February, 2011

(a1) Application server

The following image data are created by using the MODIS data from March in 2010 to the end of February in 2011, and the image data are stored into the database.

(a1.1) RGB image data (GIF image : true color image)

The color image data in the Tohoku region is created by using radiance data (Band 1: Red and band 4: Green and band 3: Blue) of MOD02 (spatial resolution: 500m). The created data is GIF image data for 1- day composite data (received every day), 15- day composite data (removed cloud effects of 15-days) and Monthly composite data (removed cloud effects of 30-days). Fig. 5 shows example of display for RGB image data.

(a1.2) Visualized data of NDVI,SST and LST (GIF image : pseudo color image)

NDVI, SST and LST are single band data and thus the image data is normally shown as a grayscale image. In order allow make the data more intuitive to non-experts, the vegetation indexes and temperature values were mapped to color values to create pseudo color images.

(a2) Web server

The Web server publishes data (a), (b) from March, 2010 to February, 2011.

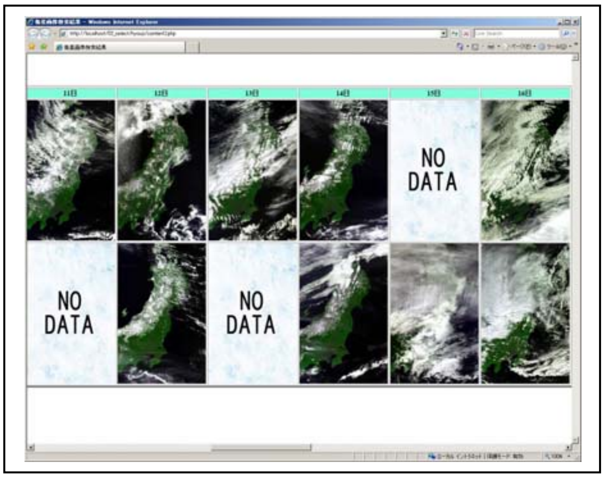

Fig. 5 Example of display for RGB image data

(b) Publish of analytical information after March 1, 2011 (The following process is executed once a day).

(b1) Application server

(b1.1) The application server retrieves the satellite data containing the Tohoku region for a single day. The number of reception from MODIS satellites is three or four times a day.

(b1.2) From the data received in (b1.1), the Tohoku region (north latitude 34°00' - 42°00' and longitude 138°00' - 43°00') is selected, and converts the HDF (Hierarchical Data Format) data to BSQ(binary Band SeQuential) data.

(b1.3) 1-day composite process is executed for the BSQ data created in (b1.2). 1-day composite processing combines the BSQ data with the best reception status (low cloud interface) from among the several MODIS data received that day and synthesizes them to one BSQ data for the selected day.

(b1.4) Create RGB image data from BSQ data (MOD02) and visualized data of NDVI, SST and LST from BSQ data (MOD11, MOS13, MOD28) created in (b1.3), and stores them into the database.

(b1.5) Execute the 15-days composite process once in the first half and once in the latter half of month, and the execute 30-days composite process once a month for BSQ data from (b1.3).

(b1.6) Create RGB image data from BSQ data (MOD02) from (b1.5).

(b1.7) Calculate the difference between the BSQ data (for LST, NDVI, and SST) of the selected observation date and the BSQ data (for LST, NDVI, and SST) created in (a) for exactly one year previous to the selected observation date, and create visualized data from the calculation results and store them into database.

(b2) Web server

Take out image data and visualization data that created in (1.4), (1.6), (1.7) from database and publish these data on the web server.

6 Conclusion and future works

In this research, we examined what information could be used to support the recovery from the East Japan Earthquake, and developed satellite data analysis system (SIDAS1.2) for this purpose. We developed SIDAS 1.2 to implement stream data processing in order to automatically publish up-to-date information on the influence of the East Japan Earthquake and to monitor the regrowth of vegetation in the tsunami stricken areas.

In future works, we intend to support the functions so that the user can acquire necessary information on demand, such as improved features to select analytical region and analytical information arbitrarily. Moreover, we plan to publish visual information incorporating other information sources such as aerial photographs, to examine the situation of the disaster and the reconstruction situation.

Acknowledgments

This research was supported by the Research project of Tokyo University of Information Sciences for the sustainable development of economic and social structure dependent on the environment in eastern Asia.

Abstract: The principal purpose of this study is to describe the development and validation of an algorithm to estimate the fraction of water area within 500-m of the Moderate Resolution Imaging Spectroradiometer (MODIS) operating on the Earth Observation System Terra spacecraft. The result of this study is shown to be effective in determine the flood areas accurately in emergency response efforts as soon as possible. Estimation of a flood periphery is important to determine a fundamental hazard for risk management. This study was to accurately extract the spatial distribution of nation-wide flood risk using MODIS time series images and estimate simple algorithm for computing the flood inundation depth using Digital Elevation Model(DEM), flow direction and river network. The authors improved the accuracy of the water extent boundary using flood inundation depth (FID) data from a one year time-series of MODIS data.

Keywords: Flood risk, flood inundation depth (FID), DEM, MODIS, time-series.

1. INTRODUCTION

Floods are of increasing public concern world-wide due to increasing damages and unacceptably high numbers of injuries. Previous approaches of flood protection led to limited success especially during recent extreme events. Therefore, an integrated flood risk management is required which takes into consideration both the hydrometeorogical and the societal processes.

Real-time determination of flood inundation has been limited to large-scale events such as nationwide inundation. The geographic information system (GIS) including satellite images is an effective method to interpret and analyze a nation-wide flood risk assessment. Moreover, satellite images are also necessary to analyze flood disasters. Remote-sensing images are an effective tool to determine flood inundation areas. Estimation of a flood periphery is important to determine a fundamental hazard for water risk management. Many studies have been conducted by using remote-sensing data to detect spatial and temporal changes in the extent of flood inundation, including the delineation of wetlands [1][2]. The Normalized Difference Water Index (NDWI), a satellite-derived index from near-infrared (NIR) and short wave infrared (SWIR) channels [3], is used to derive water fraction and a flood map from MODIS data. The SWIR reflectance reflects changes in both the vegetation water content and the spongy mesophyll structure in vegetation canopies, while the NIR reflectance is affected by leaf internal structure and leaf dry matter content but not by water content. The combination of the NIR with the SWIR removes variations induced by leaf internal structure and leaf dry matter content, improving the accuracy in retrieving the vegetation water content [4].

The land surface water index (LSWI) use a red channel in place of NIR [1][5][6] used enhanced vegetation index (EVI), LSWI and DVEL (difference value of EVI and LSWI). However, it can be difficult to discriminate water body from clouds in the visual part of the spectrum. Also, it was not easy to extract the river width accurately because of a resolution problem in each a pixel. In this study, the proposed method was applied to extract water body from a channel reflectance by using MODIS time-series images and flood inundation depth (FID). This simple approach was to determine nation-wide inundation areas from a geomorphologic point of view, rather than a hydrological model.

The purpose of this study was to accurately estimate an inundation area based on the spatial distribution of flood hazard for nation-wide flood risk assessment using GIS data and MODIS time-series images. To determine the water extent boundary more accurately, the authors aimed to improve an extraction method of surface water with a simplified decision tree method using MODIS channel 6 reflectance (CH6) and channel 7 reflectance (CH7) acquired from a regional flooding. The improved method was then applied to the Indus River basin in Pakistan, which was selected as the prime research focus area. The selected area suffered from a huge, severe flood caused by abnormally heavy rainfall from late July to early August 2010.

2. DATA

2.1 MODIS MYD09A1

The MODIS Surface Reflectance products provide an estimate of the surface spectral reflectance as it would be measured at ground level in the absence of atmospheric scattering or absorption. MYD09A1 provides channels 1-7 at 500-meter resolution in an 8-day gridded level-3 product in the Sinusoidal projection. Each MYD09A1 pixel contains the best possible L2G observation during an 8-day period as selected on the basis of high observation coverage, low view angle, the absence of clouds or cloud shadow, and aerosol loading. Science datasets provided for this product include reflectance values for channels 1-7, quality assessment, and the day of the year for the pixel along with solar, view, and zenith angles[7].

2.2 Flood inundation depth

Topography is an essential factor for hydrologic models to simulate flooding and runoff. One of the most obvious factors controlling stream flow is the gradient, or slope, of the stream channel. The definition of FID is the accumulated level index overflowing the banks of a main river. It is clear that FID indicates the depth due to overflowing the banks of a river and can be defined as the accumulated level index. Kwak & Kondoh [8] developed and proposed FID for basin-wide flood risk assessment at the national level. Actual calculation of FID required a dataset composed of DEM, flow direction and river network. FID was determined based on DEM and the highest water level (HWL) of the main stream, as shown in equation (1) below:

$$H\_{ij}\ FID = H\_{ij}(DEM) - H\_{ij}(HWL\ of\ river) \qquad (1)$$

where, H is the height of surface, i is the number of pixels, and j is the number of lines.

3. Methodology

3.1 Extraction of water body

MODIS channels were strongly absorbed by water, providing information on the inundation pattern. Fig. 1 illustrates that the reflectance rate of clean water was the lowest among the classification of soil, vegetation, snow, cloud and clean water (up of Fig. 1). Particularly, the authors found that the reflectance rates of CH6 and CH7 were the lowest than the other channels in the case of surface water such as clean water, muddy water, and flooded water (down of Fig. 1). Flood hazard assessment was performed by using MODIS dataset with FIL, population and land-cover data. The developed approach was to determine inundation areas nation-wide from a geomorphologic point of view, rather than based on a hydrological model. First of all, to identity spatial inundation distribution, a decision tree was used to associate each pixel with one of the two categories: water body or land surface.

For flood risk assessment, the quantitative assessment was divided into three steps. To estimate flood areas, two categories of the MODIS images, water and non-water areas, are combined to obtain the maximum water area. The water areas were considered to be normal water such as river, lake, pond, and so on, and the non-water areas are considered to be non-flood areas. The main stream in the Indus River basin and the water areas were extracted to composite images derived from 46 image dataset in 2009.

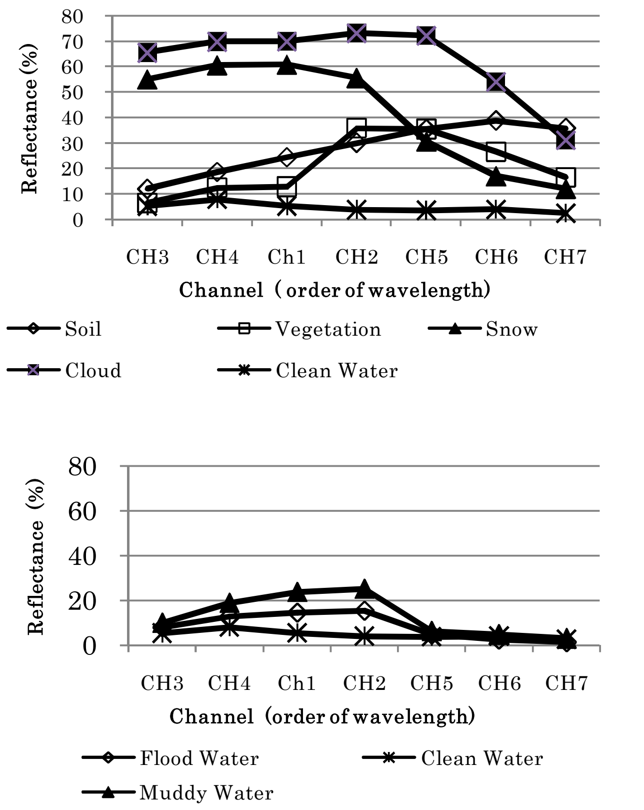

Fig. 1. Surface reflectance of MODIS land channels (up) and reflectance rate in case of surface water (down)

The MODIS channels were strongly absorbed by water, providing information on inundation patterns using Normalized Difference Index (NDI). However, the NDWI and LSWI have some weaknesses and errors to extract water bodies. For instance, the spectral reflectance rate of water is higher than that of a forest (e.g., forest = 0.14, clean water = 0.1). To assess a flood area, MLSWI was used an absorption ration instead of a reflection ration as follow; Absorption ration (A) = 1 – Reflection ration (R). The new approach also worked well to differentiate water from land under three conditions: CH7 < 10%, CH1+10% > CH2 and CH3 < 20%, where MODIS MYD09A1 land channels.

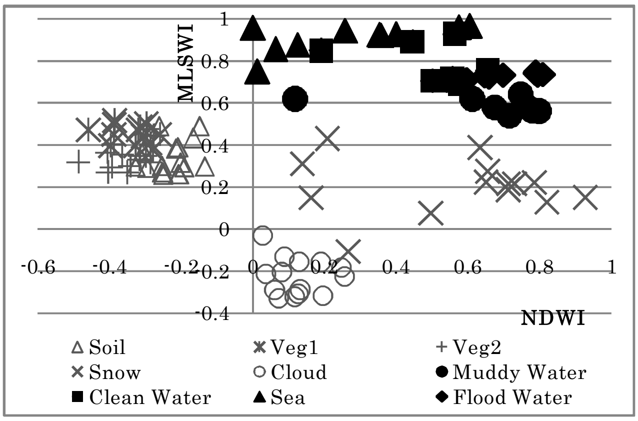

Fig.2. The index comparison of a land classification between MLSWI and NDWI for extracting flood areas

Equation (2) is a simple algorithm for identifying inundation areas by using combination of the NIR (841-875mm) with the SWIR (1628-1652mm).

$$MLSWI = \frac{A_{SWIR} - R_{NIR}}{A_{SWIR} + R_{NIR}} \quad (2)$$

As shown in Fig. 2, MLSWI can detect flood areas better than NDWI. MLSWI shows indices over 0.5 when detecting bodies of water, clean water and muddy water in flood areas. On the other hand, NDWI cannot distinguish water from land especially when the area contains snow cover, which shows indices of over 0.5. Second, the authors overlaid the FIL data and the extracted water areas which are covered two water areas (stream and flood areas) derived by MLSWI. It was considered as a major influencing factor on flood areas. The accumulated FIL of the target pixel was raised at 1 meter intervals. The calculated FIL provided a basis to estimate the flood extent areas of flood levels and inundation line in lowlands and near-zero gradients along the stream per 500 m-mesh. Potential FIL was conducted to identify flood inundation height and inundation probability. Finally, the flooded-area data obtained based on MODIS images and FIL are coupled with population and land cover datasets to estimate disaster damage. For each scenarios of the damage, the respective inundation depth and areas were obtained by extreme flood event, because FIL was a extreme analysis to the calculated results. Therefore, each exposed object can be linked to a distribution risk map related to potential FIL. FIL improved the simulation to clearly show that people living in the lowlands are more affected than those in other places. The land-cover data also improved it to identify flood risk per classification and enable damage estimation per 500 m mesh. Population and land cover classification schemes were proven very useful to assess flood damage over lowlands.

4. Result

Based on the flood water extent results, the authors conducted to identify expected flood inundation depth per 250 m-mesh. The periphery of flooded areas is directly correlated with an inundation depth around the river. Therefore, it was clear that flood inundation depth (FID) indicated the depth due to overflowing the banks of a river and can be defined as the accumulated level index. From Fig. 2 (Indus River basin), it can be concluded that, the FID of inundation area has a value ranging from -1 m to 9 m. Examining the relationship between FID ranges and MODIS images under the flooding, it was found that the inundation area was extracted 70253 pixels, 4390.8 km2 in the Indus River basin from late July to early August in 2010. For instance, the inundation area under the condition of FID = 0 m was estimated to be 31444 pixels, about 4390.8 km2. The inundation area under the condition of FID = 1 m was also estimated to be 8622 pixels, about 538.9 km2. The inundation area under the condition of FID = 2 m was also estimated to be 6468 pixels, about 404.3 km2. In detail, the right of Fig. 2 shows the enlarged view of a partial Punjab Province, Pakistan.

5. CONCLUSION

This is a case study considering the independence of the data sources and the resolution of the data available at the national level. Although flood is controlled by various risk factors, the flood vulnerable area was extracted from GIS-derived data such as FID and satellite images. To conclude flood risk assessment, the authors focused on improvement of the accuracy in determining a vulnerable inundation area using a simplified decision tree method based on MODIS time-series images in the Indus River basin, Pakistan. This new approach can be a very useful tool in emergency response efforts since it can conduct extreme value analysis and predict when and in what size a flooding event may occur. The water extent area can be classified a category of land cover for flood risk assessment affecting nation-wide flood damage based on FID. In the future, the authors are planning to improve the proposed assessment to be applicable on a national, as well as, global level.

Abstract: Remote sensing of the earth surface using satellite monitored sensor data is one of the most important methods for global environmental monitoring. For satellite monitored sensor data, MODIS (Moderate Resolution Imaging Spectoradiometer) satellite data is actively used for the remote sensing data. In remote sensing fields, similar image search which extracts local area images from a given global map image is often required. Similar image search is important because physical changes to the earth's surface caused by human or nature can be monitored. However, long calculation time is required for similar image search in MODIS data due to the very large search space. In our previous research, an effective result was yielded using genetic algorithm on the similar image search from the satellite image. Based on this result, we proposed a particle swarm optimization based search method that globally searches for the problem space using particle groups.

Keywords: particle swarm optimization, transfer learning, similar image search, remote sensing

1. INTRODUCTION

Remote sensing of the earth surface using satellite monitored sensor data is one of the most important methods for global environmental monitoring. For satellite monitored sensor data, MODIS (Moderate Resolution Imaging Spectoradiometer) satellite data is actively used for the remote sensing data. Moderate resolution remote sensing allows to quantify landscape and extent, which can be used to monitor changes in land cover and land use for extended periods of time.

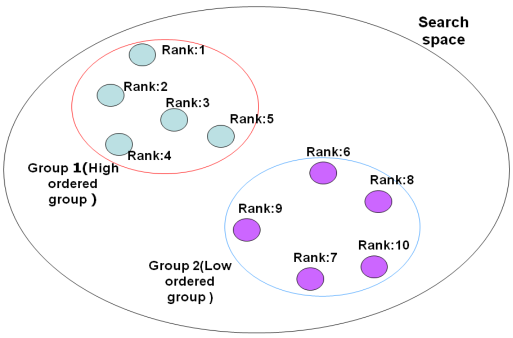
Similar image search is an important problem in the remote sensing using moderate resolution satellite images. Similar image search extracts local area images from a given global image. Similar image search is important because physical changes to the earth's surface are caused by human or nature can be monitored. However, the search space size of the similar image search using MODIS data is very large since MODIS data consists of approximately 1TByte image data per a day. Thus the search process requires long calculation time. In previous research, higher fitness value was yielded using genetic algorithm (GA) on the similar image search from the satellite image. However, the GA depends on improving the solution through a probabilistic learning process, and requires relatively long calculation time. For this result, we proposed a particle swarm optimization (PSO) based method [1] that globally searches for the problem space using particle groups. PSO has advantage in fast conversion rate by comparison with other evolutionary computation algorithm.

Recently, the transfer learning is actively researched [2]. The transfer learning is the meta learning methods that uses the knowledge and data in an domain in order to solve the problem in the another domain. In transfer learning, it is expected that the improvement of the learning efficiency and the compensation for the lack of knowledge and data is performed when the problem is solved. There exists the similarity of pixel data in similar image search. Therefore, more effectively learning can be performed using transfer learning when an image similar to the previous learned image was given. The proposed method can use the learning result for a previous input image in order to learn to another input image. By this characteristic, it is expected that the similar image search is performed effectively. In this paper, we investigated the effectiveness of proposed method.

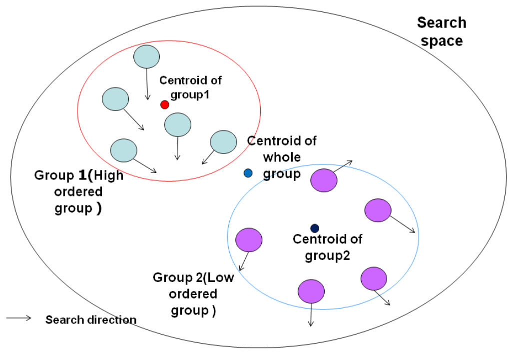
2. METHOD

In PSO [3], a i-th particle is defined by the d-dimensional position vector $\mathbf{x}_i = \{x^1{}_i, x^2{}_i, \ldots, x^d{}_i\}$ and velocity vector $\mathbf{v}_i = \{v^1{}_i, v^2{}_i, \ldots, v^d{}_i\}$ for the d-dimensional search space. A velocity is defined by the local best position $\mathbf{p}_i$ that is own best fitness position at the i-th particle and the global best position $\mathbf{p}_g$ that is best fitness position in the whole particle. Each particle moves according to velocity vector for search.

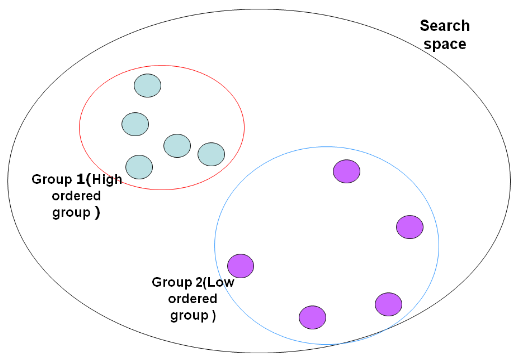
The proposed method divides the particles to the plural groups. Each group is composed of the N/K particles where N is the number of all particles and K is the number of groups. A velocity is defined by the local best position $\mathbf{p}_i$, the global best position $\mathbf{p}_g$, and the group best position $\mathbf{p}_k$ that is best fitness position in a group k. The particles are divided into the group by order of fitness value. Moreover, a velocity is defined to leave from the centroid of each group of the particles and the centroid of all groups of the particles in addition to the local best position, the global best position and the group best position. The particles of high ordered group search in the global best neighborhood and the particles of low ordered group searches around the location to leave for the centroid of each group and the centroid of all groups. In the proposed velocity determination method, the particles of high ordered group fall into local minimum and the particles of low ordered group are searched globally. In addition, the order of each group is changed by the fitness value at generation interval T. Behavior of the proposed method is shown in Figure 1 and a flow of the proposed method is shown in Figure 2.



(a) Grouping of the particle by the order



(b) Determination of search direction at every group



(c) Search of every group

Figure 1. Outline of the proposed method

Step1. A position $\mathbf{x}_i$ and a velocity $\mathbf{v}_i$ of each particle are initialized. Each particle is assigned to each group in random.

Step2. A fitness value of each particle is calculated by fitness function $f(\mathbf{x}_i)$.

Step3. The local best position $\mathbf{p}_i$ of the each particle, the global best position $\mathbf{p}_g$ and the group best position $\mathbf{p}_k$ of each group are updated.

Step4. The order $q_i = \{1,2,\ldots,N\}$ is defined by fitness value $f(\mathbf{x}_i)$ to each particle. The particle which got a best fitness value becomes rank 1 and the particle which got a worst fitness value becomes rank N. Each particle has total of the rank value R_i. R_i is calculated by q_i using equation (1)

$$R_i(t+1) = R_i(t) + q_i(t) \quad (1)$$

where t is a generation.

Step5. The position $\mathbf{x}_i$ and the velocity $\mathbf{v}_i$ of each particle are updated by equation (2) and equation (3)

$$\begin{aligned}\mathbf{v}_i(t+1) &= w_k \cdot \mathbf{v}_i(t) + c_1 \cdot \mathbf{r}_1 \cdot (\mathbf{p}_i(t) - \mathbf{x}_i(t)) \\ &+ c_2 \cdot \mathbf{r}_2 \cdot (\mathbf{p}_g(t) - \mathbf{x}_i(t)) + c_3 \cdot \mathbf{r}_3 \cdot (\mathbf{p}_k(t) - \mathbf{x}_i(t)) + h(t)\end{aligned} \quad (2)$$

$$\mathbf{x}_i(t+1) = \mathbf{x}_i(t) + \mathbf{v}_i(t+1) \quad (3)$$

where w_k is momentum rate for group k, $c_1,\ldots,c_5$ is the heaviness for each vector, $\mathbf{r}_1,\ldots,\mathbf{r}_5$ is a vector of random values from 0 to 1 and $h(t)$ is a function that updates the centroid of each group and the centroid of the whole groups. The function $h(t)$ is defined by equation (4)

$$h(t) = c_4 \cdot a(k) \cdot \mathbf{r}_4 \cdot \left\| \mathbf{x}_i(t) - \bar{\mathbf{x}}_k(t) \right\| + c_5 \cdot b(k) \cdot \mathbf{r}_5 \cdot \left\| \mathbf{x}_i(t) - \bar{\mathbf{x}}_g(t) \right\| \quad (4)$$

where $\bar{\mathbf{x}}_k$ is a centroid of group k and $\bar{\mathbf{x}}_g$ is a centroid of whole group. In addition, $a(k)$ and $b(k)$ are values of the functions to increase monotonically in [0,1].

Step6. If a generation is group reordering, go to Step7. If a generation is not group reordering and termination condition is not satisfied, return to Step2.

Step7. Based on total rank of each particle R_i, the affiliation of the particle of each group is changed. For example, the best fitness group is composed of the particles from the rank 1 to rank N/K in the low order of R_i. Each particle is assigned to the low order of R_i in each group. If termination condition is not satisfied, return to Step2.

From this characteristic, the proposed method can use the learning result of a previous input image in order to learn for another input image as transfer learning. Therefore, the proposed method has advantage in the calculation cost reduction and the finding of solution with higher fitness value when another input image is given.

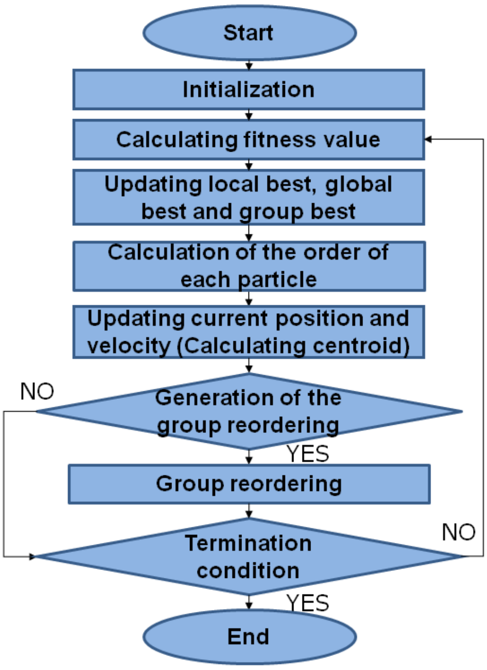


Figure 2. Flow chart of the proposed method

3. EXPERIMENT

3.1 Similar Image Search

A similar image search is a problem that extracts local area images for a given image from global map image. The similar image search is derived by information included in image (ex. a pattern of pixel data and the color). In this experiment, the new input image is given after defining an initial value through the learning of a different satellite image. Therefore, a previous learning result has an influence on the search of a new satellite image. Figure 3 shows a global image, a target image that is new input image, an image1, an image2 and an image3 that are previous input image in this experiment.

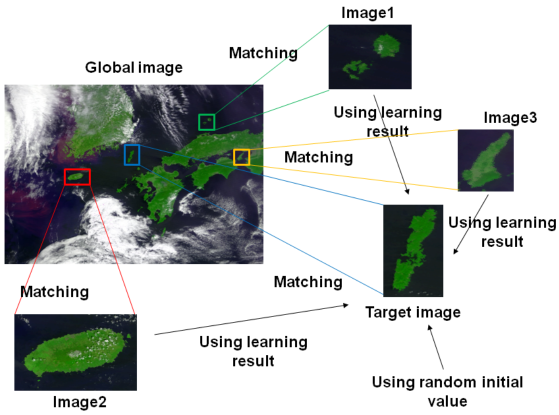

Figure 3. Similar image search in this experiment

In this experiment, the fitness value is calculated by the matching rate of the selected image pixel data specified by the search parameters. The parameters consist of translation, scale rate and rotation angle. The separation (absolute difference) of the values for each color from the compared pixel is calculated, and the sum of the separation is defined as the matching rate for the compared pixel. The fitness value fv is defined by equation (5)

$$fv = 1.0 - \left(\sum_{j}^{y}\sum_{l}^{z}\left|img1_{jl} - img2_{jl}\right|\right) / y \cdot z \cdot 255 \quad (5)$$

where $img1$ is the pixel data for the target MODIS data region, $img2$ is the pixel data for the image data modified by the search parameters and '255' is max value of each color. In addition, each pixel of the RGB color image is converted to gray-scale image using the equation (6)

$$gray = 0.299 \cdot R + 0.587 \cdot G + 0.114 \cdot B \quad (6)$$

where $gray$ is the image pixel of the gray-scale image, R, G and B are the respective red, green, blue pixel data of the color image at the same pixel location, and '0.299', '0.587', '0.114' are a coefficient for each color established in [4].

In this experiment, initial values are set to random value, learning result of image1, learning result of image2, and learning result of image3. Moreover, we evaluated the proposed PSO using the final fitness value of the global best and the conversion rate for the 50 trials. The generation of proposed PSO and GA are set to 500 in each initial value. In addition, the parameters in the proposed method were defined as follows. The number of all particles N is set to 200, the number of groups K is set to 10, the generation interval of the group reordering T is set to 20, the heaviness for each vector $c_1,\ldots,c_5$ are set to 1.5, 1.5, 1.8, 0.9, 0.9, the moment rate for each group w_k is set to from 0.4 to 0.9. GA was used for comparison with this experiment. The parameters in the GA were defined as follows. The population is set to 200, the crossover type is set to 1 point, the crossover rate is set to 0.9, the mutation rate is set to 0.05 and the strategy of selection is set to the roulette strategy and the elite strategy.

3.2 Experiment Result

Table 1 shows the average fitness value of global best position using each initial value in GA and the proposed PSO for target image. Table 1 shows that the proposed PSO yielded the fitness value higher than GA for each condition. Figure 4 shows the fitness value changes in calculation time of GA and proposed PSO when random initial value was used. The proposed PSO yielded the higher fitness value in calculation time less than GA. From this result, the proposed PSO is more effective than GA in similar image search. The search efficiency is improved by this characteristic that the particles of high order group fall into a local minimum and the particles of low ordered group are searched globally. Figure 5 shows that fitness value of a target image using each initial value in proposed PSO. In particular, the higher fitness value is yielded using a learning result of image2 in earlier generation than using random initial value. From this result, a learning result of image2 has a good influence to the search for a new input image. The proposed PSO can perform more effective search by this good influence.

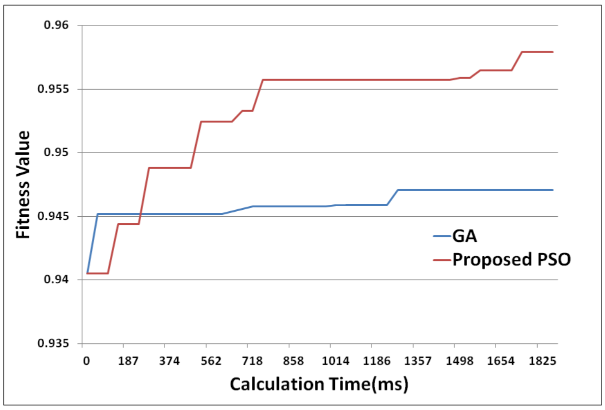

Figure 4. Fitness value changes in calculation time

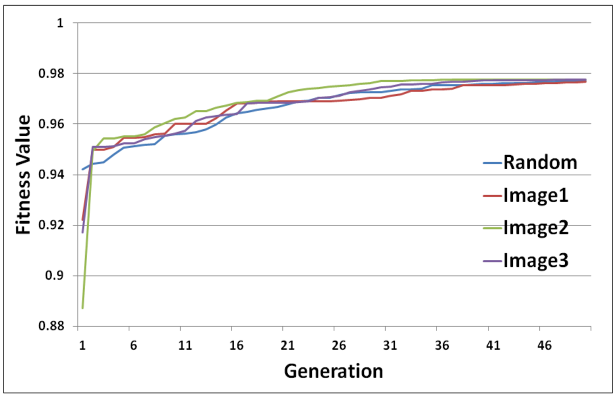

Figure 5. Fitness value of targeted image by each initial value in proposed PSO

Table 1. The average fitness value of global best using each initial value

	Random	Image1	Image2	Image3
GA	0.9609	0.9609	0.9604	0.9601
Proposed PSO	0.9775	0.9775	0.9775	0.9775

4. CONCLUSION

In this research, we proposed the particle swarm optimization based search method that searches for problem space globally by the particle groups and that applies similar image search for investigating the effectiveness of the proposed method. In this experiment, this result showed that the proposed PSO yielded the fitness value is higher than GA. In addition, the proposed PSO yielded the higher fitness value in calculation time less than GA. From this result, the effectiveness of the proposed PSO for similar image search using previous learned image is shown.

In this experiment, we compare the proposed PSO with GA. The distributed genetic algorithm (DGA) that is parallel model of GA has been applied to the similar image search using parallel processing in our previous research [5]. DGA yielded an effective result of calculation time in the similar image search using the parallel processing. For this result, we will plan to implement and evaluate the proposed method using the parallel processing as future works.

Abstract: Japan Meteorological Agency has provided various kinds of historical temperature data of local meteorological station, such as Oita since February 1887. The provided temperature data contain the maximum, the minimum and the mean records on 17 leading and 57 local meteorological stations. We apply a nonlinear curve to the datasets and estimate the trends of the maximum, the minimum and the mean temperature, especially in Oita, by a numerical iteration method.

Keywords: Nonlinear fitting, Temperature, Warmth trend, Least square method, Newton method,

1 INTRODUCTION

There are many reports concerning to the global or local trends of temperature, such as the warmth is increasing or not. In many cases, the huge datasets and a super computer are applied to the estimations. Hence the practical model and the tuning method of parameters are hardly provided, because of the complexity. We propose a simple method to conform the local temperature trends, such as local warming or not, using the Oita temperature data since January 1888.

The temperature data in Oita is provided at the following URL: `http://www.data.jma.go.jp/obd/stats/etrn/index.php`

We apply a nonlinear model $f(x)$, the variable x is month, to the data. $f(x)$ consists of two terms, that is the year trend and the month trend. Mathematica `FindFit` function is applied to determine the parameters of the model[1]. Providing a fitness criterion to the model, the parameters of $f(x)$ are practically evaluated.

Applying $f(x)$, we are able to estimate an increasing trend of the maximum and minimum temperature respectively. The program to evaluate the parameters of $f(x)$ is at most 20-line as shown in this article. The year change trend is described by a linear term of $f(x)$ and the month change trend is also described by the periodical term of $f(x)$. The results clearly show the increasing trend of the temperature and the trend is similar the report provided by NASA [2] and JMA [3]. We remark that the proposed method does not need a statistics procedure, such as Annual Mean, 5-year Running Mean or regression analysis to evaluate $f(x)$.

2 MATERIAL AND METHOD

We apply the Oita local station data from 1888 to 2010 and denote the maximum and minimum temperature data obtained from the previous URL as follows ($^\circ$C) :

max={11.2, 8.5, 14.3, 17.2, 21.4, 24.3, 28.8, 30.4, 26.3, 21.5, 17.9, 13.7, $\cdots\cdots$, 11.4, 12.9, 14.7, 17.6, 23.6, 26.6, 31.3, 34.6, 30.7, 23.1, 17.6, 13.1 }

min={1.3, -0.1, 4.6, 9.7, 12.9, 16.4, 22.0, 22.7, 18.3, 11.6, 9.4, 4.5 , $\cdots\cdots$, 2.1, 5.1, 6.8, 9.6, 13.9, 19.3, 23.8, 25.6, 22.3, 16.5, 8.2, 4.7}

For example, the first record 11.2 and the last record 13.1 in the sequence "max" are the maximum temperature of January 1888 and December 2010 respectively. And also the first record 1.3 and the last record 4.7 in the sequence "min" are the minimum temperature of January 1888 and December 2010 respectively. Both data size are $k = (2011 - 1888) \times 12 = 1476$.

We apply the following nonlinear curve to the data

$$y = f(x) = a_1 + a_2 x + a_3 \sin(\pi x/n + a_4) \qquad (1)$$

where a_1,a_2,a_3,a_4 and n are the unknown parameters. This model is simplified compared with that of NDVI [1].

We apply the least square method and the Newton iteration method to determine these parameters. For simplicity, we use Mathematic's `FindFit` function for the fixed integer n and iterate n from $n = 1$ to $n = 100$. To find the best n between them, we apply the following CR$_n$ criterion [2] to terminate the iteration.

$$\mathrm{CR}_n = \frac{\sum_{i=1}^{k} \dfrac{|y_i - \widehat{y_i}|}{\max\left(|y_i|, |\widehat{y_i}|\right)}}{k} \qquad (2)$$

where y_i and $\widehat{y_i}$, $i = 1, 2, \cdots, \cdots, k$ are the estimated and the observed temperatures respectively. This CR$_n$ is similar to the mean value of the relative errors between the observed temperatures and the estimated temperatures

If CR$_n$ is small, $y_i = f(x_i)$ of (1) corresponds well to the observed temperatures $\widehat{y_i}$. On the other hand, if CR$_n$ is large,

[1] Mathematica Ver.8 built in function
[2] `http://data.giss.nasa.gov/gistemp/graphs/`
[3] `http://ds.data.jma.go.jp/gmd/tcc/tcc/products/gwp/temp/ann_wld.html`

y_i does not correspond well to the observed temperatures. Hence the integer n, $1 \leqq n \leqq 100$, is chosen so as to give the smallest value CR_n.

For the max data, a program to find the best fit nonlinear curve is as follows:

```
Clear[CR, p, q, s];
q = max; k = Length[q];
Do[{Clear[f], f[x_]
= a1*Sin[(π x)/n + a2] + a3 + a4 x /.
FindFit[q,
a1*Sin[(π x)/n + a2] + a3 + a4 x,
{a1, a2, a3, a4}, {x}],
y[n, x_] = f[x],
p = Table[f[x], {x, 1, k}],
s = Abs[p - q]/Max[Abs[p], Abs[q]],
CR[n] = Sum[s[[i]], {i, 1, k}]/k},
{n, 1, 100}];
r0 = Table[CR[i], {i, 1, 100}];
n = First[Position[r0, Min[r0]][[1]]];
r1 = Table[i, {i, 1, 100}];
r2 = Transpose[{r1, r0}];
Print["y = " y[n, x]]
fig1 = ListPlot[q, PlotStyle -> {Blue},
AxesLabel -> {Month, °C}]
fig2 = Plot[y[n, x], {x, 0, k},
PlotStyle -> {Thickness[0.0001], Green},
AxesLabel -> {Month, °C}]
Show[fig1, fig2]
ListPlot[r2, PlotRange -> {0.0, 0.25},
AxesLabel -> {"n", CR}]
```

3 RESULTS

We have the following best fit function using the criterion (2) for the maximum temperature

$$f(x) = 19.16 + 0.00116x + 10.0\sin(3.93 + \pi x/6) \quad (3)$$

where $\mathrm{CR}_6 = 0.028$.

For the case of minimum temperature we have

$$g(x) = 10.23 + 0.00139x + 10.7\sin(3.92 + \pi x/6) \quad (4)$$

where $\mathrm{CR}_6 = 0.044$.

Figure 1 shows the maximum temperature data (blue dots) and $f(x)$ (red curve). Figure 2 shows the minimum case.

We consider the 12 trends of decade's periods, such as 01/1890 to 12/2010, 01/1900 to 12/2010, $\cdots\cdots$ and 01/2000 to 12/2010. Figures 3 and 4 show the maximum and the minimum trends of each decade.

Figures 5, 6 and 7 show the trends evaluated by 57 (maximum and minimum temperature), and the mean temperature trend of 17 leading stations.

The temperature up trend from 1880 to 1980 and down trend from 1980 to 2010 are similar to the Figures 3, 4 and 5.

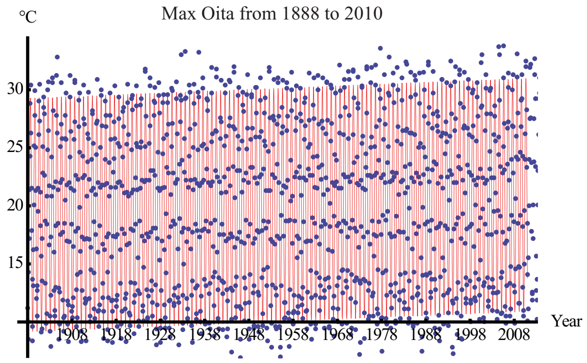

Fig. 1. The maximum data (dots) and the fitting curve

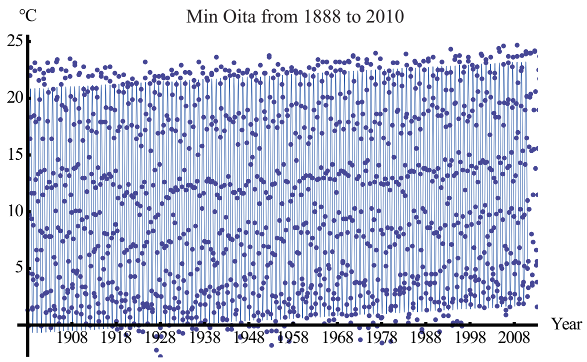

Fig. 2. The minimum data (dots) and the fitting curve

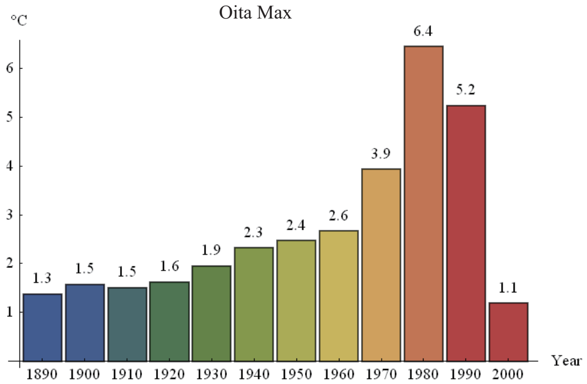

Fig. 3. The maximum trends of each decade

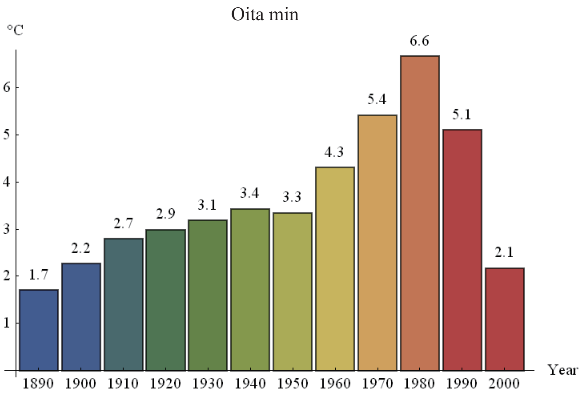

Fig. 4. The Minimum trends of each decade

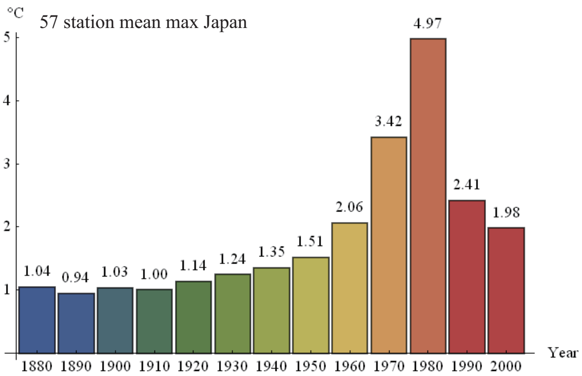

Fig. 5. The mean of maximum of 57 local stations

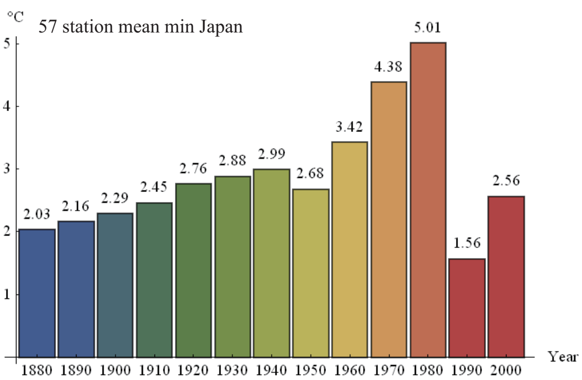

Fig. 6. The mean of minimum trend of 57 local stations

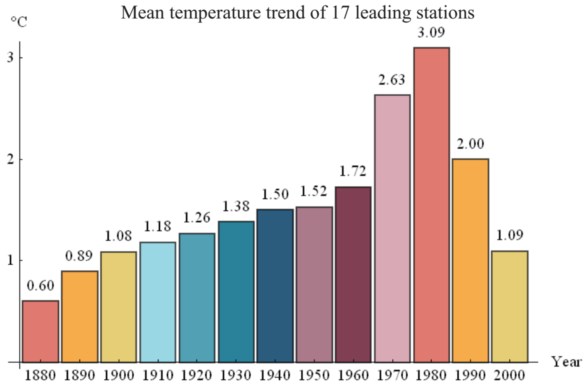

Fig. 7. The mean trend of 17 leading stations

4 DISCUSSION

The proposed criterion (2) gives $n = 6$ as the best parameter more than 200 examples. For the case of maximum temperature (3)

$$-\log_{10} \mathrm{CR}_6 = -\log_1 0.028 = 1.55$$

hence the coincident digits of y_i and $\widehat{y_i}$ are estimated more than 1.5 decimal digits in the mean for any i [3].

For the case of minimum temperature (4)

$$-\log_{10} \mathrm{CR}_6 = -\log_1 0.044 = 1.35$$

hence the coincident digits of y_i and $\widehat{y_i}$ are estimated more than 1.3 decimal digits in the mean for any i.

4.1 Year trend of max temp.

Separate f_{max} as follows:

$$f(x) = \underbrace{19.16 + 0.00116x}_{\text{Year Trend}} + \underbrace{10.0\sin(3.93 + \pi x/6)}_{\text{Month Trend}} \quad (5)$$

Ignore the Month Trend of (5), we have a following year trend

$$f_{max}(x) = 19.16 + 0.00116x$$

From

$$f_{max}(1) = 19.16 \quad \text{and} \quad f_{max}(1476) = 20.87$$

the maximum temperature increases 1.71 °C since 1888. Actually, the mean of maximum temperature from 1890 to 1894 is 19.86 °C and that of from 2006 to 2010 is 21.38 °C. Hence the difference is 1.52 °C. This shows that the estimated temperature and the actual temperature well agree and the difference is only 0.19 °C among 123 years.

4.2 Year trend of min temp.

For the case of minimum, we have followings:

$$g(x) = \underbrace{10.23 + 0.00138x}_{\text{Year Trend}} + \underbrace{10.7\sin(3.92 + \pi x/6)}_{\text{Month Trend}} \quad (6)$$

$$g_{min}(x) = 10.23 + 0.00138x$$
$$g_{min}(1) = 10.23$$
$$g_{min}(1476) = 12.26$$

Hence the minimum temperature is 2.03°C up since 1888 and the actual temperature is $13.14 - 11.36 = 1.76$(°C) up. The difference is only 0.27°C among 123 year.

4.3 Month trend of max temp.

The red dots in Figure 8 shows the mean of maximum values of each month from January 1888 to December 2010. The blue curve shows the "Month Trend" of (5) and the green curve shows the same trend from January 1998 to December 2010. Figuer 8 shows the increasing of warmth related to the maximum temperature in Oita.

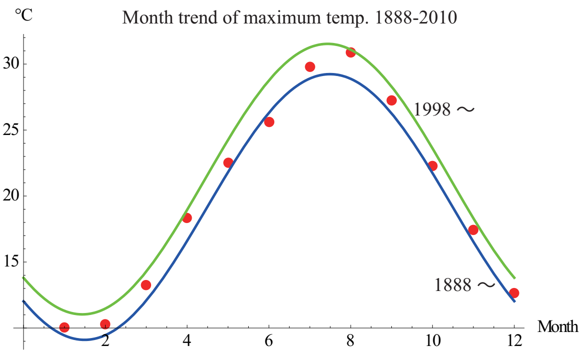

Fig. 8. The month trends of maximum temperature, the blue (green) curve is the trend since 1888 (1998)

4.4 Month trend of min temp.

The red dots in Figure 9 shows the mean of minimum values of each month from January 1888 to December 2010. The blue curve shows the "Month Trend" of (6) and the green curve shows the same trend from January 1998 to December 2010. Figure 9 also shows the increasing of warmth related to the minimum temperature in Oita.

5 CONCLUSION

The proposed model (1) is well fit the maximum and minimum temperature of Oita, because of the iteration always terminates at $n = 6$ and this means that the fundamental period of temperature change is 12 (months).

We also derive the trends of year concerning the maximum and the minimum temperature, and that the trends are described by a linear curve. The difference between the estimation and the actual temperature are 0.19 °C (maximum temperature) and 0.27 °C (minimum temperature) among 123 years.

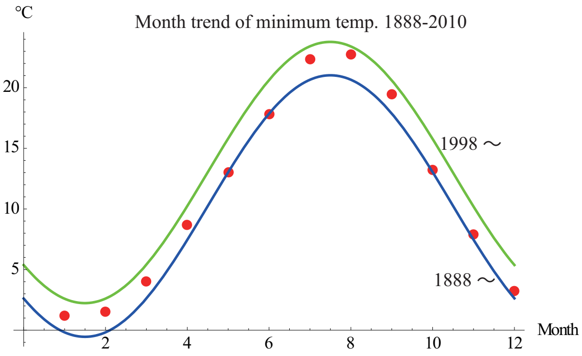

Fig. 9. The month trends of minimum temperature, the blue (green) curve is the trend since 1888 (1998)

The month trends of the maximum and minimum temperatures are increasing with the increasing decade.

The estimated results of Oita are something high compared with the 17 leading [4] and 57 [5] local meteorological stations trends of Japan.

Abstract: This paper is devoted to consensus problems in directed networks of high-order agents with disturbances. A new distributed protocol is proposed with the consideration of model uncertainty, which only depends on the agent's own information and it's neighbors' first state, an auxiliary variable is included to describe the effects of all-order derivatives' relative information. Based on Lyapunov theory, for three cases: (a) network with fixed topology and zero time-delay; (b) network with switching topology and zero time-delay; (c) network with fixed topology and non-zero time-delay, sufficient conditions are derived correspondingly to make all agents reach H_∞ consensus. Especially, the approach used in this paper does not need any model transformation. Finally, numerical simulations are provided to show the effectiveness of the obtained results.

Keywords: Consensus, directed graph, H_∞ control, high-order multi-agent systems

1 INTRODUCTION

Recently, consensus problems of multi-agent systems have attracted researchers from a wide range of disciplines, and numerous significant theoretical results have been obtained [1-9]. In engineering practice, multi-agent systems are often subjected to various disturbances such as time-delay, model uncertainty, and the variation of network topology. As we all know, these disturbances might degrade the system performance and even cause the network system to diverge or oscillate. Therefore, it is of great significance to improve the robustness of the multi-agent systems. However, to the best of our knowledge, little work has been done to consider high-order consensus problem with disturbances.

With this background, we investigate consensus problems in directed networks of high-order agents with disturbances. Firstly, a new distributed protocol is proposed with the consideration of model uncertainty. Then, based on Lyapunov theory, sufficient conditions are derived to make all agents reach consensus while satisfying desired H_∞ performance for three cases. Especially, the approach used in this paper does not need any model transformation.

2 GRAPH THEORY

Let $\mathscr{G}(\mathscr{V},\varepsilon,\mathscr{A})$ be a directed graph of order n with the set of nodes $\mathscr{V}=\{s_1,\cdots,s_n\}$, set of edges $\varepsilon\subseteq\mathscr{V}\times\mathscr{V}$, and a weighted adjacency matrix $\mathscr{A}=[a_{ij}]$. The node indexes belong to a finite index set $I=\{1,2,\cdots,n\}$. An edge of $\mathscr{G}$ is denoted by $e_{ij}=(s_i,s_j)$. The adjacency elements associated with the edges are positive, i.e. $e_{ij}\in\varepsilon\Leftrightarrow a_{ij}>0$. Moreover, we assume that $a_{ii}=0$ for all $i\in I$. The set of neighbors of node s_i is denoted by $N_i=\{s_j\in\mathscr{V}:(s_i,s_j)\in\varepsilon\}$. A diagonal matrix $D=diag\{d_1,\cdots,d_n\}$ is a degree matrix of $\mathscr{G}$, with $d_i=\sum_{j=1}^{n}a_{ij}$ for $i\in I$. Then the Laplacian of the weighted graph $\mathscr{G}$ is defined as $L=D-\mathscr{A}\in\mathscr{R}^{n\times n}$. A directed path is a sequence of ordered edges of the form $(s_{i_1},s_{i_2}),(s_{i_2},s_{i_3}),\cdots$, where $s_{i_j}\in\mathscr{V}$. A directed graph is said to have a spanning tree, if there exists a node such that there is a directed path from every other node to this node[10]. If the graph $\mathscr{G}$ has a spanning tree, then its Laplacian L satisfies: zero is a simple eigenvalue of L, and $\mathbf{1}_n$ is the corresponding eigenvector [4].

3 PROBLEM STATEMENT

Consider the multi-agent system consisting of n identical agents, each agent is regarded as a node in a directed graph $\mathscr{G}$. Suppose the ith agent has the dynamics as follows:

$$\begin{array}{rcl}\dot{x}_i^{(0)}(t) & = & x_i^{(1)}(t)\\ & \vdots & \\ \dot{x}_i^{(l-2)}(t) & = & x_i^{(l-1)}(t)\\ \dot{x}_i^{(l-1)}(t) & = & u_i(t)+\omega_i(t)\\ y_i(t) & = & x_i^{(0)}(t)\end{array}\qquad(1)$$

where $x_i=[x_i^{(0)},x_i^{(1)},\cdots,x_i^{(l-1)}]^\top\in\mathbb{R}^l$ is the state of the ith agent, $u_i\in\mathbb{R}$ is the protocol, $\omega_i(t)\in L_2[0,\infty)$ is the external disturbance, $y_i(t)$ is the measured output that can be observed by its neighbors.

A protocol u_i is said to asymptotically solve consensus problem, if for any initial state, the states of all the agents satisfy

$$\lim_{t\to+\infty}[x_i(t)-x_j(t)]=0 \tag{2}$$

for all $i,j\in I$.

In order to solve the consensus problem of high-order multi-agent system (1), we propose the following consensus protocol

$$\begin{aligned} u_i &= k_0\sum_{s_j\in N_i}(a_{ij}+\Delta a_{ij}(t))(x_j^{(0)}(t-\tau)-x_i^{(0)}(t-\tau)) \\ &\quad -\sum_{j=1}^{l-1}k_jx_i^{(j)}(t)+p_i \\ \dot{p}_i &= -\gamma_1 p_i-k_l\sum_{s_j\in N_i}(a_{ij}+\Delta a_{ij}(t))(x_j^{(0)}(t-\tau)-x_i^{(0)}(t-\tau)) \end{aligned} \tag{3}$$

where $k_i>0, i=0,1,\cdots,l,\ \gamma_1>0$ are protocol parameters to be designed, p_i is an auxiliary variable to describe the effects of all-order derivatives' relative information. τ denotes communication delay, $\Delta a_{ij}(t)$ denotes the uncertainty of a_{ij}.

A controlled output function

$$z_i(t)=[z_{i1}(t),z_{i2}(t),\cdots,z_{il}(t)]^\top\in\mathbb{R}^l \quad i\in I$$

is defined as an average of the relative displacements of all agents as follows

$$\begin{aligned} z_{i1}(t) &= x_i^{(0)}(t)-\frac{1}{n}\sum_{j=1}^{n}x_j^{(0)}(t) \\ z_{i2}(t) &= x_i^{(1)}(t)-\frac{1}{n}\sum_{j=1}^{n}x_j^{(1)}(t) \\ &\ \,\vdots \\ z_{il}(t) &= x_i^{(l-1)}(t)-\frac{1}{n}\sum_{j=1}^{n}x_j^{(l-1)}(t) \end{aligned} \tag{4}$$

Obviously, the multi-agent system (1) achieves consensus if and only if

$$\lim_{t\to+\infty}z_i(t)=0 \qquad i\in I \tag{5}$$

Let

$$A=\begin{bmatrix} 0 & 1 & 0 & \cdots & 0 & 0 \\ 0 & 0 & 1 & \cdots & 0 & 0 \\ \vdots & \vdots & \vdots & \ddots & \vdots & \vdots \\ 0 & -k_1 & -k_2 & \cdots & -k_{l-1} & 1 \\ 0 & 0 & 0 & \cdots & 0 & -\gamma_1 \end{bmatrix}$$

$$B=\begin{bmatrix} 0_{l-1} & 0_{(l-1)\times l} \\ k_0 & 0_{1\times l} \\ -k_l & 0_{1\times l} \end{bmatrix} \quad B_1=\begin{bmatrix} 0_{l-1} \\ 1 \\ 0 \end{bmatrix}$$

$$B_2=\begin{bmatrix} I_l & 0_l \end{bmatrix}$$

$$C=\begin{bmatrix} \frac{n-1}{n} & -\frac{1}{n} & \cdots & -\frac{1}{n} \\ -\frac{1}{n} & \frac{n-1}{n} & \cdots & -\frac{1}{n} \\ \vdots & \vdots & \ddots & \vdots \\ -\frac{1}{n} & -\frac{1}{n} & \cdots & \frac{n-1}{n} \end{bmatrix}$$

Under the protocol (3), the network dynamics of the multi-agent system is

$$\begin{aligned} \dot{\varphi}(t) &= (I_n\otimes A)\varphi(t)-((L+\Delta L)\otimes B)\varphi(t-\tau) \\ &\quad +(I_n\otimes B_1)\omega(t) \\ z(t) &= (C\otimes B_2)\varphi(t) \end{aligned} \tag{6}$$

where $\varphi=[x_1^\top,p_1,\ \cdots\ x_n^\top,p_n]^\top,\ \omega=[\omega_1,\cdots,\omega_n]^\top,\ z=[z_1^\top,\cdots,z_n^\top]^\top$, L is the Laplacian of the graph $\mathscr{G}$, ΔL denotes the uncertainty Laplacian satisfying $\Delta L=E_1\Sigma(t)E_2$, where $E_1\in\mathbb{R}^{n\times|\varepsilon|}$, $E_2\in\mathbb{R}^{|\varepsilon|\times n}$ are specified constant matrices and $\Sigma(t)$ is a diagonal matrix satisfying $\Sigma^\top(t)\Sigma(t)\le I$.

Define the following H_∞ performance index

$$J=\int_0^\infty[z^\top(t)z(t)-\gamma^2\omega^\top(t)\omega(t)]dt<0 \tag{7}$$

where γ is a given positive constant.

Based on the above discussion, the H_∞ consensus problem to be addressed is stated as follows.

H_∞ **consensus problem**: For a given protocol u_i, we say the multi-agent systems reach H_∞ consensus if the following two conditions are satisfied simultaneously:
1). when $\omega(t)=0$, the multi-agent systems achieve consensus, i.e. $\lim_{t\to+\infty}z(t)=0$;
2). if $z_0=0$, the inequality (7) is satisfied.

4 MAIN RESULTS

In this section, we will give conditions to make all agents achieve H_∞ consensus. Before presenting the main results, we first introduce a lemma.

Lemma 1 [7]. Consider the matrix C. Then there exists an orthogonal matrix $U=[U_1\ \ \overline{U}_1]$ with $\overline{U}_1=\frac{1}{\sqrt{n}}\mathbf{1}_n$, such that

$$U^\top CU=\begin{bmatrix} I_{n-1} & \mathbf{0}_{(n-1)\times 1} \\ \mathbf{0}_{1\times(n-1)} & 0 \end{bmatrix}$$

holds.

Theorem 1. Consider a directed network with fixed topology and zero time-delay. The multi-agent system (6) reaches H_∞ consensus, if there exist a symmetric positive-definite matrix $\overline{P}\in\mathbb{R}^{(l+1)(n-1)\times(l+1)(n-1)}$, and a scalar $\mu>0$ satisfying

$$M=\begin{bmatrix} M_{11} & M_{12} & M_{13} \\ * & -\mu I & \mathbf{0} \\ * & * & -\gamma^2 I \end{bmatrix}<0 \tag{8}$$

where $M_{11}=\overline{P}(I_{n-1}\otimes A-\overline{L}\otimes B)+(I_{n-1}\otimes A-\overline{L}\otimes B)^\top\overline{P}+\mu\overline{E}+I_{n-1}\otimes B_2^\top B_2$, $M_{12}=\overline{P}(U_1^\top E_1\otimes B)$, $M_{13}=\overline{P}(U_1^\top\otimes B_1)$, $\overline{L}=U_1^\top LU_1$, $\overline{E}=(U_1^\top E_2^\top E_2U_1)\otimes I_{l+1}$.

Proof. Let

$$\begin{aligned} \delta(t) &= (U_1\otimes I_{l+1})^\top\varphi(t) \\ \overline{\delta}(t) &= (\overline{U}_1\otimes I_{l+1})^\top\varphi(t) \end{aligned} \tag{9}$$

where $\overline{\delta}(t)$ and $\delta(t)$ describe the average and disagreement states of all agents, respectively.

Define a Lyapunov function for system (6) as follows

$$V(t) = \varphi^\top(t)P\varphi(t)$$

where $P = P^\top \geq 0$ satisfies $P(\mathbf{1}_n \otimes I_{l+1}) = 0$ and $rank(P) = (l+1)n-(l+1)$.

Let $\overline{P} = (U_1 \otimes I_{l+1})^\top P(U_1 \otimes I_{l+1})$, then $V(t)$ can be rewritten as

$$\begin{aligned} V(t) &= \varphi^\top(t)P\varphi(t) \\ &= \begin{bmatrix} \delta(t) \\ \overline{\delta}(t) \end{bmatrix}^\top \begin{bmatrix} \overline{P} & 0 \\ 0 & 0 \end{bmatrix} \begin{bmatrix} \delta(t) \\ \overline{\delta}(t) \end{bmatrix} \\ &= \delta^\top(t)\overline{P}\delta(t) > 0 \end{aligned} \tag{10}$$

Differentiating $V(t)$ along the trajectory of (6), we have

$$\begin{aligned} \dot{V}(t) &= 2\delta^\top(t)\overline{P}\dot{\delta}(t) \\ &= 2\delta^\top(t)\overline{P}[I_{n-1} \otimes A - \overline{L} \otimes B]\delta(t) \\ &\quad - 2\delta^\top(t)\overline{P}(\overline{\Delta L} \otimes B)\delta(t) + 2\delta^\top(t)\overline{P}(U_1^\top \otimes B_1)\omega(t) \end{aligned}$$

where $\overline{L} = U_1^\top L U_1$, $\overline{\Delta L} = U_1^\top \Delta L U_1 = U_1^\top E_1 \Sigma(t) E_2 U_1$.

And since $\Sigma^\top(t)\Sigma(t) \leq I$, we can obtain

$$\begin{aligned} &-2\delta^\top(t)\overline{P}(\overline{\Delta L} \otimes B)\delta(t) \\ &= -2\delta^\top(t)\overline{P}(U_1^\top E_1 \otimes B)(\Sigma(t)E_2U_1 \otimes I_{l+1})\delta(t) \\ &\leq \tfrac{1}{\mu}\delta^\top(t)\overline{P}(U_1^\top E_1 \otimes B)(U_1^\top E_1 \otimes B)^\top \overline{P}\delta(t) \\ &\quad + \mu\delta^\top(t)\overline{E}\delta(t) \end{aligned}$$

where $\mu > 0$, $\overline{E} = (U_1^\top E_2^\top E_2 U_1) \otimes I_{l+1}$.

By Lemma 1, we have

$$\begin{aligned} z(t) &= (C \otimes B_2)(U \otimes I_{l+1})(U \otimes I_{l+1})^\top \varphi(t) \\ &= (CU \otimes B_2)\begin{bmatrix} \delta(t) \\ \overline{\delta}(t) \end{bmatrix} \\ &= (U_1 \otimes B_2)\delta(t) \end{aligned}$$

we have $\lim_{t\to+\infty} z(t) = 0$ if $\lim_{t\to+\infty} \delta(t) = 0$. Thus whether the system (6) can reach consensus is only related to the component $\delta(t)$.

Denote

$$\begin{aligned} N &= \overline{P}(I_{n-1} \otimes A - \overline{L} \otimes B) + (I_{n-1} \otimes A - \overline{L} \otimes B)^\top \overline{P} \\ &\quad + \mu\overline{E} + \tfrac{1}{\mu}\overline{P}(U_1^\top E_1 \otimes B)(U_1^\top E_1 \otimes B)^\top \overline{P} \end{aligned}$$

when $\omega(t) = 0$, we can obtain

$$\dot{V}(t) \leq \delta^\top(t)N\delta(t) \tag{11}$$

$N < 0$ holds when $M < 0$, it follows from (10) and (11) that consensus can be achieved asymptotically.

To study the H_∞ performance for the multi-agent system, assume zero initial condition, that is $V(0) = 0$. Therefore, we have

$$\begin{aligned} J &= \textstyle\int_0^\infty [z^\top(t)z(t) - \gamma^2\omega^\top(t)\omega(t) + \dot{V}(t)]dt - V(\infty) + V(0) \\ &\leq \textstyle\int_0^\infty [z^\top(t)z(t) - \gamma^2\omega^\top(t)\omega(t) + \dot{V}(t)]dt \\ &\leq \textstyle\int_0^\infty \xi^\top(t)\overline{M}\xi(t)dt \end{aligned}$$

where

$$\begin{aligned} &\xi(t) = [\delta^\top(t) \;\; \omega^\top(t)]^\top \\ &\overline{M} = \begin{bmatrix} \overline{M}_{11} & \overline{P}(U_1^\top \otimes B_1) \\ * & -\gamma^2 I \end{bmatrix} \\ &\overline{M}_{11} = M_{11} + \tfrac{1}{\mu}\overline{P}(U_1^\top E_1 \otimes B)(U_1^\top E_1 \otimes B)^\top \overline{P} \end{aligned}$$

By Schur complement, $M < 0$ is equivalent to $\overline{M} < 0$. That is, (8) guarantees $J < 0$. Therefore, under the condition $M < 0$, all agents reach H_∞ consensus.

Remark 1. The approach used in Theorem 1 does not need to perform any model transformation.

Remark 2. It is worth pointing out that a necessary condition for (8) is that the graph $\mathscr{G}$ has a spanning tree.

Theorem 2. Consider a directed network with switching topology $\mathscr{G}_\sigma$ and zero time-delay. The multi-agent system (6) reaches H_∞ consensus, if there exist a common symmetric positive-definite matrix $\overline{P} \in \mathbb{R}^{(l+1)(n-1)\times(l+1)(n-1)}$, and positive scalars μ_σ for each possible communication graph $\mathscr{G}_\sigma$ satisfying

$$\hat{M}_\sigma = \begin{bmatrix} \hat{M}_{11} & \hat{M}_{12} & \hat{M}_{13} \\ * & -\mu_\sigma I & \mathbf{0} \\ * & * & -\gamma^2 I \end{bmatrix} < 0 \tag{12}$$

where $\hat{M}_{11} = \overline{P}(I_{n-1} \otimes A - \overline{L}_\sigma \otimes B) + (I_{n-1} \otimes A - \overline{L}_\sigma \otimes B)^\top \overline{P} + \mu_\sigma \overline{E}_\sigma + I_{n-1} \otimes B_2^\top B_2$, $\hat{M}_{12} = \overline{P}(U_1^\top E_{1\sigma} \otimes B)$, $\hat{M}_{13} = \overline{P}(U_1^\top \otimes B_1)$, $\overline{L}_\sigma = U_1^\top L_\sigma U_1$, $\overline{E}_\sigma = (U_1^\top E_{2\sigma}^\top E_{2\sigma} U_1) \otimes I_{l+1}$, and σ denotes the switching signal that determines the topology.

Theorem 3. Consider a directed network with fixed topology and non-zero time-delay. The multi-agent system (6) reaches H_∞ consensus, if there exist symmetric positive-definite matrices $\overline{P}, \overline{Q}, \overline{R} \in \mathbb{R}^{(l+1)(n-1)\times(l+1)(n-1)}$, and positive scalars $\mu_1, \mu_2, \mu_3, \mu_4, \mu_5$ satisfying

$$\Gamma = \begin{bmatrix} \Gamma_{11} & \Gamma_{12} \\ * & \Gamma_{22} \end{bmatrix} < 0 \tag{13}$$

where Γ_{11}, Γ_{12} and Γ_{22} are defined in (14), $\psi_1 = \overline{P}(I_{n-1} \otimes A - \overline{L} \otimes B) + (I_{n-1} \otimes A - \overline{L} \otimes B)^\top \overline{P} + \overline{Q}$, $\overline{E} = (U_1^\top E_2^\top E_2 U_1) \otimes I_{l+1}$, and $\hat{E} = (U_1^\top E_2^\top E_2 U_1) \otimes BB^\top$.

Proof. This theorem can be proved following the lines of the proof of Theorem 1 and hence omitted. It deserves pointing out that the Lyapunov function adopted here is as follows

$$\begin{aligned} V(t) &= \varphi^\top(t)P\varphi(t) + \textstyle\int_{t-\tau}^t \varphi^\top(s)Q\varphi(s)ds \\ &\quad + \textstyle\int_{-\tau}^0 \int_{t+\theta}^t \dot{\varphi}^\top(s)R\dot{\varphi}(s)dsd\theta \end{aligned}$$

5 SIMULATIONS

The simulation is given to illustrate the effectiveness of the obtained results. Fig.1. shows a directed graph with 0-1 weights. Each agent has three-order dynamics. Suppose that the uncertainty of each edge satisfies $|a_{ij}| \leq 0.01$, the communication delay $\tau = 0.1s$, and the initial conditions $\varphi(0) = [0.5\; 0\; 0\; 0\; 1\; 0\; 0\; 0\; -0.5\; 0\; 0\; 0\; -1\; 0\; 0\; 0]^\top$.

$$\Gamma_{11}=\begin{bmatrix}\psi_1+I_{n-1}\otimes B_2^{\top}B_2 & -\tau(I_{n-1}\otimes A)^{\top}\overline{R}(\overline{L}\otimes B) & \overline{P}(U_1^{\top}\otimes B_1)+\tau(I_{n-1}\otimes A)^{\top}\overline{R}(U_1^{\top}\otimes B_1)\\ * & -\overline{Q}+\mu_1\overline{E}+\tau(\mu_2+\mu_3+\mu_5)\overline{E}+\tau\mu_4\hat{E} & -\tau(\overline{L}\otimes B)^{\top}\overline{R}(U_1^{\top}\otimes B_1)\\ * & * & -\gamma^2 I\end{bmatrix}$$

$$\Gamma_{12}=\begin{bmatrix}\overline{P}(\overline{L}\otimes B) & \overline{P}(U_1^{\top}E_1\otimes B) & \tau(I_{n-1}\otimes A)^{\top}\overline{R} & (I_{n-1}\otimes A)^{\top}\overline{R}(U_1^{\top}E_1\otimes B) & \mathbf{0} & \mathbf{0} & \mathbf{0} & \mathbf{0} & \mathbf{0} & \mathbf{0}\\ \mathbf{0} & \mathbf{0} & \mathbf{0} & \mathbf{0} & \tau(\overline{L}\otimes B)^{\top}\overline{R} & (\overline{L}\otimes B)^{\top}\overline{R}(U_1^{\top}E_1\otimes B) & \mathbf{0} & \mathbf{0} & \mathbf{0} & \mathbf{0}\\ \mathbf{0} & \mathbf{0} & \mathbf{0} & \mathbf{0} & \mathbf{0} & \mathbf{0} & \mathbf{0} & \mathbf{0} & \tau(U_1^{\top}\otimes B_1)^{\top}\overline{R} & (U_1^{\top}\otimes B_1)^{\top}\overline{R}(U_1^{\top}E_1\otimes B)\end{bmatrix} \quad (14)$$

$$\Gamma_{22}=diag\{-\frac{\overline{R}}{\tau},-\mu_1 I,-\tau\overline{R},-\frac{\mu_2}{\tau}I,-\tau\overline{R},-\frac{\mu_3}{\tau}I,\begin{bmatrix}-\tau\overline{R} & \overline{R}(U_1^{\top}E_1\otimes I)\\ * & -\frac{\mu_4}{\tau}I\end{bmatrix},-\tau\overline{R},-\frac{\mu_5}{\tau}I\}$$

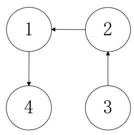

Fig. 1. A directed graph

Take $k_0=3, k_1=7, k_2=3, k_3=1, \gamma_1=1, \gamma=1$, and the external disturbance as $\omega(t)=[2\ -3\ 2.5\ -1]^{\top}\overline{\omega}(t)$, where

$$\overline{\omega}(t)=\begin{cases}1 & 0\le t\le 1\\ 0 & otherwise\end{cases}$$

is a pulse signal.

Fig.2. and Fig.3. give the state trajectories of the network, and energy trajectories of $z(t)$ and the disturbance $\omega(t)$.

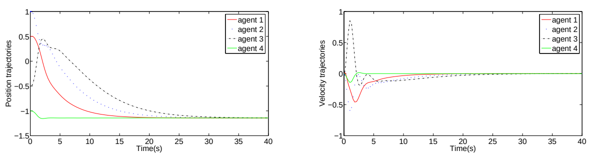

Fig. 2. Left: Position trajectories of the network
Right: Velocity trajectories of the network

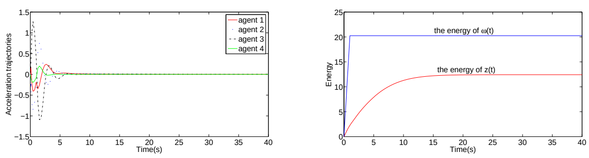

Fig. 3. Left: Acceleration trajectories of the network
Right: Energy trajectories of $z(t)$ and $\omega(t)$

Clearly, we can see that all agents achieve consensus while satisfying desired H_∞ performance.

6 CONLUSIONS

In this paper, we investigate the consensus problems in directed networks of high-order agents with disturbances. A new protocol is proposed with the consideration of model uncertainty. Sufficient conditions are derived to make all agents reach H_∞ consensus for three cases. Especially, the approach used in this paper does not need any model transformation. Finally, simulations are provided to show the effectiveness of the obtained results.

Abstract: This paper proposes a lane keeping control scheme that prevents an autonomous 4WS4WD vehicle from wheel skidding in presence of road curvature and aerodynamic drag. The control objectives can be specified as various closed-loop specifications, such as lane departure avoidance, wheel slip constraint and disturbance attenuation. An LMI approach is used to deal with these objectives simultaneously, which combines the quadratic stabilization technique with constraints on inputs. Simulations show that the proposed controller effectively limits the combined wheel slip and improves lane keeping performance.

Keywords: Combined wheel slip, lane keeping, linear matrix inequality(LMI), wheel skidding

1 INTRODUCTION

Lane departure is one of the most important causes of car accidents. NHTSA estimated that running off the road caused about 28% of the fatal crashes in the United States in 2005. Most research on lane keeping system has focused on pure lateral control [1], [2]. However, it is known that the vehicle dynamics are not completely independent in both directions. The coupling effects become increasingly significant as maneuvers involve higher accelerations, larger tire forces, or reduced road friction [3], [4]. So many efforts have been made to merge the two control tasks into a single problem.

To avoid lane departure, the strategy of controlling the vehicle's worst displacement/offset to the guideline beneath the safety requirement in [5], [6]. The combined wheel slip can be used to characterize the vector of tire/road, particularly for the situation of path following [7], [8]. In this paper, we consider an issue of guiding an autonomous vehicle to follow the curve without wheel skidding in the presence of aerodynamic drag. The design task is synthesized as a multi-objective problem, which specifies the closed-loop objectives in terms of a common Lyapunov function. This still guarantees the desired specifications at the expense of conservation. As a benefit, controller design can be reduced to a convex optimization problem.

2 PROBLEM FORMULATION

2.1 Vehicle model

As shown in Fig. 1., the model considered here for simulation consists of 7 degrees of freedom (DOF), which includes longitudinal, lateral and yaw motion of the vehicle as well as the rotational dynamics of the four wheels. The vehicle body-fixed coordinate system is used to set up the model. The governing equations of motion for the vehicle can be expressed as follows:

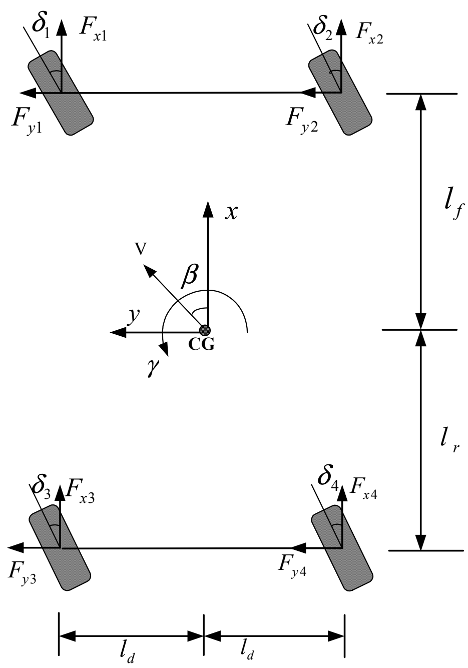

Fig. 1: Vehicle model

Longitudinal motion:

$$m(\dot{v}_x - \gamma v_y) = \sum F_x - C_{aero} v_x^2. \tag{1}$$

Lateral motion:

$$m(\dot{v}_y + \gamma) = \sum F_y. \tag{2}$$

Yaw motion:

$$J_z\dot{\gamma} = \sum M_z. \tag{3}$$

Wheel rotational equations of motion for wheels are as follows:

$$I_{wj}\dot{w}_j = T_j - r_j\begin{bmatrix}\cos\delta_j & \sin\delta_j\end{bmatrix}\begin{bmatrix}F_{xj}\\ F_{yj}\end{bmatrix}. \tag{4}$$

where m and J_z are the mass of vehicle and the inertia about z axis, respectively. F_{xj}, F_{yj}, and M_{zj} (j = 1, 2, 3, 4), defined in the body fixed $x-y-z$ coordinate system, are the external forces and yaw moments mainly resulting from tire/road friction. v_x and v_y stand for the longitudinal and lateral vehicle velocity, v the vehicle velocity, γ the yaw rate and β the vehicle side slip angle. $\sum F_x$, $\sum F_y$, $\sum M_z$ are the sum of the external forces and moments acting on the vehicle.

$$\begin{aligned}\sum F_x &= F_{x1}+F_{x2}+F_{x3}+F_{x4}\\ \sum F_y &= F_{y1}+F_{y2}+F_{y3}+F_{y4}\\ \sum M_z &= l_f(F_{y1}+F_{y2}) - l_r(F_{y3}+F_{y4})\\ &\quad + l_d(F_{x2}-F_{x1}) + l_d(F_{x4}-F_{x3}).\end{aligned}$$

where l_f and l_r and l_d are the distances from the center of gravity to to the front, the rear axles, and to the wheel side. I_{wj} and r_j represent respectively the moment of inertia and the radius of wheel j; T_j and δ_j are the wheel torque and wheel steering angle used for the control scheme.

Because the sensors that measure the lateral deviation are not normally fixed on the vertical line through CG. Moreover, feedback based on error measured at the CG leads to bad ride comfort. Hence, it is natural to describe the vehicle dynamics in terms of the lateral displacement at the sensor y_l. The dynamics of path tracking can be expressed as

$$\begin{aligned}\dot{\phi}_l &= \gamma - \rho v_x\\ \dot{y}_l &= v_x(\beta+\phi_l) + l_s(\gamma - \rho v_x).\end{aligned} \tag{5}$$

Let ϕ_l be the angle between the road centerline and the vehicle longitudinal axis in radians, ρ the road curvature.

Because the wheel subsystem converges much faster, singular perturbation theory is used for model reduction. By linearizing the above nonlinear vehicle system around the operating point:

$$\rho_{ref}=0,\ v_x=v_0,\ \beta=0,\ \gamma=0,\ y_l=0,$$
$$\phi_l=0,\ \delta_j=0,\ T_j=0,\ j=1,2,3,4,$$

we finally arrive at the following design model:

$$\begin{aligned}\frac{d}{dt}\begin{bmatrix}\partial v\\ \beta\\ \gamma\\ \phi_l\\ y_l\end{bmatrix} &= \begin{bmatrix}-2C_{aero}v_0/m & 0 & 0 & 0 & 0\\ 0 & 0 & -1 & 0 & 0\\ 0 & 0 & 0 & 0 & 0\\ 0 & 0 & 1 & 0 & 0\\ 0 & v_0 & l_s & v_0 & 0\end{bmatrix}\begin{bmatrix}\partial v\\ \beta\\ \gamma\\ \phi_l\\ y_l\end{bmatrix}\\ &+ \begin{bmatrix}1/m & 0 & 0\\ 0 & 1/(mv_0) & 0\\ 0 & 0 & 1/J_z\\ 0 & 0 & 0\\ 0 & 0 & 0\end{bmatrix}\begin{bmatrix}\sum F_x\\ \sum F_y\\ \sum M_z\end{bmatrix}\\ &+ \begin{bmatrix}-C_{aero}v_0^2/m\\ 0\\ 0\\ -v_0\rho_{ref}\\ -l_s v_0\rho_{ref}\end{bmatrix}.\end{aligned} \tag{6}$$

2.2 The combined wheel slip and friction forces

The combined wheel slip contains longitudinal and lateral components. The longitudinal slip S_L is defined in the direction of the wheel ground contact point velocity $v_j, j = 1,2,3,4$, and the lateral slip S_S at right angles to this.
When braking $(v_{Rj}\cos\alpha_j \le v_{Wj})$, the combined wheel slip is given by :

$$S_j = \begin{bmatrix}(v_{Rj}\cos\alpha_j - v_{Wj})/v_{Wj}\\ v_{Rj}\sin\alpha_j/v_{Wj}\end{bmatrix}. \tag{7}$$

When driving $(v_{Rj}\cos\alpha_j > v_{Wj})$, the combined wheel slip is given by:

$$S_j = \begin{bmatrix}(v_{Rj}\cos\alpha_j - v_{Wj})/v_{Rj}\cos\alpha_j\\ \tan\alpha_j\end{bmatrix}, \tag{8}$$

where the tire side slip angle α_j is the angle between the wheel plane and the velocity of the wheel ground contact point

$$\alpha_j = \delta_j - \beta_j,\ \beta_j = \arctan(v_{yj}/v_{xj}), \tag{9}$$

and

$$\begin{aligned}v_{W1} &= (v_x - l_d\gamma)\vec{e}_x + (v_y + l_f\gamma)\vec{e}_y\\ v_{W2} &= (v_x + l_d\gamma)\vec{e}_x + (v_y + l_f\gamma)\vec{e}_y\\ v_{W3} &= (v_x - l_d\gamma)\vec{e}_x + (v_y - l_r\gamma)\vec{e}_y\\ v_{W4} &= (v_x + l_d\gamma)\vec{e}_x + (v_y - l_r\gamma)\vec{e}_y.\end{aligned}$$

The resultant wheel slip is the geometrical sum of the longitudinal and lateral slip $S_{Res} = \sqrt{S_L^2 + S_S^2}$, and the resultant slip S_{Res} must always be between -1 and 1.

The friction forces in the body co-ordinate system (x,y) are given by

$$\begin{bmatrix}F_{xj}\\ F_{yj}\end{bmatrix} = F_{zj}\frac{\mu_{Res}(\|S_j\|,\chi)}{\|S_j\|}\begin{bmatrix}\cos\beta_j & \sin\beta_j\\ -\sin\beta_j & \cos\beta_j\end{bmatrix}\begin{bmatrix}1 & 0\\ 0 & k_s\end{bmatrix}\begin{bmatrix}S_{Lj}\\ S_{Sj}\end{bmatrix}$$

$\mu_{Res}(\|S_j\|,\chi)$ is the resultant friction co-efficient. It is a scalar saturation function depending on the magnitude of resultant slip $\|S_j\|$ and road condition χ. Define

$$k_j \triangleq \frac{\partial \mu_{Res}}{\partial S_{Res}} \tag{10}$$

where the slope k_j in equation (10) depends mainly on road conditions. A better road condition gives a larger slope k_j and in turn provides a larger friction force. Then

$$\begin{bmatrix} F_{xj} \\ F_{yj} \end{bmatrix} = F_{zj} \begin{bmatrix} \cos\beta_j & \sin\beta_j \\ -\sin\beta_j & \cos\beta_j \end{bmatrix} \begin{bmatrix} k_j & 0 \\ 0 & k_S k_j \end{bmatrix} \begin{bmatrix} S_{Lj} \\ S_{Sj} \end{bmatrix}. \tag{11}$$

In this paper, we assume that the vehicle runs on a uniform road condition, more specifically, k_j has the same value as k.

Consider yaw rate γ, lateral derivation y_l as the outputs, and $z_\infty = x$, $z_1 = y_l$ the variable to be regulated. By combining (6) and (11), we can arrive at

$$\begin{aligned} \dot{x} &= Ax + B_1 w + B_2 u \\ z_\infty &= C_\infty x \\ z_1 &= C_1 x \\ y &= C_2 x \end{aligned} \tag{12}$$

where

$$\begin{aligned} x &= \begin{bmatrix} \partial v & \beta & \gamma & \phi_l & y_l \end{bmatrix}^T, \\ u &= \begin{bmatrix} S_{L1} & S_{S1} & S_{L2} & S_{S2} \end{bmatrix}^T, \\ w &= \begin{bmatrix} f_w & \rho_{ref} \end{bmatrix}^T, f_w = C_{aero} v_0^2/m. \end{aligned}$$

The design objective is to design control laws to achieve the following objectives: 1) minimize the H_∞ norm of the transfer function matrix from w to z_∞ so as to reject disturbance; 2) keep the resultant wheel slip $S_{Res} \le s_{limi}$ to avoid wheel skidding; 3) keep z_1 bounded to satisfy the displacement constraints.

3 CONTROL LAW DESIGN

Theorem 1. *Consider system (12) with $S_j = C_u^i u$ for $i = 1,2$. Given some desired level of performance $\gamma_\infty > 0$, $\gamma_1 > 0$ and $\gamma_* = s_{limi}/w_{max}$ associated with each input, if there exist a constant matrix $Q > 0$ and a scalar $\nu > 0$ for some $\alpha > 0$ such that the following LMIs are feasible:*

$$\begin{aligned} \phi_S &\triangleq \begin{bmatrix} AQ + QA^T - \nu B_2 B_2^T & B_1 & QC_\infty \\ B_1^T & -\gamma_\infty^2 I_2 & 0 \\ C_\infty Q & 0 & -I_5 \end{bmatrix} < 0 \\ \Omega_S &\triangleq \begin{bmatrix} AQ + QA^T + \alpha Q - \nu B_2 B_2^T & B_1 \\ B_1^T & -\alpha I_2 \end{bmatrix} \le 0 \\ \theta_{Si} &\triangleq \begin{bmatrix} 4Q & \nu B_2 C_u^{iT} \\ \nu C_{ui} B_2 & \gamma_*^2 I_2 \end{bmatrix} > 0,\ i = 1,2 \\ \Pi_S &\triangleq \begin{bmatrix} Q & QC_1^T \\ C_1 Q & \gamma_1^2/w_{max}^2 \end{bmatrix} > 0. \end{aligned} \tag{13}$$

then the state feedback controller

$$u = -\frac{\nu}{2} B_2^T Q^{-1} x \tag{14}$$

guarantees quadratic stability with L_2-gain, from w to z_∞. Furthermore, within the ellipsoid $\xi_F = \{x : x^T Q^{-1} x \le w_{max}^2\}$ $\|S_j\|_\infty = \|-\frac{\nu}{2} C_u^i B_2^T Q^{-1} x\|_\infty \le s_{limi}$, $i = 1,2$.

Theorem 2. *For some desired level of performance $\gamma_\infty > 0$, $\gamma_1 > 0$ and $\gamma_* > 0$ associated with each input, assume there exist a constant matrix $P = Q^{-1} > 0$ and a scalar $\nu > 0$ for some $\alpha > 0$ such that the LMIs given in theorem 1 are satisfied. If there exist constant matrices $S > 0$ and W such that the following LMIs are feasible,*

$$\begin{aligned} \phi_L &\triangleq \begin{bmatrix} \Sigma_{11} & \frac{\nu}{2} P B_2 B_2^T P & PB_1 \\ * & \Sigma_{22} & SB_1 \\ * & * & -\gamma_\infty^2 I_2 \end{bmatrix} < 0 \\ \Omega_L &\triangleq \begin{bmatrix} \Sigma_{11}' & \frac{\nu}{2} P B_2 B_2^T P & PB_1 \\ * & \Sigma_{22} & SB_1 \\ * & * & -\alpha I_2 \end{bmatrix} \le 0 \\ \theta_{Li} &\triangleq \begin{bmatrix} P & 0 & -\frac{\nu}{2} P B_2 C_u^{iT} \\ 0 & S & \frac{\nu}{2} P B_2 C_u^{iT} \\ * & * & \gamma_*^2 I_2 \end{bmatrix} > 0 \\ \Pi_L &\triangleq \begin{bmatrix} P & C_1^T \\ C_1 & \gamma_1^2/w_{max}^2 \end{bmatrix} > 0. \end{aligned} \tag{15}$$

where $*$ represents a block matrix referred by symmetry.

$$\begin{aligned} \Sigma_{11} &= PA + A^T P - \nu P B_2 B_2^T P + C_\infty^T C_\infty \\ \Sigma_{22} &= SA + A^T S - WC_2 - C_2^T W^T \\ \Sigma_{11}' &= PA + A^T P + \alpha P - \nu P B_2 B_2^T P. \end{aligned}$$

then the observer-based output controller given by

$$\begin{aligned} \dot{\hat{x}} &= A\hat{x} + B_2 u + L(y - C_2 \hat{x}) \\ u &= -\frac{\nu}{2} B_2^T Q^{-1} \hat{x} \end{aligned} \tag{16}$$

with $L = S^{-1} W$ guarantees quadratic stability with L_2-gain, from w to z_∞. Furthermore, within the ellipsoid $\{\tilde{x} : \tilde{x}^T \hat{P} \tilde{x} <= w_{max}^2\}$, $\|\hat{S}_j\|_\infty = \|-\frac{\nu}{2} C_u^j B_2^T Q^{-1} \hat{x}\|_\infty <= s_{limi}$, $j = 1,2$, where $\hat{P} \triangleq blockdiag\{P,S\}$, $\tilde{x}^T = \begin{bmatrix} x^T & e^T \end{bmatrix}$.

Using the quasi-steady-state combined wheel slip, the wheel torque T_j and steering angle δ_j are derived

$$\begin{bmatrix} T_j \\ \delta_j \end{bmatrix} = \begin{bmatrix} 0 \\ \beta + l_j \gamma / v_0 \end{bmatrix} + \begin{bmatrix} F_{zj} r_j k & 0 \\ 0 & 1 \end{bmatrix} \begin{bmatrix} S_{Lj} \\ S_{Sj} \end{bmatrix},$$

where $l_1 = l_2 = l_f$, $l_3 = l_4 = -l_r$, $j = 1,2,3,4$. When the states of the system are unmeasurable, we substitute β_j, γ with their estimate.

4 SIMULATIONS

To examine the effectiveness of the control scheme, simulation tests are carried out as follows. The desired speed for traveling is set as $v_0 = 16.7\ m/sec$ and the reference path is assumed to be a circular path of curvature $\rho_{ref} = 1/100\ m^{-1}$. We employ the following tire model [7]

$$\mu_{Res}(\|S_j\|) = 1.1973(1 - exp(25.168\|S_j\|)) - 0.5373\|S_j\|$$

for simulating the dry concrete condition and thus obtain the related initial slope (10) as $k_j = k \simeq 30$. The data of the vehicle system is given as follows; $C_{aero} = 0.3743\ kg/m$, $m = 1480\ kg$, $J_z = 1950\ kgm^2$, $l_f = 1.421\ m$, $l_r = 1.029\ m$, $l_d = 0.751\ m$, $k_s = 0.9$, $g = 9.81\ m/s^2$. Based on the dry-concrete-covered road condition and the vehicle data, we choose the wheel slip constraint as $s_{limi} = 0.8$.

The vehicle control system is assumed to start with the following initial state: $V_0 = 16.7 m/sec$, $\beta(0) = 0\ deg$, $\gamma(0) = 0\ deg/sec$, $y_l(0) = 0.3\ m$, $\phi_l(0) = 0\ deg$. Fig. 2. and Fig. 3. illustrate the time responses of the lateral displacement and the longitudinal slip S_{L1} and lateral slip S_{S1} of the four wheels based on state feedback and output feedback. It can be seen that the maximum displacement can be kept less than 0.30 m, and the magnitudes of the resultant wheel slip S_{Res} are constrained below the pre-specified constraint $s_{limi} = 0.8$.

5 CONCLUSIONS

In this paper a robust controller is presented for an autonomous 4WS4WD vehicle to avoid lane departures and wheel skidding. The control strategy can be constructed as a multiobjective optimization problem. Simulation results are presented to validate the approach.

Abstract: In this paper, we study the problem of robust exponential stabilization for uncertain linear systems with interval time-varying delay. We first rewrite the original system into a new form, then by dividing the delay intervals into two equal subintervals, we construct the Lyapunov-Krasovskii functional with augmented vectors. By appropriate enlarging some terms that appeared in the derivative of the Lyapunov-Krasovskii functional and using a new lower bounds lemma, delay-dependent robust exponential stabilization criteria are obtained based on Lyapunov stability theory and free weighting matrix technic. For getting the design of controller, we fix some formations of the introduced free-weighting matrices with given parameters, thus the obtained criteria are in terms of Linear Matrix Inequalities(LMIs). Finally numerical examples are given to show the effectiveness and less conservativeness of the proposed method.

Keywords: Delay-dependent, Interval time-varying delay, LMI, Robust exponential stabilization

1 INTRODUCTION

Interval time-varying delay system is a type of time-delay system in which the lower bound of delay needn't to be 0. Since the existence of time delay can make system instable and degrade its performance, much effort has been done to study the stability and stabilization problem for such systems in recent years. Wang [1] research the exponential stabilization problem for interval time-delay system by using free-weighting matrix method, but in the derivative of Lyapunov functional there are some terms are enlarged improperly, which will lead conservative results. Botmart [2] get criteria to design robust exponential stabilization controller for such system by assuming the controller have some formation and using convex combination method, which get less conservative results compared to some existing papers.

When considering this problem, we find that by choosing specific Lyapunov functional and appropriate enlarging some terms appeared in its derivative, less conservative stabilization criteria can be obtained. Motivated by the above ideals, we research the problem of delay-dependent robust exponential stabilization for uncertain time-delay systems with interval time-varying delay in this paper. We divide the delay intervals into two subintervals, and construct the corresponding Lyapunov functional by using the augmented vectors. Based on Lyapunov stability theory and free weighting matrix methods, delay-dependent robust stabilization criteria are obtained, and the controller can be obtained by solving LMIs. Finally, several numerical examples are given to show the effectiveness of the obtained criteria.

2 PROBLEM STATEMENT

Consider the following uncertain linear system with time-varying delay

$$\begin{aligned}\dot{x}(t) &= (A+\Delta A(t))x(t) + (A_d+\Delta A_d(t))x(t-h(t)) \\ &\quad + (B+\Delta B(t))u(t), \\ x(t) &= \phi(t),\ t\in[-h_2,0], \end{aligned} \tag{1}$$

where $x(t)\in R^n$ is the state vector, $u(t)\in R^m$ is the control input, the initial condition $\phi(t)$ is a continuously differentiable vector-valued function, A, A_d, and B are constant system matrices of appropriate dimensions, $\Delta A(t)$, $\Delta A_d(t)$ and $\Delta B(t)$ are unknown real matrices with appropriate dimensions representing the system's time-varying parameter uncertainties and satisfy

$$[\Delta A\ \Delta A_d\ \Delta B] = [E_1F_1(t)G_1\ E_2F_2(t)G_2\ E_3F_3(t)G_3] \tag{2}$$

with E_i, G_i $(i=1,2,3)$ are known real constant matrices. $F_i(t)$ is the time-varying nonlinear function which satisfies

$$F_i^T(t)F_i(t)\le I \quad \text{for } i=1,2,3,\ \forall t\ge 0. \tag{3}$$

$h(t)$ is a continuous time-varying function satisfying

$$0\le h_1\le h(t)\le h_2, \tag{4}$$

$$\dot{h}(t) \leq \mu, \tag{5}$$

where $h_1 < h_2$, and $\mu \geq 0$ are constants.

Definition 1 [3]**.** The original state $x^* = 0$ of time-delay system (1) with uncertainty and interval time-varying delay satisfying (2-5) is said to be robustly exponentially stabilizable if for given constants $\sigma \geq 1$ and $\rho > 0$, there exists state feedback controller such that the solution $x(t)$ to the resulting closed-loop of system (1) satisfies

$$\|x(t)\| \leq \sigma \|x(t_0)\|_\theta \mathrm{e}^{-\rho(t-t_0)}, \ \forall\, t \geq t_0, \tag{6}$$

where $\|x(t)\|_\theta$ is defined by

$$\|x(t)\|_\theta = \sup_{0\leq\theta\leq h_2}\{x(t-\theta),\ \dot{x}(t-\theta)\},$$

and ρ is called the exponential convergence rate.

The purpose of this paper is to study the robust exponential stabilization problem for system (1) with uncertainty and interval time-varying delay satisfying (2-5) under the state feedback controller

$$u(t) = Kx(t). \tag{7}$$

Lemma 1 [4]**.** For scalars $\alpha, \beta \in [0,1], \alpha + \beta = 1$, and vectors η_1, η_2 satisfy $\eta_1 = 0$ with $\alpha = 0$ and $\eta_2 = 0$ with $\beta = 0$, matrices $P > 0$, $Q > 0$, there exists matrix T, satisfies

$$\begin{bmatrix} P & T \\ T^T & Q \end{bmatrix} \geq 0,$$

such that the following inequality holds

$$\frac{1}{\alpha}\eta_1^T P \eta_1 + \frac{1}{\beta}\eta_2^T Q \eta_2 \geq \begin{bmatrix} \eta_1 \\ \eta_2 \end{bmatrix}^T \begin{bmatrix} P & T \\ T^T & Q \end{bmatrix} \begin{bmatrix} \eta_1 \\ \eta_2 \end{bmatrix}.$$

3 MAIN RESULTS

We rewrite the closed loop of system (1) as the following form

$$\dot{x}(t) = \bar{A}x(t) + A_d x(t-h(t)) + \bar{E}f(t,x), \tag{8}$$

with

$$\bar{A} = A + BK, \bar{E} = \begin{bmatrix} E_1 & E_2 & E_3 \end{bmatrix}, f(t,x) = \bar{F}(t)\bar{G}(x),$$

$$\bar{F}(t) = \mathrm{diag}\,\{F_1(t), F_2(t), F_3(t)\},$$

$$\bar{G}(x) = \begin{bmatrix} x^T(t)G_1^T & x^T(t-h(t))G_2^T & x^T(t)K^TG_3^T \end{bmatrix}^T.$$

Firstly we divide the delay intervals $[0, h_1]$ and $[h_1, h_2]$ into two subintervals separately, and denote $\delta_1 = \frac{h_1}{2}$, $\delta_2 = \frac{h_{12}}{2}$, $\delta = h_1 + \delta_2$, $\zeta_1(t) = \begin{bmatrix} x^T(t) & x^T(t-\delta_1) \end{bmatrix}^T$, $\zeta_2(t) = \begin{bmatrix} x^T(t) & x^T(t-\delta_2) \end{bmatrix}^T$. Then corresponding to the divisions and augmented vectors, we construct the following Lyapunov-Krasovskii functional

$$V(x_t) = V_1(x_t) + V_2(x_t) + V_3(x_t), \tag{9}$$

where

$$V_1(x_t) = x^T(t)Px(t),$$

$$\begin{aligned} V_2(x_t) &= \textstyle\int_{t-h(t)}^t x^T(s)\mathrm{e}^{\alpha(s-t)}Qx(s)\mathrm{d}s \\ &\quad + \textstyle\int_{t-\delta_1}^t \zeta_1^T(s)\mathrm{e}^{\alpha(s-t)}Q_1\zeta_1(s)\mathrm{d}s, \\ &\quad + \textstyle\int_{t-\delta}^{t-h_1} \zeta_2^T(s)\mathrm{e}^{\alpha(s-t)}Q_2\zeta_2(s)\mathrm{d}s, \end{aligned}$$

$$\begin{aligned} V_3(x_t) &= \delta_1 \textstyle\int_{-\delta_1}^0 \int_{t+\theta}^t \dot{x}^T(s)\mathrm{e}^{\alpha(s-t)}R_1\dot{x}(s)\mathrm{d}s\mathrm{d}\theta \\ &\quad + \delta_1 \textstyle\int_{-h_1}^{-\delta_1} \int_{t+\theta}^t \dot{x}^T(s)\mathrm{e}^{\alpha(s-t)}R_2\dot{x}(s)\mathrm{d}s\mathrm{d}\theta \\ &\quad + \delta_2 \textstyle\int_{-\delta}^{-h_1} \int_{t+\theta}^t \dot{x}^T(s)\mathrm{e}^{\alpha(s-t)}S_1\dot{x}(s)\mathrm{d}s\mathrm{d}\theta \\ &\quad + \delta_2 \textstyle\int_{-h_2}^{-\delta} \int_{t+\theta}^t \dot{x}^T(s)\mathrm{e}^{\alpha(s-t)}S_2\dot{x}(s)\mathrm{d}s\mathrm{d}\theta \end{aligned}$$

with P, Q, Q_i, R_i and S_i are symmetric positive matrices. Denote $\xi(t) = \begin{bmatrix} x^T(t) & x^T(t-\delta_1) & x^T(t-h_1) \end{bmatrix.$

$\begin{matrix} x^T(t-\delta) & x^T(t-h_2) & x^T(t-h(t)) & \dot{x}^T(t) & f^T(t,x) \end{bmatrix}^T$, and e_i $(i = 1, \cdots, 8)$ are block entry matrices such that $e_i\xi(t) = \xi_i(t)$.

Theorem 1. For given scalars $\alpha > 0$, $0 \leq h_1 < h_2$, $\mu \geq 0$, γ_1 and γ_2, the closed-loop system of (1) with uncertainty and time-delay satisfied (2-5) is robust exponential stabilization if there exist symmetric positive matrices $\bar{P}$, $\bar{Q}$, $\bar{Q}_i$, $\bar{R}_i$, $\bar{S}_i$, matrices $\bar{T}_i$ $(i = 1, 2)$, $\bar{N}$ and W, positive scalars $\bar{\epsilon}$ such that the following LMIs (10-11) hold for $i = 1, 2$, then the solution $x(t)$ of the closed-loop of system (1) satisfies (6) with convergence rate $\rho = \frac{\alpha}{2}$ and the robust stabilization controller is $K = W\bar{N}^{-1}$.

$$\begin{bmatrix} \bar{\Pi}(i) & \bar{\epsilon}\tilde{G} \\ \bar{\epsilon}\tilde{G}^T & -\bar{\epsilon}I \end{bmatrix} < 0, \tag{10}$$

$$\begin{bmatrix} \bar{S}_i & \bar{T}_i \\ \bar{T}_i^T & \bar{S}_i \end{bmatrix} \geq 0, \tag{11}$$

where

$$\bar{\Pi}(i) = \bar{\Pi}_0 + \bar{\Pi}_i + \bar{\Pi}_e,$$

$$\begin{aligned} \bar{\Pi}_0 &= e_1^T\bar{P}e_7 + e_7^T\bar{P}e_1 + \alpha e_1^T\bar{P}e_1 + e_1^T\bar{Q}e_1 + e_6^T\psi(\mu)\bar{Q}e_6 \\ &\quad + e_a^T\bar{Q}_1e_a - e_b^T\mathrm{e}^{-\alpha\delta_1}\bar{Q}_1e_b + e_c^T\mathrm{e}^{-\alpha h_1}\bar{Q}_2e_c - \bar{\epsilon}e_8^Te_8 \\ &\quad - e_d^T\mathrm{e}^{-\alpha\delta}\bar{Q}_2e_d + \textstyle\sum_{i=1}^2 e_7^T(\delta_1^2\bar{R}_i + \delta_2^2\bar{S}_i)e_7 \\ &\quad - (e_1 - e_2)^T\mathrm{e}^{-\alpha\delta_1}\bar{R}_1(e_1 - e_2) \\ &\quad - (e_2 - e_3)^T\mathrm{e}^{-\alpha h_1}\bar{R}_2(e_2 - e_3), \end{aligned}$$

$$\begin{aligned} \bar{\Pi}_1 &= -(e_4 - e_5)^T\mathrm{e}^{-\alpha h_2}\bar{S}_2(e_4 - e_5) \\ &\quad - \mathrm{e}^{-\alpha\delta}\begin{bmatrix} e_3 - e_6 \\ e_6 - e_4 \end{bmatrix}^T \begin{bmatrix} \bar{S}_1 & \bar{T}_1 \\ \bar{T}_1^T & \bar{S}_1 \end{bmatrix} \begin{bmatrix} e_3 - e_6 \\ e_6 - e_4 \end{bmatrix}, \end{aligned}$$

$$\begin{aligned} \bar{\Pi}_2 &= -(e_3 - e_4)^T\mathrm{e}^{-\alpha\delta}\bar{S}_1(e_3 - e_4) \\ &\quad - \mathrm{e}^{-\alpha h_2}\begin{bmatrix} e_4 - e_6 \\ e_6 - e_5 \end{bmatrix}^T \begin{bmatrix} \bar{S}_2 & \bar{T}_2 \\ \bar{T}_2^T & \bar{S}_2 \end{bmatrix} \begin{bmatrix} e_4 - e_6 \\ e_6 - e_5 \end{bmatrix}, \end{aligned}$$

$$\bar{\Pi}_e = \bar{\Omega} + \bar{\Omega}^T,$$

$$\bar{\Omega} = (e_1 + \gamma_1e_6 + \gamma_2e_7)^T(-\bar{N}e_7 + A\bar{N}e_1 + BWe_1$$

$$+ A_d\bar{N}e_6 + \bar{\epsilon}\bar{E}e_8),$$

$$\psi(\mu) = \begin{cases} (\mu-1)\mathrm{e}^{-\alpha h_1} \ (\mu \geq 1) \\ (\mu-1)\mathrm{e}^{-\alpha h_2} \ (\mu < 1), \end{cases}$$

$e_a = [e_1^T, e_2^T]^T$, $e_b = [e_2^T, e_3^T]^T$,

$e_c = [e_3^T, e_4^T]^T$, $e_d = [e_4^T, e_5^T]^T$,

$\tilde{G} = \bar{G}_1\bar{N}^{-1}e_1 + \bar{G}_2\bar{N}^{-1}e_6 + \bar{G}_3We_1$,

$\bar{G}_1 = \begin{bmatrix} G_1^T & 0 & 0 \end{bmatrix}^T$, $\bar{G}_2 = \begin{bmatrix} 0 & G_2^T & 0 \end{bmatrix}^T$,

$\bar{G}_3 = \begin{bmatrix} 0 & 0 & G_3^T \end{bmatrix}^T$, $\sigma = \sqrt{\frac{\bar{n}}{\bar{m}}}$, $\bar{N}_1 = \mathrm{diag}\{\bar{N}, \bar{N}\}$,

$\bar{m} = \lambda_{min}(\bar{N}^{-1}\bar{P}\bar{N}^{-T})$,

$$\begin{aligned}\bar{n} = {} & \lambda_{max}(\bar{N}^{-1}\bar{P}\bar{N}^{-T}) + (\tfrac{1-\mathrm{e}^{-\alpha h_2}}{\alpha})\lambda_{max}(\bar{N}^{-1}\bar{Q}\bar{N}^{-T}) \\ & + (\tfrac{1-\mathrm{e}^{-\alpha\delta_1}}{\alpha})\lambda_{max}(2\bar{N_1}^{-1}\bar{Q}_1\bar{N_1}^{-T}) \\ & + (\tfrac{\mathrm{e}^{-\alpha h_1}-\mathrm{e}^{-\alpha\delta}}{\alpha})\lambda_{max}(2\bar{N_1}^{-1}\bar{Q}_2\bar{N_1}^{-T}) \\ & + \delta_1(\tfrac{\mathrm{e}^{-\alpha\delta_1}+\alpha\delta_1-1}{\alpha^2})\lambda_{max}(\bar{N}^{-1}\bar{R}_1\bar{N}^{-T}) \\ & + \delta_1(\tfrac{\mathrm{e}^{-\alpha h_1}+\alpha h_1-\mathrm{e}^{-\alpha\delta_1}-\alpha\delta_1}{\alpha^2})\lambda_{max}(\bar{N}^{-1}\bar{R}_2\bar{N}^{-T}) \\ & + \delta_2(\tfrac{\mathrm{e}^{-\alpha\delta}+\alpha\delta-\mathrm{e}^{-\alpha h_1}-\alpha h_1}{\alpha^2})\lambda_{max}(\bar{N}^{-1}\bar{S}_1\bar{N}^{-T}) \\ & + \delta_2(\tfrac{\mathrm{e}^{-\alpha h_2}+\alpha h_2-\mathrm{e}^{-\alpha\delta}-\alpha\delta}{\alpha^2})\lambda_{max}(\bar{N}^{-1}\bar{S}_2\bar{N}^{-T}).\end{aligned}$$

Proof. Taking the time derivative of Lyapunov functional (9) along the trajectory of closed-loop of system (1), we have

$$\dot{V}_1(x_t) = 2x^T(t)P\dot{x}(t) + \alpha x^T(t)Px(t) - \alpha V_1(x_t),$$

$$\begin{aligned}\dot{V}_2(x_t) = {} & x^T(t)Qx(t) + \zeta_1^T(t)Q_1\zeta_1(t) - \alpha V_2(x_t) \\ & - (1-\dot{h}(t))x^T(t-h(t))\mathrm{e}^{-\alpha h(t)}Qx(t-h(t)) \\ & - \zeta_1^T(t-\delta_1)\mathrm{e}^{-\alpha\delta_1}Q_1\zeta_1(t-\delta_1) \\ & + \zeta_2^T(t-h_1)\mathrm{e}^{-\alpha h_1}Q_2\zeta_2(t-h_1) \\ & - \zeta_2^T(t-\delta)\mathrm{e}^{-\alpha\delta}Q_2\zeta(t-\delta),\end{aligned}$$

$$\begin{aligned}\dot{V}_3(x_t) = {} & \textstyle\sum_{i=1}^2 \dot{x}^T(t)(\delta_1^2R_i + \delta_2^2S_i)\dot{x}(t) - \alpha V_3(x_t) \\ & - \delta_1\textstyle\int_{t-\delta_1}^{t} \dot{x}^T(s)\mathrm{e}^{\alpha(s-t)}R_1\dot{x}(s)\mathrm{d}s \\ & - \delta_1\textstyle\int_{t-h_1}^{t-\delta_1} \dot{x}^T(s)\mathrm{e}^{\alpha(s-t)}R_2\dot{x}(s)\mathrm{d}s \\ & - \delta_2\textstyle\int_{t-\delta}^{t-h_1} \dot{x}^T(s)\mathrm{e}^{\alpha(s-t)}S_1\dot{x}(s)\mathrm{d}s \\ & - \delta_2\textstyle\int_{t-h_2}^{t-\delta} \dot{x}^T(s)\mathrm{e}^{\alpha(s-t)}S_2\dot{x}(s)\mathrm{d}s.\end{aligned}$$

Then by using Jensen inequality [5] and enlarging some terms appropriately, we get

$$(\dot{h}(t)-1)\mathrm{e}^{-\alpha h(t)} \leq \psi(\mu), \tag{12}$$

$$\begin{aligned}& -\delta_1\textstyle\int_{t-\delta_1}^{t} \dot{x}^T(s)\mathrm{e}^{\alpha(s-t)}R_1\dot{x}(s)\mathrm{d}s \\ & \leq -\delta_1\mathrm{e}^{-\alpha\delta_1}\textstyle\int_{t-\delta_1}^{t} \dot{x}^T(s)R_1\dot{x}(s)\mathrm{d}s \\ & \leq -(\textstyle\int_{t-\delta_1}^{t} \dot{x}(s)\,\mathrm{d}s)^T\mathrm{e}^{-\alpha\delta_1}R_1(\textstyle\int_{t-\delta_1}^{t} \dot{x}(s)\,\mathrm{d}s) \\ & = -\xi^T(t)(e_1-e_2)^T\mathrm{e}^{-\alpha\delta_1}R_1(e_1-e_2)\xi(t),\end{aligned} \tag{13}$$

$$\begin{aligned}& -\delta_1\textstyle\int_{t-h_1}^{t-\delta_1} \dot{x}^T(s)\mathrm{e}^{\alpha(s-t)}R_2\dot{x}(s)\mathrm{d}s \\ & \leq -\xi^T(t)(e_2-e_3)^T\mathrm{e}^{-\alpha h_1}R_2(e_2-e_3)\xi(t),\end{aligned} \tag{14}$$

for the case time delay $h(t) \in [h_1, \delta]$, by Lemma 1, there exists matrix T_1, such that

$$\begin{bmatrix} S_1 & T_1 \\ T_1^T & S_1 \end{bmatrix} \geq 0, \tag{15}$$

$$\begin{aligned}& -\delta_2\textstyle\int_{t-\delta}^{t-h_1} \dot{x}^T(s)\mathrm{e}^{\alpha(s-t)}S_1\dot{x}(s)\mathrm{d}s \\ & \leq -\delta_2\mathrm{e}^{-\alpha\delta}\textstyle\int_{t-d(t)}^{t-h_1} \dot{x}^T(s)S_1\dot{x}(s)\mathrm{d}s \\ & \quad - \delta_2\mathrm{e}^{-\alpha\delta}\textstyle\int_{t-\delta}^{t-d(t)} \dot{x}^T(s)S_1\dot{x}(s)\mathrm{d}s \\ & \leq -\mathrm{e}^{-\alpha\delta}\xi^T(t)\begin{bmatrix} e_3-e_6 \\ e_6-e_4 \end{bmatrix}^T \begin{bmatrix} S_1 & T_1 \\ T_1^T & S_1 \end{bmatrix} \begin{bmatrix} e_3-e_6 \\ e_6-e_4 \end{bmatrix}\xi(t).\end{aligned}$$

Similarly to above procedure, we can cope with the situation $h(t) \in [\delta, h_2]$.

According to (3), there exists scalar $\epsilon > 0$ such that

$$\epsilon f^T(t,x)f(t,x) \leq \epsilon\bar{G}^T(x)\bar{G}(x),$$

thus we have

$$\epsilon\xi^T(t)\bar{G}^T\bar{G}\xi(t) - \epsilon\xi^T(t)e_8^Te_8\xi(t) \geq 0 \tag{16}$$

with $\bar{G} = \bar{G}_1e_1 + \bar{G}_2e_6 + \bar{G}_3Ke_1$.

By using system's information we add the left side of following equation into the derivative of Lyapunov functional:

$$\begin{aligned}& 2(x^T(t)N_1 + x^T(t-h(t))N_2 + \dot{x}^T(t)N_3)(-\dot{x}(t) \\ & + \bar{A}x(t) + A_dx(t-h(t)) + \bar{E}f(t,x)) = 0,\end{aligned} \tag{17}$$

where N_i are matrices with appropriate dimensions.

For getting LMI criteria and obtaining the controller, we set $N_1 = N$, $N_2 = \gamma_1N$, $N_3 = \gamma_2N$ and assume N^{-1} exist, and from the above equations we can get

$$\dot{V}(x_t) + \alpha V(x_t) \leq \xi^T(t)(\Pi(i) + \bar{G}^T\bar{G})\xi(t), \tag{18}$$

with some transformation of the matrices. By Schur Complement, the negative of (18) imply

$$\begin{bmatrix} \Pi_i & \epsilon\bar{G} \\ \epsilon\bar{G}^T & -\epsilon I \end{bmatrix} < 0. \tag{19}$$

Pre-multiplying and post-multiplying both sides of (19) by $\mathrm{diag}\{\sum_{i=1}^7 e_i^TN^{-1}e_i + \epsilon^{-1}e_8^Te_8, \epsilon^{-1}I\}$ and its transpose, denoting $N_1 = \mathrm{diag}\{N, N\}$, $\bar{P} = N^{-1}PN^{-T}$, $\bar{Q} = N^{-1}QN^{-T}$, $\bar{Q}_i = N_1^{-1}Q_iN_1^{-T}$, $\bar{R}_i = N^{-1}R_iN^{-T}$ $\bar{S}_i = N^{-1}S_iN^{-T}$, $\bar{T}_i = N^{-1}T_iN^{-T}$ $(i = 1, 2)$, $\bar{N} = N^{-1}$, $W = K\bar{N}^T$ and $\bar{\epsilon} = \epsilon^{-1}$, then the hold of (19) is equivalent to (10). By applying the similar transformation to (15), and notice that from (9) and (18), we have

$$V(x_t) \geq \bar{m}\|x(t)\|^2, V(x_{t_0}) \leq \bar{n}\|x(t_0)\|_\theta^2, \tag{20}$$

$$V(x_t) < \mathrm{e}^{-\alpha(t-t_0)}V(x_{t_0}), \tag{21}$$

by some computation we can get Theorem 1, thus complete the proof.

Remark 1. The term $(\dot{h}(t)-1)\mathrm{e}^{-\alpha h(t)}$ appeared in the derivative of Lyapunov functional can be enlarged as $\mu e^{-\alpha h_1} - e^{-\alpha h_2}$, to reduce the conservativeness of the criteria, we consider the situations that $\mu \geq 1$ and $\mu < 1$, respectively, and enlarge it as $\psi(\mu)$, while the equation (24) in Wang [1] only holds when $\mu \geq 1$ but have some conservativeness when $\mu < 1$.

4 NUMERICAL EXAMPLES

In this section, we consider three examples to show the effectiveness of the obtained criteria.

We compare our methods to that of Botmart [2] in Example 1. The obtained results are listed in Table 1 below, which show the less conservativeness of our criteria.

Example 1. Consider the system (1) with

$$A = \begin{bmatrix} 0 & 0 \\ 0 & 1 \end{bmatrix}, A_d = \begin{bmatrix} -2 & -0.5 \\ 0 & -1 \end{bmatrix}, B = \begin{bmatrix} 0 \\ 1 \end{bmatrix}.$$

Table 1. Admissible upper bound h_2 for unknown μ and various (ρ, h_1) with $(\gamma_1, \gamma_2) = (0, 1.9)$.

	(ρ, h_1)	(0.1, 0)	(0.1, 0.5)	(0.2, 0)	(0.2, 0.5)
[2]	h_2	0.406	0.590	0.381	0.545
T1	h_2	1.2152	1.4650	1.0859	1.3172

Remark 2. Following the same method, we can get better results by dividing the time intervals into more subintervals while more computational burden will be taken.

Remark 3. To get the controller matrix K, we fix the formation of free-weighting matrices S_i, to get less conservative results the values of γ_1 and γ_2 need to be appropriate chosen, we will do further research to this problem.

In Example 2, we compare our method to that of Wang [1] with the robust exponential stabilization problem.

Example 2. Consider the uncertain system (1) with

$$A = \begin{bmatrix} -2 & 0 \\ 0 & -0.9 \end{bmatrix}, A_d = \begin{bmatrix} -1 & 0 \\ -1 & -1 \end{bmatrix}, B = \begin{bmatrix} 0 \\ 1 \end{bmatrix},$$

$$E_1 = \begin{bmatrix} \sqrt{0.2} & 0 \\ 0 & \sqrt{0.05} \end{bmatrix}, E_2 = \begin{bmatrix} \sqrt{0.1} & 0 \\ 0 & \sqrt{0.3} \end{bmatrix}, E_3 = \begin{bmatrix} \sqrt{0.01} & 0 \\ 0 & \sqrt{0.1} \end{bmatrix}, G_1 = E_1, G_2 = E_2, G_3 = \begin{bmatrix} 0.01 \\ 0 \end{bmatrix}.$$

For $\mu = 1.1$, $\rho = 0.1$, $h_1 = 0.3$, and $h_2 = 0.7$, in Wang [1] the state convergence rate is estimated as

$$\|x(t)\| \leq 2.0463 e^{-0.1(t-t_0)} \|x(t_0)\|_\theta,$$

while with $(\gamma_1, \gamma_2) = (0.1, 1)$, from Theorem 1 we get the stabilization controller is $K = [-0.2273, -3.0087]$, and with a smaller $\sigma = 1.5947$, the state convergence rate satisfy

$$\|x(t)\| \leq 1.5947 e^{-0.1(t-t_0)} \|x(t_0)\|_\theta.$$

Furthermore, by Theorem 1 we can get the allowable upper bound h_2 is 1.5815, and the stabilization controller is $K = [-49.5411, -157.8835]$ with $\sigma = 5.4790$. From Fig.1. we can see that the state of controlled closed-loop system is exponential stable under initial condition $\varphi(s) = [3, -1]$, interval time-varying delay $[h_1, h_2] = [0.3, 1.5815]$ and $\mu = 1.1$ with the convergence rate $\rho = 0.1$.

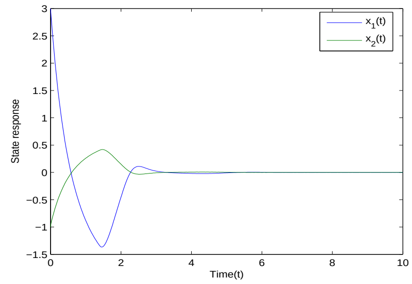

Fig.1. State response with controller $u(t)$

5 CONCLUSION

In this paper, the problem of robust exponential stabilization for interval time-varying delay systems have been investigated. By dividing the delay intervals into two equal subintervals and using free-weighting matrix technic, robust exponential stabilization criteria are obtained in terms of LMIs. Numerical examples are given to show the effectiveness and less conservativeness of our obtained criteria.

Abstract: We consider the problem of multiple target tracking in the presence of clutter (false alarm) measurements. To improve the performance of the Rao-Blackwellized particle filter (RBPF) data association algorithms, some simple but effective strategies are implemented. We first present a sequential likelihood method, i.e., all measurements are used to update the particles more than one time in each time step. It is observed that the tracking performance of the algorithm is not severely loss with fewer particles. We then present a simple gating technique to reduce the validated measurements to a feasible level. It is worth mentioning that the association probabilities are not calculated by grouping targets into clusters as the joint probabilistic data association (JPDA), but only reserve the validated measurements in the joint validation region (gate) and ignore the measurements outside. Simulations are also presented to compare the performance of the proposed algorithms.

Keywords: Multiple target tracking, data association, Rao-Blackwellized particle filter, sequential likelihood

1 INTRODUCTION

In multi-target tracking, data association remains a challenge in cluttered environment [1]-[3]. As an important enhancement of the particle filter, Rao-blackwellized particle filter (RBPF) has also been used to solve this problem in recent years [4]-[6]. The idea of this approach is that the joint data association and target tracking problem can be solved by partly sequential Monte Carlo method instead of pure particle filter sampling [7], [8], so that the needed number of particles may be reduced to a low order of magnitude.

However, in the application of the RBPF multi-target tracking algorithms, we found that the success rate of data association could not be improved only by increasing the number of particles. To improve the ability of the algorithms but not increase the time cost, we present in this paper some simple but effective methods. The main contribution of this paper has two folders, one is the development of a sequential likelihood method in RBPF multi-target tracking algorithms, the other is the application of the simple gating technique, which restrict data association into validation regions.

The rest of this paper is organized as follows. In Section 2, we give a brief introduction of the RBPF data association algorithms. The sequential likelihood and simple gating methods are presented in Section 3. Finally, simulation results and conclusions are given in Section 4 and Section 5, respectively.

2 RAO-BLACKWELLIZED PARTICLE FILTER FOR MULTIPLE TARGET TRACKING

In this section we will give a brief introduction of the RBPF algorithms for multi-target tracking. The basic RBPF model is assumed to be time-varying system as follows:

$$x_k^2 = F_{k-1} x_{k-1}^2 + w_{k-1} \quad (1)$$

$$z_k = H_k x_k^2 + v_k \quad (2)$$

where, w_{k-1} and v_k are zero mean Gaussian random vectors, F_{k-1} and H_k are matrices with compatible dimensions. This type of system can be termed conditionally linear-Gaussian for the set of variables x_k^1, a RBPF algorithm can be applied to estimate the state $x_k = \{x_k^1; x_k^2\}$. The RBPF can be seen as a form of constrained PF (Particle Filter) applicable to a subclass of state-space models. By choosing N_p particles at time step k, a generic RBPF algorithm, applicable to problems of the form (1) and (2) is presented as follows [9].
Step 1. For every $i \in \{1, 2, ..., N_p\}$:

- Draw $x_k^{1(i)} \sim q(x_k^1 | x_{1:k-1}^{1(i)}, z_{1:k})$
- Set $x_{1:k}^{1(i)} = \{x_k^{1(i)}; x_{1:k-1}^{1(i)}\}$
- Compute the normalized weights:
$\tilde{w}_k^{(i)} \propto w_{k-1}^{(i)} \frac{p(z_k | x_{1:k}^{1(i)}, z_{1:k-1}) p(x_k^{1(i)} | x_{1:k-1}^{1(i)}, z_{1:k-1})}{q(x_k^{1(i)} | x_{1:k-1}^{1(i)}, z_{1:k})}$,

Step 2. For every $i \in \{1, 2, ..., N_p\}$:

- Update $p(x_k^2|x_{1:k}^{1(i)}, z_{1:k})$ using $p(x_{k-1}^2|x_{1:k-1}^{1(i)}, z_{1:k-1})$, $x_k^{1(i)}$, $x_{k-1}^{1(i)}$, and z_k.

Step 3. Resample the particles if needed.

In [5] it has been shown that the RBPF based data association algorithm can be obtained directly from the RBPF framework when the latent values x_k^1 are defined to contain the data association event indicators c_k,

$$x_k^1 = c_k \tag{3}$$

The advantage of RBPF is that only the index of data association needs to be sampled from the importance distribution so that the required number of particles can be greatly reduced. Nevertheless, it seems that the number of particles should still be large enough in dense clutter environment, because as data association becomes more difficult the importance distribution will be more complex. In experiments, it is found that only a few particles had unnegligible weights after a certain number of recursive steps, that is to say most of the particles are degenerated prematurely and we cannot improve the performance only by increasing the number of particles. Of course, the resampling strategy can be implemented when a significant degeneracy is observed, but the resampling threshold cannot be calculated analytically. Typically, the values of the threshold are selected ad hoc and degeneracy may possibly happen.

3 PROPOSED ALGORITHMS

In the following discussions, we will show two simple but effective methods to improve the performance of the RBPF algorithm in the application of multi-target tracking.

3.1 Sequential likelihood function based algorithms

we first present a sequential likelihood function based method to resolve the particle degeneracy problems, i.e., all validated measurements are used to update the state of particles more than one time in each time step. The proposed algorithm is derived based on an existing RBPF data association algorithm termed Rao-Blackwellized Monte Carlo data association (RBMCDA), in which the optimal importance distribution is used as the association sampling function. The main procedure of the proposed sequential likelihood technique based RBMCDA data association algorithm (S-RBMCDA) is presented as follows:

i. Calculation of the predicted measurement $\hat{z}_{j,k}$ and the related innovation $S_{j,k}$

$$\hat{z}_{j,k} = H_{j,k}\hat{x}_{j,k|k-1},\ S_{j,k} = H_{j,k}P_{j,k|k-1}H_{j,k}^T + R_{j,k} \tag{4}$$

where

$$\begin{cases} \hat{x}_{j,k|k-1} = \sum_{i=1}^{N_p} w^{(i)}\hat{x}_{j,k|k-1}^{(i)}, \\ P_{j,k|k-1} = \sum_{i=1}^{N_p} w^{(i)}P_{j,k|k-1}^{(i)}. \end{cases} \tag{5}$$

ii. Calculation of the association priors $p(c_k^{(i)}|c_{k-m:k-1}^{(i)})$ according to the Markov chain method introduced in [5].

iii. Calculation of the measurement likelihood for each data association hypothesis, $j = 1, \cdots, T$.

$$p(z_k|c_k = j, c_{1:k-1}^{(i)}, z_{1:k-1}) = \mathcal{N}(z_k|\hat{Z}_{j,k}^{(i)}, S_{j,k}^{(i)}) \tag{6}$$

and

$$p(z_k|c_k = 0, c_{1:k-1}^{(i)}, z_{1:k-1}) = V^{-1}, \tag{7}$$

where V is volume of the detection region.

iv. Calculation of the posterior distribution of $c_k^{(i)}$

$$\begin{aligned} &p(c_k^{(i)}|c_{1:k-1}^{(i)}, z_{1:k}) \\ &= p(z_k|c_k^{(i)}, c_{1:k-1}^{(i)}, z_{1:k-1})p(c_k^{(i)}|c_{k-m:k-1}^{(i)}), \end{aligned} \tag{8}$$

v. Sampling a new association $c_k^{(i)} = j$

vi. Calculation of the new weights for each particle

$$w_k^{(i)} \propto w_{k-1}^{(i)} \frac{p(z_k|c_k^{(i)}, c_{1:k-1}^{(i)}, z_{1:k-1})p(c_k^{(i)}|c_{k-m:k-1}^{(i)})}{p(c_k^{(i)}|c_{1:k-1}^{(i)}, z_{1:k})} \tag{9}$$

vii. Resampling the particles if needed.

In this procedure the target state priors can be represented as a weighted importance samples set

$$p(x_{j,0}) = \sum_{i=1}^{N_p} w_0^{(i)}\mathcal{N}(x_{j,0}|x_{j,0}^{(i)}, P_{j,0}^{(i)}) \tag{10}$$

where N_p is the number of particles. The dynamics and measurements for target j (j=1, $\cdots, T$) are assumed to be linear Gaussian

$$p(x_{j,k}|x_{j,k-1}) = \mathcal{N}(x_{j,k}|F_{j,k-1}\ x_{j,k-1}, Q_{j,k-1}) \tag{11}$$

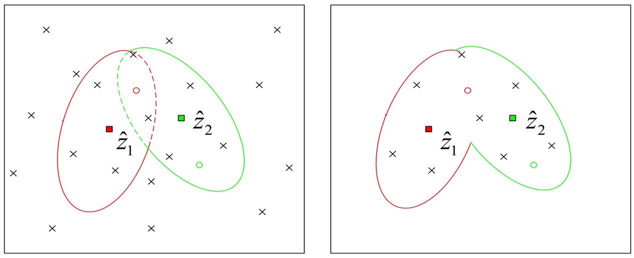
$$p(z_k|x_{j,k}, c_k = j) = \mathcal{N}(z_k|H_{j,k}x_{j,k}, R_{j,k}). \tag{12}$$

Note that this algorithm is generally the same as the generic RBMCDA [4], [5] except the sequential likelihood procedure which is used to improve the ability of the data association. It just need to repeat from the procedure ii. to v. several times.

3.2 Simple gating

In the RBMCDA algorithms, gating techniques for selecting validated measurements are not introduced. For the known number of target version of the RBMCDA algorithm, it always deals with all measurements in the entire detection region, which is the same as the unknown number of target version. Obviously, too many clutter originated measurements are considered in data association and high computational complexity arises.

To overcome this difficulty, we then present a simple gating technique which can be incorporated into the known



(a) (b)

Fig. 1: Example of the measurement validation. (a):Two targets tracking situation. (b): The equivalence simple gate.

number of target version of the RBMCDA algorithm for reducing the validated measurements to a feasible level. It is worth mentioning that the association probabilities are not calculated by grouping targets into clusters as the joint probabilistic data association (JPDA), but only reserve the validated measurements in the joint validation region (gate) and ignore the measurements outside. Following [10], the validation region is the elliptical region

$$\Gamma(k,\gamma) = \{z : [z - \hat{z}(k|k-1)]' S(k)^{-1} [z - \hat{z}(k|k-1)] \le \gamma\} \tag{13}$$

where γ is the gate threshold corresponding to the gate probability P_g, which is the probability that the gate contains the true measurement if detected, and $S(k)$ is the covariance of the innovation corresponding to the predicted measurement.

In Fig. 1, the target originated measurements "o" and clutter originated measurements "$\times$" are shown. A measurement is validated for target j if it falls inside the elliptical region centered at $\hat{Z}_j$ (the predicted measurement of target j), and only the validated measurements for a particular target are candidates to be association with that target. The simple gating technique can be easily incorporated into the framework of the algorithm in Section 3.1. In this gating based algorithm (G-RBMCDA), only the validated measurements are used to enumerate the data associations.

It should be noted that, the introduce simple gating technique can not be directly used in the sequential likelihood based algorithms. In fact, we found that the combinational algorithm may possibly be failed in experiments. An intuitive explanation of this problem is that the fixed validation regions should be changed even in one time step.

4 SIMULATIONS

The performance of S-RBMCDA and G-RBMCDA algorithms are compared with generic RBMCDA in this section. We model the two targets with near constant velocity model in 2-dimensional Cartesian coordinates and the discrete-time dynamic and measurement model of target j has the following form:

$$x_{j,k} = F x_{j,k-1} + w_{k-1} \tag{14}$$

$$z_{j,k} = H x_{j,k} + v_k \tag{15}$$

where

$$F = \begin{pmatrix} 1 & 0 & T & 0 \\ 0 & 1 & 0 & T \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \end{pmatrix}, H = \begin{pmatrix} 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \end{pmatrix} \tag{16}$$

w_{k-1} and v_k are zero mean Gaussian process noise. The Process noise variance and the variance in the measurements are selected as 0.1. The sample interval $T = 0.1$ and the correct measurements returns with a know detection probability $P_d = 0.99$. The clutter are modeled as independent and identically distributed with uniform spatial distribution in a detection region of the coordinate plane $[0,\ 25] \times [0,\ 25]$, and the number of clutter measurements obeys a Poisson distribution with the Poisson random number λ. The gating region used is $P_g = 0.9997$ with $\gamma = 16$. The number of particles used in the three algorithms: 50 (RBMCDA), 20 (S-RBMCDA, repeat 2 times), 50 (G-RBMCDA). in All simulations are run on a PC with a 2.8-GHz Intel processor.

Fig. 2 and Fig. 3 show the position RMSE for tracking two crossing targets. The clutter rate $\lambda = 10$ and the experiments are repeated 100 times. It is observed that the RMSE of the S-RBMCDA algorithm is lower than the generic RBMCDA even with fewer particles. In fact, G-RBMCDA can further improve the ability of none-validation-region algorithms (RBMCDA and S-RBMCDA) mainly because only the validated measurements are considered in data association and the clutter measurements outside the validation regions are abandoned reasonably.

Fig. 4 gives the running time as a function of N_p, we can see that the S-RBMCDA and G-RBMCDA algorithms are computationally efficient than the generic RBMCDA as expected. The G-RBMCDA is the most efficient algorithms, but it can only be implemented in the known number version of target tracking. For each method we run the algorithms with the increasing number of particles and repeat each experiment 50 times to get an average results.

5 CONCLUSION

In this paper, the improved RBPF algorithms have been presented for multi-target tracking in clutter. The proposed sequential likelihood method can be used to improve the performance of the generic algorithm with less particles. If the number of targets is fixed, the simple gating based algorithm only consider validation regions where the true measurements are concentrated with high probability. The computational time is greatly decreased for less clutter needs to be considered. Moreover, the gating based algorithms can

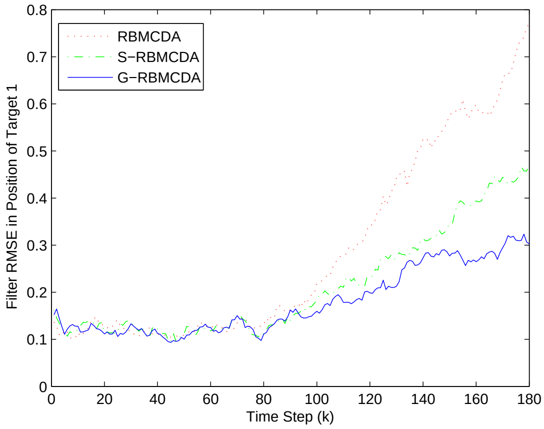


Fig. 2: Comparison of the average position estimation errors (RMSE) of target 1.

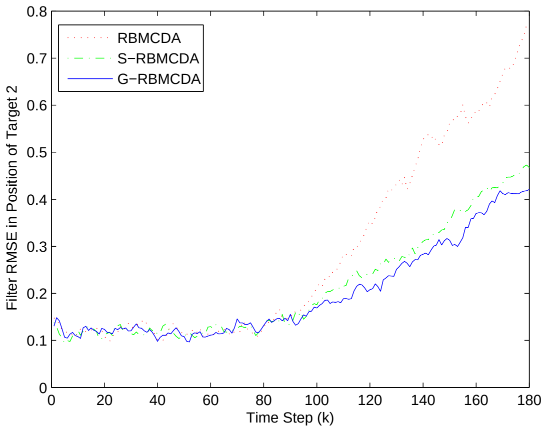

Fig. 3: Comparison of the average position estimation errors (RMSE) of target 2.

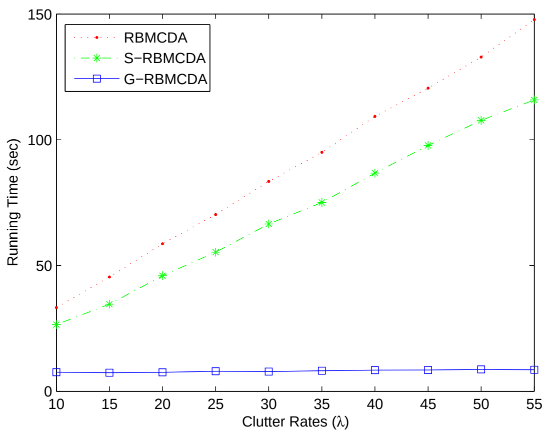

Fig. 4: Comparison of the average running time of the three algorithms.

improve the tracking ability of the algorithm without the disturbance of clutter outside the validation region. Future work should be done to intensively study the sequential likelihood method for the general particle filtering algorithms.

Abstract: The artificial assistant suit is a kind of assistant suit which can be put on the human upper body and help the actions of human's two arms. It is actuated by Mckibben pneumatic artificial muscles (simply call it Mckibben muscles later). This paper introduces the whole system and its structure. The configuration of the Mckibben muscles is discussed. The measurement and control system is introduced in detail. The electropneumatic valve's characteristics are analyzed. The detection of the motion intention of human arms by SEMG signals is discussed too.

Keywords: Artificial assistant suit, Mckibben muscle, electropneumatic valve, SEMG signal.

1. Introduction

The McKibben muscle has advantages such as small size, safe and compliance, great power/weight ratio. And it is simply constructed, easy-fixed, and cheap. Its force-length characteristic is similar to that of the biological muscle. Mainly it is used in robots. The robot joint actuated by it behaves a little like humen's or anminal's because of its similarity to the biological muscle. The robot actuated by McKibben muscles is much safer to human who interacts with it. Therefore, the McKibben muscle is a kind of very promising actuator in human recuperate field [1].

The world should be welfare. Developments of the robot capable of assisting elders, handicappeds, and patients are one of the main directions. Developing the devices capable of help getting well for patients is one of the main tasks of the modern technology. It's expectant for the McKibben muscle to play an important role in these fields. In some places such as Japan, china, America, and Europe, the artificial assisted suit made of McKibben muscles has come out. The suit is called as "dressable robot"[2]. Besides, the bipedal robot actuated by McKibben muscles has been developed. But to all of the developed artificial suit, Their structure is very complicated, and their weights are very large. Here what we are developing is a very light one, and its cost is very low.

2. Structure of the artificial assistant suit

To help the human arms act correctly, the Mckibben muscle actuators must be configured reasonably. Only one piece of the Mckibben muscle can't complete all the actions, because that the structure of the human arm is complicated and its actions are many and varied. Therefore, many pieces of the Mckibben muscles are required and they need to operate coordinately to achieve the required force. Based on the above analysis, we resolve the arm actions into the following basic ones：

①Shoulder's rising up and down (including to the front, to the back, and to the side)；

②Shoulder's swinging around the vertical axis；

③Elbow's bending and stretching；

④The forearm's rotating around the anatomic axis.

We think that all of the main arm actions can be realized based on the above four basic actions. The configuration of the Mckibben muscles can be done based on the requirement of the four basic actions. Let's analyze the anatomic structure of the human arm firstly. There are more than 20 pieces of muscles with the actions of both the shoulder joint and the elbow joint in the same arm[3]. All the actions of the shoulder and the elbow can be realized by these muscles' operating coordinately. Based on both the analysis to the anatomic structure and the dynamic requirement for the artificial assistant suit, 8 pieces of the Mckibben muscles are selected for the configuration of each arm of the suit, shown in Fig.1. They are corresponding to the functions of the following 8 muscles:

① Triceps brachii
② Brachioradialis
③ Biceps brachii short head
④ Biceps brachii long head
⑤ Deltoid anterior part
⑥ Deltoid middle part 1
⑦ Deltoid posterior part
⑧ Deltoid middle part 2

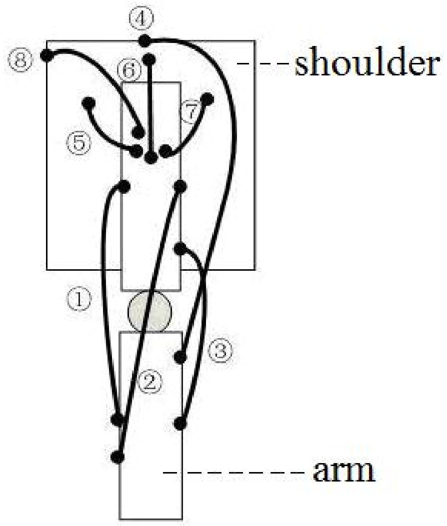

Fig.1 Configuration of the Mckibben mucles

3. Measurement and control system

The main characteristics of the artificial assistant suit are that it can sense the action intention of human arms and output forces to help the arm actions. To get the action intention of human arms exactly, the system uses both the SEMG signals and the gravity acceleration sensors to judge the action intention. Therefore the whole system should include at least the following parts:

① The compressor
② The electropneumatic volves
③ The artificial assistant suit actuated by pieces of Mckibben muscles
④ The SEMG signal detection device
⑤ The computer

The whole system is shown in Fig.2.

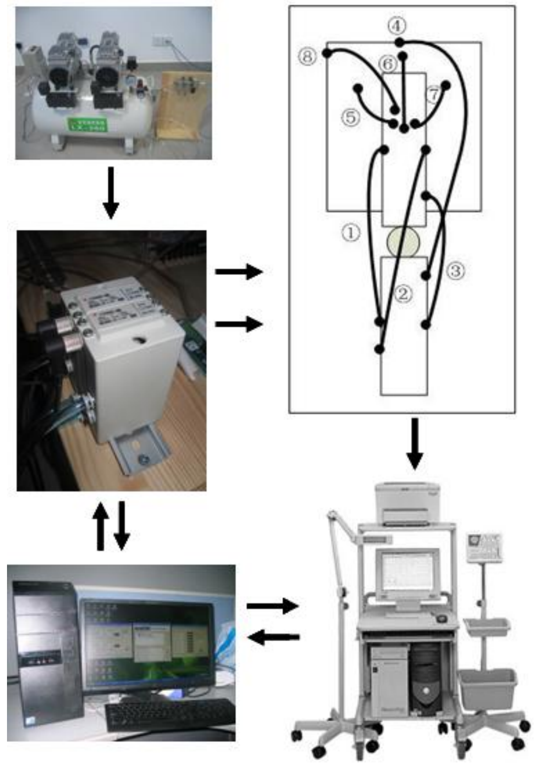

Fig.2 The whole system

The compressor is the source of the pressed gas. The Mckibben muscle needs pressed gas. Here the air is used. The electropneumatic valve is used to regulate the pressure of the air so that the Mckibben muscles can be input by the needed pressure of air. The SEMG signal device is used to detect the arm action by the SEMG signal of the arm. The computer is used as the center of measurement and control, which can control the electropneumatic valves to output the desired pressure of the air and sample the SEMG signals.

The compressor is a un-oil′s, the air from it must be passed through the air filter, the oil separator and the pressure-reducing valve, because that the air input into the electropneumatic valve have to be dry and pure. Otherwise the electropneumatic valve is easy to be damaged. The highest pressure of air must be lower than the highest pressure that the electropneumatic valve permits.

The electropneumatic valve in the system is made by SMC, Japan. The model is ITV0050-2ML. The permitted gas pressure varies from 0.1MPa-0.9MPa. So the highest output gas pressure of the compressor should be less than 0.9MPa. Its specification is DC24V/0.12A. So the max consumed power is 2.88W. The system has 16 valves. The whole power needed is 46.08W than which the source power of the electropneumatic valves should be larger. So we choice NES-200-24 made by Mingwei power source company as the electric power, shown in Fig.3. It can output 200W/24V, which can satisfy the requirement of the 16 valves. And the valve requires the input signal is DC0-5V. Its input impedance is about 10kΩ. Therefore, the max input power of the signal is about 2.5mW. The total input power of the signal is about 40mW. So the provided power from the signal input unit is larger than 40mW. Otherwise the voltage the valve got will be less than the required.

To satisfy the route number and the requirement for the input signal, The I/O card is selected as PCI-1724U which is 14-bit and has 32-channels' analog output, shown in Fig.4. Its output signal is DC0-10V. The required input signal voltage is 0-5V

Fig.3 The Power source (NES-200-24)

Fig.4 The I/O card (PCI-1724U)

To PCI-724U, the output current is 10mV, and if its output voltage is DC0-5V, the output power is 50mW. Fig.5 shows that the power requirement of the two valves can be satisfied by the I/O card.

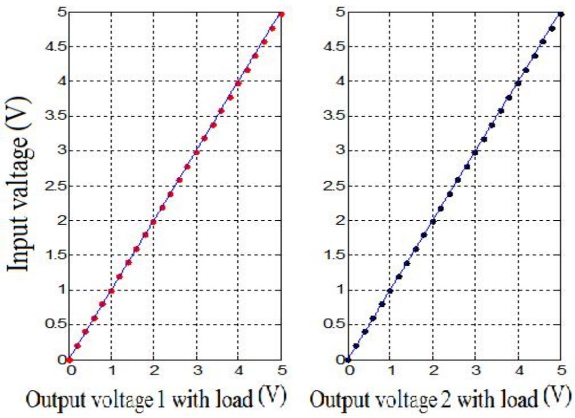

Fig.5 The voltage characteristics with loads

Fig 6 shows the good linearity of the electropenumatic valve. And Fig.6 indicates that the top voltage 5v is corresponds to the top pressure 0.9MPa. The highest pressure of air is 0.67MPa because that the compressor only provides the pressure 0.67MPa. It shows that the pressure gets its highest 0.67MPa when the input voltage is 3.8v. Therefore the input voltage 0-5v corresponds to the output pressure 0-0.9MPa instead of 0-0.67MPa.

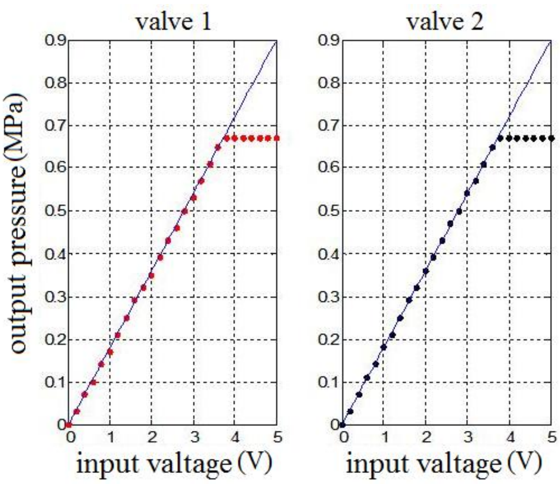

Fig.6 The linearity of the valve

The SEMG signal is used to detect the action intention because it can inform the muscle contraction[4]. We put six pairs of the SEMG signal electrodes on the arm, shown in Fig.7, which are used to detect the action intention of the related muscles. After analyzing, the computer can judge the action intention of the arm by the electrode distribution. A neural network is used to analyze the relationship between the SEMG signals and the action intention.

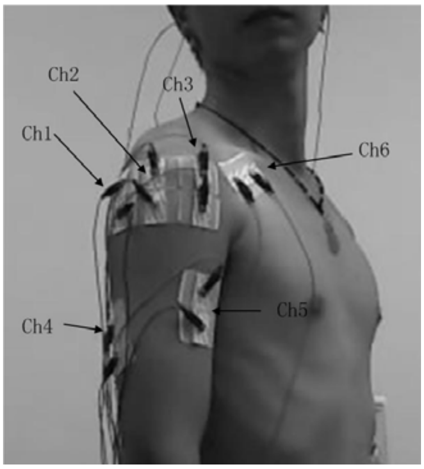

Fig.7 The distribution of the SEMG electrodes

4. conclusion

This paper introduced the whole system including the configuration of the Mckibben muscles in the artificial assistant suit, the integration of the system hardware, and the detection method of action intention of human arms. Of course some research still hasn't been finished including the software and the final experiments.

This study is supported by the project from Shanghai Committee of Science and Technology, China (Pujiang Plan: 10PJ1409200).

Abstract: The fuzzy control to the experimental autonomous airship is introduced in this paper. The fundamental development and research on the hardware and the program to control the airship navigating along the shortest flight path to the target point is executed. The fuzzy control is used because the airship system is nonlinear and it is difficult to describe the accurate motion equations of the system. At last, to compare the efficiency, the traditional PD control is also applied. The result of comparison shows the validity of the fuzzy control.

Keywords: autonomous airship, fuzzy control, side thruster

1 INTRODUCTION

Manned helicopters are used for aerial photography to obtain the geographical information. However, it results to the atmosphere pollution by the exhaust fumes. Also it will be very dangerous to navigate the region that is bearing the disaster or war.

To solve these problems, the unmanned autonomous green flying system is needed. Unmanned helicopter and airship have been developed for uses in the mine detecting, crop dusting and military surveillance. Aerosonde [1], Predetor [2], RQ-4A Global Hawk [3] and the unmanned helicopter developed by Nakamura et al. [4] are examples of these kinds of flying systems. Also Suzuki et al. [5] presented the research result of the control for the airship by reinforcement learning and adaptive control.

However, some of above systems have a little intelligent feature, and some of them have a few references and literature about the control unit because of the technology patents. Thus the detailed information cannot be gotten.

In this paper, the airship in our lab is introduced, which can remain stationary in the air and has low fuel consumption due to the usage of helium gas for buoyancy. Also the basic technology including the hardware and the control method by which the airship navigates along the shortest path to the target point is discussed.

2 STRUCTURE OF THE SYSTEM

To control the whole system, the mechanical control of the airship, determination of flight path to the target point and the flight technology along the flight path, real-time image recognition, and the telecommunication technology, is required.

2.1 Hardware

Fig. 1 shows the airship system. The balloon is elliptical with an overall length of 5.8 meters, its maximum diameter is 2.2 meters and the volume is 17.5m^3. Helium gas is used for buoyancy. The gondola under the balloon contains a microcomputer, a CCD camera, motors, batteries, a geomagnetic and a GPS sensor, a notebook computer and ballast, shown in Table 1 [6]. For navigation, the antenna for receiving GPS signals is fixed on the head of the balloon.

Table1 Specification of Equipment

	Equipment	Company
Notebook computer	Libretto L1/060TNCM	TOSHIBA
Micro computer	H8/3048F	HITACHI
Micro computer board	AKI-H8	AKIZUKIDENSHI
GPS receiver	GM-38	SANAV
DGPS receiver	NDIDEV003	Nippon Denso Industry
Earth magnetism sensor	3D motion sensor	NEC tokin

The notebook computer mounted on the system receives the latitude and longitude values of the airship from the GPS sensor, and obtains the direction for the airship to fly to by the geomagnetic sensor. The values of control variables are calculated and transmitted to the microcomputer. And then the microcomputer converts the values into the motor drive pulses and outputs them to each motor.

The power for the motion consists of a side thruster and two main fan ducts. The side thruster is used to rotate the airship around the vertical axis (yawing rotation). Two main fan ducts are used to control the airship flying up or down, and forward or backward.

Since the volume of the gondola can be negligible if it is compared with that of the envelope, it is reasonable to assume that the center of the volume lies on the axis of symmetry of the envelope. The airship is able to move in translation and rotate in three-dimensional spaces (rolling, pitching and yawing). In this paper the yawing rotation of the airship is mainly tested.

2.2 Control algorithm

The flow chart of the control algorithm is shown in Fig. 2. The airship goes up first. Next, the notebook computer that mounted in the gondola receives data from each sensor. Subsequently, the position of the airship compares with the target point. When it reaches the target, the program terminates and the airship hovers. Otherwise the notebook computer calculates the direction and distance to the target point shown in Fig. 3. Later the control is determined and outputted to each motor. Eventually by repeating these processes, the airship arrives at the target point.

2.3 Control of the side thruster

2.3.1 PD control

The side thruster is first controlled by the PD control as comparison. As shown in Fig. 3, the thrust S_t is determined by the angular difference θ_d (=$\varphi - \theta$), the angular velocity ω (=$d\theta_d/dt$) and the angular acceleration α (=$d^2\theta_d/dt^2$). Thus the thrust of the side thruster is expressed by

$$S_t = K_\theta(0-\theta_d) + K_\omega(0-\omega) + K_\alpha(0-\alpha) \qquad (1)$$

where K_θ, K_ω and K_α are constants and the target is set to (0, 0, 0). However, it is difficult to determine these constants because the airship is slow to respond and the characteristic of the airship is non-linear. Therefore, these constants are adjusted and determined by repeating the experiment.

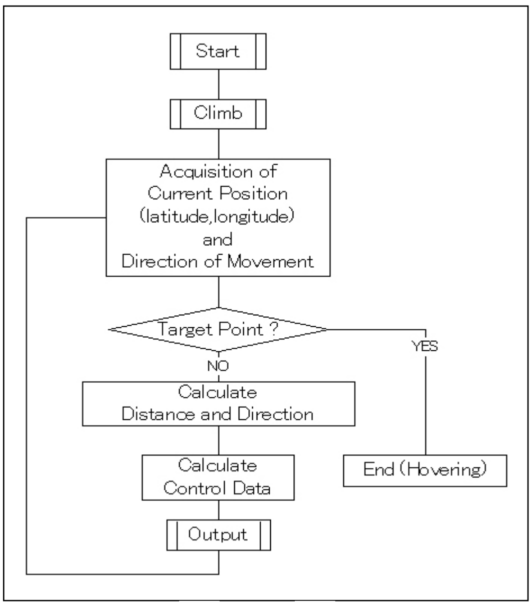

Fig. 2. Flow chart of the control algorithm

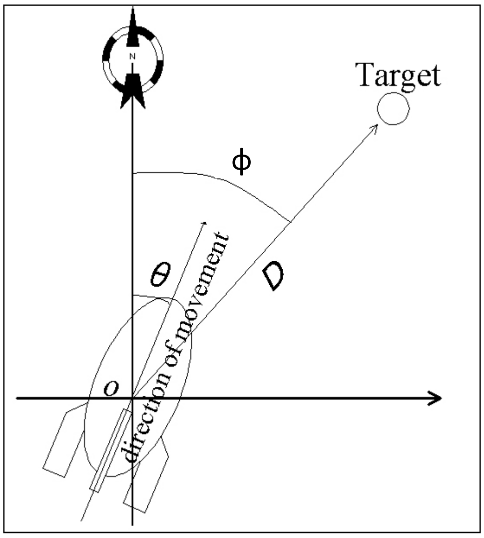

Fig. 3. Coordinate of the airship to target

2.3.2 Fuzzy control

Fig. 4 shows the fuzzy membership functions being used. Inputs are the angular difference θ_d and the angular velocity ω, output is S_t. The membership functions have triangular forms and seven vertices. Each set is labeled NL, NM, NS, ZR, PS, PM and PL, meaning negative or positive large, medium, small, and zero for each symbol. Fuzzy rules are

If θ_d is A_{11} and ω is A_{12} then S_t is B_1

If θ_d is A_{21} and ω is A_{22} then S_t is B_2 (2)

where A_{ij} and B_i are labels of each fuzzy set, and the fuzzy output set B_i is discrete, shown in Table 2.

Table 2. Rule Table S_t.

ω \ θ_d	NL	NM	NS	ZR	PS	PM	PL
NL	0	0.5	1	1	1	1	1
NM	0	0.4	0.7	0.3	1	1	1
NS	-0.7	0.3	0.5	0.1	0.3	1	1
ZR	-1	-0.5	-0.3	0	0.1	0.4	1
PS	-1	-1	-0.6	-0.4	-0.6	-0.4	0.6
PM	-1	-1	-1	-0.5	-0.8	-0.5	0
PL	-1	-1	-1	-1	-1	-0.6	0

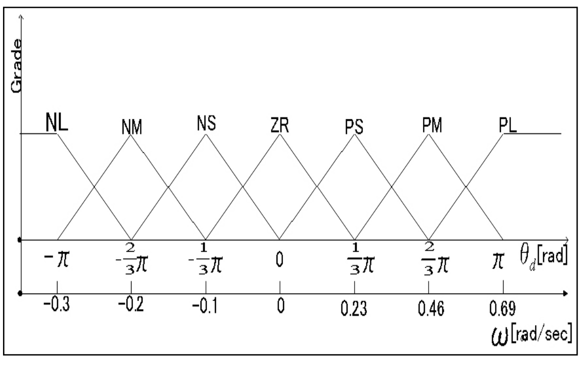

Fig. 4. Membership functions for inputs

2.4 Data Flow

Fig. 5 shows the block diagram of the data flow. Latitude and longitude values of the target point are set initially. In Fig. 3, D and φ are calculated as the difference between the positioning data of the target point and those obtained from the GPS. The angular difference θ_d ($=\varphi - \theta$) is the input variable to the side thruster controller, where the angle θ is the forward direction of the airship. D and θ_d are also inputs to the main fan duct controller [7].

3 EXPERIMENT

3.1 The task

The purpose of the experiment is to confirm that the airship navigates to the target point and to compare the two control methods for controlling the side thruster. It is desirable that the experiment is done indoors, where there is little influence to disturb the flight.

3.2 Result and analysis

The result is shown in Fig. 6. It gives two trajectories of the flight path, plotting longitude along the ordinate and latitude along the abscissa. By PD control, the airship flew changing the direction right and left before arriving at the target point. The main reason is that the gains K_θ, K_ω, K_α in equation (1) are not set properly. The adjustment is very

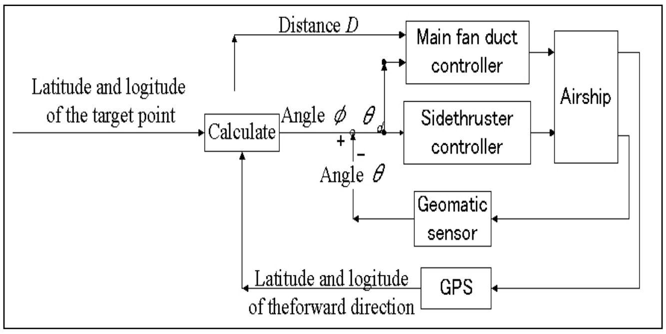

Fig. 5. Block diagram of data flow

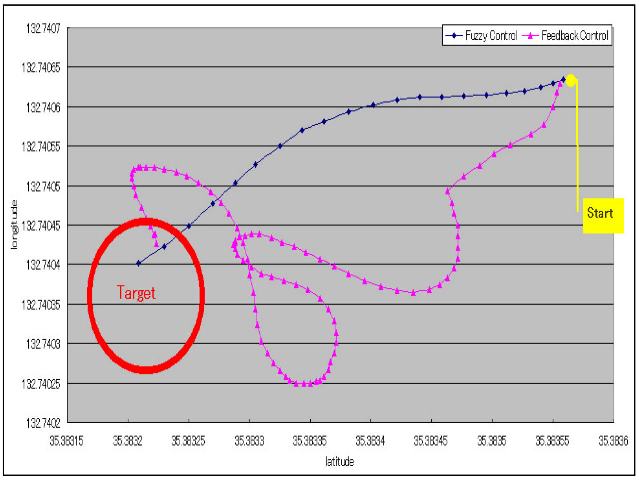

Fig. 6. Results of flight controlled by Fuzzy and PD

difficult without getting the perfect dynamic characteristics of the airship. By fuzzy control, the airship could autonomously navigate by almost the shortest flight path. The flight time is 1 minute and 27 second by PD control, and 20 second by the fuzzy control.

Fig. 7 shows another experiment controlled by the fuzzy algorithm. The airship starts from the "Start" point, and returns from the position "Target" to the "Goal" [8].

The results of the experiment show that the fuzzy control method is more effective than the PD control from the viewpoint of controlling an autonomous motion system, and the PD control is not suitable for the autonomous airship system in the present situation.

3.3 Landing stage

When the flying action is accomplished, it is time for the airship to land (or hover). The CCD camera on the airship searches the letter P or H (means parking point) on the land. Operation, such as image processing and segmentation, is done to find the letter P. And then automatically adjust the airship to land on the mark.

The question is how to make the airship recognize the mark rapidly. In practical application, the camera on the airship seldom sees the perfectly vertical P, always is italic or has random angle. Thus the recognition system needs to store a large number of templates for the letter P. In fact, moment invariance [9] can solve this problem. We can mapping the different angles to the few templates by invariant moment shown in Fig. 8.

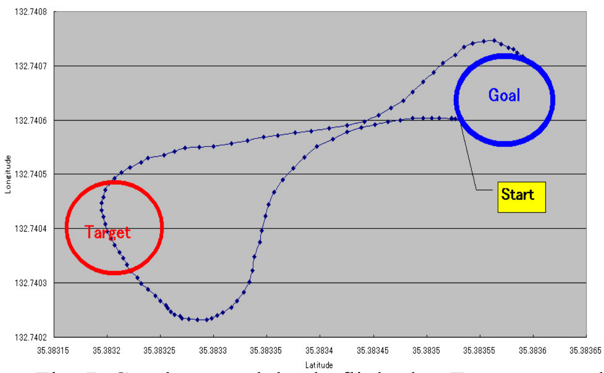

Fig. 7. Go there and back flight by Fuzzy control

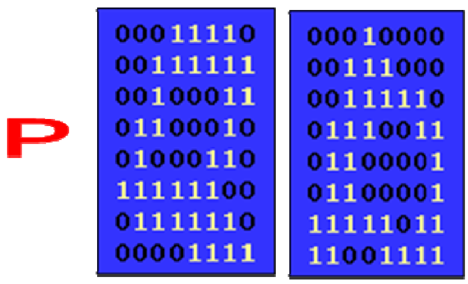

Fig. 8. Template of the letter P

4 CONCLUSION

In this paper, the simplified control system and the algorithm for the airship to navigate autonomously to the target point are proposed. To control the side thruster, the PD and the fuzzy control are applied respectively as comparison. As the result, it is clear that the fuzzy algorithm enables better control for the airship to reach the preset target point.

Of cause if the kinematics description of the airship's side thruster control and the PD parameters are set more accurate, the result for the PD control should be better than the proposed result in this paper. The contribution of this paper is to express that the fuzzy control is more suitable for the intelligent control system.

Further work of pattern recognition to a special object on the land by the single or stereo CCD cameras and the technology of telecommunication are being considered. Telecommunication technology is used to communicate mutually the data between the notebook computer mounted on the airship and the computer at the base station to establish the servo-client system. And the monitoring program by using wireless LAN should also be developed, which enables us to monitor the condition of the airship remotely.

Abstract: With the further need for security, the fingerprint pattern recognition technology began to be used in various fields, from the theoretical field to practice. Digital fingerprint processing concerns the algorithms and processes of automated fingerprint image processing, feature measurement, detail description, pattern analysis, recognition and classification by the computer instead of manual. In this article, four modules for fingerprint identification are introduced: the modules for fingerprint image sampling, for image pre-processing algorithm, for feature extraction and for feature matching algorithm. Finally this article gives the completed procedure of the fingerprint image processing and feature extraction.

Keywords: fingerprint recognition, image processing, feature extraction, pattern recognition

1 INTRODUCTION

Fingerprint refers to the finger's end positive skin with uneven ridge, which is arranged in a regular formation of different texture. As the fingerprint has lots of characteristic (lifelong invariance, uniqueness, etc.) and convenience, it almost becomes synonymous with biometric identification [1].

At present, the solutions of security problems and the problem of identification method have been more and more important, it also has increasingly and widely application. Fingerprint characteristic is the inherently physiological feature and compared with traditional identification method, it has many advantages. Consequently the method of fingerprint identification has become one of the most important methods in the identification field.

Fingerprint identification is executed after fingerprint analysis. The purpose of fingerprint analysis is to extract the fingerprint features, in order to match the template of the special fingerprint. These features include the types of the texture (the arch, loop and whorl types), the shapes of the line (the straight line, arc or wavy lines), and the details in fingerprint (the end, the branch, the central point, the short line, etc.) [2].

There are three processes for the traditional manual fingerprint identification: establishing the fingerprint template card, sampling the fingerprint, and matching the sampled fingerprint to the templates. This method requires excessive personnel and needs many staffs. Thus it is gradually replaced by the digital fingerprint identification method.

Digital fingerprint identification method depends on the computer vision, and it can establish the electronic fingerprint templates automatically, sample the electronic fingerprint and match it with the templates.

The usage of the RFID technology, the embedded system, the communication and other technologies expands the application of fingerprint recognition. Further more, with the rapid development of the network information technology and E-Commerce, the research on the fingerprint pattern recognition becomes more important.

2 PREPROCESSING

2.1 Fingerprint mode conversion

There are six steps for the conversion of the fingerprint modes, from the real fingerprint to the final extracted features, which is shown in Fig. 1.

(1) Transfer the real fingerprint to the color image: scan the real fingerprint digitally by the fingerprint-sampling device using the proper resolution rate.

(2) Transfer the color image of fingerprint to the grayscale image: calculate all the pixels one by one by the color/gray conversion formula. The converted gray levels range from 0 to 255. The higher the value, the brighter the point is.

(3) Transfer the grayscale fingerprint image to the object mode: the fractal dimension of pixels between the background and fingerprint in the image is different. Thus we can extract the fingerprint object from the background.

(4) Transfer the fingerprint object to the fingerprint textural characteristic mode: by using the knowledge of the fingerprint analysis, we can mark each fingerprint feature point, so that we can obtain the information of the fingerprint texture and form the fingerprint feature pattern.

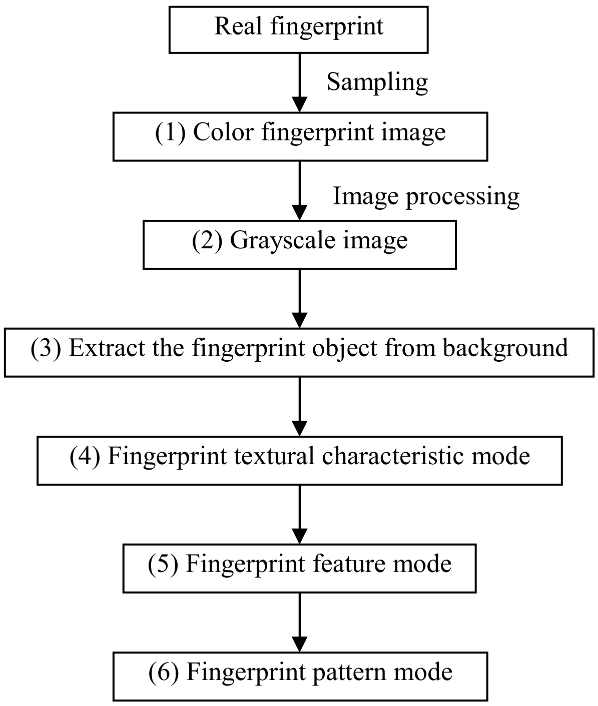

Fig.1. Fingerprint mode conversion

(5) Transfer the fingerprint textural characteristic mode to the fingerprint feature mode: using knowledge of topology, the fingerprint texture characteristic is classified according to the different characteristic branches. After transferring, the pattern can be recognized with high efficiency, and the recognition time can be decreased.

(6) Transfer the fingerprint feature mode to the fingerprint pattern mode: we form a template by combining the fingerprints and the holder's ID number, so that the database is established. Thus the pattern of the sampled fingerprint can be recognized.

2.2 Fingerprint recognition algorithm

There are four modules consist of the fingerprint pattern recognition algorithm [2], which is shown in Fig. 2:

(1) Fingerprint image acquisition module: the fingerprint image is sampled and the digital fingerprint data matrix is obtained.

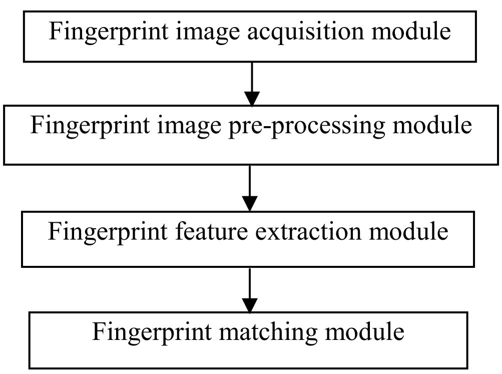

Fig.2. Four modules for fingerprint pattern recognition

(2) Fingerprint image pre-processing modules: restoration from the original fingerprint image. The process includes three steps, which are restoration, intelligent enhancement processing and thinning processing.

(3) Fingerprint feature extraction module: extract the features of the fingerprint.

(4) Fingerprint matching module: matching and comparison are included in this module.

3 DESIGN AND ANALYSIS

For the four modules discussed above, we need to make overall process planning and selection to each module respectively [1, 2].

First is the fingerprint image acquisition module: fingerprint image collector is used to sample the fingerprint image, but we need to judge its integrity and clarity. Here the difference-filtering algorithm is chosen for process, and then through the threshold to judge whether the image is qualified. If the result is zero, it means that none of the fingerprint data is collected, if it is more than the threshold, it means that the complete clear fingerprint image has been collected.

Secondly, the fingerprint image pre-processing module is executed: by using the aberration correction, segmentation, equilibrium, convergence, smooth, intelligent enhancement, binarization and thinning algorithms to get a clearer skeleton of the fingerprint image. The detailed algorithm is divided into the following seven steps, which is shown in Fig. 3 and Fig. 4.

(1) Distortional image correction processing includes geometrical optics and grayscale mapping.

(2) By calculating the distribution of intensity and gradient field to extract the fingerprint object: the fingerprint object has a higher value of both intensity and gradient fields than those of the background.

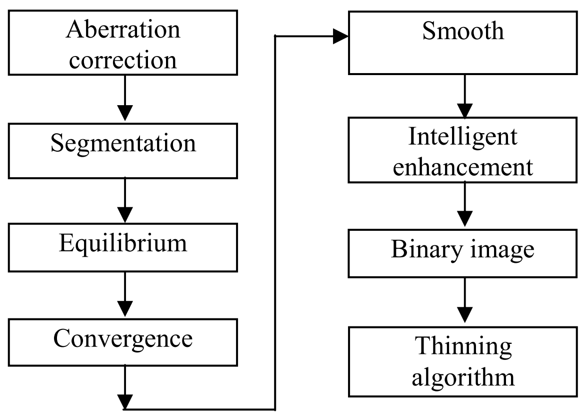

Fig.3. Fingerprint image pre-processing module

(3) The purpose of the gray level balance is to calculate the gray value of each pixel, and make images evenly distributed for each gray level.

The contrast processing for images is to solve the problem of balance. Because histogram is always used to describe the distribution of gray values, we need to establish a histogram distribution of the image and then make use of the grayscale algorithm to establish the mathematical model to balance the image.

(4) It exists objectively that the fingerprint image is divergent, and the convergence of overall picture is a micro process. Thus according to the chaotic divergent fingerprint physical model, the Gaussian function is used to do the image convergence.

(5) When the fingerprint image is sampled by the photoelectric sensor, it is easy to bring the surrounding dust and stain in the image, and this forms the noise points. In order to eliminate the noisy points in the fingerprint image, the average template for relevant pixels should be considered to smooth the image.

(6) Intelligence enhancement is the inherent ability of human eyes. To apply that ability to the computer, the Gabor physical model, which can do intelligence convergence and intelligence enhancement, is set up according to the fingerprint field of line direction.

(7) Threshold makes the gray value to be 255 at the valley line pixels in the fingerprint image, and 0 at the ridgeline pixels. There are two methods to realize binarization, which are the gray threshold segmentation method and the intelligent binary domain analysis method. If we want to extract the fingerprint skeleton, it's necessary to do the refined fingerprint image processing, and the common thinning algorithm and querying method are always used.

The third is the fingerprint feature extraction module: extracting all the fingerprint feature points from the preprocessing module, eliminating the false and retaining the true feature points, and saving to the database.

The last is the fingerprint pattern matching module: its main content is to match the fingerprint feature point topologically to the database precisely.

4 RESULT

Fig. 4 gives the completed procedure of fingerprint image processing and feature extracting. The gray level image Fig. 4(a) is used as the original image, at last the fingerprint feature points are extracted, which is shown in Fig. 4(k). And then, pattern matching and recognition [3] is used to find the fingerprint belongs to which person that is stored in the database.

5 CONCLUSION

In this article, the background and the basic content of the traditional and the digital fingerprint are described. And then the four modules for fingerprint identification are introduced: the modules for fingerprint image sampling, for image pre-processing algorithm, for feature extraction and for feature matching algorithm. After that, the detailed description for each module is expressed.

From the article, we see that the fingerprint recognition is not difficult unless the feature points can be defined and extracted by image processing, pattern matching and recognition.

In the future, the face recognition, voice recognition and signature recognition [4-6] are also considered for the security recognition system.

Abstract: The artificial assistant suit is a kind of assistant equipment, which is actuated by Mckibben muscles and can be put on the human upper body, to help the upper limb act. It can detect the action intention of human's upper limb automatically and output definite force complying with the intention. The configuration of the Mckibben muscles is introduced in detail. How to detect the action intention by the surface electromyography signal is discussed deeply. The related experiments and their results are given.

Keywords: artificial assistant suit, Mckibben muscle, action intention, SEMG, classifier.

1. Introduction

Recently, our lab has been developing an artificial assistant suit actuated by the Mckibben muscles, which can be put on the human's upper body to help the two arms act. It can detect the action intention of human's two arms automatically and output definite force complying with the action intention (mainly including the actions of the shoulders and the elbows). Therefore it is a kind of action assistant equipment for human arms. To the ordinary or the old people, it can be used as the action assistant equipment to make them act easier. To patients, it can be used as the recuperate equipment to help them train their arms. To part of the disables, it can be used as the motive force equipment to help them to recovery their arm functions. Based on the functions and its characteristics of the artificial assistant suit, it must refer to the following problems. One, how many pieces of the Mckibben muscles are needed? How to distribute them and connect them with the artificial assistant suit? Two, how to detect the action intention of the human arms automatically? It should detect the action intention correctly in real time. Then it can output the corresponding force complying with the action intention correctly. Three, how will each of the Mckibben muscles operate after the action intention is got? Of course, only all of the Mckibben muscles must operate coordinately, the artificial assistant suit can output the required force and human feels comfortable. This paper mainly aims at the first two problems.

2. Configuration of the Mckibben muscles

To help the human arms act correctly, the Mckibben muscle actuators must be configured reasonably。Only one piece of the Mckibben muscle can't complete all the actions [1], because that the structure of the human arm is complicated and its actions are many and varied. Therefore, many pieces of the Mckibben muscles are required and they need to operate coordinately to achieve the required force. Based on the above analysis, we resolve the arm actions into the following basic ones：

①Shoulder's rising up and down (including to the front, to the back, and to the side), shown in Fig.1(a) and Fig.1(b)；

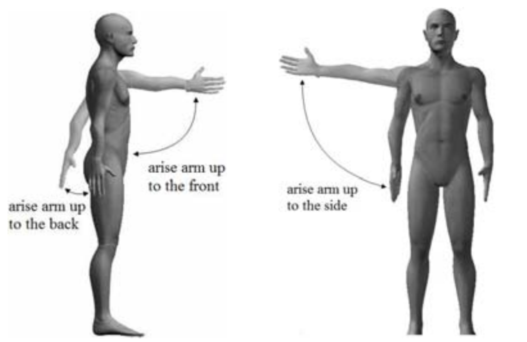
②Shoulder's swinging around the vertical axis, shown in Fig.1(c)；

③Elbow's bending and stretching, shown in Fig.1(d)；

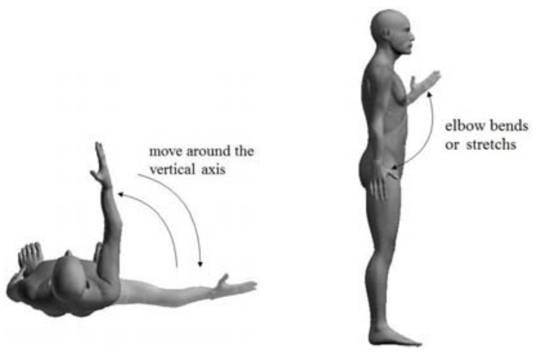
④The forearm's rotating around the anatomic axis.

We think that all of the main arm actions can be realized based on the above four basic actions. The configuration of the Mckibben muscles can be done based on the requirement of the four basic actions. Let's analyze the anatomic structure of the human arm firstly. There are more than 20 pieces of muscles with the actions of both the shoulder joint and the elbow joint in the same arm[2]. All the actions of the shoulder and the elbow can be realized by these muscles' operating coordinately[3]. Based on both the analysis to the anatomic structure and the dynamic requirement for the artificial assistant suit, 8 pieces of the Mckibben muscles are selected for the configuration of one arm of the suit, shown in Fig.2. They are corresponding to the functions of the following 8 muscles:

① Triceps brachii
② Brachioradialis
③ Biceps brachii short head
④ Biceps brachii long head
⑤ Deltoid anterior part
⑥ Deltoid middle part 1
⑦ Deltoid posterior part
⑧ Deltoid middle part 2



1(a) 1(b)



1(c) 1(d)

Fig.1 The basic actions

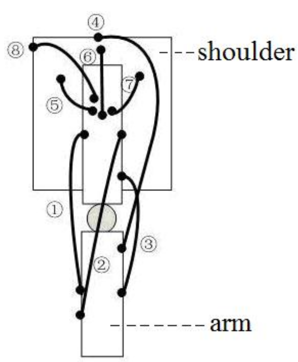


Fig.2 Configuration of the Mckibben muscles

3. The detection of the action intention of the human arm

To assist the actions of the human arm correctly, the artificial assistant suit should know the action intention of the person who is putting on it firstly. Then it calculates the quantity and the direction of the force. To the analysis of the motion intention of the human, the traditional way is getting it by analyzing the unbiological signals such as the angle, acceleration, force, or vision and hearing. All these unbiological signals are not direct to the motion intention. But the surface electromyography signal (SEMG) is generated directly by the muscles. Therefore, SEMG signals can express the motion intention more directly and more precisely [4], which is more suitable to be the control signal of the artificial assistant suit. This paper is right just to discuss how to detect the motion intention of both the human shoulder joint and the elbow joint by collecting the SEMG signals of the human.

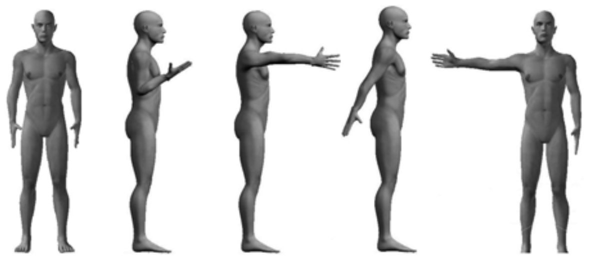
On whole, we collect the data about the SEMG signal related with the given basic action. Then we establish the relationship between the motion intention and the SEMG signal by the classifier or BP neural network. We select the classifier in our research.

3.1 Design of the experiments

The motions of the human arm are very complicated. Here only the motions of both the shoulder and the elbow are considered. The experiments only referring to the four basic actions and their combination are done。Actually the first three actions are selected for the experiments. And they are divided into different degrees of freedom, which are degree 1 of freedom - shoulder's rising up and down, degree 2 of freedom – shoulder's swing around the vertical axis, degree 3 of freedom – elbow's bending and stretching.

The five motion states of the arm when human standing freely on the ground needs to be defined before experiment, shown in Fig.3. State 0 corresponds to when the arm is relaxing. State 1 corresponds to when the elbow is bending to almost its largest angle. State 2 corresponds to when the arm is rising up frontward to almost the same level with the shoulder and the elbow doesn't bend. State 3 is when the arm is rising up backward to the largest angle of the shoulder joint and the elbow doesn't bend. State 4 is when the arm rises up sideward to almost the same level with the shoulder.

Three healthy male master students took part in the experiments. The electroencephalogram apparatus, EEG1100 made by a Japan company is used, which's sampling frequency is set as 100Hz，sensitivity as 100μV, passband as 0.1~200Hz. A pair of electrodes, which locates 3cm apart from each other, are used and the distribution is consistent with the muscle fiber. The referential voltage is the average of the voltages of the two earlobes. To get the motion intention of human arm on every degree of freedom, the SEMG signals of Biceps brachii, Triceps brachii, Deltoid anterior part, Deltoid middle part, Deltoid posterior part and pectoralis major are detected.



3(a 3(b) 3(c) 3(d) 3(e)

Fig.3 The different states of the upper limb

The experiments are divided into two stages which are training stage and test stage. In the training stage, the data of the SEMG signals of the four basic actions are sampled to establish and train the classifier. In the test stages, the classifier is tested to prove whether or not it can forecast the action intention correctly.

In the training stages, the experimenter's arm acts circularly as the following sequence（seeing Fig.3）: 0, 1, 0, 2, 0, 3, 0, 4, 2, 4, 0. The training is divided into two groups. Every group circulates this way ten times.

In the test stages, two complex actions are designed, shown in Fig.4. The classifier is used to forecast the action intention. The motions are recorded by a video camera so that it can be compared with the result calculated by the classifier.

4(a) 4(b)

Fig.4 The complex actions

3.2 Data process

In the training stages, the action between state 0 and state 1 is actually the motion on the degree 3 of freedom. The actions between state 0 and 2, state 0 and 3, state 0 and 4 actually are the motions on the degree 1 of freedom. The action between state 2 and 4 is actually the motion of the degree 2 of freedom. The task of the training stage is to train the three classifiers by the data of the SEMG signals to judge the motion intention on the three degrees of freedom. In the test stages, the experimenter does the complex actions. The complex action 1 includes the motions on all the three degrees of freedom, and the complex action 2 includes the motions of both degree1 of freedom and degree 3 of freedom.

To realize the judgment to the real-time motion intention of the human arm on the three degrees of freedom, the six pairs of SEMG signals are divided into three groups, shown in Table 1. Every group corresponds to one degree of freedom, which is used to judge the motion intention. The group 1, consisting of the SEMG signals of Deltoid anterior part, the middle part and the posterior part, is to judge the motion intention on degree 1 of freedom. Group 2, consisting of the SEMG signals of Pectorals Major, is to judge the motion intention of the degree 2 of freedom. The group 3, consisting of the SEMG signals of both Biceps brachia and Triceps brachia, is to judge the motion intention on degree 3 of freedom. The data processing of the three groups of SEMG signals are independent. For example of the group 1, affected by the weight on the vertical direction，the motion intention of the experimenter is to arise up when both the arm keeps the state 2, 3, 4 and it really rises up.

Like Fig.5, the three classifiers are designed and trained. Like Fig.6, the data in the test stage are used to check whether or not the classifiers work correctly. The output of the classifiers will be compared with the videos taken by video camera.

3.3 Experiment results

Fig.7 shows that the experimenter does the complex action 1. The former six figures show the relative SEMG signals, the later three figures show the analysis result of the motion intention which is clearly consistent with the real motion intention. Fig.8 is something with the complex action 2, and it shows the same situation with Fig.7

Table 1 Three signal groups and the corresponding degrees of freedom

Signal group	Related SEMG signals	Related degree of freedom	Motion intention
Group 1	SEMG of Deltoid anterior part, the middle part and the posterior part	Degree 1 of freedom	Rise up, put down
Group 2	SEMG of Pectorals major	Degree 2 of freedom	Swing forward, relaxed
Group 3	SEMG of Biceps brachia and Triceps brachia	Degree 3 of freedom	Bend forward, relaxed, stretch backward

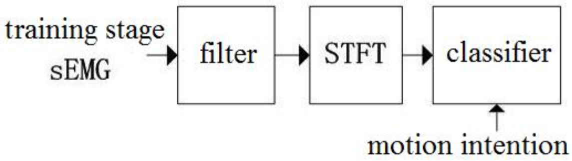


Fig. 5 data processing in the training stage

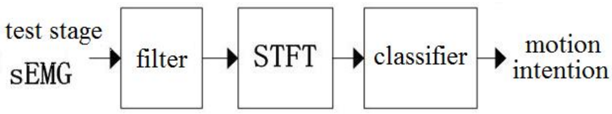

Fig. 6 data processing in the testing stage

4. Conclusion

Based on the requirement of the artificial assistant suit, the configuration of the Mckibben muscles is investigated. The detailed detecting methods of the action intention by SEMG signals are introduced. The experiment results show that the action intention detection is efficient and accurate. Of course, the research hasn't been completed. The third problem still hasn't been resolved. This is right just we are going to do in the next step.

This study is supported by the project from Shanghai Committee of Science and Technology, China (Pujiang Plan: 10PJ1409200).

Abstract: The wheel robot is one of the very popular research topics. Applications of wheel robots include security, searching and rescue tasks in the indoor environment. In this paper, the image-sensing techniques, including an image system and a laser range finder, are used for obstacle avoidance and environment identification. The image system could provide 2D information of indoor environment, and the depth information is provided from the laser range finder. Therefore the 3D environment can be reconstructed and the position of the robot can be obtained. The moving paths of robot are automatically real-time regulated with 3D environment information. Moreover, a monitoring station is proposed for supervising the robot. The display of the station includes the laser range finder display and real-time video. In the experimental results, the 3D environment information is displayed on station and the robot can indeed avoid the obstacles in the indoor environment automatically.

Keywords: Patrol robots, Image processing, Obstacle avoidance**.**

1. INTRODUCTION

The developments of the robots are generally divided into two categories. They are service robots and industrial robots. In 90's, the mechatronic systems are extensively used for manufacturing and precision industry. In recent years, this technology is applied to robot systems. After years of researches, the functions of service robots are more and more comprehensive. For example, the home cleaning robots of Cyberhuis Company [1] are one kind of the service robots. Another application of wheel robots is security robot. Since the security robot has to take multiple tasks, the control of the security robot has to be more intelligent.

Chien et al [2] proposed the system architecture of security robot with multiple sensors. Obviously, designing functions of positioning and obstacle avoidance of a security robot is a difficult and important research problem. To achieve better performance, the dynamic of a robot system, which has been discussed in [3], [4] and [5], has to be considered. Yun et al described the wheeled mobile robot dynamic with physical analysis. The robot system used in this paper is s wheeled mobile robot. In this paper, we will propose a method for an indoor patrol robot to avoid obstacles automatically, based on the mobile robot model.

The planning of automatic obstacle avoidance includes "*Searching Mode*" and "*Obstacle Avoidance Mode*". The feedback of sensors will be the mode switching condition. From the experimental results, we will verify that the proposed method can achieve not only the obstacle avoidance but also basic navigation of robots. Moreover, the robot has been announced in robot competition conducted by SKS Co., Ltd., Taiwan, 2011.

2. OBSTACLE AVOIDANCE METHOD OF THE ROBOT

2.1. Modeling of robot system

Consider the mobile robot system with two fixed wheels as illustrated in Fig. 1. We define two coordinates, which are the inertial coordinate and the robot coordinate, for the robot system. In addition, the nonholonomic motion constraints [6] [7] are

$$\dot{X}_{cp}\cos\theta+\dot{Y}_{cp}\sin\theta-k\dot{\theta}-r\dot{\omega}=0 \qquad (1)$$

$$\dot{X}_{cp}\sin\theta-\dot{Y}_{cp}\cos\theta=0 \qquad (2)$$

where $Q(X_{cp}, Y_{cp})$ is the mass center of the robot, and ω is the wheel speed.

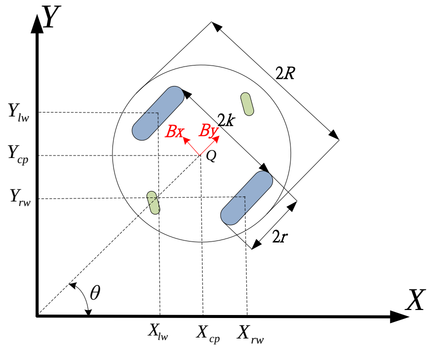

Fig. 1. The coordinate definitions of the robot.

Based on the Appell Equation, the dynamic equation of the robot system is

$$A(y)\ddot{y} + C(y,\dot{y})\dot{y} = B(y)\tau \tag{3}$$

where τ is the torque of the wheel, and

$$\begin{cases} \dot{y} = \mathrm{u} = \begin{bmatrix} \dot{\omega} & \dot{\theta} \end{bmatrix}^T \\ A(y) = \begin{bmatrix} \eta M_2 & M_1 \\ M_2 & \eta M_1 \end{bmatrix} \\ C(y,\dot{y}) = \begin{bmatrix} m_b r d_r \dot{\theta} & 0 \\ 0 & -m_b r d_r \dot{\theta} \end{bmatrix} \\ B(y) = \begin{bmatrix} 0 & 2\eta \\ 1 & 1 \end{bmatrix} \end{cases} \tag{4}$$

Moreover, in (4), M_1 and M_2 are

$$M_1 = m_b(d_r^2 + k^2) + U_p + 4m_w k^2 + 2U_w + 8\eta^2 U_w \tag{5}$$

$$M_2 = m_b r^2 + 2m_w r^2 + 4U_w \tag{6}$$

and the parameters in (4)-(6) are

$$U_p = \frac{1}{3} m_b \left(2R^2\right) \tag{7}$$

$$U_w = \frac{1}{2} m_w \left(r^2\right) \tag{8}$$

$$\eta = \frac{k}{r} \tag{9}$$

where U_p and U_w are the moments of inertia of the robot and wheels, respectively. The m_b and m_w are the mass of robot and wheels, respectively.

Equation (3) can be transformed into the state equation

$$\dot{\mathrm{x}} = \mathrm{f}(\mathrm{x}) + \mathrm{H}(\mathrm{x})\tau \tag{10}$$

where

$$\mathrm{x} = \begin{bmatrix} x_1 & x_2 & x_3 & x_4 \end{bmatrix}^T = \begin{bmatrix} \omega & \dot{\omega} & \theta & \dot{\theta} \end{bmatrix}^T, \tag{11}$$

$$\mathrm{f}(\mathrm{x}) = \begin{bmatrix} x_2 \\ -\eta\kappa J_s x_2 x_4 - \kappa J_v x_4^2 \\ x_4 \\ J_s \kappa\left(x_2 x_4 + \eta x_4^2\right) \end{bmatrix} \tag{12}$$

$$\mathrm{H}(\mathrm{x}) = \begin{bmatrix} 0 & 0 \\ -J_v & 2\eta^2 J_s - J_v \\ 0 & 0 \\ \eta J_s & -\eta J_s \end{bmatrix} \tag{13}$$

$$J_s = \frac{1}{\eta^2 M_2 - M_1} \tag{14}$$

$$J_v = \frac{M_1}{M_2} J_s, \kappa = m_b r d_r \tag{15}$$

Therefore the dynamic model of the robot system could be described by (10).

2.2. Image processing and image guiding method

Since it is possible that there is more than one room that the robot has to patrol, the area of door or corridor has to be computed. In this case, the image guiding method can be one solution to compute the area of doors or corridors and then label them. The image guiding method is illustrated as Fig. 2.

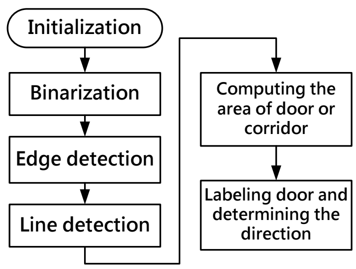

Fig. 2. Flowchart of the image guiding method.

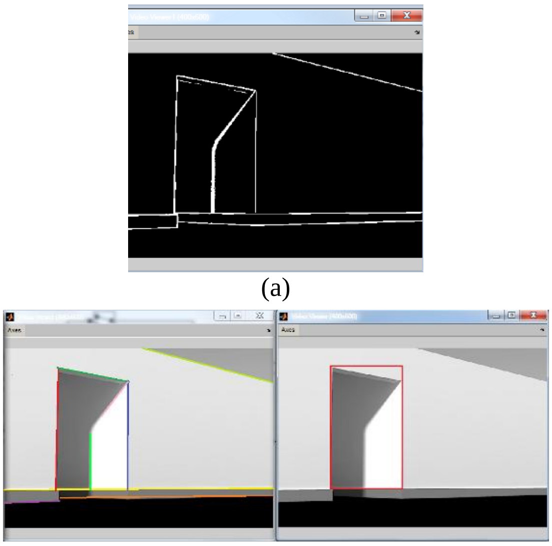
There are three things that have to be considered in designing the algorithm. The first is the length and width of the room. The second is the dynamic restrictions of the robot. Finally, in order to prevent the collision with any obstacle near to the robot unexpectedly, the urgent distance is necessary. When there is any object entering the urgent area, the robot should stop immediately.

Hence, at first of the algorithm, the edges of the wall are detected [8] and the lines are extracted with Hough transform [9]. Then we compute the area of doors or corridors with information feedback from the laser range finder and the image information. The final step is labeling the door and determining the moving direction. The robot will turn toward the door with the image guiding method. Fig. 3 is a simulation of door labeling with the computer graphics (CG). Fig. 4 shows the real-time edge and line detecting results.

Since the robot may move in an unknown environment, two mission modes "***Searching Mode***" and "***Obstacle Avoidance Mode***", which constitute the automatic obstacle



(a)

(b) (c)

Fig.3. Simulation of door labeling with the computer graphics (CG). (a) The detected edge. (b) The line detection. (c) The door labeling.

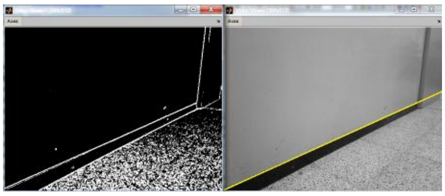


Fig.4. The real-time edge and line detecting results.

avoidance method, are defined in our setup. Two warning areas are defined by the distance from the robot for touching off the robot to run "*Searching Mode*" or "*Obstacle Avoidance Mode*".

Define an inner warning area W_2 which is the area with distance to the robot less than w_2, and an outer warning area W_1 which is the area with distance to the robot greater than w_2 but less than w_1. Base on these two warning area, there are three possible cases. Case 1 is the case if there is no obstacle located in region W_1. Case 2 is the situation that there are obstacles located in W_1. Case 3 occurs when any obstacle is located in W_2. The corresponding actions of the robot in each case are summarized in Table 1. The automatic obstacle avoidance method is illustrated as Fig. 5.

Table 1. The corresponding actions of robot in Case1~3.

Case	Robot actions
1	Running in "***Searching Mode***".
2	Warning and computing the distances of obstacles.
3	Running in "***Obstacle Avoidance Mode***".

All the orientation parameters are obtained by laser range finder in one scanning. The distance between the each edge points are

$$L_j = \sqrt{(x_j - x_{j+1})^2 + (y_j - y_{j+1})^2}, \quad j = 1,2,\cdots k. \qquad (16)$$

All possible passages are defined as "Candidate Passages". In order to select the correct passage, we further define the requirements of "Final Passage" and "Spurious Passages" are

$$\begin{cases} L_j \geq 2R + u, & \text{Final Passage} \\ \text{Otherwise}, & \text{Spurious Passage} \end{cases}. \qquad (17)$$

where R is the radius of the robot chassis and u is the urgent distance. Moreover the "Spurious Passages" will be regarded as obstacles. The automatic obstacle avoidance is illustrated as Fig. 6.

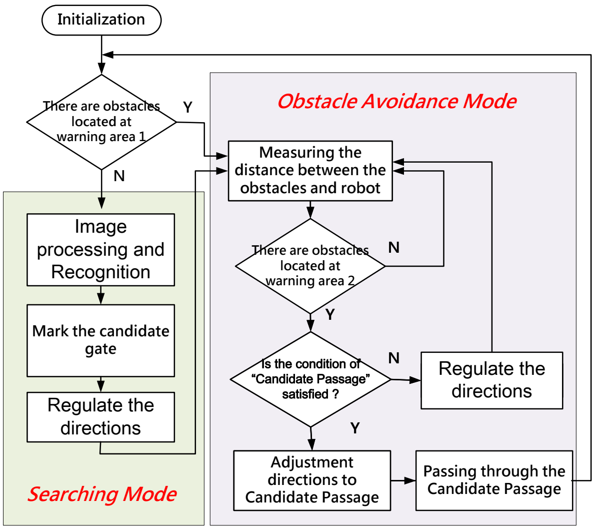

Fig.5. The automatic obstacle avoidance method.

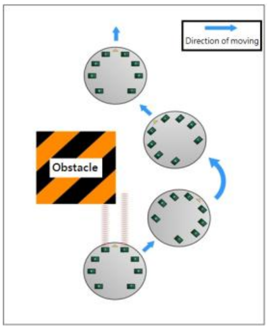

Fig.6. "*Obstacle avoidance mode*" of the robot.

3. SIMULATION RESULTS

There are two layers in the platform of the robot for the paper. The platform is constituted with aluminum panels. The maximum payload of the robot is 8 kg. The diameter and height of the mobile robot are 0.4 m and 0.44 m, respectively. The wheels are directly driven by the motors.

The design of the chassis is differential drive moving platform. The scanning laser finder used for the robot is UTM-30LX (Hokuyo Automatic Co., Ltd., Osaka, Japan), as shown in Fig. 7. The scanning angle and the guaranteed detection range are 0°~270° and 30 m, respectively. The interface of the robot system and the real-time image obtained from the robot are shown in Fig. 8.

Considering the experimental environment, the area W_1 is defined as the distance less than 3 m and the area W_2 is defined as the distance between 3 m and 0.75 m. The urgent distance is defined as 0.15 m. A tortuous corridor is designed for testing our method. Fig. 9 (a) (b) show the robot passing through the tortuous corridor successfully with "*Obstacle Avoidance Mode*". In addition, this testing example shows the obstacle avoidance performance of robot.

Fig. 9. The robot passing through a corridor and patrolling in the room.

The next testing example is in the site of the SKS Company Robot Competition. In Fig. 9 (c) (d), the robot is patrolling in the room automatically. The algorithm can recognize the door and guide the robot passing through the door.

4. CONCLUSION

In this paper, we proposed a simple method for achieving autonomous obstacle avoidance and basic navigation of robot. Based on the feedback of the camera and laser range finder, the robot is more intelligent and sensitive. Moreover, the proposed algorithm is simple, therefore that could be used for real-time robot obstacle avoidance. In experimental results, we have shown that a robot with our algorithm could not only search rooms automatically but also pass through the narrow gallery in flexibility. It shows that the performance of the robot will be good for most indoor environments.

Abstract: This paper shows the design of a twisting algorithm second order sliding mode controller (SOSMC) for a synchronous reluctance motor. The second order sliding mode control is an effective tool for the control of uncertain nonlinear systems since it conquers the main shortcomings of the conventional sliding mode control, namely, the large control effort and the chattering effect. Its theory implies simple control laws and assures an improvement of the sliding accuracy with respect to conventional sliding mode control. This paper proposes a novel scheme that based on the technique of twisting second order sliding mode control. First, the SOSMC is obtained by mathematics. Finally, the proposed method is verified by simulation. The proposed SOSMC shows the robustness for the motor parameters variation and the development of chattering effect.

Keywords: Twisting Algorithm, Second Order Sliding Modes, Synchronous Reluctance Motor, Chattering Effect.

1 INTRODUCTION

Fast accurate dynamic response is of primary importance in control systems. The motor control system with the high robustness is an important issue in research. Synchronous reluctance motor (SynRM) have a mechanically simple and robust structure. They can be used in high speed and high temperature environments. The rotor circuit of the SynRM is open circuit such that the flux linkage of SynRM is directly proportional to the stator currents. The torque of SynRM can be controlled by adjusting the stator currents. Therefore, there has been renewed interest in SynRM [1-3].

Sliding mode control (SMC) has attracted increasing attention in recent years because it is an effective and robust technology for parameter variation and external disturbance rejection. It has been applied to robot and motor control [3,4-6]. SMC is a robust control for nonlinear systems. However, sliding mode is a mode of motions on the discontinuity set of a discontinuous dynamic system. Therefore, reducing the chattering is very important for SMC. The second-order sliding mode technique has the same properties of robustness to uncertainties of model and external disturbances. Second-order SMC (SOSMC) [7] improves the chattering phenomenon. Due to few literatures about SOSMC in SynRM control application, therefore, it has valuable on investigation in SynRM control application for SOSMC.

Distinct from the conventional first order SMC, the SOSMC is belonging to the region of higher-order sliding mode (HOSM). Levant [7] had discussed the theory of HOSM. HOSM control have been applied to motor, and automatic docking [8-10].

There is no paper choosing twisting algorithm SOSMC in SynRM speed control so far. Therefore, this paper proposes a novel scheme that based on the technique of twisting algorithm SOSMC. Finally, the presentation of the proposed method is verified by simulation.

2 MODELING OF THE SYNRM

The d-q equivalent voltage equations of ideal SynRM model with a synchronously rotating rotor reference frame are shown in Fig. 1.

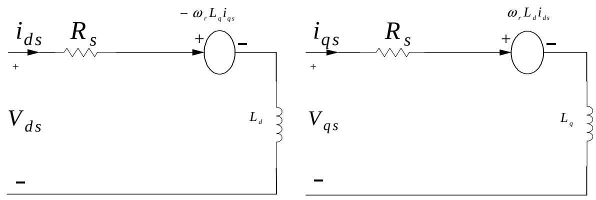

Fig.1. The d-q axis equivalent-circuit of SynRM

$$V_{ds} = R_s i_{ds} + L_d \frac{di_{ds}}{dt} - \omega_r L_q i_{qs} \tag{1}$$

$$V_{qs} = R_s i_{qs} + L_q \frac{di_{qs}}{dt} + \omega_r L_d i_{ds} \tag{2}$$

The corresponding electromagnetic torque T_e is:

$$T_e = \frac{3}{4} P_{ole} \left(L_d - L_q\right) i_{ds} i_{qs} \tag{3}$$

The corresponding motor dynamic equation is:

$$T_e - T_L = J_m \frac{d\omega_r}{dt} + B_m \omega_r \tag{4}$$

where V_{ds} and V_{qs} are direct and quadrature axis terminal voltages, respectively; i_{ds} and i_{qs} are, respectively, direct axis and quadrature axis terminal currents or the torque producing current; L_d and L_q are the direct and quadrature axis magnetizing inductances, respectively; R_s is the stator resistance; and ω_r is the speed of the rotor. P_{ole}, T_L, J_m, and B_m are the poles, the torque load, the inertia moment of the rotor, and the viscous friction coefficient, respectively. In this paper, the maximum torque control (MTC) strategy [3,4] is adopted. The torque current commands are shown in equations (5) and (6) [3]:

$$i_{ds}^{*} = \sqrt{\frac{|T_e|}{\frac{3}{8}P_{ole}\left(L_d - L_q\right)}}\cos\left(\frac{\pi}{4}\right) \tag{5}$$

$$i_{qs}^{*} = \operatorname{sgn}\left(T_e\right)\sqrt{\frac{|T_e|}{\frac{3}{8}P_{ole}\left(L_d - L_q\right)}}\sin\left(\frac{\pi}{4}\right) \tag{6}$$

3 INTEGRAL VARIABLE STRUCTURE SLIDING MODE CONTROLLER

We can rewrite the equation (4) as

$$\begin{aligned}\frac{d\omega_r}{dt} &= \left(-\frac{B_m}{J_m}\right)\omega_r + \frac{1}{J_m}\left(T_e - T_L\right)\\ &= a\omega_r + b\left(T_e - T_L\right)\\ &= \left(a_0 + \Delta a\right)\omega_r + \left(b_0 + \Delta b\right)\left(T_e - T_L\right)\\ &= a_0\omega_r + b_0\left(u(t) + f\right)\end{aligned} \tag{7}$$

where

$$a \equiv -\frac{B_m}{J_m} = a_0 + \Delta a$$

$$b \equiv \frac{1}{J_m} = b_0 + \Delta b$$

$$u \equiv T_e$$

$$f \equiv \frac{1}{b_0}\left(\Delta a\omega_r + \Delta b u(t) - bT_L\right)$$

$$J_m \equiv J_0 + \Delta J$$

$$B_m \equiv B_0 + \Delta B$$

The subscript index "o" indicates the nominal system value; "Δ" represents uncertainty, and f represents the lumped uncertainties.

Define the velocity error as $e(t) = \omega_r^{*} - \omega_r$, where ω_r^{*} is the velocity command. The velocity error differential equation of SynRM can be expressed as equation (8):

$$\frac{de(t)}{dt} = \dot{\omega}_r^{*} - a_0\omega - b_0\left[u(t) + f\right] \tag{8}$$

Let

$$S = e(t) + c\int_{-\infty}^{t} e(t)\,d\tau,\quad c > 0 \tag{9}$$

The input control $u(t)$ (the electromagnetic torque T_e) of (8) can be defined as equation (10).

$$u(t) = u_{eq}(t) + u_n(t) \tag{10}$$

where $u_{eq}(t)$ is used to control the overall behavior of the system and $u_n(t)$ is used to suppress parameter uncertainties and to reject disturbances. By making mathematical calculation, we get the overall control $u(t)$ as equation (10) [3].

$$u(t) = \frac{1}{b_0}\left[\dot{\omega}_r^{*} - a_0\omega_r + ce(t)\right] + (K + \frac{\eta}{b_o})\operatorname{sgn}(S) \tag{11}$$

where $|f| \le K$.

4 TWISTING SECOND-ORDER SLIDING MODE CONTROLLER

In conventional SMC design, the control target is let the system state move into sliding surfaces $S = 0$. But a second-order sliding mode controller aims for $S = \dot{S} = 0$. The system states converge to zero intersection of S and $\dot{S}$ in state space.

Twisting method mainly develops relative one order system for reducing chattering event [7]. The state trajectory of S and $\dot{S}$ phase plane is shown in Fig. 2. It converges to the origin of phase plane in finite time.

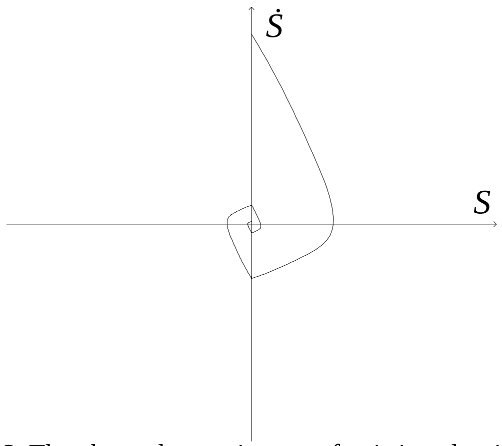

Fig.2. The phase plane trajectory of twisting algorithm

Now consider the following uncertain second order system:

$$\begin{cases}\dot{y}_1(t) = y_2(t))\\ \dot{y}_2(t) = \varphi\left(\mathbf{x}(t), \mathbf{y}(t), t\right) + \gamma\left(\mathbf{x}(t), \mathbf{y}(t), t\right)v(t)\end{cases} \tag{12}$$

in which $\varphi(\cdots)$ and $\gamma(\cdots)$ are uncertain functions with the upper and lower bounds of equation (13).

$$\begin{cases}\left|\varphi\left(\mathbf{x}(t), \mathbf{y}(t), t\right)\right| \le \Phi\\ 0 < \Gamma_m \le \gamma\left(\mathbf{x}(t), \mathbf{y}(t), t\right) \le \Gamma_M\end{cases} \tag{13}$$

By the control rule of equation (14), we can define this control method [8,9]:

$$v(t)=\begin{cases}-u\,, & if\quad |u|>U\\ -V_m\,\mathrm{sgn}(y_1)\,, & if\quad y_1y_2\le 0;|u|\le U\\ -V_M\,\mathrm{sgn}(y_1), & if\quad y_1y_2>0;|u|\le U\end{cases}\tag{14}$$

where U is control value boundary, and the sufficient condition of finite time converges to sliding situation as equation (15) [8].

$$\begin{cases}V_M>V_m\\ V_m>\dfrac{4\Gamma_M}{S_0}\\ V_m>\dfrac{\Phi}{\Gamma_m}\\ \Gamma_mV_M-\Phi>\Gamma_MV_m+\Phi\end{cases}\tag{15}$$

where S_0 is a boundary layer around the sliding surface S. Equation (4) can be rewritten as equation (16):

$$\frac{d\omega_r}{dt}=\frac{1}{J_m}(T_e-T_L-B_m\omega_r)\tag{16}$$

We define state variable as shown in equation (17):

$$\begin{cases}x_1(t)=\int_{-\infty}^{t}x_2(\tau)d\tau\\ x_2(t)=e(t)=\omega_r^*-\omega_r\end{cases}\tag{17}$$

We define sliding function y_1, and y_2 as

$$\begin{cases}y_1=x_2+cx_1\\ y_2=\dot{y}_1\end{cases}\tag{18}$$

Then, the system equation can be expressed as

$$\begin{cases}\dot{y}_1(t)=y_2(t)\\ \dot{y}_2(t)=\ddot{\omega}_r^*+\dfrac{B_m}{J_m}\dot{\omega}_r^*+\left(-\dfrac{B_m}{J_m}+c\right)\dot{x}_2+\dfrac{1}{J_m}\dot{T}_L+v(t)\end{cases}\tag{19}$$

where

$$\begin{cases}\varphi(\cdot)=\ddot{\omega}_r^*+\dfrac{B_m}{J_m}\dot{\omega}_r^*+\left(-\dfrac{B_m}{J_m}+c\right)\dot{x}_2+\dfrac{1}{J_m}\dot{T}_L\\ \gamma(\cdot)=1\\ v(t)=-\dfrac{1}{J_m}\dot{T}_e\end{cases}\tag{20}$$

According to (20), T_e is calculated from the integration of $v(t)$ which is a switching signal defined in (14), so improving the chattering problem in SOSMC control of SynRM.

5 SIMULATION RESULTS

A block diagram of the experimental SynRM drive and the super-twisting second-order sliding mode controller speed control block diagram of the SynRM servo drive are shown in Fig. 3. The synchronous reluctance motor modeled in this paper is a 0.37 kW, 2 pole, 230V, 4.7A, 60Hz, 3600rpm machine. The machine parameters are as follows: (1).Stator resistance Rs =4.2Ω, (2).Direct axis magnetizing inductance L_{dS} =328mH, (3).Quadrature axis magnetizing inductance L_{qS}=181mH, (4).Rotor inertia J_m = 0.00076Kg.m^2, and (5). Friction coefficient B_m =0.00012 Nt-m/rad/sec.

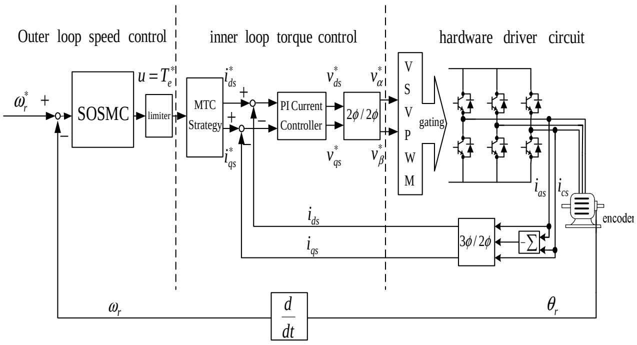

Fig.3. Twisting algorithm SOSMC speed control block diagram of SynRM servo drive

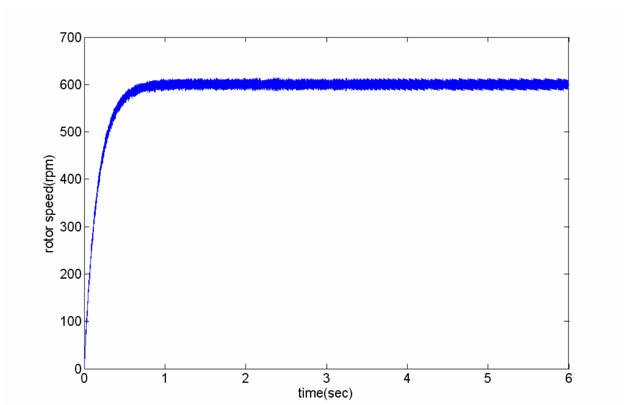

Fig.4. Simulation velocity response of the SMC due to $\omega_r^*=600$ rev/min without machine load in the nominal motor inertia and friction coefficient condition

In Fig.4, the simulation velocity response of the SMC due to $\omega_r^*=600$ rev/min without machine load in the nominal motor inertia and friction coefficient condition is depicted. In Fig.5, the simulation velocity response of the SOSMC due to $\omega_r^*=600$ rev/min without machine load in the nominal motor inertia and friction coefficient condition is depicted. The velocity response of SOSMC is smoother than the convention SMC.

In Fig.6, the simulation velocity response of the SOSMC due to $\omega_r^*=600$ rev/min under an 0.3 Nt-m machine load at the beginning and an 0.9 Nt-m machine load at 3seconds is added for the 2 times nominal case of the motor inertia and friction coefficient condition is presented. Hence, the SOSMC is a robust controller and improve the chattering phenomenon when the system has external disturbances and parameter variations.

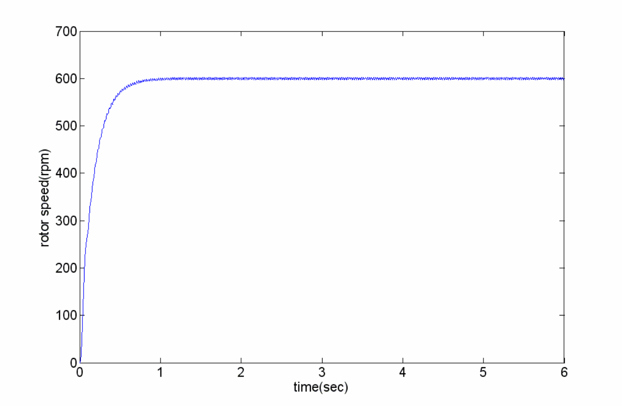

Fig.5. Simulation velocity response of the twisting algorithm SOSMC due to $\omega_r^* = 600$ rev/min without machine load in the nominal motor inertia and friction coefficient condition

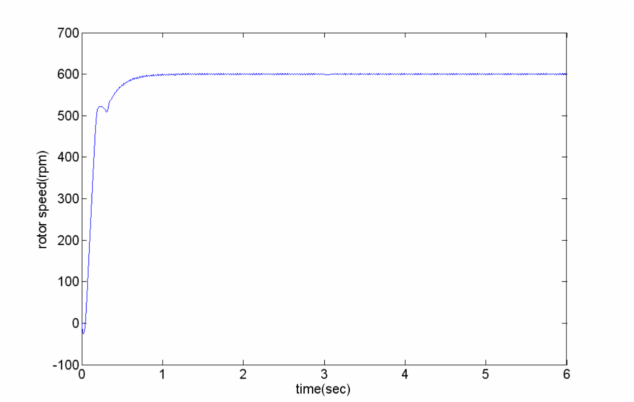

Fig.6. Simulation velocity response of the twisting algorithm SOSMC due to $\omega_r^* = 600$ rev/min under a 0.3 Nt-m machine load at the beginning and a 0.9Nt-m machine load at 3 seconds in the 2 times nominal case of the motor inertia and friction coefficient condition

6 CONCLUSION

In this paper, a twisting algorithm second-order sliding mode speed control design for robust stabilization and disturbance rejection of SynRM is presented. The simulation results show good performance of SOSMC under uncertain load subject to variaitons in inertia and system frcition. Also with SOSMC, there is no need for acceleration feedback. The proposed SOSMC law shows the advantage of continuous control signal which eliminates the chattering effect apparently and is more acceptable in application.

Abstract: Pedometers are known to have steps estimation issues. This is mainly attributed to their innate acceleration based measuring sensory. In this work, purposes a novel implementation of microcontroller and accelerometer sensor- based for multi-function pedometer in calorie consumption calculation. To verify the output voltage stability of accelerometer sensor, the methods of statistics analysis is introduced to extract the useful features. Three kinds of different steps are employed to obtain the analytic data. The proposed pedometer dimension of a proto-type is 68 mm(L) X 42 mm(W) X 15 mm(H).

Keywords: Pedometers, Three-axis accelerometer, Calorie consumption, Microcontroller.

1 INTRODUCTION

Walking is one of the principle gaits of locomotion among legged animals. Walking motion is defined by an 'inverted pendulum' movement in which the body vaults over the stiff limb or limbs with each step. This applies regardless of the number of limbs – even to arthropods with six, eight, or more limbs [1]. In humans and other bipeds, walking is characterized by only one foot leaving the ground at any given time, resulting in a period of double-support. In contrast, running involves both feet leaving the ground with each step. This distinction assumes the status of a formal requirement in competitive walking events [1].

Sustained walking for a minimum of thirty to sixty min. a day, five days a week, with correct walking posture, [2-3] provides a variety of benefits in reducing health risks [4]. These benefits include a reduced chance of developing cancer, type 2 diabetes, heart disease, anxiety, and depression [1,5]. Walking can increase life expectancy, particularly among individuals suffering from obesity or high blood pressure. Walking enhances bone health, especially the hip bone, reduces harmful low-density lipoprotein (LDL), and increases useful high-density lipoprotein (HDL) cholesterol[6]. Studies have determined that walking can even prevent dementia and Alzheimer's.

Pedometers are often worn on the belt to record how many steps the wearer has taken, and thus determine the distance walked each day (distance = number of steps × step length) [5].

Some pedometers will also erroneously record movements other than walking, such as bending to tie one's shoes, or road bumps incurred while riding a vehicle, though the most advanced devices record fewer of these 'false steps'. Step counters provide encouragement by enabling the user to compete with oneself in getting fit and losing weight. A total of 10,000 steps per day, equivalent to 5 miles (8.0 km), are commonly recommended as a benchmark for an active lifestyle, although this remains an issue of debate among experts [5]. Step counters are increasingly being integrated into portable electronic devices such as music players and mobile phones.

Many pedometers erroneously record road bumps incurred while riding in vehicles or movements other than walking (such as bending over), although more advanced devices record fewer of these 'false steps'. Pedometers generally detect steps from vertical acceleration at the human trunk [7]. The technology for a pedometer includes a mechanical sensor and software to count steps. Today advanced step counters rely on MEMS inertial sensors and sophisticated software to detect steps. These MEMS sensors have either 1-, 2- or 3-axis detection of acceleration [5]. The use of MEMS inertial sensors permits more accurate detection of steps and fewer false positives. The software technology used to interpret the output of the inertial sensor and "make sense of accurate steps" varies widely [7-8].

This study develops the design and fabrication for an accelerometer and embedded system-based multi-functional pedometer in calorie consumption calculation.

2 MATHEMATICS MODEL & SYSTEM STRUCTURE

The system schematic diagram is shown in Fig. 1. The system is using PIC16F877A microcontroller [9] as the pedometer core, uses its embedded 10 bits A/D converter. The variation voltage value of exercise angles detected by MMA7260Q accelerometer [10] sends to the microcontroller for handling. When the angle is bigger the setting threshold value, it will start step-counting program for recording. Finically, the LCD displays the calorie consumption and the step counting during exercise by means of the calorie calculation formula. By means of the element of MAX232, this system also has an interface that links to the UART of personal computer for program initial debugging and development.

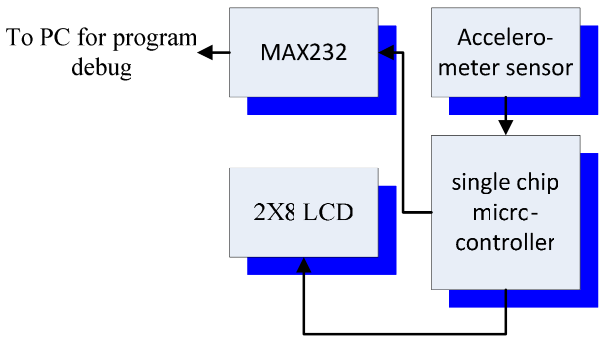

Fig. 1. Schematic diagram of proposed pedometer

The detected g value is hardly make mathematic analysis with the corresponding x axis voltage (V) in static acceleration mode of MMA7260Q. So these two values relationship is obtained from the measurement of the experimental data in table1. And the linear fit equation is expressed by

$$g = 1.25 \cdot V - 2.0625 \qquad (1)$$

where

$g \equiv$ The acceleration value after converting

$V \equiv$ The output voltage of x axis at three-axis accelerometer

Table 1. The experimental data in static acceleration mode

g value	+1	0	-1
x axis voltage (V)	2.45	1.65	+0.85

The correlation coefficient of curve fitting is 0.9999. From the food information websites in Department of Health at Taiwan [11], the relationship between speed and calorific capacity that can be a main reference issue about the calculation of exercise calorie is shown in Fig. 2.

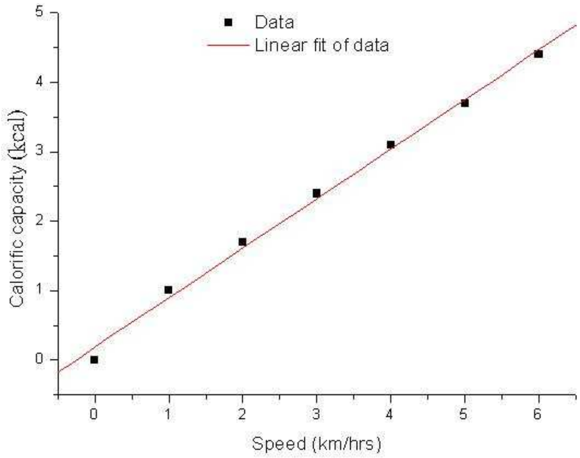

Fig. 2. The relationship between speed and calorific capacity [11]

We can get the Linear Fit equation is expressed as Equation (2). Where, $V(t)$ is the walking speed, and K is the Calorie consumption after converting. The correlation coefficient of curve fitting is 0.99761. Human weight is one of exercise calorie consumption factors, but we simplify the development of proto-type system. We make the human weight that is equals to 60kg as the basis, and leave the weight fitting as furthermore research in the future. Finally, the calorific capacity after converting displays in LCD module.

$$K = 0.71429 \cdot V(t) + 0.18571 \qquad (2)$$

3 WALKING STEP SIZE CONDITIONS

The system also can set three modes that include big step, middle step, and small step. Apart of the human weight factor, walking calorie consumption has the relationship of a linear equation with walking speed. In theory, the big step mode will take more calorie than others. But it has slower speed in big step mode and it results in the calorie consumption is smaller than others in per step.

After the practical pedometer calculation, the calorie consumption is shown in Table 2. Theoretically, on condition of uniform velocity, the paces are the greater to walk, the more its calorific consumed is. However, the speed would be slowdown in actual measurement when it walks in great paces. Thus, the calorie consumption of average in single paces consume will be reduced instead.

For calibration purpose between g value and voltage of x axis accelerometer, we take the voltage measurements at small step, middle step, and big step. Among these three modes, we take 10 points data and make statistical analysis respectively, for classifying these data sets. In the small and big step modes, there mean value

(Mean), variance (Var.) and coefficient of variance (CoefVar.) are nearly equal to each others. In Table 3, the mean value of small step is only smaller 0.003 than big step. Although the standard deviation (Std.) of small step is bigger than big step, but there is only 0.0125 difference between small step and big step. Find in the test, the average calorie consumption of steps in these two modes are nearly equal to each others. Besides, three parameters that described above have the same trend as shown in Fig. 3.

Table 2. The comparison of 3 modes for different step sizes

Steps mode	No. (steps)	Calorie (cal.)	Average cal./step
Small (40cm)	16	11	0.7
Middle (50cm)	10	14	1.4
Big (70cm)	20	16	0.8

Table 3. The statistics analysis for 3 steps modes

Steps	Mean	Std.	Var.	CoefVar.
Small (40cm)	1.754	0.27645	0.07643	0.15761
Middle (50cm)	1.858	0.23925	0.05724	0.12877
Big (70cm)	1.757	0.26395	0.06967	0.15023

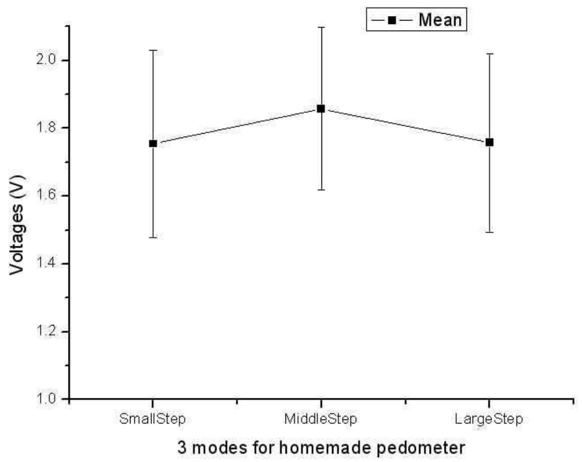

Fig. 3. The statistics data calculated at X axis in the pedo meter for 3 modes.

4 SYSTEM PROGRAMMING

Firstly, put the proposed pedometer on the shank. Then, turn on the power, it will display the words of Calorie (Calorie), st (step number), and se (setting) on LCD screen. Secondly, using push-button to select suitable step range by yourself. The region 1 is small step, and sensing range is from 0.25g to 0.05g. The region 2 is middle step, and sensing range is from 0.53g to 0.28g. The region 3 is big step, and sensing range is from 0.8g to 0.55g. If the user sets region 2 for walking step counting, then the setting location will display 2 on the screen of pedometer. After above procedures, the user pushes the "start" push-button for time counting, and then, it waiting the input signal.

By user walking, this action induces a signal to the X axis of accelerometer. This procedure contains the actions of step-counting plus one and time-counting during setting regions. By means of converting g value and formula (V=g • t) within software program setting, the program calculates the calorie consumption and displays the value on LCD screen. If the step span doesn't belong within setting sensing region, and then the program doesn't have step-counting action.

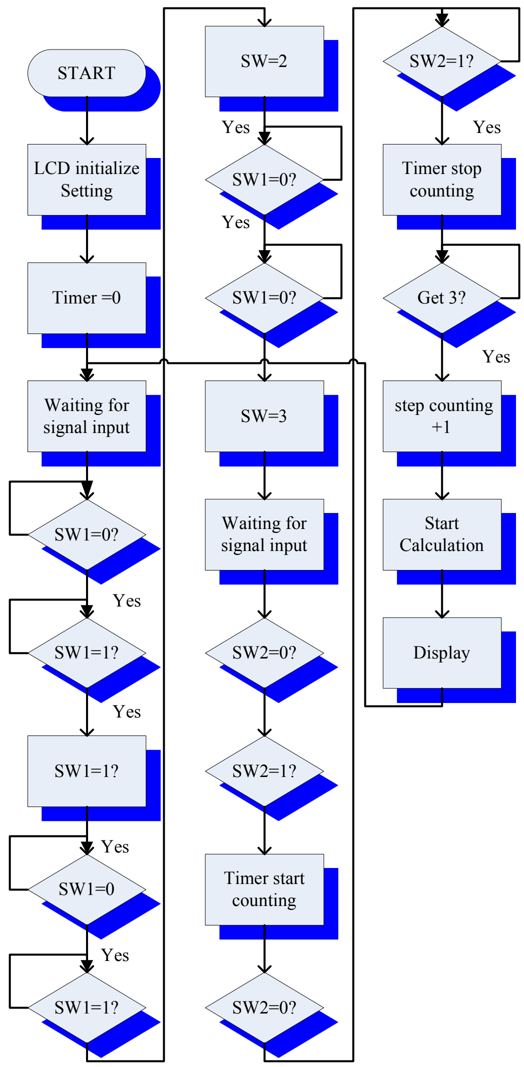

Fig. 4. The program flow chart of proposed pedometer [11]

After above procedures, the program will return last process. The setting procedures of region 1 and region 3 are the same as region 2. The user walk one step within setting sensing range, the program will plus one in step-counting procedure. After stop walking for one minute, it displays the data. And then, time counting, calculation, and display, the proposed pedometer will repeat the same actions again. The program flow chart of proposed pedometer is shown in Fig. 4.

5 CONCLUSION

The hardware pictures of this proposed pedometer are shown in Fig. 5 and Fig. 6. This study purposes a novel implementation of microcontroller and accelerometer sensor- based for multi-function pedometer with LCD display. It has the advantages with low power consumption, more robust and small dimension. Pedometer software is tested and showed 90% of step count accuracy. After verify the accuracy of the hardware design due to complete various function tests, the proposed hardware is realized that based on above concepts. The output voltage of accelerometer in three kind of different steps is employed to obtain the analytic data. The four parameters are calculated by statistics method. Finally, the three modes of hypothesis testing are verified for application. The 'mean' parameter is shown to be good to index the calorie consumption.

Abstract: Utility mining finds out high utility itemsets by considering both the profits and quantities of items in transactions. In this paper, a three-scan mining approach is proposed to efficiently discover high utility itemsets from transaction databases. The proposed approach utilizes an itemset-generation mechanism to prune redundant candidates early and to systematically check the itemsets from transactions. Finally, the experimental results on a synthetic dataset show the superior performance of the proposed approach.

Keywords: Data mining, utility mining, high utility itemsets, the filtration mechanism.

1 INTRODUCTION

In the field of database knowledge, data mining techniques have been widely applied to various practical applications, such as supermarket promotions, biomedical data applications, multimedia data applications, and so forth. Association-rule mining [1] is one of the most important issues in data mining since the relationship among items in a database can be found by association-rule mining techniques. Traditional association rule mining [1], however, considers the occurrence of items in a transaction database but do not reflect any other factors, such as price or profit. Then, some product combinations with low-frequency but high-profit may not be found in association-rule mining. For example, assume there is a product combination like {DVD player, LCD TV}. The product combination may not have a high frequency in a transaction database, but may contribute a high utility in this database due to LCD TV. To handle this, a practical issue, namely utility mining, was thus proposed by Chan *et al.*, in 2003 [2]. In Chan *et al.*'s study [2], their proposed approach considered both the individual profits and quantities of products (items) in transactions, and used them to measure actual utility value for an itemset. The high utility itemsets, which had their utility values larger than or equal to a predefined minimum utility threshold, were then found as the desired.

However, since the downward-closure property in association-rule mining cannot directly be adopted to find high utility itemsets in utility mining. To deal with this, a new downward-closure property was designed by Liu *et al.*, in 2005 [6]. The property was called transaction-weighted utilization (abbreviated as *TWU*) model [6]. In addition, Liu *et al.* applied the model to their proposed two-phase utility mining algorithm (abbreviated as *TP*) [6] to complete the utility mining task. However, Liu *et al.*'s utility mining approach had to run level by level as the *Apriori* algorithm in association-rule mining, thus needing scanning database multiple times. As described above, it is quite urgent to efficiently complete the utility mining task.

In this study, we propose an efficient three-scan utility mining algorithm (abbreviated as *TSA*) for handling the problem of utility mining. Especially, a new filtration mechanism in the proposed algorithm is designed to effectively prune a large number of unpromising candidates for mining. Also, the proposed algorithm calculates both the transaction-weighted utility and the actual utility of each itemset at the same time. Finally, the experimental results show that the proposed *TSA* algorithm executes faster than the *TP* algorithm under various parameter settings.

The remaining parts of this paper are organized as follows. Some related works, the problem to be solved and related definitions are reviewed in Section 2. The proposed mining algorithm with a filtering strategy for finding high utility itemsets from a transaction database is stated in Section 3. The experimental results are shown in Section 4. Conclusions and future works are finally given in Section 5.

2 REVIEW OF RELATED WORKS

According to the principle of association-rule mining [1], only binary itemsets are considered. In practical applications, however, products bought in transactions usually contain both profits and quantities. Thus, for some high-profit products with low frequency, these items may not be found by the association-rule mining algorithms. For example, both jewel and diamond have high utility values but may not be a high frequency combination when compared to food and drink in a database. To deal with this, Chan *et al.* subsequently proposed utility mining to find high utility itemsets from a transaction database [2]. In this study [2], a utility itemset considers not only the quantities of the items in transactions, but also their individual profits.

However, traditional association-rule mining keep the downward-closure property, but utility mining does not. Liu *et al.* thus proposed a two-phase utility mining (*TP*) algorithm to handle this [6]. This approach used a new property, which was named as the transaction-weighted utilization (*TWU*) model, to find all high utility itemsets. It used the summation of utility values of all the items in a transaction as the upper bound of any itemset in that transaction to keep the downward-closure property. In Liu *et al.*'s study [6], their proposed algorithm could be divided into two phases. In the first phase, the possible candidates were found from a database by the *TWU* model. Then, in the second phase, an additional data scan was executed again to find the actual utility of each candidate, and then itemsets with actual utility values larger than or equal to a predefined minimum utility threshold were output. However, since the *TP* algorithm adopted the level-wise technique to find high utility itemsets from a database, the algorithm had to spend a great deal of time on data scan. Afterward, although some related studies about utility mining were published [3][5][7][8], but most of them were still based on the principle of the *TP* algorithm to find their desired interesting utility patterns. It is thus desirable to effectively find high utility itemsets from a database and reduce the number of candidate itemsets.

3 THE PROPOSED MINING ALGORITHM

In this section, the filtration mechanism in the proposed algorithm is first described below.

3.1 The Filtration Mechanism

In the proposed algorithm, we design an itemset-generation approach to reduce the number of database scans. In particular, a filtration mechanism in the itemset-generation approach is proposed to avoid producing a big number of unpromising candidate utility itemsets. The mechanism is based on the high transaction-weighted utilization (*HTWU*) *2*-itemsets and on Liu *et al.*'s approach to generate possible transaction-weighted utilization itemsets [6]. Thus, the high transaction-weighted utilization *2*-itemsets (abbreviated as $HTWU_2$) have to be first found, and then these itemsets are used to check a candidate itemset whether there exists at least a low transaction-weighted utilization *2*-itemset in the candidate itemset. If it does, the candidate itemset is identified as an unpromising candidate itemset, and then it is removed; otherwise, it is can be kept in the set of candidate itemsets. A simple example is first given below to illustrate the idea.

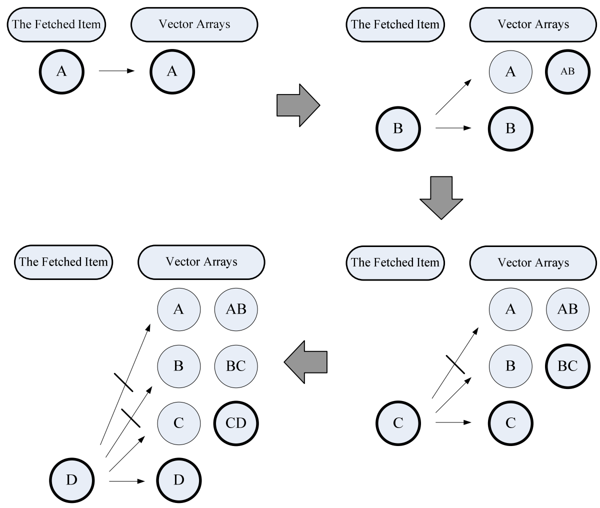

Fig. 1. The whole process of generating itemsets by using the filtration mechanism.

Example 1: Assume that a transaction *T* includes four items, 3*A*, 2*B*, 25*C* and 3*D*, where the numbers represent the quantities of the items. Also assume their profit values are 3, 10, 1 and 6, respectively, and the three itemsets {*AB*}, {*BC*}, and {*CD*} are all high transaction-weighted utilization *2*-itemsets, which have been found. Figure 1 shows the process of generating itemsets by using the filtration mechanism.

In Figure 1, the proposed algorithm first fetches the first item *A* in *T* and allocates it to the first row of the two dimensional vector array. The algorithm then fetches the second item *B* in *T* and allocates it to the second row of the vector array. Since there is only the item *A* in front of the fetched item *B*, the algorithm then checks whether items *A* and *B* have high transaction-weighted utilization relationship. In this example, {*AB*} is a high transaction-weighted utilization *2*-itemset. It is thus generated and put into the back of {*A*} in the first row because the first item in {*AB*} is *A*. The algorithm then continues to fetch the third item *C* and performs the same process. It puts {*C*} in the third row of the vector array, forms {*AC*}, and checks whether {*AC*} is a high transaction-weighted utilization *2*-itemset. In the example, {*AC*} is not, such that no combination of a subset in the first row with {*C*} is necessary. The algorithm then forms {*BC*} from the second row and finds it is a high transaction-weighted utilization *2*-itemset. {*BC*} is thus put in the back of {*B*} in the second row. Two new subsets {*BC*} and {*C*} are generated for the third item. Similarly, the fourth item *D* is fetched and the above process is repeated again. The two new subsets {*CD*} and {*D*} are derived and put into the suitable vector array.

As seen in this example, the filtering mechanism can be effectively adopted to reduce the number of unpromising candidate itemsets and speed up the execution efficiency.

3.2 The Three-scan Utility Mining Algorithm, *TSA*

The details of the algorithm are listed below.

INPUT: A set of items, each with a profit value; a transaction database, in which each transaction includes a subset of items with quantities; the minimum utility threshold.

OUTPUT: The final set of high utility itemsets (*HU*).

Scan 1:

STEP 1. For each y-th transaction $Trans_y$ in D, do the following substeps.

(a) Calculate the utility value u_{yz} of each z-th item i_{yz} in $Trans_y$ as:

$$u_{yz} = s_{yz} * q_{yz},$$

where s_{yz} is the profit of item i_{yz} and q_{yz} is the quantity of i_{yz} .

(b) Calculate the transaction utility tu_y of $Trans_y$ as:

$$tu_y = \sum_z u_{yz} .$$

STEP 2. For each item i in D, calculate the transaction-weighted utility twu_i of the item i as the summation of the transaction utility values of the transactions which include the item i. That is:

$$twu_i = \sum_{i \in Trans_y} tu_y .$$

STEP 3. For each item i in the set of candidate *1*-itemsets, if the transaction-weighted utility twu_i of i is larger than or equal to the minimum utility threshold, put it in the set of high transaction-weighted utilization *1*-itemsets, $HTWU_1$.

Scan 2:

STEP 4. For each $Trans_y$ in D, do the following substeps.

(a) Check each item in $Trans_y$ whether it is a member in the set of $HTWU_1$. If it is, put it in the modified transaction $Trans_{y'}$; Otherwise, it is omitted.

(b) Check the number of items in the modified transaction $Trans_{y'}$ whether its number of items is larger than or equal to 2. If it is, keep the transaction $Trans_{y'}$ in the set of the modified transactions, and do the next step; Otherwise, remove the transaction $Trans_{y'}$, and do substep (a).

(c) Generate all possible *2*-itemsets in $Trans_{y'}$, and then put them in the set of C_2.

(d) Add the transaction utility tu_y in the suitable transaction-weighted utility field values of the generated *2*-itemsets in the set of C_2.

STEP 5. Check whether the transaction-weighted utility twu_x of each *2*-itemset x in the set of C_2 is larger than or equal to the minimum utility threshold , put it in the set of high transaction-weighted utilization *2*-itemsets, $HTWU_2$.

Scan 3:

STEP 6. Initialize the temporary itemset table as an empty table, in which each tuple consists of two fields: itemset and actual utility.

STEP 7. For each transaction $Trans_{y'}$ in the set of the modified transactions, do the following substeps.

(a) Generate all possible itemset x in $Trans_{y'}$ by using the set of $HTWU_2$, where the relationship between any two items in an itemset has to be a high transaction-weighted utilization relationship.

(b) Find the utility values u_{yx} of the itemsets in $Trans_{y'}$, and then add in their actual utility field values in the temporary itemset table.

STEP 8. Check whether the actual utility au_x of each r-itemset x in the temporary itemset table is larger than or equal to the minimum utility threshold , put it in the set of high utility r-itemsets, HU_r.

STEP 9. Output the final set of high utility itemsets, *HU*.

4 EXPERIMENTAL EVALUATION

In the experiment, the public *IBM* data generator was used in our experiment to produce the dataset [4]. Since our purpose was to find out high utility itemsets, we thus developed a simulation model, which was similar to that used in Liu *et al*. [6], to generate the quantities of the items in the transactions. In addition, the parameters used in the *IBM* data generator [4] were *T*, *I*, *N* and *D*, which represented the average length of items per transaction, the average length of maximal potentially frequent itemsets, the total number of different items, and the total number of transactions, respectively. All the algorithms were implemented in J2SDK 1.5.0 and executed on a PC with 3.0 GHz CPU and 1 GB memory.

Figure 2 then showed the execution time comparisons of the two algorithms for the synthetic T10I4N4KD200K dataset with various minimum utility thresholds, *min_util*.

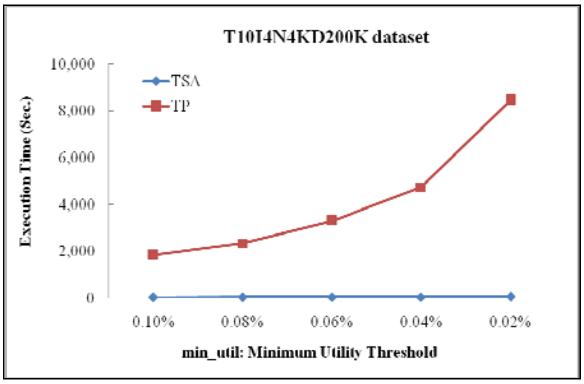

Fig. 2. Execution time of the two algorithms along with various minimum utility thresholds

It could be seen in the figure that the efficiency of the *TSA* algorithm was better than that of the *TP* algorithm, especially when the minimum utility threshold decreased. With the filtration mechanism, the *TSA* algorithm could thus effectively reduce a great number of unpromising candidates to achieve the goal of finding high utility itemsets. For the *TP* algorithm, since it adopted a level-wise technique to handle the problem of utility mining, a huge number of candidates had to be generated for mining. Thus, the candidate itemset requirement of the *TSA* algorithm was smaller than that needed by the *TP* algorithm.

5 CONCLUSIONS

In this paper, we have proposed an efficient three-scan utility mining approach (*TSA*) to find high utility itemsets from a transaction database. Especially, the proposed algorithm only needs three data scan to achieve the utility mining task. Also, the filtration mechanism adopts in this work can effectively skip unpromising candidate itemsets and thus further save time. The experimental result shows that the proposed mining algorithm is able to execute faster than the traditional *TP* algorithms for the synthetic datasets generated by the public *IBM* data generator.

Abstract: The Pennes' bio-heat conduction equation is common used to simulate temperature distribution for bio-heat transfer problems, it adopted the classical Fourier heat conduction law that is obviously incompatible with physical reality when research on microscopic heat transfer, low-pressure gases, cryogenic engineering, etc. Applying the concept of finite heat propagation speed, a thermal wave model of bi-heat transfer has developed. In order to analyze the thermal wave effect on temperature distributions, the different boundary heating conditions are considered with thermal wave model of bi-heat transfer and also compare to the Pennes'. The differential transform method combined with the finite difference scheme is proposed to simulate the temperature distributions. From results show it takes a period of time for the surface heating to propagate to a desired point inside the living tissue by the effect of thermal wave.

Keywords: Thermal wave, Thermal relaxation time, Differential transformation method**.**

1. INTRODUCTION

Temperature predictions for living tissues have attracted a lot of interesting in the processes of hyperthermia, thermal diagnostics, cryosurgery, thermal comfort analysis, and thermal parameter analysis. There were many models have been developed for describing bio-heat transfer behavior [1]. Among these models, the well known Pennes' model is the most commonly adopted [2]. It used the classic Fourier's law for its conduction term and was given as

$$q(\vec{r},t) = -\kappa\nabla T(\vec{r},t) \tag{1}$$

where κ is conductivity. The thermal signal propagates in infinite velocity in Eq. (1) that is obviously incompatible with physical reality when studies the processes of microscopic heat transfer, low-pressure gases, cryogenic engineering, etc. Thus, the concept of finite heat propagation wave velocity was proposed to apply for the bio-heat transfer processes [3-4]. Vernotte and Cattaneo [5] proposed a modified unsteady heat condition equation with the thermal relaxation time and was given as

$$q(\vec{r},t+\tau) = q(\vec{r},t) + \tau\frac{\partial\vec{q}(\vec{r},t)}{\partial t} = -\kappa\nabla T(\vec{r},t) \tag{2}$$

here $\tau = \alpha / V^2$ is defined as the thermal relaxation time, and α is the thermal diffusivity, V is denoted as the heat propagation velocity in the medium.

In homogeneous substances, τ is in the range of $10^{-8} \sim 10^{-10}$s as for gases, and $10^{-8} \sim 10^{-14}$s for liquids and dielectric solids [6]. The time of heating process is much longer than the thermal relaxation time scale in homogeneous substances, so the phenomenon of heat wave is relatively more difficult to observe. In non-homogeneous materials such as living tissues, τ is the characteristic time that needs to take time to accumulate the thermal energy in order to transfer to the nearest element. Kaminski [7] reported the value of τ is 20~30 s in meat product. Liu et al. [8] used the thermal wave model of bio-heat transfer (TWMBT) to analysis the thermal signal wave of bio-heat transfer. Liu [9] performed the Laplace transform method to investigate the thermal propagation behaviors. Liu and Lin [10] investigated physiological parameters by the hybrid numerical scheme. It is difficult to obtain the fundamental solution of the thermal propagation wave model of bio-heat transfer for living tissue [11]. In this article, a differential transform method is proposed to predict temperature distributions for living tissues with different boundary heating conditions. The effects of thermal wave on temperature distribution are also investigated.

2. THE DIFFERENTIAL TRANSFORMATION METHOD

Zhou [12] proposed the concept of the differential transform and can be summarized below.

$$X(k;t_0) = M(k)\left[\frac{d^k}{dt^k}(q(t)x(t))\right]_{t=t_0}, \quad k \in K \tag{3}$$

where k belongs to a set of non-negative integer denoted as K domain. $X(k;t_0)$ is the differential transformation of

$x(t)$ at $t = t_0$, *M(k)* ($M(k) \neq 0$) is called the weighting factor and *q(t)* ($q(t) \neq 0$)is a kernel corresponding to *x(t)*. Thus, if *q(t)x(t)* can be expressed in terms as Taylor's series, then *x(t)* can be presented by using the differential inverse transformation of $X(k;t_0)$ as

$$x(t) = \frac{1}{q(t)} \sum_{k=0}^{\infty} \frac{(t-t_0)^k}{k!} \frac{X(k;t_0)}{M(k)}, \quad \forall t \in T \tag{4}$$

If $M(k) = H^k / k!$ and $q(t) = 1$, then Eq. (3) and (4) become

$$X(k) = T[x(t)] = \frac{H^k}{k!} \left[\frac{d^k x(t)}{dt^k} \right]_{t=0}, \quad k \in K \tag{5}$$

$$x(t) = T^{-1}[x(t)] = \sum_{k=0}^{\infty} \left(\frac{t}{H} \right)^k X(k), \quad \forall t \in T \tag{6}$$

3. BIOHEAT TRANSFER PROBLEMS

The Pennes' bio-heat transfer equation is described as

$$-\nabla \cdot \vec{q} + W_b C_b (T_b - T) + q_m + q_r = \rho C \frac{\partial T}{\partial t} \tag{7}$$

where, ρ C, and T denote the density, specific heat, and temperature of living tissue, C_b is the specific heat of blood, W_b blood perfusion rate, q_m and q_r are the heat generation from metabolism and the spatial heat source respectively, T_b is the artery temperature. Liu et al. [13] introduced a general model of thermal wave form of the bio-heat transfer in living tissue from Eq. (2) and (7) as

$$\begin{aligned} &\nabla \cdot (\kappa \nabla T) + W_b C_b (T_b - T) + q_m + q_r \\ &+ \tau(-W_b C_b \frac{\partial T}{\partial t} + \frac{\partial q_m}{\partial t} + \frac{\partial q_r}{\partial t}) = \rho C (\tau \frac{\partial^2 T}{\partial t^2} + \frac{\partial T}{\partial t}) \end{aligned} \tag{8}$$

Equation (8) is a general form of TWMBT in living tissue. When heat mainly propagates in the perpendicular direction to the living tissue surface, one-dimensional heat transfer can be a good approximation. With constant thermal properties, $q_m =$ constant, and $q_r = 0$, Eq. (8) can be expressed as

$$\kappa \frac{\partial^2 T}{\partial x^2} + W_b C_b (T_b - T) + q_m - \tau W_b C_b \frac{\partial T}{\partial t} = \rho C (\tau \frac{\partial^2 T}{\partial t^2} + \frac{\partial T}{\partial t}) \tag{9}$$

By assuming $T_i(x,0)$ is the initial steady state temperature, then Eq. (9) is turned into a new form as

$$\kappa \frac{\partial^2 T_i}{\partial x^2} + W_b C_b (T_b - T_i) + q_m - \tau W_b C_b \frac{\partial T_i}{\partial t} = \rho C (\tau \frac{\partial^2 T_i}{\partial t^2} + \frac{\partial T_i}{\partial t}) \tag{10}$$

Define a transformation of $\theta(x,t) = T(x,t) - T_i(x,0)$ and combine Eq. (9) and (10), the final result becomes

$$\rho C \tau \frac{\partial^2 \theta}{\partial t^2} + (\rho C + \tau W_b C_b) \frac{\partial \theta}{\partial t} + W_b C_b \theta - \kappa \frac{\partial^2 \theta}{\partial x^2} = 0 \tag{11}$$

By taking differential transformation of Eq. (11), then

$$\begin{aligned} &\rho C \tau \frac{(k+1)(k+2)}{H^2} U(k+2) + (\rho C + \tau W_b C_b) \frac{(k+1)}{H} U(k+1) \\ &+ W_b C_b U(k) = \kappa \frac{\partial^2 U(k)}{\partial x^2} \end{aligned} \tag{12}$$

where $U(k) = U(x,t)$ is the differential transformation function at $\theta(x,t)$. By dividing the coordinate of x into N equal internals and taking the finite difference approximation to Eq. (12)

$$\begin{aligned} &\rho C \tau \frac{(k+1)(k+2)}{H^2} U_i(k+2) + (\rho C + \tau W_b C_b) \frac{(k+1)}{H} U_i(k+1) \\ &+ W_b C_b U_i(k) = \kappa \frac{U_{i+1}(k) - 2U_i(k) + U_{i-1}(k)}{(\Delta x)^2} \end{aligned} \tag{13}$$

3. NUMERICAL SIMULATION

When the surface of living tissue is heated by different boundary heating conditions, the bio-heat conduction equation and relative conditions are discussed.

3.1. Case 1：Constant surface temperature heating

The skin surface is heated for constant temperature and the temperature distributions have simulated.

$$\rho C \tau \frac{\partial^2 \theta}{\partial t^2} + (\rho C + \tau W_b C_b) \frac{\partial \theta}{\partial t} + W_b C_b \theta - \kappa \frac{\partial^2 \theta}{\partial x^2} = 0 \tag{14}$$

Assume there is no heat flux at x=L [8], then the initial and boundary conditions are described as

$$\theta(x,0) = 0 \tag{15}$$

$$\frac{\partial \theta(x,0)}{\partial t} = 0 \tag{16}$$

$$\theta(0,t) = \theta_0 \tag{17}$$

$$\frac{\partial \theta(L,t)}{\partial x} = 0 \tag{18}$$

The differential transformation of Eq. (15)-(18) are

$$U_i(0) = 0 \tag{19}$$

$$U_i(1) = 0 \tag{20}$$

$$U_1(0) = \theta_0 \quad , \quad U_1(k) = 0 \quad k \neq 0 \tag{21}$$

$$U_N(k) - U_{N-1}(k) = 0 \tag{22}$$

The differential transformation equation from Eq. (14) can be resulted in tow situations.

For $\tau = 0$

$$U_i(k+1) = \frac{H}{\rho C(k+1)} \left\{ \begin{aligned} &-W_b C_b U_i(k) \\ &+ \frac{\kappa}{(\Delta x)^2} \begin{bmatrix} U_{i+1}(k) - 2U_i(k) \\ + U_{i-1}(k) \end{bmatrix} \end{aligned} \right\} \tag{23}$$

For $\tau \neq 0$

$$U_i(k+2) = \frac{H^2}{\rho C \tau (k+1)(k+2)} \left\{ \begin{aligned} &-(\rho C + \tau W_b C_b) \frac{(k+1)}{H} U_i(k+1) \\ &- W_b C_b U_i(k) \\ &+ \frac{\kappa}{(\Delta x)^2} \begin{bmatrix} U_{i+1}(k) \\ -2U_i(k) + U_{i-1}(k) \end{bmatrix} \end{aligned} \right\} \tag{24}$$

3.2. Case 2：Constant surface flux heating

For a constant heat flux heat at the living surface, the corresponding boundary conditions typically can be described as

$$\begin{cases} -\kappa \dfrac{\partial\theta(0,t)}{\partial x} = q(t) \ \ 0 < t < t_s \\ -\kappa \dfrac{\partial\theta(0,t)}{\partial x} = 0 \ \ t > t_s \end{cases} \tag{25}$$

$$\frac{\partial\theta(L,t)}{\partial x} = 0 \tag{26}$$

Where t_s is defined as the duration of heating period and $q(t)$ denotes the heat flux that is time variable. Considering the heating time is short then the heat flux is approximately assumed as a constant, q_0. In the practices the heat flux is 83.2kw/m^2 as for the flash fire on the human skin surface.

3.3 Case 3：Constant temperature pulse surface heating

In the cases of eye surgery by using laser pulse or skin subjects to hot plate for a short period of time, the boundary conditions are expressed as

$$\begin{cases} \theta(0,t) = \theta_0 \ \ 0 \le t \le t_s \\ \theta(0,t) = 0 \ \ t > t_s \end{cases} \tag{27}$$

$$\frac{\partial\theta(L,t)}{\partial x} = 0 \tag{28}$$

4. RESULT AND DISCUSSION

The thermal property for homogeneous tissue are taken as $\rho = 1000 kg/m^3$, $C = C_b = 4200 J/kg°C$, $W_b = 0.5 kg/m^3$, $T_b = 32.5°C$, and $\kappa = 0.2 W/m$ [5]. As shows in Fig. 1, the computation domain is taken as L=0.01208m and the value of θ_0 is specified as 12℃ [5] and temperature distributions were analytically estimated at x=0.00208m inside the body.

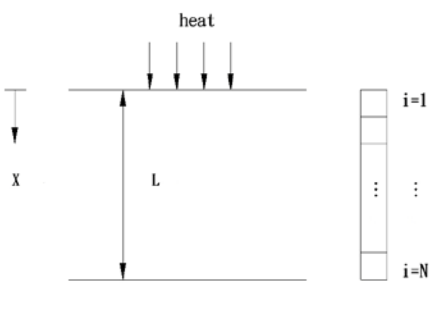

Fig. 1. The physical model

4.1. Case 1：Constant surface temperature heating

In Fig. 2, the temperature distributions predicted from Pennes' and TWMBT equation were different. As $\tau = 0$, the Pennes' bio-heat equation is used to characterize the thermal conduction, the thermal gradient has no jump discontinuity because of the infinite speed of thermal wave and the thermal signal can arrive the positions instantaneously. For $\tau \neq 0$, the influence of thermal relaxation time can result in a finite thermal wave propagation velocity and a travel time for thermal heat to distribute. The time for thermal heat to arrive at x=0.00208m is evaluated by using $t = L/\sqrt{\alpha/\tau}$. For $\tau = 20$ s and $\tau = 30$ s, the thermal wave reach x=0.00208m in $t = 0.00208/\sqrt{0.2/(1000 \times 4200 \times 20)} = 42.627(s)$ and $t = 0.00208/\sqrt{0.2/(1000 \times 4200 \times 30)} = 52.21(s)$, respectively.

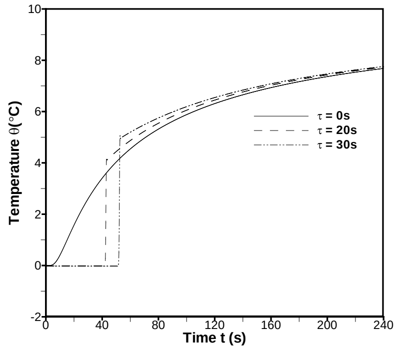

Fig. 2. Temperature distribution during constant surface temperature heating at x=0.00208m

4.2. Case 2：Constant surface flux heating

When there is a constant heat flux on the living skin surface for a period of heating time, as shows in Fig. 3. A substantial deviation was found between temperature predictions from the Pennes' and TWMBT equation. The temperature distributions predicted by the Pennes' equation increase at the initial then quickly decrease when the surface heat flux becomes zero. As in TWMBT equation, a period of time is needed for the thermal signal to travel from the surface to the particular position, the temperature distribution increase with a slope for the period of heating time then decrease. In Fig. 4, the different heat time were carried out to analyze the effect of thermal wave. The longer the heating time is the higher temperature is.

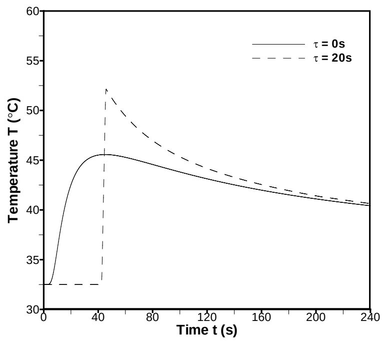

Fig. 3. Temperature distribution for t_s =3s during constant surface flux heating at x=0.00208m

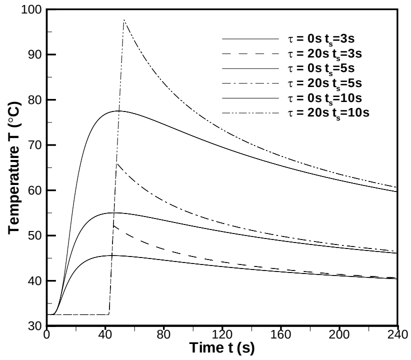

Fig. 4. Temperature distribution for various t_s during constant surface flux heating at x=0.00208m

4.3 Case 3：Constant temperature pulse surface heating

When the living tissues heat by the constant temperature pulse heating, such as eye surgery by laser irradiation or a flash fire on skin. As shows in Fig. 5, the temperature distributions predict by Pennes' and TWMBT equations for 3s, 5s, and 10s heating time. There is a travelling time for the thermal wave propagates from the heating living tissue surface to the particular and the temperature increase for the period of temperature pulse heating time. The longer heating time is, the higher temperature is. As for $\tau = 0$, the temperature increases at the period of temperature pulse heating time from begin, then gradually decreases at the end of heating.

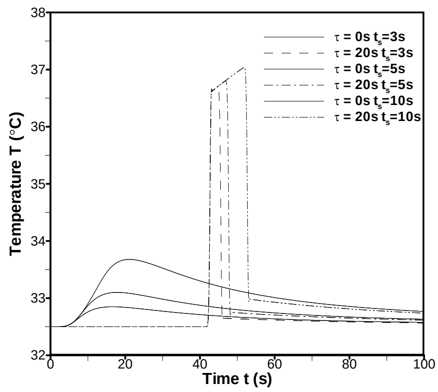

Fig. 5. Temperature distribution for various t_s, $\theta_0 = 12°C$ during constant temperature surface flux heating at x=0.00208m

5.CONCLUSION

The paper presents the effect of thermal wave in the living tissues for different surface heating problems. We simulate the bio-heat conduction problems with different values of the thermal relaxation time and also compares the results simulated by Pennes' and TWMBT equations. The results show that the heat wave speed under the effects of various thermal relaxation time and heat transfer wave propagation, can be expressed as $V = \sqrt{\alpha / \tau} = \sqrt{\kappa / \rho C \tau}$ and the travelling time also be calculated. In the non-homogeneous substance, the thermal wave propagates in a finite speed and cause a delay time to heat transfer compare with the temperature predicted by the Pennes' equation.

Abstract: This paper is investigation of the effect of the large deformation on the forming parameter for the circular plate forming. This analysis tool of this paper is the ANSYS LS DYNA software. The forming parameter of the paper includes the punching velocity and die material property. From the analysis result, this can be known the variable result can be got under the differential parameter condition. When the punching velocity is increasing, the extrusive material will appear. When the die material strength increase, the forming thickness of the forming shape becomes small. When the deform velocity of the die material is increasing, the forming thickness of the forming shape becomes small. Therefore, the effect of the die material effect on the thickness of the forming shape is very clear. This analysis tool can effectively predict the forming shape.

Keywords: ANSYS LS DYNA , die material property, Oil Seal Cover, punching velocity,

1 INTRODUCTION

Now, the manufacturing velocity of the industry is very fast. So, the plastic injecting forming is used in many lifting field. But, the plastic structure strength is very weak. Therefore, the high structure product can not use the plastic material. The metal material is good material for the high structure product. The injecting forming method can not be used for the metal material. The fast forming method of the metal can use punching forming or deep drawing. This object of the punching forming is the forming shape for the beforehand plane plate or the undeveloped product. The forming shape include square, circular, rectangle, triangle …, etc. The punching forming action is by way of the mold interaction. The die material have the metal flow. This cause the die plate into the mold, then the die plate have pressured into the inside of the mold. In order to pressure the die plate forming, the die material cause metal flow.

In the process of the metal deep forming, the metal flows include the bending, stretching, friction and compressed. This can cause the deformation of the die plate. In general, the forming of the circular cup shape can cause the crack of the cup well in the place of the subjected force and transportation. When the plate material extend by using the force, the plate material thickness become thin. The thickness of the sheet plate on the place of the interaction between sheet plate and the corner of the punch pin become too thin. When the plate material is formed, the status of the forming force and transportation can be controlled. The forming shape can be get the best result.

From the literate, this can be known the parameter can be controlled to get the best forming result.[1] J.P.Fang etc [2] use the ABAQUS software to analyze the deep forming to understand the wrinkle of the plate material. This is closed compare between the experiment result and analysis result. Manabe etc [3] analyze the thickness variation of the plate material by using the 「LS-DYNA90」 soft ware. From the analysis result, this can be known that the LS-DYNA90 can be used to analyze the thickness variation. Natarajan and Venkataswamy[4] analyze the circular cap forming by using the finite element method. Compare the experiment result and analysis result, this can be found that the thickness of the plate material in the compressed plate and the flange of the mold become thin. This can be known that the finite element method can to analyze the forming process. In 2002, the Naval Kishor and Ravi Kumar[5] use the LSDYNA software to explore the forming shape optimization. This tool is used to reduce the ratio of the wrinkle shape. This result is close to the experiment result. In 2006, Yang [6] used the DEFORM software to analyze the semi circular deep. This simulate the thickness variation and the effect of the forming force. From the analysis result, this can be known that as the blank holder force and friction force become great, the forming force become great and the thickness of the plate become thin. Kirby and Wild[7] use the MARC software to analyze the deep forming. From the analysis result, this can be known that the effect of the friction coefficient and the blank holder gap on the principal strain of the blank material is very small. When the friction coefficient increase linearly, the maximum punch force increase linearly. When the blank holder gap increases, the blank hold force and punch force decrease. Therefore, this can be known that the effect of the friction coefficient on the maximum punch force is very clear. The effect of the blank holder gap on the maximum blank holder force is very clear. From the above literate, this can be known that the computation add engineer can be used to predict the forming shape.

2 Theory Analysis

In order to get the correct analysis result, the real material measurement is very important. The material test is satisfying the ASTM standard. The test material show in Fig. 1. The thickness of the blank plate material is 2.62mm. The test result show in Fig. 2. The test result is the displacement and force curve. In general, the analysis model property must is the real stress-strain curve. The relation of the engineering material property and the real material property can be get from equ. (1)-(4), shown in following:

$$\sigma = \frac{F}{A_0} \quad (1)$$

$$\varepsilon = \frac{l - l_0}{l_0} = \frac{\Delta l}{l_0} \quad (2)$$

$$\sigma_t = \frac{F}{A_0}(1+\varepsilon) \quad (3)$$

$$\varepsilon_t = \ln(1+\varepsilon) \quad (4)$$

Where σ is the engineering stress, σ_t is the real stress, ε is the engineering strain. ε_t is the real strain. F is the extend force. l_0 is the length of the test material. l is the length of the test material after extending. A_0 is the area.

Fig. 1. Flat sheet of material testing standard map

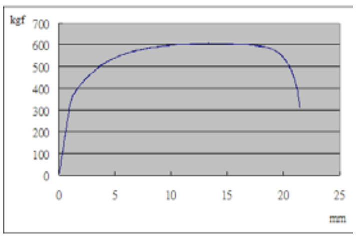

Fig. 2. Pull test of strength and displacement application diagram Flat sheet of material testing standard map

From the tensile test, the coefficient of elasticity is 593kgf/mm^2, yielding stress 168MPa limited strength is 273.5MPa, ratio of the extension 49.5%. The stress strain curve can be get, show in Fig 3. The relation of the punch forming velocity is shown in Fig.4.

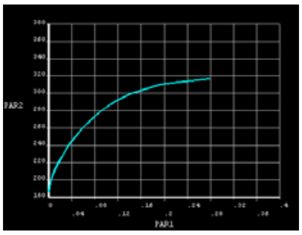

Fig. 3. Stress-strain diagram

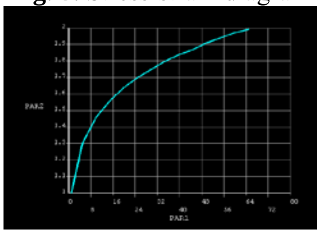

Fig. 4. Speed and strain rate graph

This paper uses the ANSYS/LS-DYNA software to build the solid modeling. This modeling includes the punch mold, draw die and blank plate. Due to, the analysis object is the thickness and Flange of the circular cup. The blank plate use the shell 163 element of the ANSYS, this element is show in Fig.5. The punch and die element is the solid 164 of the ANSYS, this shows in Fig.6.

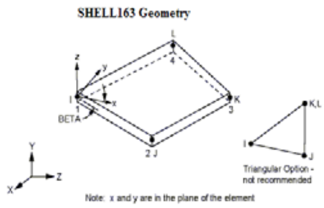

Fig. 5 shell163 of the ANSYS diagram [8]

3 Analysis Result

In order to understand the effect of the punching velocity on the forming shape, this consider the constant distant of the punching and die with the variation time. The trip of the punch from the top to down is 0.05m. These six times of the punching 0.05m trip include 0.05s、0.1s、 0.2s、0.3s、0.4s and 0.5s. These analysis results show in following:

. **(a) T=0.05** This consider the punching time is t=0.05s. The punching velocity is very fast. This analysis result shows in Fig.7. Fig. 7 show the deformation shape of the circular cup and the thickness contour of the circular cup. From the Fig. this can be found that the flange of the circular cup appear. The thickness of the circular cup become very thin (0.053mm). In order to understand the effect of the material strength on the deformation shape, the Fig.8 show the deformation shape curve of the circular cup with the differential multiplicand of the stain rate of the material (in Fig.4). From Fig.8, this can be found the effect of the strain rate of the material on the deformation shape curve is very small.

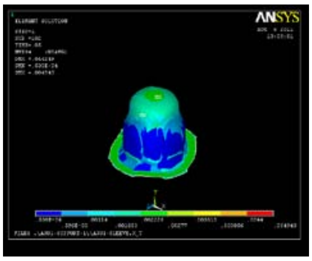

Fig. 7. The thickness contour and the forming shape diagram t=0.05s

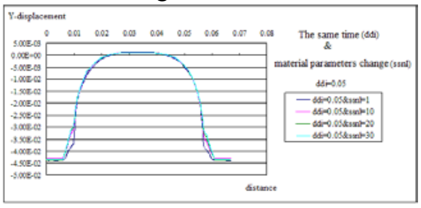

Fig. 8. The shape curve with variation strain ratio in t=0.05s

(b) T=0.1 The t=0.1s is applied in this system.

The analysis result show in Fig.9. From the Fig.9, this can be found that the flange of the circular cup appear. The flange of the punching time 0.1s is smaller than the punching time 0.05s. The thickness of the circular cup become very thin (0.225mm). In order to understand the effect of the material strength on the deformation shape, the Fig.10 show the deformation shape curve of the circular cup with the differential multiplicand of the stain rate of the material (in Fig.4). From Fig.10, this can be found the effect of the strain rate of the material on the deformation shape curve is not clear..

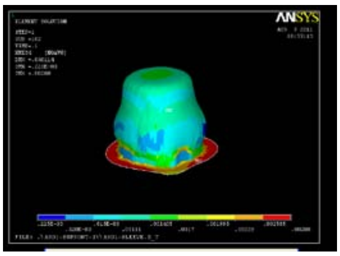

Fig. 9. The thickness contour and the forming shape diagram t=0.1s

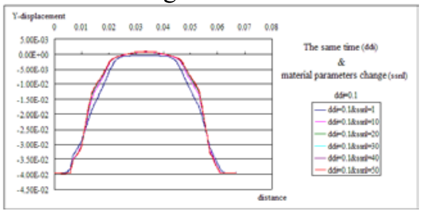

Fig. 10. The shape curve with variation strain ratio in t=0.1s

(c) T=0.2 The t=0.2s is applied in this system. The analysis result show in Fig.11. From the Fig.11, this can be found that the flange of the circular cup disappear. The thickness of the circular cup become very thin (0.915mm). The Fig.12 shows the deformation shape curve of the circular cup with the differential multiplicand of the stain rate of the material (in Fig.4). From Fig.12, this can be found the effect of the strain rate of the material on the deformation shape curve is not clear..

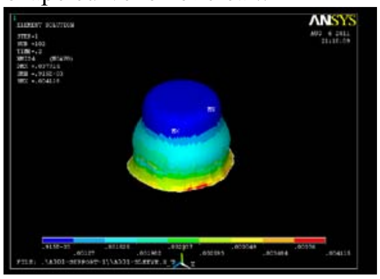

Fig. 11. The thickness contour and the forming shape diagram t=0.2s

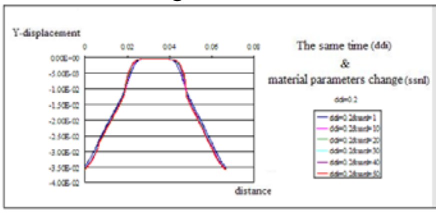

Fig. 12. The shape curve with variation strain ratio in t=0.2s

From the above analysis result, this can be known the effect of the train ratio of the material on the deformation shape is not clear. But, the thickness of the circular cup is too thin after the blank plate is formed, shown in Fig.13. From this can be found that the strain ratio of the material is great, the flow of the material is very difficult.

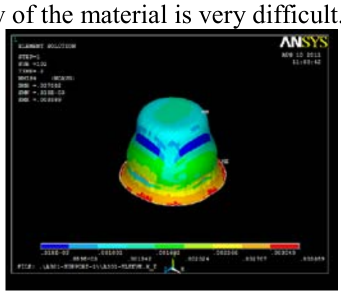

Fig.13. The thickness contour and the forming shape diagram t=0.2 with multiplicand of the strain ratio 50

(c) T=0.3 The t=0.3s is applied in this system. The analysis result show in Fig.14. From the Fig.14, this can be found that the flange of the circular cup disappears. The thickness of the circular cup becomes very thin (1.16mm). The Fig.15 shows the deformation shape curve of the circular cup with the differential multiplicand of the stain rate of the material (in Fig.4). From Fig.15, this can be found the effect of the strain rate of the material on the deformation shape curve is not clear.

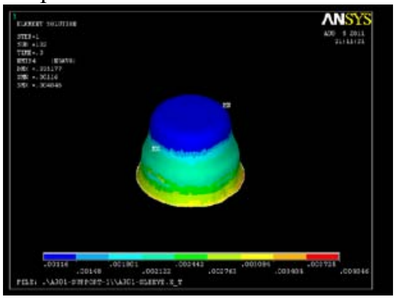

Fig.14. The thickness contour and the forming shape diagram t=0.3

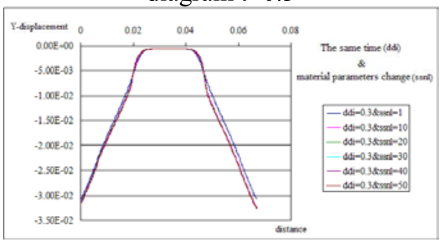

Fig.15. The shape curve with variation strain ratio in t=0.3s

(d) T=0.4 The t=0.4s is applied in this system.

The analysis result show in Fig.16. From the Fig.16, this can be found that the flange of the circular cup disappears. The thickness of the circular cup becomes very thin (1.395mm).

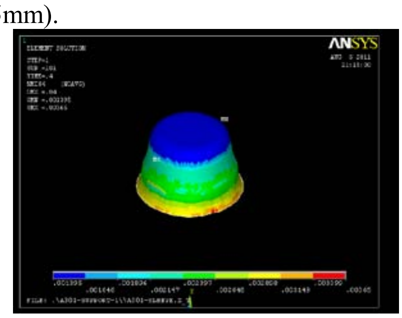

Fig.16. The thickness contour and the forming shape diagram t=0.4

(e) T=0.5 The t=0.5s is applied in this system. The analysis result show in Fig.17. From the Fig.17, this can be found that the flange of the circular cup disappears. The thickness of the circular cup becomes very thin (1.598mm).

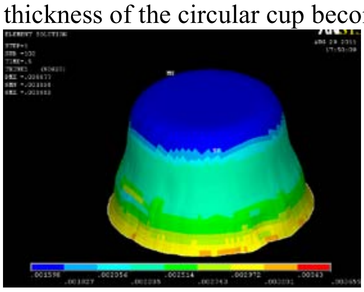

Fig.17. The thickness contour and the forming shape diagram t=0.5s

4 CONCLUSION

This object of the paper is analysis of the plate forming by using the CAE software. This uses the AN SYS LS-DYNA to analyze the circular cup forming. Fr om the above analysis result, this can be get this follo wing:

1. This can get the good analysis result by using the CAE.
2. From analysis result, this can be found that the differential result can be get as the differential forming parameter.
3. In the deformation shape, the effect of the punching velocity is very clear. As the punching time is smaller than 0.2s, the flange of the circular cup appers.
4. In the thickness of the forming product, the effect of the punching velocity is very clear.
5. When the stain ratio of the blank material is great, the thickness of the circular cup is thin. When the punching time is greater, the thickness of the circular cup become big.

Abstract: A hierarchical memetic algorithm (MA) is proposed for the path planning of swarm robots. The proposed algorithm consists of a global path planner (GPP) and a local motion planner (LMP). The GPP plans a trajectory within the Voronoi diagram (VD) of the free space. An MA with a non-random initial population plans a series of configurations along the path given by the former stage. The MA locally adjusts the robot positions to search for better fitness along the gradient direction of the distance between swarm robots and intermediate goals (IGs). Once the optimal configuration is obtained, the best chromosomes are reserved as the initial population for the next generation. Since the proposed MA has a non-random initial population and local searching, it is more efficient and the planned path is faster than the traditional genetic algorithm (GA).

Keywords: memetic algorithm, genetic algorithm, hierarchical, local motion planner, swarm robots, Voronoi diagram

1 INTRODUCTION

In recent years, an increasing number of multi-robot systems have been proposed. Swarm robotics [1][2][3] is an approach for coordinating multi-robot systems. The swarm shares information about the environment and individual members interact with each other. Cooperative behavior may be used to complete a task. Most studies on robot swarm cooperation have focused on formation control, which refers to the task of controlling a group of mobile robots to follow a predefined path or trajectory while maintaining the desired formation pattern. Numerous methods have been proposed for formation control, which can be roughly categorized into four basic approaches, namely behavioral, virtual structure, leader-follower, and potential field.

In virtual structure approaches, the robot swarm is considered as a single rigid robot. A rigid geometric relationship among group members is maintained [4]. Therefore, the path planning of a robot swarm can be simplified as the path planning of a rigid robot. The advantage of the virtual structure approach is ease of implementation. However, the approach has low path planning flexibility.

For behavior-based approaches, several desired behaviors, i.e., movement towards the goal, obstacle avoidance, collision avoidance, and keeping formation, are defined for each robot to create its trajectory. The planning of robots can be done concurrently. Since each robot is considered individually, it is difficult to guarantee precise formation control.

In leader-follower approaches, the ability of a robot depends on its job. In the swarm, one or a few robots act as leaders which move along predetermined trajectories and other robots in the group follow while maintaining the desired relative position with respect to the leader. Generally, leader-follower-based robot systems are implemented as centralized systems. However, most leader-follower approaches are not complete algorithms because the safe path, that which gives a robot sufficient distance from obstacles and other robots is difficult to derive.

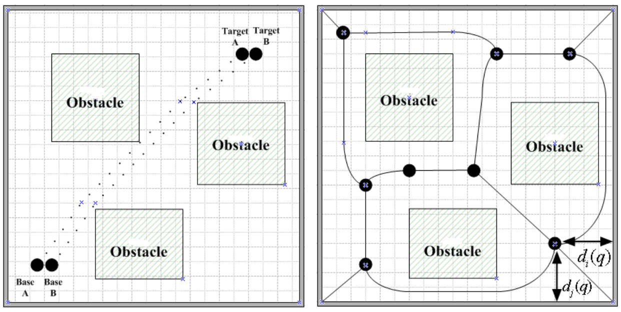
In order to obtain a safe path for swarm robots, the present paper proposes a hierarchical path planning algorithm. The proposed algorithm consists of a global path planner (GPP) and a local motion planner (LMP).

The rest of this paper is organized as follows. The GPP and the LMP of the proposed hierarchical path planning algorithm for swarm robots are introduced in Section 2 and 3, respectively. In Section 4, simulation results are given. Finally, conclusions and suggestions for future work are given in Section 5.

2 GLOBAL PATH PLANNING

Global path planning can be considered as a planning problem for a point robot. In Fig. 1(a), a swarm of two robots moves to the goal configuration; the planned path is close to obstacles [5]. In order to obtain a safe path, a Voronoi diagram (VD) is adopted since it is easy to implement and has been shown to work well in many cases. There are many variants of VD [6][7][8]. In the present study, a VD consisting of line segments is considered. A VD shows a set of free points which are equidistant to two closest obstacles. In [9], the VD was constructed using

Voronoi vertices and Voronoi arcs. The Voronoi vertices are points equidistant to the closest features of three (or more) polygons. The vertices are connected by continuous chains of Voronoi arcs. An arc may be equidistant to two closest vertices or to two closest obstacle edges or to an obstacle vertex and an obstacle edge.

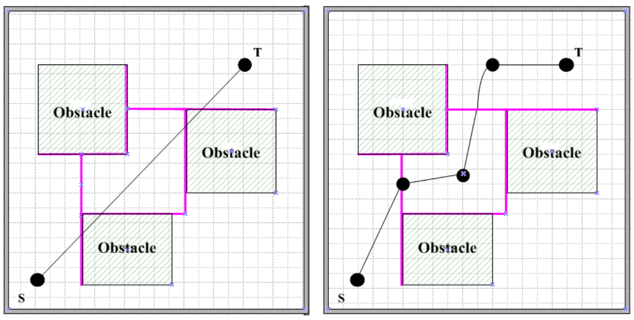


(a) (b)

Fig. 1. (a) Simple path of moving straight from start to goal. (b) Voronoi graph for Fig. 1(a).

As shown in Fig. 1(b), all edges and vertices of obstacles are used to construct the VD. The computation complexity is proportional to the total number of features of obstacles. Only a partial VD is used for global path planning for swarm robots. An efficient approach for constructing the partial VD is proposed in this paper.

Unlike approaches which construct the whole Voronoi diagram of the free space and then search for the path, the proposed scheme constructs a partial VD of the region of interest. As shown in Fig. 2(a), the proposed approach explores Voronoi vertices constructed from obstacles which are near the straight line from start to goal. Then, the Voronoi vertices are connected by a Voronoi arc which is formed by the nearest edges along the line, as shown in Fig. 2(b). The approach significantly reduces the computation complexity. Since a VD is the medial axis of the free space, the global path derived using a VD for swarm robots is the safest path.



(a) (b)

Fig. 2. The Voronoi vertices are connected by a Voronoi arc which is formed by the nearest edges along the line.

3 LOCAL MOTION PLANNING

The global path obtained in the previous stage can be sampled as a series of positions, denoted as (q_1, q_2, q_3,…,q_n), which the center of the swarm robots should follow. These positions can be considered as the intermediate goals (IGs). For each position q_i, the memetic algorithm (MA)-based local motion planner plans a set of configurations for the robots to which the center of swarm is fixed at point, q_i. The proposed memetic algorithm is:

Potential-based Memetic Algorithm
Begin
***i* = 1; /* Initialize the first intermediate goal */**
***t* = 0; /* Initialize the evolutionary generations */**
  Randomly generate an initial population *Pi (t)*;
  fitness(*Pi(t)*);
    repeat until (reach the final goal *qn*) Do
    Pi+1(t)= Pi(t);
      repeat until (reach the intermediate goal *qi*)
      Do
        select *Pi(t+l)* from *Pi(t)*;
        crossover(*Pi(t+l)*);
        mutate (*Pi(t+l)*);
        fitness(*Pi(t+l)*);
        apply FT Local Search to *Pi(t+l)*
        t = t +1;
      end
    i= i +1;
  end
End

To apply an MA search for the optimal configurations, the coordinates of the robot swarm are encoded into one chromosome. The configuration of k robots is defined as their displacements, denoted as ((x_1, y_1), (x_2, y_2) ,…,(x_k, y_k)).

3.1 Initialization

The population, $P_1(0)$, of the first intermediate goal is generated randomly. The initial populations, ($P_i(0)$, i >1), of other intermediate goals are partially obtained from the last generation of the preceding intermediate goal and are partially randomly generated. Since these initial populations are eugenic and inherit from ancestors, the evolution time is reduced.

3.2 Natural selection

Natural selection is a genetic operator that chooses a chromosome from the current generation's population for inclusion in the next generation's population. Before making it into the next generation's population, selected chromosomes may undergo crossover and/or mutation (depending upon the probability of crossover and mutation) in which case the offspring chromosome(s) are actually the ones that make it into the next generation's population.

The aim of selection is to preserve optimal chromosomes and abandon suboptimal ones. In this study, the top percent scheme is adopted. The top 10 percent of the population is reserved as the next generation's population and the others are selected randomly.

3.3 Crossover and mutation operators

Selection alone cannot generate any new chromosomes for the population. The reproduction operators, crossover and mutation, are used to generate new offspring for the next generation. Crossover is performed between two selected chromosomes, called parents, by exchanging parts of their genomes to form two new chromosomes, called offspring. The most popular types of crossover operations are one-point, two-point, uniform, and blending. In this paper, since the *i-th* gene of a chromosome represents the position of robot *i*, the crossover operator exchanges similarly positioned genes of a pair of chromosomes.

For the mutation operator, an arbitrary bit in a genetic sequence is changed with a probability. The purpose of mutation in evolutionary algorithm (EA) is as a genetic operator used to maintain genetic diversity from one generation of a population of chromosomes to the next while attempting to avoid local minima.

3.4 Fitness function

Generally, selection is conducted according to the fitness of every chromosome, where the fitness evaluation of the GA is an objective function for chromosomes.

The fitness function can be rewritten [10] as:

$$V_q = f_{collide}(q)\times\left(\sum_{i=1}^{k} D^i{}_q + \rho U_{rep}\left(q\right)+\frac{1}{2}k\sum_{i=1}^{n} X_i^2\right) \tag{1}$$

where $D^i{}_q$ is the distance between robot i and the intermediate goal of the swarm center, q. The ρ is a constant and $U_{rep}(q)$ is the repulsive potential of swarm robots from obstacles. When a configuration collides with obstacles, the collision function, $f_{collide}(q)$, is equal to V_{max}, which is a penalty; otherwise, it is equal to 1. The potential $U_{rep}(q)$ can be calculated analytically as:

$$U_{rep}(q) = \sum_{i=1}^{k} U^i_{rep}(q) \tag{2}$$

where $U^i{}_{rep}(q)$ is the repulsive potential of robot i from the nearest obstacle.

$$U^i{}_{rep}(p) = \begin{cases} \frac{1}{2}\eta\left(\frac{1}{Dist(p)} - \frac{1}{Q^*}\right)^2, & Dist(p)\le Q^* \\ 0, & Dist(p) > Q^* \end{cases} \tag{3}$$

where Q^* is the minimum distance from obstacles and η is a gain of the repulsive gradient. *Disp (i)* is the distance between robot *i* and the closest obstacle. For swarm cohesion, a robot in the swarm should keep a certain distance from the swarm center and not stray far from other robots. In the proposed algorithm, a spring function is adopted as a repulsive/attractive potential function in the fitness function. In (1), X_i^2 is the difference between the distance between robot i and the nearest neighbor robot and the safe distance which should be kept between robots.

3.5 Local search of memetic algorithm using gradient between swarm robots and IGs

Conventional genetic algorithms (CGAs) don't have a fine-tuning (FT) process to get closer to optimal solutions. Unlike CGAs, an MA is an EA with a local search process to refine individuals. In this paper, the local research scheme is used to adjust the position of the center of the robot swarm moving toward the IG. The top 20 percent of chromosomes are reserved for the next generation. The chromosomes are fine-tuned before the next evolution. Consider the position of the swarm center of a chromosome as $R^c = (R^c_x, R^c_y)$ and the current intermediate goal as $IG_i = (IG_{ix}, IG_{iy})$. The best movement direction is defined as:

$$\vec{p} = IG_i - R^c = \left(IG_{ix} - R^c_x, IG_{iy} - R^c_y\right) \tag{4}$$

Therefore, the fine-tuning procedure of the genes of the chromosomes is defined as:

$$gene_i = \begin{cases} gene_i + p_i, & if \quad gene_i + p_i \le gene_{\max} \\ gene_{\max}, & if \quad gene_i + p_i > gene_{\max} \end{cases} \tag{5}$$

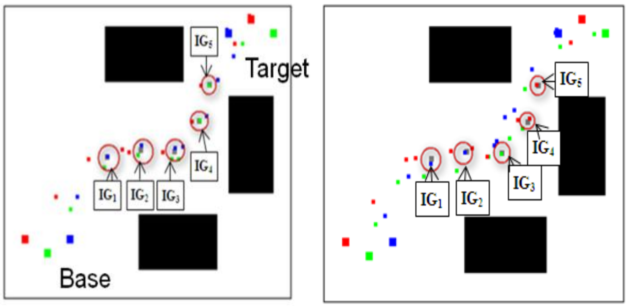
4 SIMULATION RESULTS

The proposed algorithm consists of the GPP and the LMP. The former was implemented using a modified Voronoi algorithm. The population was 100 and the maximum number of generations was set to 120. The probabilities of mutation and crossover were both 10%. The safe distances, *l* and Q^*, were set to 10 pixels and 2 pixels, respectively. The range of the genes was 30 to -30.

4.1 Swarm robot path planning by genetic algorithm and memetic algorithm

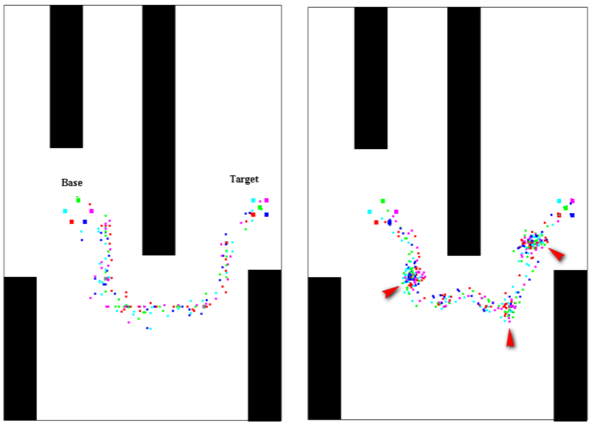
Case 1

The 3-robot swarm is shown in Fig. 3(a). There are 5 IGs and 3 obstacles in this case. The simulation took 8.609 seconds to plan a 10-configuration collision-free path. A similar simulation of the CGA is shown in Fig. 3(b). The CGA took 10.11 seconds to plan a 12-configuration path. The proposed algorithm is faster and more efficient.



(a) (b)

Fig. 3. Three trajectories for 3-robot swarm example. Motion planning obtained using (a) MA and (b) CGA.



(a) (b)

Fig. 4. Five trajectories for 5-robot swarm example. Motion planning obtained using (a) MA and (b) CGA.

Case 2

The simulation of a 5-robot swarm is shown in Fig. 4(a). The planned path is smooth. There are 4 IGs and 4 obstacles in this case. The simulation took 56.094 seconds to plan a 39-configuration collision-free path. A similar simulation of the CGA is shown in Fig. 4(b). The simulation took 88.563 seconds to plan a 59-configuration path.

5 CONCLUSION

The proposed MA has a non-random initial population and fine-tuning based local searching, which make it more efficient and faster than the traditional CGA. The proposed hierarchical approach avoids becoming trapped in local minima. The path planning problem for swarm robots was considered for 2-D workspaces. The proposed algorithm can be extended to 3-D workspaces without significant modification. For example, the gene of a robot can be represented as (x, y, z). In future works, we will focus on smoothing the planned paths to reduce redundant movements. With this modification, the proposed algorithm should be more efficient.

Abstract: A speed correction circuit is proposed in this paper, the speed measurement is based on Hall sensor signal. Brushless DC (BLDC) motors are more and more popular, and the Hall sensors are usually built in for commutation. The Hall sensors and poles of the rotor are supposed to be placed in uniform distance and angle, then Hall sensor signal feedbacks are also used to measure motor speed. However, there is misalignment, and what will cause the error of measurement. A method is discussed to estimate the error of misalignment, and the inaccuracy could be corrected by the proposed circuit. This circuit is based on the hardware description language and implemented in FPGA, and then the synthesizing simulation results are presented to prove this circuit is workable.

Keywords: Hall sensor, FPGA, BLDC Motor, misalignment correction.

1 INTRODUCTION

The speed measurement of BLDC motors is usually based on the Hall sensor signals, but there are some errors have to be suppressed. Due to its high power density, easy maintenance and simple driving, BLDC motors are more popular. Although, an accurate rotor encoder is not necessary, to decide the commutation, the rotor position information is still important, and Hall sensors are a regular solution. Basically, the Hall sensor signal feedbacks could be used to measure motor speed, Hall sensors are supposed on uniform distance and the angles of rotor poles are considered as equal. However, there are misalignments for placement of Hall sensors and poles in consumer motors, and the inaccuracy will cause the speed measurement error. For example, for a four poles three phase BLDC motor, the Hall sensor should feedback a new signal in every 30 degree rotation, but the misalignment will cause that the feedback angle is not exactly 30 degree, and include the measurement error. A typical real experimental example is shown in Fig. 1, a motor runs in steady state and MCU clock is captured to calculate motor speed when Hall sensor signal is updated. Here, vertical axis is clock count between every two Hall sensor feedbacks and the waveform is similar to a periodic signal in 12Hz, then period should be caused by the misalignment. Author discussed this phenomenon in Chung-Wen Hung [1], and proposed dynamic moving average filter to get a trade-off between stable and fast response. Samoylenko [2] also proposed different filters and compared the performances. Chung-Wen Hung [1] and N. Samoylenko[2] treated the variation of Hall sensor feedback intervals caused by unbalance placement of Hall sensors and poles as noise, then designed a suitable filter to get correct signal. Neither required hardware circuit, but both took CPU calculation resource and induced phase delay.

P.B. Beccue [3] discussed a compensation method that implemented a Hall effect position observer to estimate the rotor position. This method used the angle and axes to define the rotor position and based on those to build a table. And it used the table to compute the error of the rotor angle and compensate the phase of the rotor.

S.-Y. Kim [4] intro- deuced a vector-tracking observer that used a feed forward input of the average rotor speed to calculate the rotor speed. And this observer is utilized to obtain the phase detector, which is used to estimate the angle error of the rotor. Using the observer to estimate the back-EMF and compare with the reference back-EMF to define the position and implement the compensation. Anno Yoo [5] used the d-q axis to define the phase and current, and utilized the dual observer to estimate rotor speed and position, respectively. Based on the rotor position to obtain the error value and implemented the compensation algorithm. Kuang-Yao Cheng [6] implemented a mixed mode integrated circuit (IC) of the sensorless commutation for BLDC motor. This circuit utilized the back-EMF and zero-crossing point to detect the phase error. Compensation the phase error by the rotor speed estimation depended on the changing phase lag due to the low-pass filtering of the terminal voltages. The said compensation methods have to implement the complex observer and the other Hall sensor detection circuit to perform the estimator.

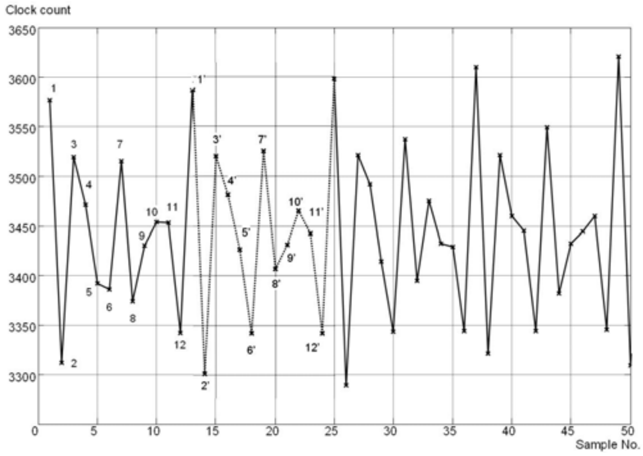

Fig. 1. The intervals of the Hall sensor updating

This paper presents a speed correction circuit for a HALL sensor signal base. This circuit is implemented in hardware description language and on filed programming gate array (FPGA), and it could calibrate the speed measurement what is caused by the misalignment of the poles of the rotor and Hall sensors. A method is discussed to estimate the error of misalignment, and the circuit structure will be introduced. Then, the synthesizing simulation results are presented to prove this circuit is workable

2 A CORRECTION OF HALL SENSOR SIGN AL BASE SPEED MEASUREMENT

Normally, the Hall sensor feedback will be used to measure motor speed if Hall sensors are build-in for commutation, and the sequence is depend on rotate direction as shown in Fig. 2. The change of the Hall sensor signal means that the rotor rotated 60 degree for 2-pole, or 60 degree for 4-pole motor. Next, the time interval between two signal changing could be measured to calculate motor speed. The speed correction method and circuit are also depended on the information of Hall sensor signals and time intervals.

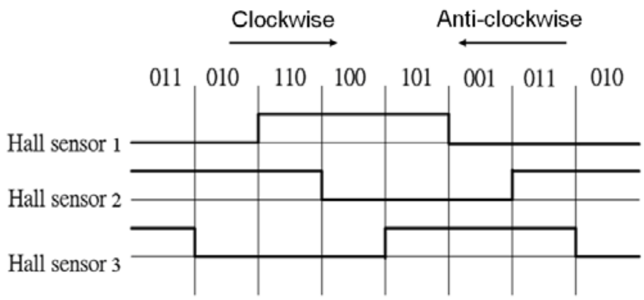

Fig. 2. The intervals of the Hall sensor updating

2.1 A calibration method of Hall sensor signal base speed measurement

A calibration method [1] is discussed to get more accurate speed estimation based on Hall sensors. To get the error ration of every sector caused by misalignments of Hall sensors and rotor poles, the motor could be driven by another constant speed motor or fixed PWM duty to free, and get every sectors average speed error ratios. The correction of speed would be based on these error ratios. As shown in Fig. 3, a zoom figure of Fig. 2, and the average clock count of a 3-phase 4-pole BLDC motor is about 3390, and the clock count samples is corrected by the error ratio and shows more accurate results. Note, in Fig. 3, the samples is a periodic signal with the period of twelve samples caused by the sensor and pole misalignments, however, the correction is indexed in only 6 Hall sensor signal and only 6 correction ratio could be used. The R.M.S. of error is reduced less than 40% of original's. If this method is used in a 2 pole BLDC motor, the effect should be better.

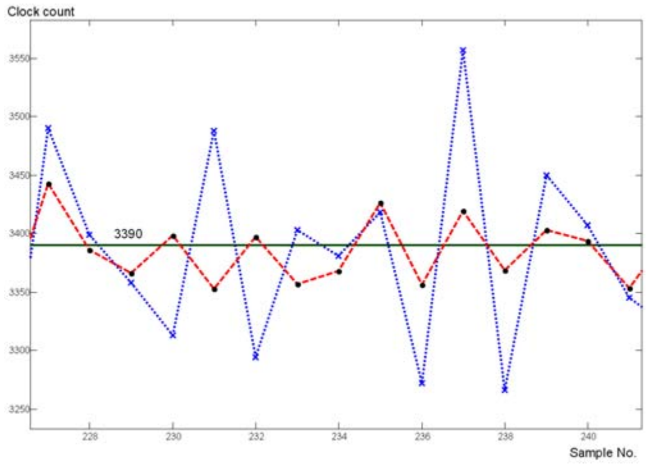

Fig. 3. The average (solid), sampling (dot) and correction (dash) clock count

2.2 A Correction circuit of Hall sensor signal base s peed measurement

Based on above discussion, a correction circuit is proposed to implement the algorithm. The system block diagram is shown in Fig. 4: there are three one-bit inputs for Hall sensor signals, six register inputs for correction ratios and clock; one output is the interrupt to inform the controller to read the new 16 bits corrected time interval and update the speed calculation.

The clock source is connected to the controller or MCU system clock, it is much faster than Hall sensor changing, and then the clock could be used to latch the Hall sensor signals. A previous Hall sensor capture is applied to latch the last the Hall sensor status, and the previous and current Hall sensor statuses are send to a compare block. When the Hall signals in two capture registers are different, an interrupt signal is declared to indicate that the rotor already rotes over a new sector, 30 or 60 degree, and the controller could get new speed measurement and change the commutation status. This interrupt signal is also used to latch the content of the clock counter into correction block, which counter is used to accumulate the clock in a sector, then the counter is reset to zero for next new sector. The signal of the previous Hall sensor capture register is employed to index the corresponding correction ratio from the six correction registers, which contents are got based on correction method what is discussed in last section. Note, to use the previous Hall sensor signal to select correction register is better than the current signal, and it could ignore the direction of a motor because it is the previous sector could be corrected. If the current Hall sensor signal is used to index, the direction should be consider in the structure and circuit would be more complicated.

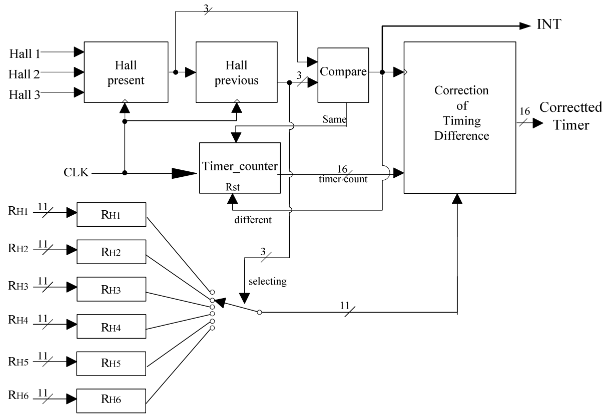

Fig. 4. The block diagram of HALL sensor signal base speed measurement

3 Hardware Implementation and Simulation Results

3.1 Hardware implementation

The structure is implemented in verilog HDL and on FPGA, Altera Cyclone II EP2C70: 176 logic elements, 63 registers and 2 embedded multiplier 9-bit elements are used. The bit width of timer counter is set to 16 bits, what is depend on clock source and lowest speed motor, means the clock number between two Hall sensor changes, and the correction ratio registers are set to 11 bits for the fraction format.

For reduction of circuit the complexity, the number format should be fixed pointed. The number correction ration is in the quasi positive I1Q10 mode, due to that the error ranges are about 15% which means correction ration is a fraction number from 0.85 to 1.15. Every correction number is multiplied with 1024 before written into the register. When interrupt occurs, the product of clock counting and correction ratio is right shifted by 10 bits, then fraction effect is achieved.

Table 1. Correction ratios

Hall sensor Index	Correction Ratio
100	1.00 = 10000000000 B
110	0.95 = 01111001100 B
010	1.05 = 10000110011 B
011	1.10 = 10001100110 B
001	0.97 = 01111000011 B
101	0.93 = 01101110101 B

3.2 Simulation Results

The simulation results are shown in this section to presented workability of the proposed structure. The values of correction ratios are list in table 1, what includes Hall sensor index, fraction mode ratios and I1Q10 mode ratios. The function is verified by Fig. 5. The clock is set on 100M Hz, 10 nS, and Hall sensor signal changes every 511 clock cycles. The output 485 is the product of 511 and correct ratio of a110, because the correction ration is indexed by previous Hall sensor signal "110", which ration is 0.95. Next out put is 511, due to previous index is 100. The simulation result shows the structure works well.

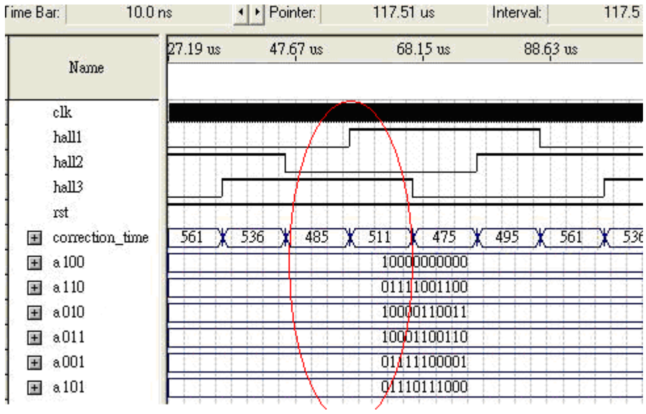

Fig. 5. The simulation results of fixed Hall sensor intervals

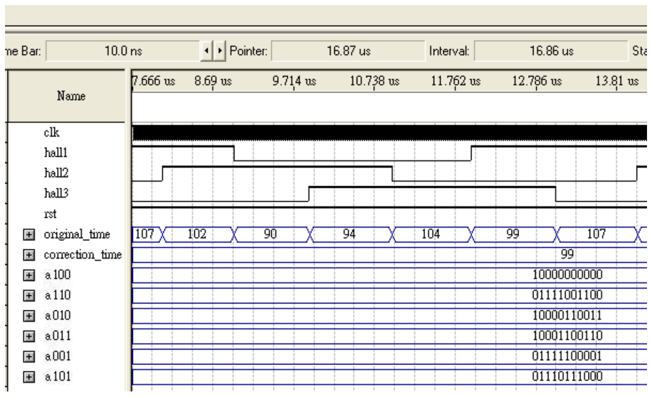

Fig. 6. The simulation results of variable Hall sensor intervals of misalignment

To get more detail simulation result, the Hall sensor intervals are set similar to real misalignments, and the counter will catch the different intervals corresponded with Hall sensor sectors. The result is present in Fig. 6, the timer counter before correction and correction output are probed. All of outputs are 99 cycles; no matter counter is capture 107 or 90. For example, when the content of counter is 90, the previous Hall sensor signal is "011", which indicates that correction ration is 1.10, and the corrected output is 99 cycles. Again, for the 107 output, the previous index is "101" and the ration is 0.93, so, the output should be 99. Note, to get more accurate result, 512 is added to product before shift to perform rounding.

4 CONCLUSION

A correction circuit of speed measurement what is based on Hall sensor signals for BLDC motors is proposed this paper. The Hall sensors are originally built in for commutation in BLDC motors, and normally there are misalignments in the placement of sensors and rotor poles in consumer motors due to cost issue. To get accurate speed, FPGA is used to implement a correction circuit, the correction ratios are prepared in the calibration processor, then a corresponding ratio what is index previous Hall sensor signal multiplier with the content of timer counter what is rest every Hall sensor changes. The simulation results show the structure is work successfully, and could provide more accurate speed measurement. Moreover, the resource requirement of the circuit is few and could be implemented easily to improve the performance of a BLDC motor system.

Abstract: An image sensor based virtual mouse with fingertip detection in face mark (FDIFM) function is proposed in this paper. As the image sensors or webcams are more and more cheap and popular, the algorithms are developed to detect the fingertip location and its motions. The motion information could be used to define the mouse functions and perform a virtual mouse. When the fingertip locates in the face area, it is difficult to detected, due to similar skin colors. The FDIFM algorithm is developed to handle this exceptional situation, using the red component image of the face area, the fingertip could be detected successfully. In this paper, the algorithms and simulation results are described, and the experimental results are also presented to verify the virtual mouse workable.

Keywords: virtual mouse, image sensor, webcam, fingertip detection in face mask (FDIFM).

1 INTRODUCTION

Improving the efficiency of human computer interface (HCI) devices, such as keyboard and mouse, has been an important issue for a long time. Due to the development of new technologies and cost down, there are a lot of new HCI devices and methods are proposed, such as touch panel and its user friendly control. However, with the price reduction and popularity of a digital image capture sensor, another HCI technology which is based on image processing and detection made progress, and the Microsoft's Kinect is a good example[1], but the function focuses on TV games. Chen [2] proposed an interface method which is based on hand-gesture and facial expression, and Qzawa [3] utilized the data glove to control a robotic hand. These researches tacked a lot of CPU resource or needed some extra equipment.

A webcam based virtual mouse is proposed in this paper. As the price reduction of CMOS image sensors and the popularity of social communication software, the webcam became a regular peripheral. Based on such a low cost webcam, the simplified algorithms are development to perform the functions of a traditional mouse in this research. First, every single image frame is captured and processed with several operations, which include the background removal, the skin color detection, the background updating, and the fingertip detection. Then the fingertips are tracked, and the traveling direction and distance are measured. Furthermore, when the fingertip overlaps the user's face region, a special algorithm is proposed to detect. Finally, the specific fingertip motions are defined as to the corresponding functions of the virtual mouse. The algorithm will be discussed as following, and the experimental results also will be presented.

2 The algorithm

The algorithm includes several procedures: background removal, skin detection, hand detection, connected regions labeling, hand region extraction, fingertip detection, fingertip motion tracking, and fingertip extracting from overlapping facial region. The details and operations are described as following:

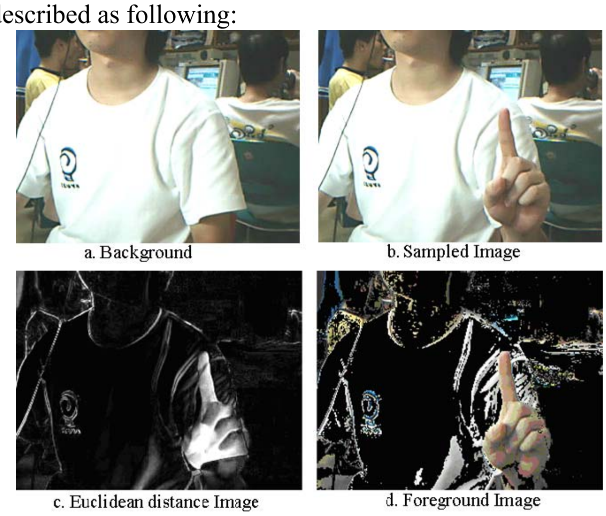

Fig. 1 The background, sampled and background-removed Images

2.1 Background Removal

First, take an image in advance as background, as shown in Fig. 1.a; then calculate the RGB Euclidean distance between sampled image, shown in Fig. 1.b, and background for every pixels as (1), Y. Cui [4]:

$$A = \sqrt{(I_{CR}(x,y) - I_{BR}(x,y))^2 + (I_{CG}(x,y) - I_{BG}(x,y))^2 + (I_{CB}(x,y) - I_{BB}(x,y))^2} \quad (1)$$

Here, I is the brightness, C and B show current sampled image and background, respectively, and R, G and B indicate red, green and blue, respectively. If the Euclidean distance of a pixel is greater than threshold, it means that this pixel is not similar to the background and will be retained. Finally, the background is removed, and the foreground is obtained, as shown in Fig. 1.c.

2.2 Skin Detection

Based on the database proposed by Maricor Sorian [5], [6], the skin detection processing is used to detect the skin region on the previous foreground image. The normalization values of red and green are determined from (2) and (3), respectively.

$$r = \frac{R}{R+G+B} \quad (2)$$

$$g = \frac{G}{R+G+B} \quad (3)$$

If the r and g values of a pixel are located in the skin region as shown in Fig. 2, in which the region is bound in a pair of 2nd order functions as (4)~(7), the pixel will be treated as the skin.

$$f_1(r) = -1.3767r^2 + 1.0743r + 0.1452 \quad (4)$$

$$f_2(r) = -0.776r^2 + 0.5601r + 0.1766 \quad (5)$$

$$W = (r - 0.33)^2 + (g - 0.33)^2 \quad (6)$$

$$s = \begin{cases} 1, & \text{if}\,(g < f_1(r))\,\&\,(g > f_2(r))\,\&\,(r > 0.2) \\ & \&\,(r < 0.6)\,\&\,(W > 0.0004) \\ 0, & \text{otherwise} \end{cases} \quad (7)$$

The S=1 marks the pixel as the skin. The result is shown in Fig. 3.

Fig. 3 The binary image of skin detection.

2.3 Hand Detection

The morphological erosion and dilation operators are used to detect the hand region in the above binary image, H. J. Lee [7]. The erosion is utilized to eliminate the small noise area, and then the dilation operation is applied to reconstruct the hand region which is shrunken and broken by the previous erosion operator. The result image of erosion and dilation operators is shown in Fig. 4, and the hand region is successfully detected with some noise blocks.

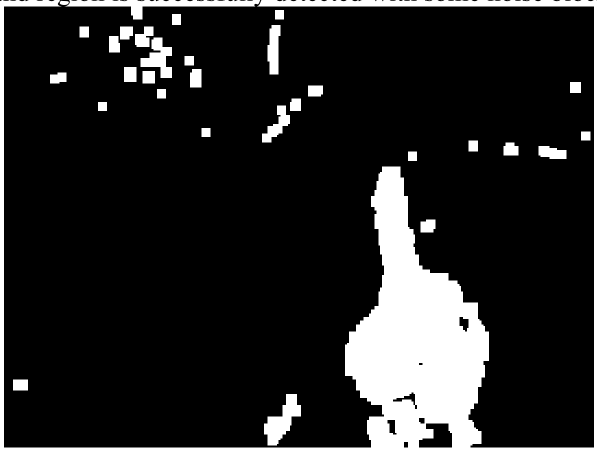

Fig. 4 The result image of hand detection.

2.4 Connected regions labeling

The result image of erosion and dilation operators would contain only few bigger skin regions. They will be labeled for every connected region for the calculation of the region size.

2.5 Hand Region Extraction

For all the connected skin labeled region, their sizes of regions are calculated. The maximum is treated as the hand region, because the user's hand is supposed to be closest to the webcam, and the other region is supposed to be noise or the region closed to the skin color. The extraction result is shown in Fig. 5, it proves that the extraction algorithm is workable.

Fig. 5 The extracted hand region.

2.6 Fingertip Detection

When the hand region is extracted, the edge detection is next processed. The Prewitt algorithm is employed to detect the edge boundary, and then the contour will be more obvious, D. Wang [8]. Next, the contour search criteria are proposed, H. Soltanian-Zadeh [9]: the lowest and leftest point of the hand region edge is the starting point; and the left-to-right and bottom-to-top search criteria are used to find the next connected pixel of edge; then the searching is repeated until back to the starting point.

When the contour of a hand is detected, the pixels are compared one-by-one to find the top point. Because the default command finger is fixed to the forefinger, and this point is treated as a candidate fingertip point. However, some other gestures would lead to a wrong detection.

To confirm this point is the fingertip point and filter out wrong hand gestures, a checking processing is necessary. Fist, based on this point, the next 10-points pair and next 15-points pair are located on the contour by forward and backward searching; then, the angles of a candidate fingertip point with the next 10-points pair and next 15-points are calculated. Based on the characteristic of a forefinger, the former angle should be bigger than latter's. Otherwise, the image will be treated as an invalid image. The fingertip detection result is shown in Fig. 6.

2.7 Fingertip Motion Tracking

If a fingertip is marked, the fingertip is tracked and the traveling direction and distance are measured. Then the direction and distance will be used to define the mouse action, like a left-key click. The Lucas-Kanade optical flow method is used to track the motions, which will be applied to measure the direction and distance, S. N. Tamgade [10].

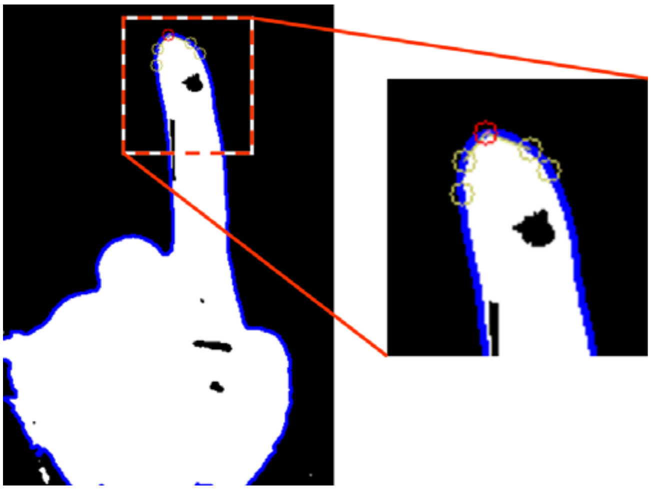

Fig. 6 The fingertip detection result.

2.8 Fingertip Motion Tracking

In normal cases, the mentioned procedures could successfully detect the fingertip and track the motions. However, some errors happen when the finger locates in the face region, because the face and finger have similar colors and the gesture region will be lost in above methods. The FDIFM algorithm is proposed to handle such situation.

First, the face mask sensing area is defined, which is based on a rectangular face mask with extended outward 50 pixels. It is used to decide that processing should fast switch to the FDIFM procedure. When the fingertip moves into the mask area, the mask area is extracted, names region of interest (ROI). Next, the negative image of the ROI is calculated, as shown in Fig. 7.a. Based on the red component of ROI negative image, the fingertip will be found, due to it is a obvious dark region in face area as shown in Fig. 7.b. Finally, the grayscale image is transformed into a binary image, and the fingertip will be detected more easily, as shown in Fig. 7.c.

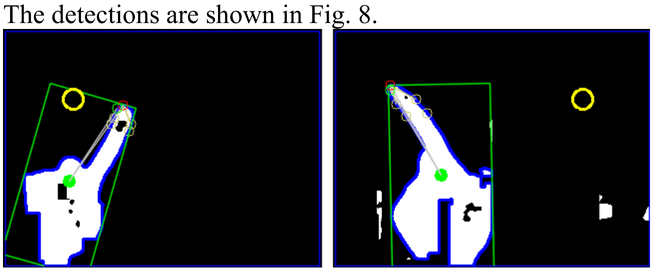
a. Negative image b. Red component image c. Binary image

Fig. 7 The processed images in FDIFM algorithm.

2.8 The function definition of the virtual mouse

When the fingertip and its motion are tracking successfully, the functions of the virtual mouse could be defined by the motion of fingertip, such as the double click of fingertip indicates a click action of a mouse, and the angles of fingertips could be used to define other functions of a mouse.

To differentiate between the vertical movement and the click action, the mouse click should be defined as double click of the fingertip. If the locations of fingertip in several consecutive images show fingertip motion is in "up-down-up-down" moving, the mouse click message will be send to the PC system. Similarly, the angle of the line from the center of the minimal rectangular to the fingertip could be measurement, and then the clockwise and counterclockwise angles could be used defined as other function of a mouse. The detections are shown in Fig. 8.



a.The fingertip move clockwise b. The fingertip moves counterclockwise

Fig. 8 The images of clockwise and counterclockwise motions detection.

3 Experimental Results

The above algorithms are developed in desktop or notebook personal computers. So the experiments are implemented on following specifications: the hardware specification is Intel Core 2 Quad 2.4GHz CPU with 3 GB DDR2 DRAM; software is programmed under Microsoft Visual Studio 2008 and program runs in Windows 7 professional 32bit OS; the image is captured by Logitech QuickCam which is set to 24bit RGB colors, 640×480 resolution, and 12 frames per second. The program occupies about 28% of CPU resource.

The fingertip detection is the base of the proposed algorithm, and the experimental result is shown in Table. 1, the average success rate is about 94.4%.

Table. 1 The correct fingertip detection rate

	Total frame	Correct fingertip frame	Success rate
User 1	600	575	95.8%
User 2	600	574	95.6%
User 3	600	540	90.0%
User 4	600	565	94.2%

The experimental results of the left-key click function for a virtual mouse are shown in Table. 2. Here, the rates of the User 1 and 2 are lower, which should be caused from too fast clicks. The average successful rate is about 83.5%. The other two functional experiments for clockwise- and counterclockwise-motion detections are respectively listed in Tables 3 and 4, in which the successful rates are about 95% and 100%, respectively. Due to distinct shapes, the detection rates are higher than other functions.

Table. 2 The successful click detection ratio

	Total frame	Correct fingertip frame	Success rate
User 1	20	15	75%

4 CONCLUSION

An image sensor based virtual mouse including the FDIFM algorithm is proposed in this paper. Based on popular image sensors or webcams, the proposed algorithms could efficiently detect the fingertip locations and motions, which information could be used to replace the mouse and act as the virtual mouse. The FDIFM algorithm is also developed to handle the exceptional situation that the fingertip locates in the facial region. From the experimental results, the virtual mouse is workable, and the algorithms could be extended to other new HCI devices.

Abstract: The objective of this study is going to develop a tri-rotor flying robot, which adopts the Y-shaped three-rotor structure. In order to balance the yaw torque produced by the three rotors, it installs the RC servo motor and linkage on the tail axis, so as to improve the angle of the rolling axis of the tail motor. Moreover, through the torque generated by the horizontal component of the lift from the inclined motor on the tail axis, it balances the yaw torque of the three rotors.

The dynamic equations of the tri-rotor flying robot were determined in this paper. The relationship between motor thrust, angular acceleration and voltage input were also studied in this research. In order to study the effect of control parameters on the flight stability completely, this study develops a universal stability experimental platform to help tuning the control parameters safely. Based on this, the tri-rotor flying robot can rapidly change flying gesture and avoid oscillation.

Finally, we made some indoor and outdoor flight tests. From the experimental results, the tri-rotor flying robot can fly and hover stably in the sky.

Keywords: tri-rotor, tricopter, flying robot, dynamic equations, stability experiment, hover

I. INTRODUCTION

The unmanned aerial vehicles (UAV) are widely applied in aerial photography, marine or air pollution detection, aerial security surveillance and disaster response. The lifting force of a rotorcraft is mainly the air reaction force produced by the rolling of one or multiple rotors. However, when the rotor provides lift, the fuselage will also tend to roll towards the opposite direction due to the effect of reaction torque. For the multi- rotor helicopter, it mostly uses the opposite rolling between the rotors to balance the effect of the reaction torque.

Fig. 1 is the real view of the tri-rotor flying robot. The yaw control in this study adopts the variable inclination angle mechanism of the back rotor. The rolling axis of the back rotor uses the RC servo motor and the linkage mechanism to control the variable declination angle. The rolling axis is fixed by using two pillow block ball bearings. Yaw angular speed is detected by a MEMS (Micro Electro Mechanical Systems) based Gyro, which is also used to adjust the inclination angle of the rolling axis of the back propeller. These are then taken as the compensation of the yaw torque produced by the three rotors.

Fig. 1 Real view of the tri-rotor flying robot

II. FLIGHT PRINCIPLE OF THE Y-SHAPED TRI-ROTOR FLYING ROBOT

The tri-rotor flying robot in this study adopts the Y-shaped three-rotor structure (as shown in Fig. 2). The three rotors are divided into two right-handed and one left-handed, one right-handed and two left-handed, or three right-handed. In order to balance the yaw torque produced by the three rotors, it installs the RC servo motor and linkage structure on the tail axis, so as to improve the angle of the rolling axis of the motor on the tail axis. Moreover, through the torque generated by the horizontal component of the lift from the inclined motor (motor 3) on the tail axis, it balances the yaw torque of the three rotors.

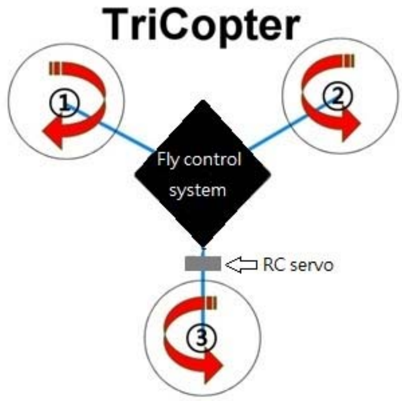

Fig. 2 Rolling directions of the propellers of the Y-shaped tri-rotor flying robot

Below will introduce the flight principle of the tri-rotor flying robot:

- *Fly forwards:*

When flying forwards, motor 1and 2 must decelerate, while motor 3 on the tail axis must accelerate. As a result, the fuselage of the tricopter is inclined forwards, so it flies towards the same direction. On the contrary, when flying backwards, motor 1and 2 must accelerate, while motor 3 must decelerate.

- *Fly to the right direction:*

When the tri-rotor flying robot flies to the right direction, motor 1 on the left side must accelerate, while motor 2 on the right side must decelerate, so as to allow the fuselage incline to the right side and make the tricopter fly to the right direction.

- *Clockwise yaw*

When the tri-rotor flying robot yaws in the clockwise direction, it needs to use the RC servo motor and linkage to drive the propeller of the motor 3 inclined in the left side. When the motor 3 rolls, it will generate the clockwise yaw torque, so as to make the tri-rotor flying robot yaw in the clockwise direction.

III. KK MULTICOPTER FLIGHT CONTROL SYSTEM

The KK multicopter controller (as shown in Fig. 3) is a kind of flight control system, which can be applied in the multi-rotor aircraft with different axes, including: single-axis, dual-axis, tri-axis, quad-axis, hex-axis, eight-axis, as well as the aircraft with fixed wings. The KK multicopter flight controller has an Atmega micro-processor, and tri-axis Gyro that can detect the angular velocity of roll, pitch and yaw directions, as well as 8-channel PWM signal output. It can control 8 motors or RC servos at most, so that the aircraft can fly stably.

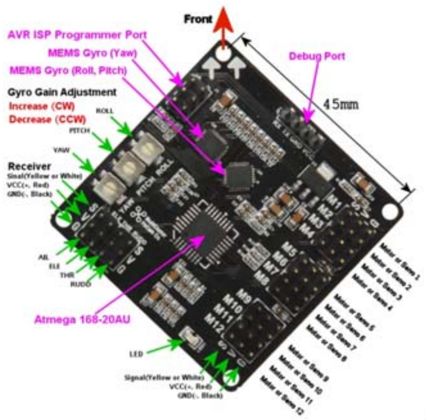

Fig. 3 KK multicopter flight controller

3.1 Basic functions of KK multicopter flight controller:

Tri-axis Gyro-stabilized system has contra-rotating Gyro chips, with the functions of electronic adjustment and calibration of the accelerator pedal and locking protection. Fig. 4 is the hardware architecture of the flight controller applied on the tricopter, in which the remote control receiver is used to receive the remote control signal sent from the radio controller. And the MEMS gyro can be used to detect the angular velocity of the directions of roll, pitch and yaw for the three rotors. The simulated voltage output by the gyro can be directly read by the single chip Atmega 168-20AU on the flight controller, based on which the axis declination angles of the three rotors are calculated. The single chip on the flight controller can control the speed difference between the three motors, and the declination angle of the RC servos, so as to maintain the balance gesture of the three rotors.

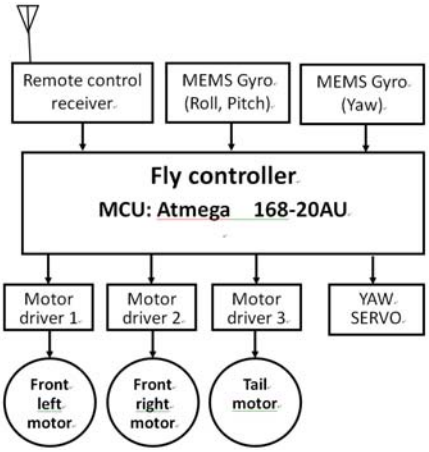

Fig. 4 Hardware architecture of the KK multicopter flight controller applied on the tri-rotor flying robot

IV. MATHEMATICAL MODEL

Fig. 5 is diagram of dynamic equation of the tricopter, in which the lower right side is the diagram of dynamic equation of the Yaw control. That is because in Yaw control, RC servo motor drives the tail axis to change the declination angle of the tail axis.

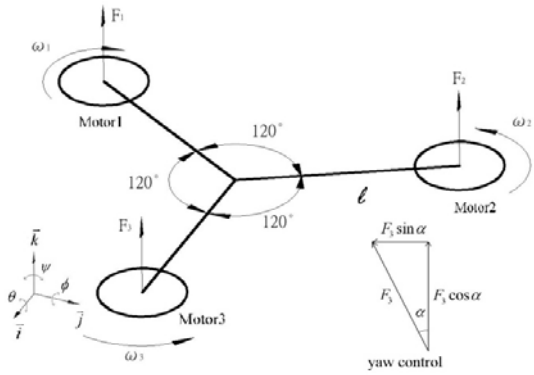

Fig. 5 Diagram of dynamic equation of the tri-rotor flying robot

4.1Moment of Inertia of tricopter

Fig. 6 is the diagram of the moment of inertia of the tri-rotor flying robot. When calculating the inertia torque of the tri-rotor flying robot, we assume the fuselage is rectangular shape, the three motors are cylinder shape, and moreover, the inertias of the round rods of the axes are neglected.

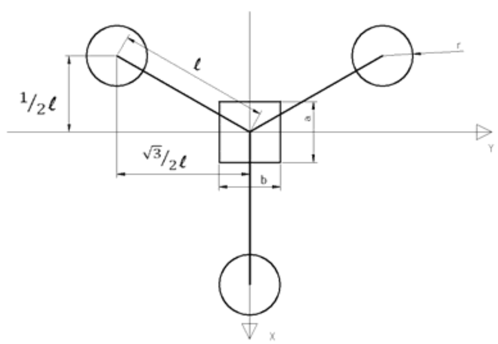

Fig. 6 moment of inertia of the tri-rotor flying robot

Moment of inertia of each axis:

- Moment of inertia about axis X:

The total moment of inertia about X-axis:

$$I_{xx} = \frac{3}{2}m\ell^2 + \frac{1}{12}m_0 b^2 + \frac{1}{12}m(3r^2 + h^2) \tag{1}$$

- Moment of inertia about axis Y:

The total moment of inertia about Y-axis:

$$I_{yy} = \frac{3}{2}m\ell^2 + \frac{1}{12}m_0 a^2 \tag{2}$$

- Moment of inertia about axis Z:

The total moment of inertia about Z-axis:

$$I_{zz} = \frac{1}{12}m_0(a^2 + b^2) + 3m\ell^2 \tag{3}$$

4.2 Relationship between motor thrust and voltage

The thrust of the motors on the rotorcraft is the most important variables to determine the load and lift of the entire craft. The pre-condition to select the suitable motor is the net weight and expected payload of the entire tricopter. After that, it needs to determine the cruising ability of the craft, namely, how long it can fly. Next, it will select the suitable battery based on the voltage and power consumption of the motor. Therefore, the relation between the motor and voltage needs to be discussed.

The air speed generated by the propeller:

$$V_h = \sqrt{\frac{F}{2A\rho_a}} \tag{4}$$

$$P_h = F\sqrt{\frac{F}{2A\rho_a}} \tag{5}$$

where: P_h:*the power induced in air*

F: thrust of the propeller

ρ_a:*air density*

A: area scanned when the properller spins

Motor torque:

$$\tau_m = K_t F \tag{6}$$

voltage input can be obtained as follows:

$$F = 2\rho_a A\left[\frac{f\eta K_t}{K_q}\right]^2 V^2 \tag{7}$$

where: K_t:*constant of torque*

4.3 Relationship between angular acceleration of the motor and the voltage

$$\mathrm{V} = \frac{\mathrm{JZ}\dot{\Omega}}{\mathrm{K_q}} + \mathrm{K_e}\Omega + \frac{ZD\Omega^2}{K_q} \tag{8}$$

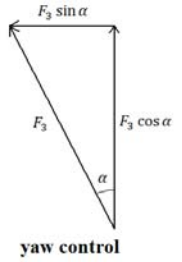

Fig. 7 Thrust force diagram of Yaw control

4.4 Relationship between the declination angle of the Yaw motor and the Yaw control

The yaw control of the tricopter is realized by the declination angle of the motor M_3. The declination angle is determined by a RC servo motor and a linkage. Assume the thrust force of the tail motor M_3 is F_3, and the declination angle is α, as shown in Fig. 7. The vertical component of F_3 is $F_3 \cos\alpha$, and the horizontal component of F_3 is $F_3 \sin\alpha$.

4.5 The principle of rotor torque

The torque rotors have a circular are profile. With this profile the torque forces increase as the angle of attack increases. While the rotor blades are fixed in place, they are quite flexible and probably change attack angle when they are accelerated.

$$F_{drag} = \frac{\rho C_d U^2 S}{2} = K_d \rho_{mp}^2 \tag{9}$$

Where :ρ is the fluid density, U is the flow velocity, C_d is the torque coefficient and $\mathrm{S} = \mathrm{span} \times \mathrm{chord}$

4.6 Relationship between the angular acceleration and voltage of the motors

When the tricopter rolls, pitches, yaws and moves vertically, it is directly related with the motor's angular velocity or voltage input. Rolling to axis X is called Roll, to axis Y is Pitch, to axis Z is Yaw, moving along the Z-axis is vertical motion.

Assume the rolling torque is τ_{xx}, angular acceleration is $\ddot{\theta}$, moment of inertia of axis X is I_{xx}, unit vector of axis X is $\hat{\imath}$, therefore, the rolling torque is:

$$\tau_{xx} = I_{xx}\ddot{\theta}\hat{\imath} \tag{10}$$

- Rolling about X-axis

The rolling motion equation finally:

$$\ddot{\theta} = \frac{\sqrt{3}\rho_a A\ell}{I_{xx}}\left[\frac{f\eta K_t}{K_q}\right]^2 ({V_2}^2 - {V_1}^2) \tag{11}$$

- Pitching about Y-axis

The pitching motion equation finally:

$$\ddot{\phi} = \frac{2\rho_a A\ell}{I_{yy}}\left[\frac{f\eta K_t}{K_q}\right]^2 [\frac{({V_1}^2 + {V_2}^2)}{2} - {V_3}^2\cos\alpha] \tag{12}$$

- Yawing about Z-axis

The yawing motion equation finally:

$$\ddot{\psi} = \frac{F_{drag}}{I_{zz}} - \frac{2\rho_a A\ell}{I_{zz}}\left[\frac{f\eta K_t}{K_q}\right]^2 {V_3}^2 \sin\alpha \tag{13}$$

- Vertical acceleration

The vertical lift is generated by the three propellers, in which the thrust of the vertical component force of motor M_3 is $F_3\cos\alpha$. The resultant force of three motors is vertical to the plane of three propellers. If the pitch angle (ϕ) and roll angle (θ) are not equal to zero. The Z-axis component of the resultant force is $F_{total}\cos\theta\cos\phi$, which is applied on the centroid of the tricopter.

The lift in the centroid is:

$$F_{all} = Ma_z = (F_1 + F_2 + F_3\cos\alpha)\cos\theta\cos\phi - Mg \tag{14}$$

Substitute it into equation (7) to get the relationship between the vertial acceleration and input voltage of motor:

$$a_z = \frac{2\rho_a A}{M}\left[\frac{f\eta K_t}{K_q}\right]^2 \left(V_1{}^2 + V_2{}^2 + V_3{}^2 \cos\alpha\right)\cos\theta\cos\phi - g \quad (15)$$

V. EXPERIEMENTS OF THE TRI-ROTOR AERIAL VEHICLE

5.1 The universal test platform:

The gains of the response parameters of pitch, roll and yaw on KK multicopter flight controller need to be slightly adjusted, so we made a universal test platform to adjust the gains of pitch, roll and yaw for the tri-rotor flying robot, with the expectation to rapidly return to the stable gesture without oscillation state. The universal test platform (as shown in Fig. 8) is designed to test the stability and balance of the tricopter. The biggest advantage of this test platform is to conduct the balance test of pitch, roll and yaw in all directions, and the error between the frictional force and the inertia of the test platform is the smallest.

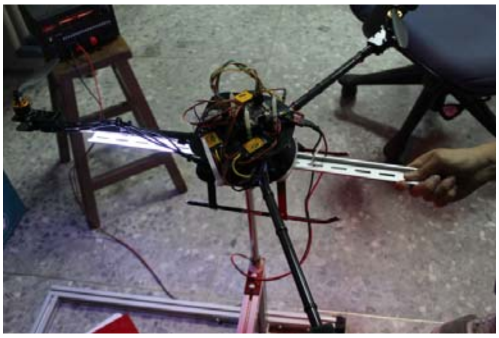

Fig. 8 Mount the tricopter on the universal test platform

5.2 Outdoor flight test

In terms of outdoor flight test, comparing the generation I tri-rotor flying robot (without KK multicopter installed) with the generation II tri-rotor flying robot with KK multicopter installed, it is found the latter one performs better than the former one in terms of auto-hovering and stability. Fig. 9 is the actual test of outdoor flight for the generation II tri-rotor flying robot with KK multicopter installed.

Fig. 9 Outdoor flight test of the tri-rotor flying robot with KK multicopter installed

VI. CONCLUSION

The rolling speed of the rotor on the fueling helicopter is not suitable for indoor flight, and there is potential injury risk of the operator in case of high rolling speed. Moreover, the waste gas produced by burning the fuel will cause environmental pollution. Therefore, using the brushless motor as the resource of driven force is safe and environmental-friendly.

At present, the stable hovering of the tri-rotor flying robot has been completed, which is quite good flight platform. When studying this copter, most cases are the application of chemical, biological and radioactive (C.B.R.) detection, reconnaissance combat, disaster prevention and criminal prevention. The purpose of this study expects the stability of the tri-rotor flying robot can reach some level, and the tri-rotor flying robot can fly indoor or outdoor with hovering in the fixed indoor point, so as to accomplish the assigned tasks.

Abstract: We present the path planning techniques of the fire escaping system using multiple smart mobile robots for intelligent building. The fire escaping system contains a supervised computer, an experimental platform, some fire detection robots and some navigation robots. These mobile robots have the shape of cylinder and its diameter, height and weight is 10cm, 15cm and 1.5kg, and contain a controller module, two DC servomotors (including drivers), three IR sensor modules, a voice module and a wireless RF module, and acquire the detection signal from reflective IR sensor through I/O pins, and receive the command from the supervised computer via wireless RF interface. The fire detection robot carries the flame sensor to detect fire sources. The supervised computer controls the fire detection robots to detect fire source moving on the grid based experiment platform, and calculates the more safety escaping path using piecewise cubic Bezier curve on all probability escaping motion paths on the user interface. Then the system uses A* searching algorithm to program escaping motion paths to approach to Bezier curve. Then the navigation robot guard peoples moving to the safety area or exit door using the escaping motion path. In the experimental results, the supervised computer can programs the escaping paths using the proposed algorithms, and presents the scenario using the multiple smart robots on the platform. The user interface transmits the motion command to the mobile robots moving on the grid based platform, locates the positions of fire sources by the fire detection robots. The navigation robots guard peoples leaving the fire sources using the low risk escaping motion path, and moves to the exit door.

Keywords: path planning, fire escaping system, multiple smart robots, intelligent building, wireless RF module, piecewise cubic Bezier curve, A* searching algorithm

I. INTRODUCTION

Fire event is one of the great scourges on the human life. Thousands of people are injured each year by accidental fire event explosions on the known or unknown environment. There are approximately many thousand million dollars buried each year in many countries. Fire event is many risks to human life and property of societies which must be managed. How to develop a safety processing method to detect fire sources and guard peoples leaving the dangerous environment very quickly is a challenge problem.

In the past literatures, many experts research in the mobile robot. Wang et al [1] develops a multisensor fire detection algorithm using neural network. One temperature and one smoke density sensor signal are fused for ship fire alarm system. Healey et al. [2] presents a real-time fire detection system using color video input. The spectral, spatial, and temporal properties of fire were used to derive the fire-detection algorithm. Neubauer [3] apply genetic algorithms to an automatic fire detection system. The on-line identification of stochastic signal models for measured fire signals was presented. Ruser and Magori [4] described the fire detection with a combination of ultrasonic and microwave Doppler sensor. Luo and Su [5, 6] use two smoke sensors, two temperature sensors and two flame sensors to detect fire event, and diagnosis which sensor is failure using adaptive fusion method. These papers have not considered how to program the escaping paths on the fire environment on real-time, and reduce the risks of human life and property.

The paper considers the problems of the fire event, and uses the multiple robot system working together. Mobile robots are active detection modules to be more merits than passive detection modules, and are applied in fire source detection and escaping system. The multiple mobile robot system has more advantages than one single robot system [7]. First, the multiple mobile robots have the potential to finish some tasks faster than a single robot [8]. Furthermore, using several robots introduces redundancy. Multiple mobile robots therefore can be expected to be more fault tolerant than only one robot. Another advantage of multiple mobile robots is due to merging of overlapping information, which helps compensate for sensor uncertainty [9]. How to program the escaping motion path in the fire area is a important research problem. The paper uses piecewise cubic Bezier curve and A* searching algorithm to program the safety escaping path, and guards people leaving the fire area using navigation robots.

II. SYSTEM ARCHITECTURE

The system architecture of the fire escaping system is shown in Fig. 1, and contains a supervised computer, an experimental platform, some wireless RF modules, some fire detection robots and some navigation robots. The supervised computer transmits the command to control all mobile robots, and receives detection signal, and location, and orientation, and ID code of each mobile robot via wireless RF interface. The fire detection robot (FDR) detects fire sources using flame sensors moving along the experimental platform. The navigation robot (NR) guards people leaving the fire sources according to the programmed escaping motion path. The supervised computer transmits motion command to the mobile robots, and improves the mobile robot moving to the assigned location or not.

The mobile robot has the shape of cylinder, and is equipped with a microchip (MCS-51) as the main controller. Two DC servomotors transmit the pulse signals to the controller, and program orientation and displacement according to pulse numbers. The reflective IR sensors detect obstacles and cross points of the experimental platform, and decide the location of the mobile robot. The flame sensor is R2686 to detect fire sources on the front side of the mobile robot, and detection range is about 6m. The mobile robot can control two DC servomotors and voice module through I/O pins, and communicate with the supervised computer using wireless RF module. The core of the RF module is microprocessor (AT89C2051), and communicates with the controller via wire series interface (RS232).

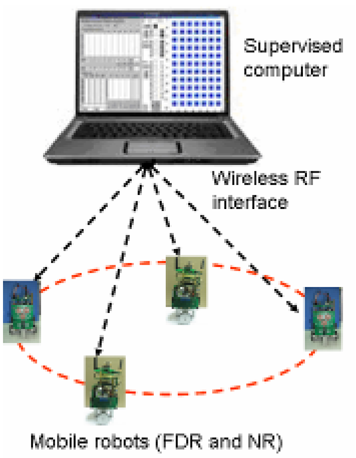

Fig. 1. System architecture

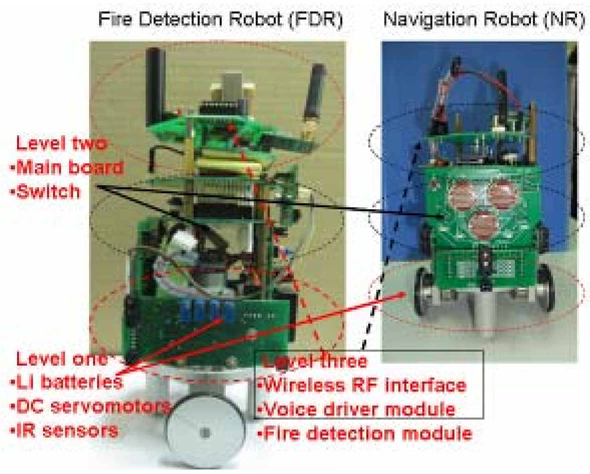

Fig. 2. The mobile robots (FDR and NR)

The structures of the two mobile robots are shown in Fig. 2. The two mobile robots contain some hardware circuits that are classified three levels. The level one of the mobile robot is two DC servomotors, three IR sensor modules and Li batteries. The three reflective IR sensors are embedded on the right side, left side and front side of the mobile robot. In general, the mobile robot moves on the aisle of the experimental platform, and detects obstacles using the three reflective IR sensors. Otherwise the mobile robot detects obstacles on the right side, left side and front side. The power of the mobile robot is three Li batteries to be connected with parallel arrangement. The level two of the mobile robot has main board. The controller of the mobile robot receives the status of the environment, and communicates with the supervised computer via wireless RF interface. The switch input can turn on the power of the mobile robot, and selects power input to be Li batteries or adapter. The level three contains a wireless RF module, a fire detection module and a voice driver module for the FDR. The NR has not fire detection module in the level.

The encoder module of the DC servomotor calculates the movement displacement on the experimental platform. We can set the pulse numbers for per revolution to be A, and the mobile robot moves total pulse numbers to be B. The controller of the mobile robot can calculates the movement displacement D on the platform as following

$$D = 4.25 \times \pi \frac{B}{P} (cm) \tag{1}$$

The diameter of the driver wheel is 4.25 cm. We can calculate per pulse number to be 0.0845cm displacement. Each grid of the platform is 30cm to be computed about 355 pulse numbers. Users can set the grid numbers for mobile robots moving on the platform. The controller of the mobile robots improves the motion trajectory to be right according to the pulse numbers.

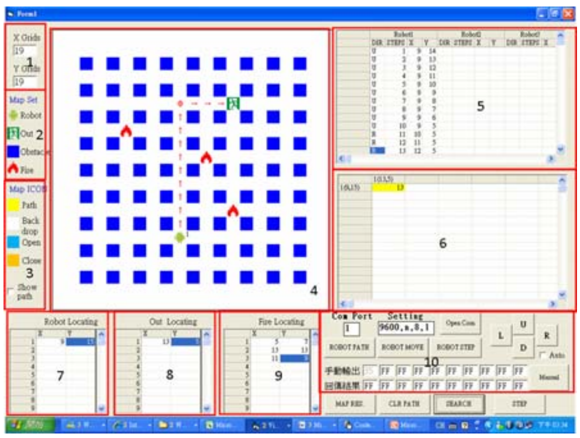

Fig. 3. The user interface

The user interface of the multiple mobile robot based escaping system has ten parts to be shown in Fig. 3. Users can set the size of the experimental platform in the part "1". The graphic labels of each function are listed in the part "2" and "3". Such as fire source, exit door, FDR and NR. The part "4" is the experimental platform to display the motion path that is computed by piecewise cubic Bezier curve and A* searching algorithm. The part "5" displays the searching processing of A* searching algorithm. The part "6" calculates the cost functions for navigation robot moving to the exit door. The supervised computer transmits the control command to the mobile robot, and receives the status of the mobile robot, and displays the position of the mobile robot moving on the platform simultaneously to be shown in the part "7". The parts "8" and "9" display locations of exit doors and fire sources. The part "10" sets the communication protocol between the user interface and mobile robots. The communication port of the user interface is 1, and sets baud-rate to be 9600.

III. PATH PLANNING

We use Piecewise cubic Bezier curve (PCBC) to program the escaping path of the intelligent building, and use A* searching algorithm to approach the programmed escaping path and decide the final escaping motion path to leave the fire sources using mobile robots. The piecewise cubic Bezier curve (PCBC) is used between each waypoint to connect with smooth curve. The equation of a cubic Bezier curve is listed as following [10].

$$\vec{p}(t) = \vec{a}t^3 + \vec{b}t^2 + \vec{c}t + \vec{p}_0 , \quad \text{For } 0 < t < 1$$
$$\text{where } \vec{p} = (x, y), \vec{c} = 3(\vec{p}_1 - \vec{p}_0) \tag{2}$$
$$\vec{b} = 3(\vec{p}_2 - \vec{p}_1) - \vec{c}, \vec{a} = \vec{p}_3 - \vec{p}_0 - \vec{b} - \vec{c}$$

Since the parameter of Bezier curve is not time or distance dependence, the curve trajectory cannot be used directly. Some researchers used a modification method of curves as a time variable [11]. Others used an approximation of curves by dividing the parameter t into n intervals [13].

We use numerical method to calculate parameter t of Bezier curves with respect to the distance s of curve. If the curve parameter t of the current position can be calculated, then the directional vector of the curve can be calculated at the position, too. Finally, we can fine the relation between the distance and the parameter t can be shown in equation (3). We can use a fourth order Runge-Kutta method to calculate the inverse of the equation as following.

$$\frac{ds}{dt} = \sqrt{\left(\frac{d}{dt}x(t)\right)^2 + \left(\frac{d}{dt}y(t)\right)^2} = S(t) \tag{3}$$

$$t_{n+1} = t_n + T(t_n, s_n)$$
$$\text{where } T(t_n, s_n) = \Delta s \frac{(f_1 + 2f_2 + 2_3 + f_4)}{6} \tag{4}$$
$$f_1 = \frac{1}{S(t_n)}, \ldots, f_4 = \frac{1}{S(t_n + \Delta s f_3)}$$

Finally, we can calculate the directional vector as following [12].

$$\vec{V} = \left(\frac{dx(t)}{dt}, \frac{dy(t)}{dt}\right) \tag{5}$$

We use the proposed method to program the escaping path to be a curve. The programmed curve is tuning by two control points that are fixed on the fire sources. Then we use A* searching algorithm to improve the curve to be applied in the grid based experimental platform. We select the minimum distance between the programmed Bezier curve and the improved escaping motion path. A* searching algorithm is explained in the reference [14].

IV. EXPERIMENTAL RESULTS

In the fire escaping system, we use multiple mobile robots to detect fire sources on the experimental platform to be shown in Fig. 4. The mobile robots transmit the location of fire source to the supervised computer, and detect the other fire source moving on the horizontal direction and vertical direction. We use candle to present fire source on the experimental platform. The mobile robot starts at the initial position is shown in Fig. 4(a). The mobile robot moves one grid, and turns right to face the aisle. Then the mobile robot finds the first fire source using flame sensor, and transmits the detection results to the supervised computer via wireless RF interface. The fire source is detected by the mobile robot, and is recoded the horizontal direction on the user interface. The fire detection robot moves over the horizontal direction to record the positions of the three flame sources. The supervised computer only knows the horizontal locations of the three fire sources, and can't appear the fire symbol on the user interface. The experimental results are shown in Fig. 4(b) - (d).

Then the mobile robot turns right 90^0 to detect the vertical direction of the platform. Finally, the robot (FDR) detects the vertical locations of the three flame sources to be shown in Fig. 6(e) - (g), and transmits vertical locations of the three fire sources on the user interface of the supervised computer. The supervised computer locates the coordinate locations of the three flame sources.

Next the supervised computer uses piecewise cubic Bezier curve to program the escaping curves from the people to the exit door to be shown in Fig. 5(a). The leaving people are the start position, and the exit door is the target position. The navigation robot can't moves according to the escaping curve. The supervised computer uses A* searching algorithm to decide the final escaping motion path that is approach to the escaping curve. The experimental result is shown in Fig. 5(b). We can see the final escaping motion path to be near the escaping curve. The final escaping motion path is plotted along the aisle of the experimental platform, and is implemented the movement scenario by the navigation robots. Finally, the navigation robot guards the people moving to the exit door, and leaves the three fire sources. The experimental results are shown in Fig. 5(c) – (h).

V. CONCLUSION

We have developed the fire escaping system to guard peoples leaving the dangerous area using some smart mobile robots. The system contains a supervised computer, some wireless RF modules, a experimental platform and some mobile robots. Mobile robots contain two types. One is fire detection robot; the other is navigation robot. In general, the intelligent mobile robot has huge size, and is not easily to implement the experimental scenario in the environment. We use some smart mobile robots to integrate the supervised computer to instead of the huge size based intelligent mobile robots. The supervised computer programs the escaping path using piecewise cubic Bezier curve and A* searching algorithm, and controls multiple mobile robots to present the movement scenario via wireless RF interface. In the future, we want to extend the escaping path programming algorithms using mobile robot, and develop more application fields of the multiple robots' system to be work cooperation in free space. The mobile robot can communicates with the other robots, and combines with the passive security modules in the intelligent building.

Abstract: The article presents multiple pattern formation control of the multi-robot system using A* searching algorithm, and avoids the collision points of motion paths. We use speech recognition algorithm to control the variety pattern formations exchange, and use mobile robots to present the movement scenario on the grid based motion platform. We have been developed some pattern formations according to game applications, such as long snake pattern formation, phalanx pattern formation, crane wing pattern formation, sword pattern formation, cone pattern formation and so on. The mobile robot contains a controller module, three IR sensor modules, a voice module, a wireless RF module, a compass module, and two DC servomotors. The mobile robot can acquires the detection signals from reflect IR sensor modules and compass module, and decides the cross points of the aisle, and receives the command from the supervised compute, and transmits the status of environment to the supervised computer via wireless RF interface. We develop the user interface of the multi-robot system to program motion paths for variety pattern formation exchange on the minimum displacement. Users can use speech to control the multiple mobile robots to executed pattern formation exchange on step by step or continuously. In the experimental results, mobile robots can receive the pattern formation command from the supervised computer, and change the pattern formation on the motion platform, and avoid other mobile robots.

Keywords: pattern formation exchange control, multi-robot system, A* searching algorithm, phalanx pattern formation, DC servomotors, wireless RF interface

I. INTRODUCTION

With the robotic technologies development with each passing day, mobile robot systems have been widely employed in many applications. Recently, more and more researchers are interest in the intelligent mobile robots which can help people in our daily life, such as entertaining robots, museum docent robots, educational robots, medical robots, service robots, office robots, security robots, home robots, and so on. In the future, we believe that intelligent robot will play an important role in our daily life. To design a big sized mobile robot to be equipped with many functions to become complex and huge, and the development period is too long. Thus, recently small-sized mobile robot systems have been investigated for a specific task, and program the optimal motion path on the dynamic environment [1].

There is a growing in multi-robot cooperation research in recent year. Compare to single mobile robot, cooperation multiple mobile robots can lead to faster task completion, higher quality solution, as well as increase robustness owing its ability adjust to robot failure [2]. Grabowski and Navapro-serment [3] suggested multiple mobile robots in which each mobile platform had a specific sensor for some purpose and therefore the system's task can be distributed to each mobile platform during surveillance. The feature of this system is that each mobile robot had a common motion platform, but had different sensors. Some papers consider the problem of the multiple robot system working together. The multiple mobile robot system has more advantages than one single robot system [4]. The multiple mobile robots have the potential to finish some tasks faster than a single robot using searching algorithm or ant colony algorithm [5].

Liu proposed a motion planning approach to coordinating multiple mobile robots moving along specified paths for minimizing formation errors [6]. The mobile robots are required to maintain the formation relationship, and are subject to the restrictions of velocity and acceleration bounds and collision avoidance [7]. Javier described work on multi-robot pattern formation. Arbitrary target patterns are represented with an optimal final formation [8]. The pattern formation is developed in ancient Chinese history. Sun Tzu and Zhuge Liang that are the symbol of resourcefulness and wisdom in Chinese Folklore proposed many pattern formations. The paper develops the multiple mobile robots to implement some pattern information.

II. SYSTEM ARCHITECTURE

The system architecture of the team robot system is shown in Fig 1. The system contains a supervised computer, a microphone, a motion platform, some wireless RF modules and five mobile robots. The supervised computer programs five pattern formations to be shown in Fig. 2. We name the pattern formations to be long snake pattern formation, wild goose pattern formation, sword pattern formation, cone pattern formation and crane wing pattern formation. Users can select each pattern formation using Chinese speech on the supervised computer. The supervised computer can programs the motion paths of the multiple mobile robots using minimum displacement method, and transfer change the pattern formation to the assigned pattern formation. The mobile robots move on the motion platform, and avoid collision with other robots. The supervised computer can transmits the command of the final locations to each mobile robot. The mobile robots can move to the final locations autonomous according to the programmed motion paths.

There are more merits in the mobile robots to use team robot cooperation capabilities to such a large fleet of robots. In general, the control structure of the large fleet mobile robots is classified centralized control and decentralized control. A centralized control requires robust and permanent communication capabilities between all mobile robots and the supervised system. A decentralized control only requires local communication between robots and the supervised system. Each mobile robot of the multiple robots' system will communicates with the other robots [9]. The paper uses the centralized control in the pattern formation arrangement. That is to say, the multiple mobile robots only communicate with the supervised computer via wireless RF interface. The mobile robot has been developed in my laboratory.

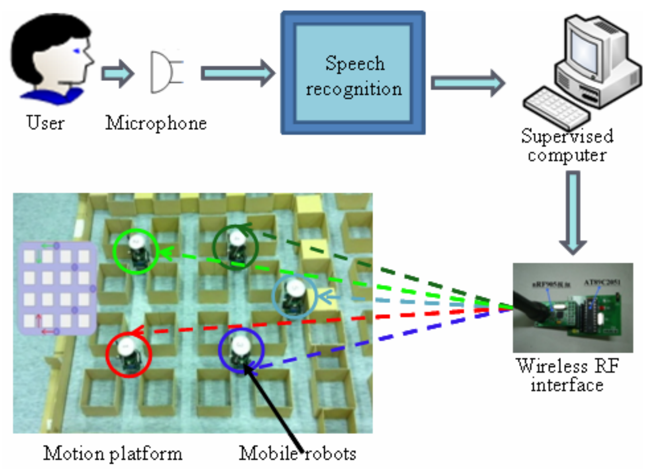

Fig. 1. The system architecture

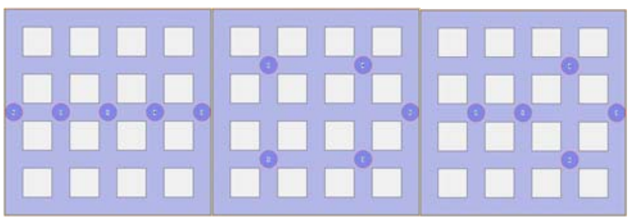
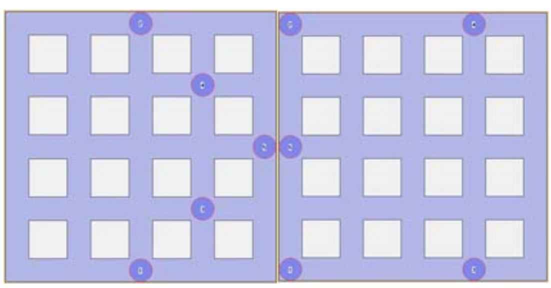


(a) Long snake pattern (b) Wild goose pattern (c) Sword pattern



(d) Cone pattern (e) Crane wing

Fig. 2. The pattern formation model of multiple mobile robots

The core of the wireless RF module is microprocessor (AT89C2051), and communicates with the controller of the mobile robot or the supervised computer via series interface (RS232). The communication protocol of the system is 10 bytes. There are start byte (1 byte), data byte (8 bytes) and check byte (1 byte). The data bytes contain ID code (1 byte), robot code (1 byte) position and orientation data bytes. The ID code decides the transmitting direction between of the supervised computer and the multiple mobile robots.

III. Pattern Analysis

We program the shortest motion path of the pattern formation exchange using A* searching algorithm for each mobile robot, and locate the start position and final position of each mobile robot. The start position is the start point of the pattern formation, and the final position is the final point of the assigned pattern formation. The programmed motion paths have collision condition at the cross point of the programmed motion paths. The short displacement based mobile robot must stay at the original position to wait the long displacement based mobile robot moving through the point. Then the mobile robot moves through the point.

A^* searching algorithm solves the shortest path problem of multiple nodes travel system. The formula of A^* searching algorithm is following

$$f(n) = g(n) + h(n) \qquad (1)$$

The core part of an intelligent searching algorithm is the definition of a proper heuristic function $f(n)$. $g(n)$ is the exact cost at sample time n from start point to the target point. $h(n)$ is the minimum cost. In this study, n is reschedules as n' to generate an approximate minimum cost schedule for the next point. The equation (1) can be rewritten as follows:

$$f(n) = g(n) + h(n') \qquad (2)$$

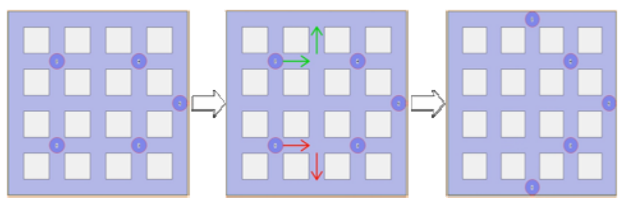


Fig 3. Wild goose pattern formation to cone formation

Now we make some examples to explain how to control pattern formation exchange using A* searching algorithm. The first example, the wild goose pattern formation transfers to the cone pattern formation to be shown in Fig. 3. The supervised computer programs the minimum robots to move on the assigned pattern formation, and can computes the shortest displacement of the selected robots moving to the assigned positions. We can see the only two mobile robots moving to the new assigned positions according to the cone pattern formation. Then the three mobile robots stay at the original positions. The total movement displacement is minimum value. The experimental results are shown in Fig. 3(b) and (c).

In the other example, is shown in Fig. 4. The long snake pattern formation transfers to the sword pattern formation. We program the motion paths of five mobile robots to exchange the formation, and use A* searching algorithm to program motion paths of moving robots, and uses the minimum moving robots on the pattern formation. Finally, we can see the only two mobile robots moving to the assigned positions. The others are stay at the original positions.

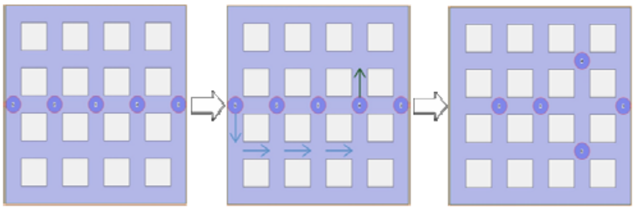

Fig 4. Long snake pattern formation to sword pattern formation

The structure of speech recognition is shown in Fig. 5. In speech signal processing, preemphasis, namely, the compression of the signal dynamic range by flattening the spectral tilt, preemphasis can also be accomplished after A/D conversion through differential calculation or through application of the first-order digital filter.

$$H(z) = 1 - a \times z^{-1} \quad (3)$$

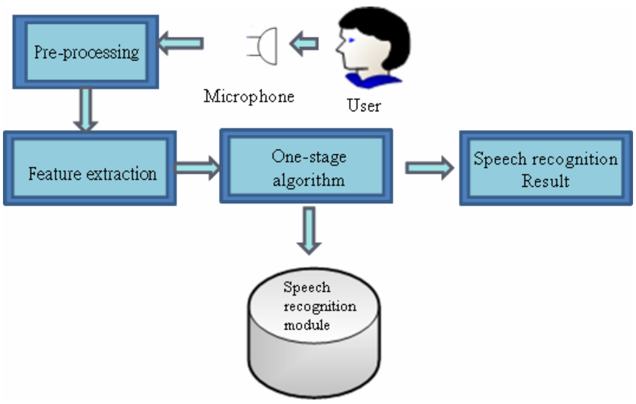

Fig 5. The structure of speech recognition

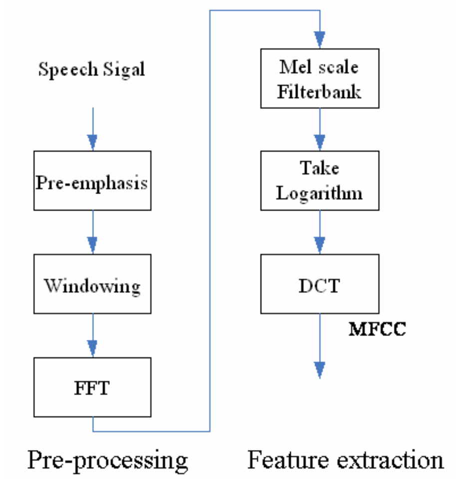

Fig. 6. The flow-chart of feature extraction

In the speech recognition, we want to extract the N-sample interval from the speech wave for calculating the autocorrelation function and spectrum. The speech wave must multiply by an appropriate time window. Thus several compromise window functions have been proposed. Among these, we use the Hamming window $W(n)$ as following [10]:

$$W(n,a) = (1-a) - a \times \cos(2\pi n/(N-1)), 0 \le n \le N-1 \quad (4)$$

We take $a = 0.46$ in the paper. We want to analyze the speech wave, and transfer the speech signals in the time domain to the frequency domain. The energy spectrum presents the phenomenon of variety speech signals. Then we can use Mel frequency to analyze the speech signals. The relation of Mel frequency and general frequency as following:

$$mel(f) = 2595 * \log 10(1 + f/700) \quad (5)$$

or

$$mel(f) = 1125 * \ln(1 + f/700) \quad (6)$$

Then we can find 12-level Mel-scale coefficients using discrete cosine transform (DFT) as following:

$$C_m = \sum_{k=1}^{M} E_k \cos[\left(k - \frac{1}{2}\right)\frac{\pi}{M}], m = 1, \ldots\ldots, L \quad (7)$$

Then we program the flow chart of feature extraction for speech recognition for variety pattern formation of the team robots to be shown in Fig. 6.

IV. EXPERIMENTAL RESULTS

We implement the pattern formation exchange control using five mobile robots, and presents the movement scenarios of the pattern formation exchanges on the grid based motion platform (One grid is 30 cm on the platform). The first formation exchange is the wild goose pattern formation transform to the cone pattern formation. The formation exchange only moves two robots, and uses A* searching algorithm and minimum movement displacement to program the motion paths that are plotted in Fig. 7, and transfers the wild goose pattern formation to the cone pattern formation.

In the experiment scenario, we use five mobile robots to arrange the wild goose pattern formation on the motion platform. The supervised computer transmits the cone pattern formation command to the five mobile robots via wireless RF interface, and assigns the new positions for five mobile robots. The experimental scenario of the first step is shown in Fig. 7(a). The two mobile robots move forward 30 cm (one grid) according to the programmed motion paths. Then one turns right 90^0 moving forward 30cm. The other turns left 90^0 moving for ward 30cm. The two mobile robots stop, and face the right side to be the same direction as the original direction for all mobile robots. The experimental scenarios are shown in Fig. 7(b) and (c). Finally, the five mobile robots leave the original location, and stay at the new positions to arrange cone pattern formation on the platform.

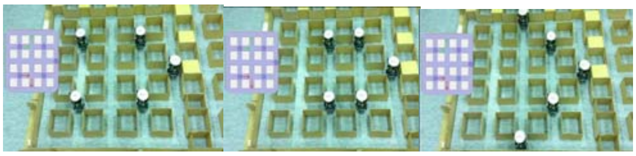

Fig. 7. The scenario of wild pattern to cone pattern

Next we implement the pattern formation exchange control using five mobile robots, and present the movement scenarios from the cone pattern formation to the wild goose pattern formation. The formation exchange only moves two robots, too. In the experiment scenario, the supervised computer transmits the wild goose pattern formation command to the five mobile robots via wireless RF interface, and transmits the new positions to the assigned two mobile robots. The experimental scenario of the first step is shown in Fig. 8(a). The two mobile robots turn 180^0 to move forward 30 cm (one grid). Then one turns right 90^0 moving forward 30cm. The other turns left 90^0 moving for ward 30cm. The two mobile robots stop, and face the right side. The experimental scenario of the first step is shown in Fig. 8(b) and (c).

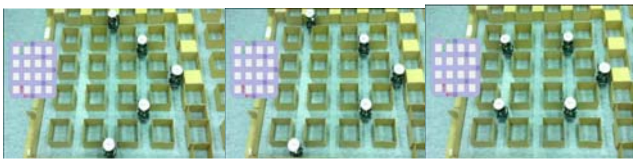

Fig. 8. The scenario of cone pattern to wild pattern

Finally we implement the pattern formation exchange control using five mobile robots, and present the movement scenarios from the long snake pattern formation to the sword pattern formation. The formation exchange only moves two robots, too. In the experiment scenario, the supervised computer transmits the sword pattern formation command to the five mobile robots via wireless RF interface, and transmits the new positions to the assigned two mobile robots. The experimental scenario of the first step is shown in Fig. 9(a). One mobile robot turn left 90^0 to move forward 30 cm (one grid), and turns right 90^0 to face right side. The tail of the snake (robot) turns right 90^0 moving for ward 30cm. Then the robot turns left 90^0 to move forward 90cm (3grids). The five mobile robots stop, and face the right side. The experimental scenario of the first step is shown in Fig. 9(b) and (c).

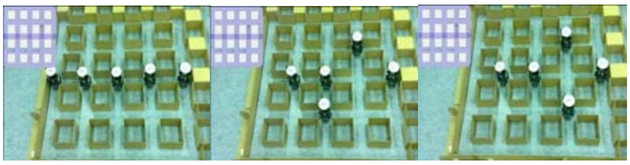

Fig. 9. The scenario of long snake pattern to sword pattern

V. CONCLUSION

We have developed five pattern formations' exchange control of the team robot system. The five pattern formations have long snake pattern formation, wild goose pattern formation, sword pattern formation, cone pattern formation and crane wing pattern formation. The formation control system contains a supervised computer, some wireless RF modules, a motion platform and five mobile robots. Users can use Chinese speech to control the multiple mobile robots to exchange pattern formation. The supervised computer can controls five mobile robots, and receives the status of the multiple mobile robots via wireless RF interface. The paper has been presented multiple pattern formation exchange control using five mobile robots. The experimental scenario of the four mobile robots moves on the motion platform, and obeys the programmed motion paths using A* searching algorithm. The five mobile robots can avoid the other mobile robots in the pattern formation control. In the future, we want to develop more complexity pattern formation using more and more mobile robots for war game, and develop the pattern formation programming according to the war laws of Sun Tzu or Zhuge Liang.

Abstract: The article presents a multiple residual power prediction system to be applied in mobile robots or automation fields. The system contains multiple power detection units to measure multiple on-line power values. Each power detection unit uses four current sensors to measure the current variety, and uses weighted average method and redundant management method to calculate the exact current value, and isolates faulty measurement values. We use the proposed algorithms to be applied in voltage detection of each power detection unit, too. Then we can calculate the real-time power values according to the current and voltage measurement values. The control core of the power detection unit is HOLTEK microchip, and communicates with the data integration unit via wire I2C interface. The power detection units transmit the measurement values of current and voltage to the controller of the system. The main controller of the power detection system is PC based system, and communicates with the data integration unit via wire RS232 interface. The main controller of the system can controls each power output ratio of the power sources, and predicts the power loading and the residual power for each power detection unit using auto-regression algorithm, and computes the residual time of mobile robots to work in the free-space, and arrange the residual power of the enough power source to the weakness power sources using sequential single-item auction algorithm. In experiment result, the residual power prediction system can adjusts the working time of the power sources to be the maximum value.

Keywords: multiple residual power prediction system, weighted average method, redundant management method, HOLTEK microchip, I2C interface, RS232 interface, auto-regression algorithm, sequential single-item auction algorithm.

I. INTRODUCTION

Intelligent power management system can provides convenience and high efficiency for human living in the 21st century, and allows effective management of power source with minimum life-time costs at the same time. In the recently, Intelligent system has been widely applied in many fields. The residual power of the intelligent system is under the critical power. The system can't work and shutdown. The power supply of the system must be stability. The power management system may knows the residual using time, and adjust the power output to improve the working time of the intelligent system to be maximum. We must detect power variety of the intelligent system all the time very carefully, and program each power output to supply all devices of the intelligent system in the limited total power condition.

We have been designed a power detection module applying in Chung Cheng I security robot using microprocessor (MCS51), and the on-line experimental results are very successful [1,2]. We are implemented the new power detection module applying in the fire fighting robot using HOLTEK microchip, too. The goals of the paper integrates many new power detection modules to extend the interface function, and transmits the measurement values to the controller of the intelligent power management system using series interface, and extends the function of the power detection module to isolate the faulty measurement values, and reduce detection error, and predict the residual time using multi-level multisensor fusion algorithms [3].

In the past literature, many researches have been proposed power detection and prediction algorithms. Levi was one of the first persons to comment upon the characteristics of CMOS technology which make it special amenable to I_{DD} Testing [4]. Malaiya and Su use I_{DD} testing to estimate the effects of increased integration on measurement resolution [5,6].Hawkins et al reported on numerous experiments where current measurements have forecast reliability problems in devices which had previously passed conventional test procedures [7,8]. Then, researches dedicated to improving the accuracy of measuring current [9,10]. Maly et al proposed a build-in current sensor which provides a pass/fail signal when the current exceeds a set threshold [11,12].

II. SYSTEM ARCHITECTURE

We develop the residual prediction system in the paper, and measure the exact power values to isolate the error measurement values, and calculate the residual time under the critical values to adjust working time to be maximum value. The system architecture of the residual power prediction system is shown in Fig. 1. There are many power detection units, many power sources, one data integration unit and a controller. The system measures the variety power outputs of the power sources respectively. These power detection units can detects multiple DC power sources.

Each detection unit assigns identification (ID) code to be classified the data sequence.

The data integration unit connects with many power detection units via I2C interface, and deals with the received measurement values according to ID code of each power detection unit, and transmits the measurement values to the controller of the residual power prediction system via RS232 interface. The prototype of the power detection unit is shown in Fig. 2. The controller unit of the power detection unit is HOLTEK microchip, and monitors each power variances of the power sources. The controller of the residual power prediction system is PC-based structure, and adjusts each power output of the power sources via wire series interface.

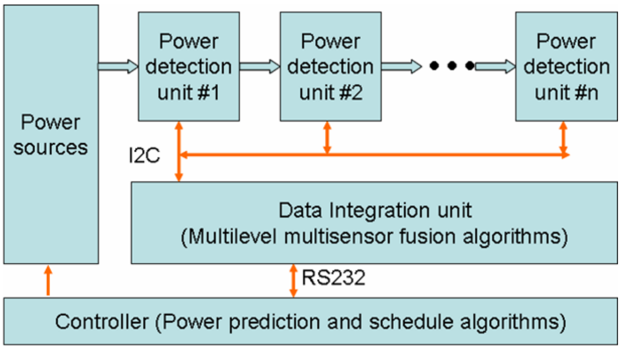

Fig. 1 The system architecture

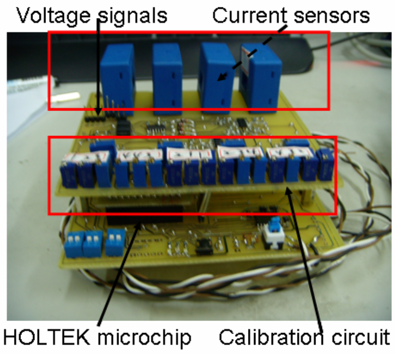

Fig. 2 The prototype of the power detection unit.

Each power detection unit contains four current sensors, a HOLTECK microchip, a calibration circuit and a series interface, and measures four current and four voltage signals. The control core is a HOLTEK microchip (HT46R25) to detect the power variance using four DC type current sensors, and measures four voltage values simultaneously. Users can adjust the sensitiveness of the measurement signal, and delete offset value, and select all measurement values are the same sensitiveness. The output signal contains safety switch, I2C interface, display and alarm. The safety switch may be used to turn on or off the supply power to the target devices. The current range tuning can be assigned the maximum measurement current up to about 50A.

The user interface of the residual power prediction system is shown in Fig. 3. Users can select any time point of these curves, and display these current and voltage measurement values on the upper side of the monitor to be shown in the part "1" and "2". Uses can select each power detection unit to display current measurement values and voltage measurement values, power estimated value, and plot the curves for these measurement values to be shown in the part "3". The part "4" of the user interface presents the color curve to display the variety detection power sources for each power detection unit. The part "5" can displays the real-time power, critical power, residual power, assigned power and residual time of each power detection unit. The part "6" displays the set residual time of the system to be 60 second, and calculates the power efficiency.

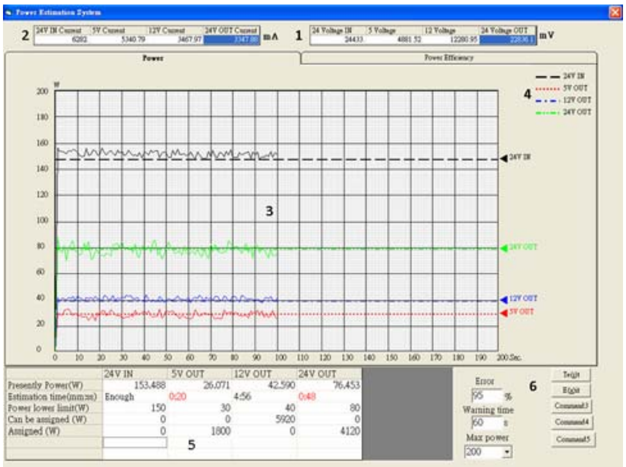

Fig. 3 The user interface

III. ALGORITHM ANALYSIS

In the power detection unit, we use weighted average method and redundant management method to compute power measurement values. The proposed methods are implemented in the HOLTEK microchip. The weighted value of the nth sensor measurements x_i is w_i with $0 \le w_i \le 1$. We can compute the weighted value according to the precious of the measurement value relation to the others; thus

$$I_i = \sum_{j=1}^{n} u_i, \quad i = 1,2,\ldots\ldots,n \tag{1}$$

$$u_i = \begin{cases} 1, & \text{if } |m_i - m_j| \le b_i \\ 0, & \text{if } |m_i - m_j| > b_i \end{cases} \tag{2}$$

$$w_i = \frac{I_i}{\sum_{j=1}^{n} I_j}, \quad i = 1,2,\ldots\ldots,n \tag{3}$$

The b_i is a threshold value for each measurement value m_i, and m_j is another measurement value. The maximum value of w_i is n, and the minimum value is zero. Then we can compute the estimated value $\overline{m}$ according to each weighted value to be

$$\overline{m} = \sum_{i=1}^{n} w_i m_i \tag{4}$$

Where $\sum_i w_i = 1$ and $w_i = 1$ if m_i is not within some specified thresholds. The weights can be used to account for the differences in accuracy between sensors, and a moving average can be used to fuse together a sequence of measurement values from a single sensor so that the more recent measurement values are given a greater weight.

Then we want to calculate the residual time under the critical power using power prediction algorithm for each power detection unit. The algorithm is based on ARIMA (p,d,0) model structure and least square method. It general form of model is as following.

$$\varphi(B)w(t) = a(t) \tag{5}$$

Where $a(t)$ is zero mean value white noise, B is backward operator, and

$$\varphi(B) = 1 - \varphi_1 B - \varphi_2 B^2 - \cdots - \varphi_p B^p \tag{7}$$

Then equation can be expressed in the vector form can be rewritten as

$$w(t) = u^T(t)\lambda + a(t) \tag{8}$$

$$\lambda = [\varphi_1, \varphi_2, \cdots, \varphi_p]^T \tag{9}$$

$$u^T(t) = [w(t-1), w(t-2), \cdots, w(t-p)] \tag{10}$$

Take the place of λ and u^T into recursive least square formula with forgetting factor. Given the original value, regressive parameters estimation can be found out on line.

Next we can compute each residual time of each power detection unit on the assigned critical power. If the power detection units measure the average powers of the n power sources to be $\overline{P_1}, \overline{P_2}, \ldots\ldots, \overline{P_n}$. We use sequential single-item auction algorithm in the paper. The weakness power source bides the enough power source. The goal of the proposed method wants to increase the working time in the fixed power condition. A formal definition of the auction algorithm is given a number of enough power sources $p_1, p_2, \ldots\ldots, p_m$, and a number of weakness power sources $s_1, s_2, \ldots\ldots, s_l$. The total power sources $n = m + l$, and subtasks are, $P = \{P_1, P_2, \ldots\ldots, P_n\}$. A subtask $P(s_i)$ is a set that contains some enough power sources that are bided by the weakness power sources s_i. A function $F(s_i, p_j)$ specifies the cost of using the enough power source p_j to provide to the weakness power sources s_i.

$F(s_i, P(s_i))$ specifies the cost of using power sources $P(s_i)$ by the weakness power source s_i. We have two performance function to compare the efficiently for the multiple target devices executing power sources' allocation. The residual time of the ith power detection unit is T_{pi} $i = 1,2,\ldots m$, T_{si} $i = 1,2,\ldots,l$. The kth power is under the critical power, and the residual time is smaller than the threshold time (60 second). The lth power source is enough to provide the lth target device. The part of the lth power source is assigned to provide the power to the ith target device using single-item auction algorithm. We define the maximum average working time to be T_M, and fine the balance relation s following:

$$\underset{T_M}{MAX}\left[\sum_{i=1}^{m} p_i (T_{pi} - T_M) = \sum_{j=1}^{l} s_j (T_M - T_{sj})\right] \tag{11}$$

IV. EXPERIMENTAL RESULTS

The residual power prediction system measures multiple power sources to display on the user interface. Users select the measurement range value of each power detection unit on the user interface to be shown in the upper side of Fig. 4. The user interface can plots four power curves and four prediction curves that are selected by users (5V, 12V 24V input and 24V output). The sample time is 1 second for the PC-based controller of the residual power prediction system.

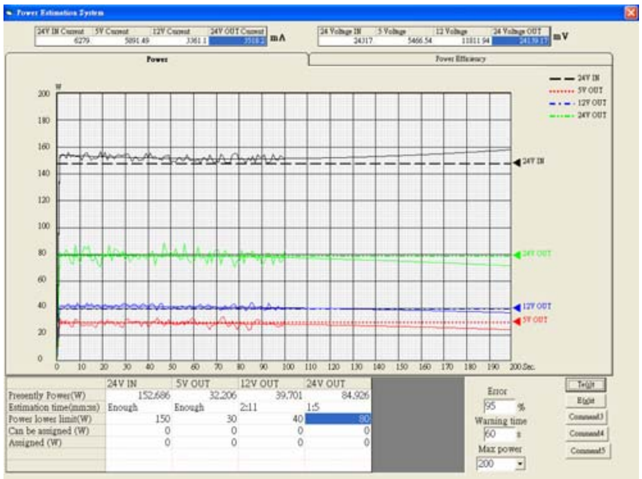

Fig. 4 The residual power prediction experimental result (I).

In the residual power prediction experiment, users can set the four critical powers and four residual times on the user interface of the system. We can select the critical power for 5V to be 30W, 24V (IN) to be 150W, 12V to be 40W and 24V (OUT) to be 80W, and the same critical time to be 60 second. The controller plots curve lines on the monitor of the interface according the real-time measurement value. First, the system can fits four second-order curves using polynomial regression algorithm for each assigned power sources. Then it computes the cross points of the critical power lines and the second-order curves. The cross points are the residual times (unit is second) for each detection power sources, Otherwise, the cross point is not exist, and the power source is enough. These cross point times displayed on the bottom of the interface. The user interface computes the residual times under the critical power to be 2 minute 11 second for 24V (output), and enough time for 12V and 24V (input) (no cross point). All residual times are bigger than the threshold time (60 seconds). The system can't execute the power assigned in the case.

In the other case, the residual power prediction system can knows the residual time to be 35 seconds. The 5V power source shutdowns on weakness power, and programs the enough power source 12V to provide the power to the weakness power source (5V) using single-item auction algorithm. Then we can compute the residual power until the critical power for each power source. The residual power output is about 2480W for 12V power source, and the residual time of 24V is about 1 minute 13 second. We can know the arrangement percent on each power source of the residual power prediction system, and program the 12V power source to provide 1000W to the 5V power source using the proposed algorithm. The experimental result is shown in Fig. 5.

The residual power prediction system can knows the residual time to be 49 seconds for the power source 24V (output), and the others are enough. The system programs the enough powers 5V and 12V to provide the power to the weakness power source (24V output) using single-item auction algorithm. Then we can compute the residual power until the critical power for each power source. The residual power output is about 1800W for 5V power source, and the residual power output is about 2400W for 12V. We can know the arrangement percent on each power source of the residual power prediction system, and program 5V and 12V power source to provide power to the 24V power source output using the proposed algorithm. The experimental result is shown in Fig. 6.

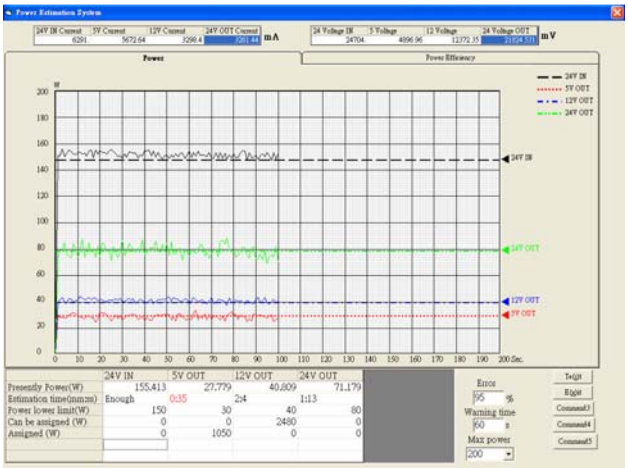

Fig. 5 The residual power prediction experimental result (II).

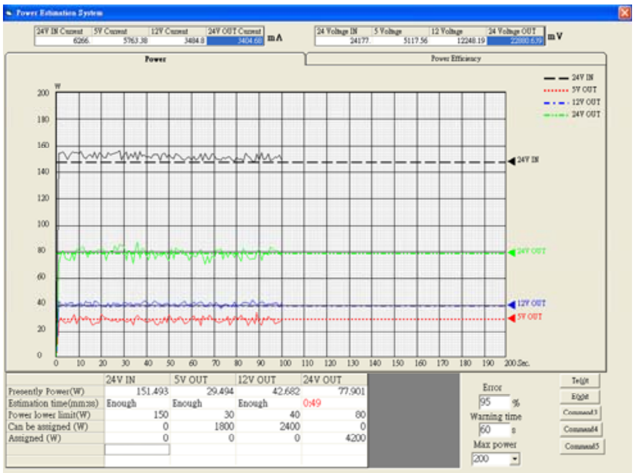

Fig. 6 The residual power prediction experimental result (III).

V. CONCLUSION

We have successful designed a residual power prediction system that has been applied in the multiple power source management. We developed the new power detection unit that used the HOLTEK microchip as controller to measure multiple power sources. The residual power prediction system used statistical signal detection algorithm and auto-regression algorithm to predict the residual times on the critical threshold power values for each power detection unit, and used single-item auction algorithm to adjust the power output ratio according the residual time. The system used the proposed algorithms to program the maximum working time of the target device before the weakness of the power source. We develop the user interface to integrate multiple power detection units to measure the power values. The power detection units can transmits the measurement values to the data integration unit via wire I2C interface. The PC based controller of the residual power prediction system communicates with the data integration unit via wire RS232 interface. In future, we want to adjust the more and more power sources of the system to increase the maximum working time of the target devices of the intelligent system, and implement the experimental results using the improved power detection unit.

Abstract: This paper describes the system design and the structural design to evaluate the tactile sensor using the microbending fiber optic (MBFO) sensors. The small light emitted diode (LED) and charge coupled device (CCD) are used as a single light source and a light detector for the bundle of optical fibers respectively. And the structure of this type tactile sensor which is composed of crossed fibers in the silicone rubber is very simple. And the tactile sensor element using MBFO sensor is fabricated and the performance of this sensor is evaluated.

Keywords: 3-6 key words or phrases in alphabetical order, separated by commas.

1 INTRODUCTION

The tactile sensor is one of the essential means for interfacing between human and robots [1]. Some tactile sensors using the MEMS(Micro Electro Mechanical System) technology have been introduced [2-5]. Even though these sensors have several merits such as their small size, good spatial resolution, and so on, they still have some problems to apply the practical system: they don't have enough flexibility to attach on the curved surface and the more elements of sensor are connected, the more wires they need. To mimic human skin, a new design for a tactile sensor array that uses optical fiber both as sensing elements and as signal-transmission media is tried. Heo, Cheong and Lee [6] introduced an optical fiber tactile sensor using fiber Bragg grating sensors embedded in silicone rubber, which to a degree mimics the feeling of human skin. This type of tactile sensor has simple wiring for application of the wavelength division multiplexing method with a broadband light source and some fiber Bragg gratings, which have different Bragg wavelength in a given optical fiber. Nevertheless, the optical system, especially the broadband light source, is too expensive to be applied to a practical system. Therefore, in this paper, we designed the flexible tactile sensor using microbending optical fiber sensor with the structure of crossed fibers in the silicone rubber. And, we designed the tactile sensor system using a single light source and a detector for the bundle of optical fibers which are not expensive.

2 STRUCTURE AND SYSTEM OF THE TACTILE SENSOR

2.1 Structure of the tactile sensor

Using the taxel of this study, we designed the tactile sensor with the fabric structure of the optical fibers embedded in the silicone rubber like Fig. 1.

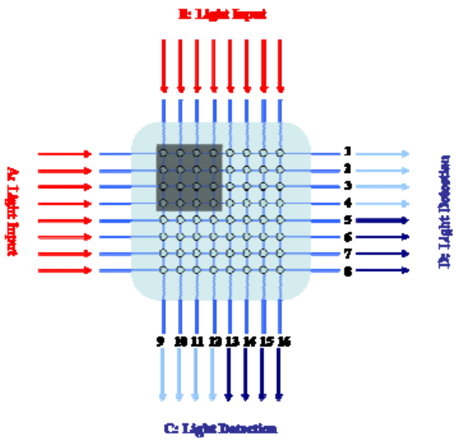

Fig. 1. Schematics of the tactile sensor using microbending optical fiber sensors with the fabric structure

If the some area is contacted by a wide material, the contact mesas make the microbending on the optical fibers in the silicone rubber which decreases the output of the light intensity of optical fiber. The numbers of the optical fiber contains the position information of the contact area, and the light intensity informs the change of the contact force. Hence, using this structure, the point contact load and distributed contact load can be measured.

The input light is incident to the optical fibers, which are located on sides A and B in Fig. 1. The output light is transmitted through optical fibers of sides C and D. If some area is pressed, as in Fig. 1, the intensities of the output light from the optical fibers, which are related to the pressed area, are decreased by the microbending loss. Based on the intensity changes and positions of the optical fibers, the quantity and the position of the applied force can be calculated at each taxel. And Fig. 2 shows the fabricated prototype tactile sensor using the microbending fiber optic sensors and its flexibility.

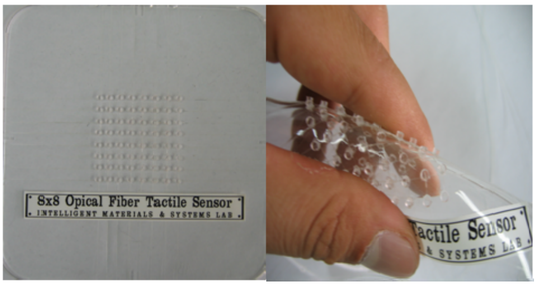

Fig. 2. Fabricated prototype tactile sensors and its flexibility.

2.2. Tactile sensor system

The Fig. 3 indicates the concept of the optical measurement system for the tactile sensor system using microbending optical fiber sensors. The wider distributed tactile sensor we fabricate, the more optical fibers are needed. To solve this problem, we use the optical fiber bundle as shown in Fig. 3. Many optical fibers can be united as one optical fiber bundle. Hence, using the optical fiber bundle, many fibers can be handled as one line.

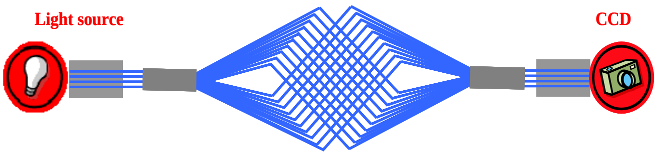

Fig. 3. Schematics for the tactile sensor system

As mentioned before, the optical measurement system of the intensity based optical fiber sensor is composed of a simple light source and a light detector. In this study, a small power LED(Light Emitted Diode) is used as the light source and a CCD(Charge Coupled Device) module is used for the light detector of this sensor system. The intensity changes of each optical fiber can be measured at once by the CCD module. This means that a CCD module makes the optical measurement system minimized. When the light intensity of the optical fiber is changed by contact force, the light intensity is evaluated from the output signal of the CCD. The gray scale value from the output signal of the CCD expresses the light intensity change of the optical fiber.

2.3. Light detection of multiple fibers using CCD

Using the prototype sensors, we can design artificial skin including the fabric-structured microbending optical fiber tactile sensors, as shown in Fig. 4. The fabric structure allows the implementation of simple and well arranged wiring. In addition, the fiber-cross area plays the role of a microbender, inducing light loss via perpendicular contact force.

Although this tactile type sensor needs many optical fibers compared with a FBG tactile sensor [6], they can be arranged as a bundle of optical fibers. In a general case, one light detector is used at one optical fiber when light intensity is measured. Thus, numerous detectors are required when the tactile sensor array is evaluated. However, by using a CCD as a light intensity detector, the intensity changes of all optical fibers can be measured at once. Thus, the CCD makes it possible to minimize the number of the optical measurement system and detect multiple light intensity changes from the optical fiber bundle.

In order to realize accurate and reliable measurement, a connector to a CCD must be designed to make intensities from all optical fibers similar at the same light input. An aligner, which is the main part of the connector, consists of four V-grooved plates to align the optical fibers on a plate a nd four dummy plates so that the space will not interfere with the neighboring lights, as illustrated in Fig. 4. The V-grooved plates and dummy plates are made of Si wafer and are fabricated by a wet etching process.

Using the plastic molding, the connector body can be made. Finally, the end of the connector needs to be polished to align all fibers on the bottom plate. Fig. 5 shows the fabricated fiber bundle connectors to align the optical fibers to the CCD.

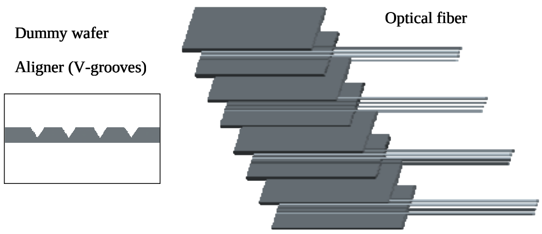

Fig. 4. Structure of the aligner

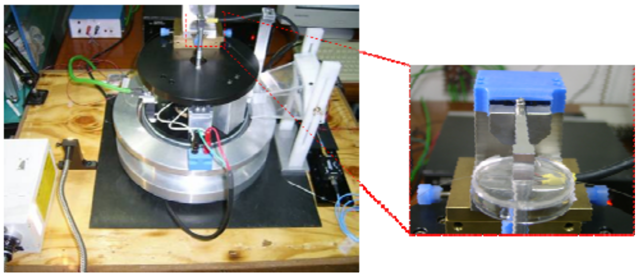

Fig. 6. Experimental setup for the evaluation of the taxel.

3 EXPERIMENTAL RESULTS

3.1. Evaluation of the tactile sensor element

The fabricated prototype taxel is evaluated by the verified experimental equipments composed of a uniaxial load-cell and a fatigue test system for small load as shown in Fig. 6.

This main device applies perpendicular load to the taxel which is placed on the top of this device. So, when the perpendicular load is applied to the taxel, the light intensity of the optical fiber is changed because of the low of action and reaction between the taxel and the load-cell. Also the load-cell detects the load. Therefore, through comparing the light intensity change of the optical fiber with load-cell load signal, the load information which is applied on the taxel is obtained.

The output signal of this prototype taxel is shown in Fig. 7. The light intensity of this taxel is decreased for its microbending light loss as the contact load is increased. The sensitivity of this sensor is -20 gray scale value / N and the resolution of this prototype sensor is 0.05N. And the exact load amount which is applied on the taxel is obtained by calibrating the sensitivity of the taxel.

The calibration process is very simple. By multiplying the sensitivity to the light intensity change, we can calculate the applied contact force as shown in Fig. 8. And the hysteresis error of this sensor is about 6.3% as shown in Fig. 9. This hysteresis error is caused by the characteristic of the silicone rubber which is the material of its transducer because the characteristic of silicone rubber is nonlinear. And the error of repeatability is about 2%.

Next, we verified the maximum capacity of this prototype taxel. The linearity between the light intensity change and the applied load is broken after 15N is applied. This phenomenon can be estimated as the abrupt stress change of the silicone rubber by the insertion of sensor is 15N which the linear response of the light intensity guarantees.

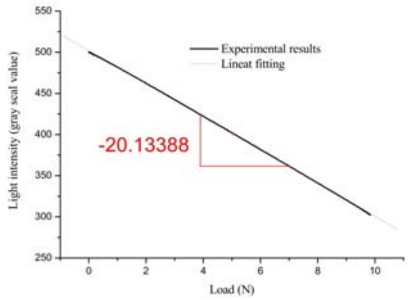

Fig. 7. Experimental verification of the prototype taxel.

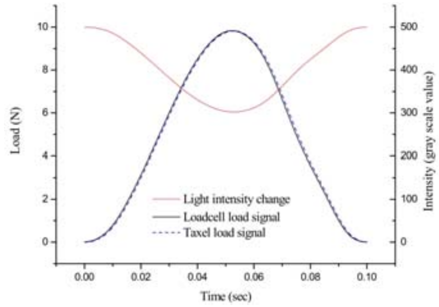

Fig. 8. Calibration of this prototype taxel.

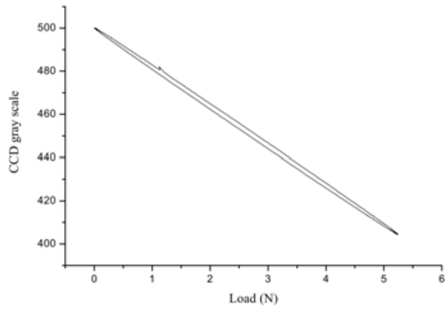

Fig. 9. Hysteresis of the prototype taxel.

3.2. Evaluation of the connector for the tactile sensor

To check the performance of the connector, the intensities changes from 16 optical fibers included in a bundle were tested, the results of which are graphically displayed in Fig. 10.

A single light input is incident to a bundle of 16 optical fibers and the light intensities measured from the output signal of the CCD. All light intensities indicate an approximately 500 gray scale value, and the difference between the maximum intensity value and the minimum inten sity value is about a 10 gray scale value. This indicates that all fibers in a bundle are well arranged and aligned to measure the light intensities changes. Point load and distributed load tests are conducted to check the proper output load from the fabricated tactile sensors. When a point load of 1.8N was applied to the pixel (6, 3) in the 5mm spatial resolution tactile array sensor, approximately 1.8N is indicated from the change of light intensity. When 5N is applied to nine taxels, as illustrated in Figure 12, each taxel that is pressed by the weight displays about 0.5×0.6 N. The small deviation of mesa depth and the relatively long spatial resolution result in differences in the output load from the taxels. A 8×8 tactile array sensors are fabricated using a molding process, as mentioned with regard to taxel fabrication. From the evaluation process, we confirmed that fabricated artificial skin by using microbending optical fiber sensor system showed us good performance during the demonstration for verification as shown Fig. 11.

4 CONCLUSION

In this paper, the force sensor using microbending light loss for the tactile sensor is newly designed and experimentally verified. The structure of this sensor with the crossed optical fibers embedded in the silicone rubber is very simple. The linear light intensity change by the applied load is verified by the experimental results. And this prototype sensor has a good performance: the resolution of this sensor is 0.05N and its maximum capacitance is 15N. However, a little hysteresis error exists due to the material of its transducer, silicone rubber. And we designed the tactile sensor with the fabric structure of the optical fibers based on the taxel. When the tactile sensor is fabricated, even though many optical fiber sensors are needed, they can be handled as one line by using the optical fiber bundle. This prototype sensor is sufficient for its application of the artificial skin which includes the tactile sensor. And, we introduce the tactile sensor system using a power LED and a CCD module which are used as a light source and a light detector respect ively. Especially, as a CCD can process hundreds of optical fibers' light output, this type of tactile sensor can be easily expanded maintaining the same optical systems. And, we design the connectors to align the cross sectional area of the optical fiber. A connector which contains 16 optical fibers shows the good performance and it is sufficient to align the optical fibers.

Abstract: This paper reports some recent results from a study on multimodal communication between life-supporting robots and their users. In the study, novice users understood how to use four types of hand gestures, raising, lowering, pushing, and pulling in a short period of time. They successfully conveyed their intensions to a robot using gestures, after watching a video for four minutes that explained how to use gestures and practicing for less than four minutes. The robot guided the users by displaying messages on its front screen and detected gestures by tracking the user's head and right hand based on depth and color information. The results show that novice users can learn quickly how to convey intentions to our robot and imply that it is easy for untrained users to combine hand gestures and spoken messages, in order to make a robot to turn to them, move forward to them, back away, approach them, and so on.

Keywords: communication, gesture detection, life-supporting, multimodal, robot

1 INTRODUCTION

These days, there are robots that work in various kinds of places. We predict that in near future, there will be more and more life-supporting robots, which are supposed to help non-experts, especially in aging societies, including Japan. Millions of robot cleaners are already in homes and offices all over the world and help people who do not have special knowledge or training experiences. However, many robots are still operated by experts and it is difficult for untrained people to command them.

This study focuses on communication between a life supporting robot and its user, in particular, commanding the robots to look at the user, come close to the user, and move forward and backward to keep appropriate distance from each other, which would be necessary before the user gives a task to the robot, receive help from it, or work on a cooperative task.

We believe that multimodal communication using spoken messages and three dimensional hand gestures is effective when we want a life-supporting robot to turn to us or come close to us. The robot can also send verbal and nonverbal messages on its screen and through its speakers.

We realized a 3D hand gesture detection system for life-supporting robots that understand multimodal commands and conducted a user study in order to verify hypotheses that novice users can convey their intensions through 3D hand gestures in a short period of time and that our system can recognize their gestures without errors. There have been studies in multimodal languages, combining speech and key input, speech and body touch, or speech and 2D gestures, for untrained users of home-use and life-supporting robots [1-4], which have shown that the languages are beginner friendly for some groups of tasks, such as moving the robot and moving an object. However, it is difficult to specify 3D positions and distances in the real world in those multimodal languages.

We have proposed a multimodal language in which one can command robots using a touch screen and a speech interface [5]. However, the language requires a hand-held device and it is difficult to let robots know one's own location or distance information. In this paper, we propose a multimodal language which combines speech and 3D gesture, which allows users to intuitively convey their own location, goals, and short distances. For example, one can raise the hand and say "turn to me" in order to turn a robot to the person. Without gestures, they would give a spoken command, say, "make a 73-degree right turn," which is not very natural and difficult for untrained users: they have to determine angles, distances, and other spatial quantities by eye. Without speech, it is also difficult to give robots a variety of commands: one needs to learn many types of gesture [6].

These days, it is possible to obtain depth images [7], find and track an object, and recognize spoken commands in real time using inexpensive computers and input devices. Therefore, one can develop and test robots that understand multimodal commands combining speech and 3D gesture.

Our gesture recognition system detects four types of 3D single-hand gestures: raising, lowering, pushing, and pulling, which we find important for communication between a life-supporting robot and its user. These types of gesture are useful when one wants to start communicating and collaborating with a robot and to maintain a comfortable distance during communication. Pushing and pulling gestures convey a 3D direction, forward or backward, and length information. A raising gesture can inform a robot of a 3D position. Finally, raising and lowering gestures can be used to start and stop robot actions.

In the rest of this paper, we describe our gesture detection system and a user study of it. Eleven novice users learned to use the four types of 3D gesture within ten minutes and all of their properly used gestures were classified correctly by our system. These facts and question sheets filled out by the users imply that our gesture detection system is of a great value for multimodal communication between life-supporting robots and their users, none the less because the system works well on a single laptop computer equipped with a microphone and an inexpensive motion input device to capture color and depth images.

2 GESTURE DETECTION SYSTEM

2.1 User detection

Our gesture detection system can find the nearest user sitting on a chair in the view in the following steps:

1. find every person in the view
2. mark each person's top of head
3. find the closest sitting person using 3D information

Our current system is built using OpenNI [8], a free SDK for Kinect motion sensor [9], and OpenCV [10] for image processing and GUI. OpenNI includes a function to obtain a depth map from a Kinect and a function to label image pixels by person. Both are incorporated into our system.

2.2 Hand detection and tracking

The system can find the right hand of the nearest sitting person, when the person moves the hand up close to the face. It traces the boundary of the sitting person's label looking for the right elbow, i.e. the lowest point, and then the right hand (see **Fig. 1**). If this does not work, the system assumes that the hand is near the label closest to the view

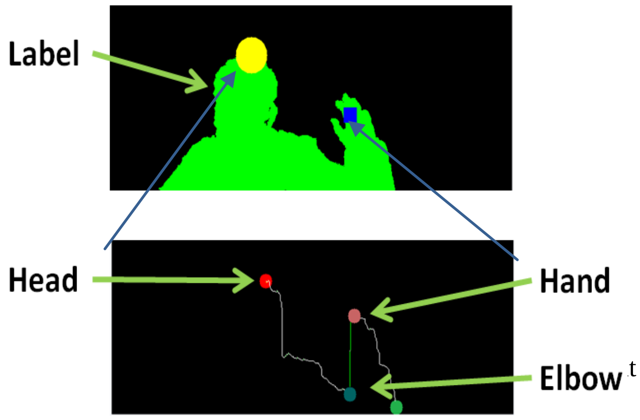

Fig. 1. Finding the right hand

2.3 3D gesture detection

Our system can detect raising, lowering, pushing, and pulling gestures based on the results of real-time 3D hand tracking described above. It looks for a 3D motion segment that fulfills several conditions of duration, speed, the location of the start/end point relative to the head position, distance between the start and end point, and direction. **Table 1** shows some of the criteria for each type of 3D gesture. For instance, to give a raising gesture, one must stop the right hand below the top of head ($y < 0$), move it fast and straight upward, and stop it above the top of head ($y > 0$).

Table 1. Gesture detection criteria

Gesture Type	raise	lower	push	pull
average speed [m/s]	0.3	0.3	0.15	0.15

	up	down	forth	back

2.4 Messages and images on the screen

Our system displays verbal messages, a face, and a hand on a PC screen (see **Fig. 2**). When the system finds a sitting person, a frontal face appears (bottom-left). When the right hand is successfully tracked, a hand and a "ready" sign are displayed near the face and up-left corner of the screen, respectively (top). The screen shows a verbal sign such as "up" and "back" and an image that depicts a gesture for two seconds after a gesture is detected (middle).

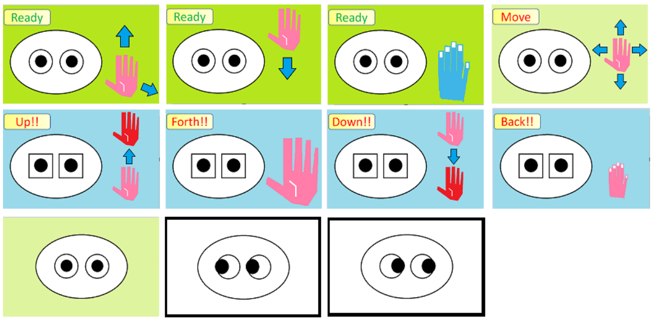

Fig. 2. Screen messages

3 USER STUDY

Fig. 3 shows Rocky, our life-supporting robot platform, which we used in the user study of our gesture detection system. It has a Kinect motion sensor on top, a 10 inch touch screen at front, and a laptop PC with an Intel Core i7 processor inside the body. The gesture detection system ran on the PC and the touch screen, connected with the PC via a USB cable, displayed messages and images to the users.

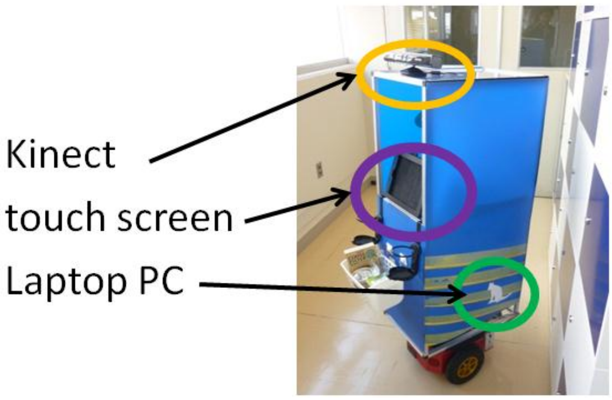

Fig. 3. Rocky, our life-supporting robot

We showed each of the eleven novice users a four-minute demonstration video, who then sat on a chair 2[m] away from the robot and moved the right hand as instructed.

The users were advised to move the right hand fast and straight when the screen displays a "ready" sign and let it down immediately after each gesture. We also suggested them to move the hand up or to the right when the system could not find it.

The first six users (Group A) practiced for two minutes after watching the demonstration video. Then, they were given pieces of advice described above and instructed to show the robot three gestures in a row for each type to test the system.

The other five users (Group B) practiced until we judged they learned the four gestures, since some of the former six users failed to practice all the types. We advised them during the practice and emphasized that they needed to wait for a "ready" sign. In the test phase, they were instructed to show gestures one by one rather than three in a row, in order to avoid unnecessary confusions.

Each of the eleven users filled out a question sheet which included eight questions (see **Table 2**).

4 RESULTS

Our system detected and correctly classified all the 3D gestures given properly by the eleven novice users. All of them moved their hand quickly and straight. However, some moved their hand when there was no "ready" sign on the screen, and also, there were three users, two in Group A and one in B, who did not put their hand down immediately after some of their pushing and pulling gestures. They told us that they had moved their hand "without thinking." In addition, some users moved their hand forward when our system happened to give a false alarm on the screen.

Table 3 shows the results of the first six questions in **Table 2**. A user (Group A) answered that the system failed to detect pulling and pushing gestures. Four in Group A thought that our system classified pulling as pushing and vice versa.

Six people found the screen messages comprehensible, and three thought they were slightly comprehensible. The other two's answers were neutral.

Table 2. Questions to the users

Id	Question
Q1	Do you understand how the four types of 3D gesture work?
Q2	Do you know exactly when to gesture?
Q3	Did our robot fail to detect your gesture during the final test?
Q4	Did our robot fail to classify your gesture?
Q5	During the final test, did the robot react to your unintended hand motion?
Q6	Have you mastered the four types of 3D gesture?
Q7	Were the pictures and signs on the screen comprehensible?
Q8	Any problems or comments?

Table 3. Answers to Q1-Q6

Id	Yes	No
Q1	11	0
Q2	10	1 (Group A)
Q3	1(Group A)	10
Q4	4 (Group A)	7
Q5	0	11
Q6	11	0

5 DISCUSSION

The results imply that our gesture detection system is of great value for multimodal communication between a life-supporting robot and its novice users. Even beginners can learn to use the four types of 3D gestures given some simple advice within less than ten minutes. Our system can detect 3D gestures properly given by beginners at a very high probability. It can be applied to understanding multimodal commands combining speech and 3D gesture. Our robot would be able to detect and classify multimodal commands at a high rate and reduce false alarms since it is unlikely that speech and gesture false alarms are given simultaneously.

Although our system ignored hand motions for two seconds after a gesture was detected, in multimodal communication it would not be necessary because only gestures that match spoken messages are in question. The users, mostly in Group A, who tried to give gestures when the screen was not displaying a ready message, were probably confused by images and messages that showed detected gestures (**Fig. 2**). Presumably, they tried to give a second gesture and our system detected a hand motion in the opposite direction as a gesture. We need to avoid such confusions when designing multimodal human-robot communication.

Users in Group B, who practiced given our advice, had better impression about our system, so it is important that novice users learn to wait for a ready message and give a gesture properly.

Although our current system is already highly reliable with respect to detection classification of four types of 3D gesture, we can improve it by reducing false positives and negatives. We presume that we can add more types without performance degradation. Finally, our 3D gestures are more intuitive than static hand gestures [11] for multimodal commands.

6 CONCLUSION AND FUTURE WORK

We built a 3D gesture detection system for multimodal communication with a life-supporting robot and conducted a user study. In the study, eleven novice users learned using 3D gestures properly within a short period of time, and our system correctly recognized the users' intentions when they moved their hand as instructed. The results show that our 3D gesture detection system can be readily applied to multimodal communication with life-supporting robots. We are currently developing a life-supporting robot one can command by combining spoken messages and 3D hand gestures.

Abstract: We have already proposed a new concept of 'universal multimedia access' intended to narrow the digital divide by providing appropriate multimedia expressions according to users' (mental and physical) abilities, computer facilities, and network environments. Our previous work has evaluated some types of multimedia user interfaces only for younger persons who can utilize keyword search functions. In this paper, we describe several multimedia contents particularly for elderly persons' aid and evaluate them based on a questionnaire survey.

Keywords: Multimedia, User Interface, Digital Divide.

1 INTRODUCTION

Recently, immense multimedia information has come to be exchanged on the Internet, where 3DCG, video, image, sound, and text are involved in various circumstances with terminal devices, networks and users different in their competences and performances. This fact may easily lead to 'digital divide' so called unless any special support is given to the weaker.

The universal design concept is proposed to support handicapped people in their social activities [1]. In the computer science field, the universal web [2] has been proposed to evolve this concept. However, this does not support to switch the contents, media or its quality of service (QoS) function to work the devices and network environments in their full performances. On the other hand, many studies about QoS function proposed to optimize video quality for priorities on users' requests [3]. These studies focused on performances of devices and network environments but neither users' abilities nor contents. Of course, there were also several studies on 'universal multimedia access (UMA)' but they could not narrow the digital divide because they concerned 'content switching' only [4].

Considering this fact, we have already proposed a new concept of UMA and its switching functions [5] intended to narrow the digital divide by providing appropriate multimedia expressions according to users' (mental and physical) abilities, computer facilities and network environments. In this paper, we introduce some multimedia contents for user switching function and evaluate a questionnaire survey conducted for elderly persons.

2 UNIVERSAL MULTIMEDIA ACCESS

The digital divide is caused by the differences in users' personal competences, computer facilities and network environments with such detailed items as follows.

(1) Personal competence: Physical abilities for seeing, hearing and manipulating; linguistic literacy; computer skill and cultural background,

(2) Computer facility: Processing power, resolution, color quality, sound quality and battery life,

(3) Network environment: Bandwidth availability, specification and transfer mode.

Therefore, multimedia information is necessarily accompanied by switching user interface, media and QoS parameters reflecting these differences. Here, we present a new approach to UMA for elderly people with handicap in working their devices and network environments in full performances based on such a concept as shown in Fig.1.

3 SWITCHING FUNCTIONS

UMA is to selectively provide three kinds of switching function, namely, user interface switching (UIS), media switching (MS) and QoS switching (QS). Fig.2 shows these switching functions working as follows:

(SF1) UIS: Switch to user interfaces (UI) appropriate for users' competences and display devices,

(SF2) MS: Switch to media appropriate for users' competences, performances of terminal devices and networks,

(SF3) QS: Control media qualities appropriate for users' competences and terminal devices.

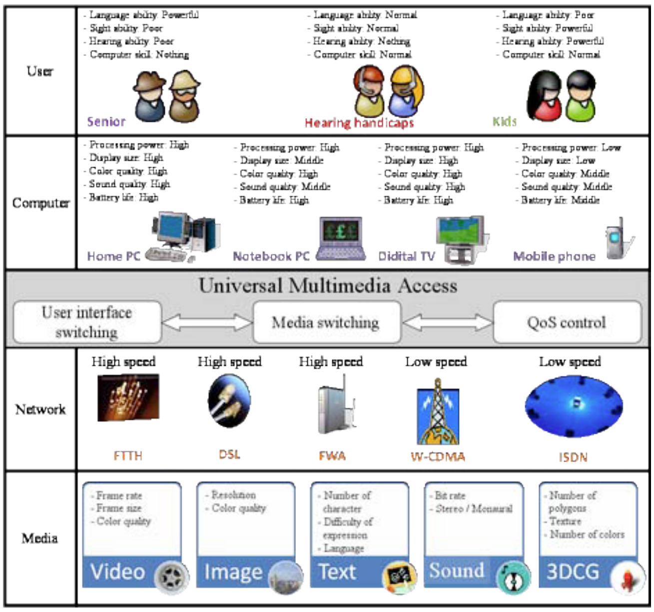

Fig. 1. UMA.

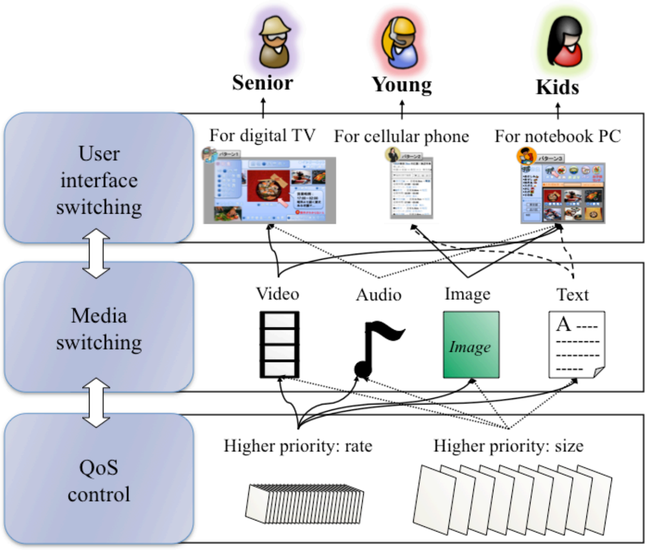

Fig. 2. Switching functions

These functions are applied in the ascending order (from SF1 to SF3) at beginning to play multimedia information or in the descending order at playing.

4 USER INTERFACE SWITCHING

UI provides users with appropriate operations and media according to their computer skill and computer facilities.

Computer skill is graded in such a way as follows.

(G0) No Knowledge about Computer: Unable to operate any computer functions.

(G1) Computer Beginner: Able to start up an application software such as Web browser and play media.

(G2) General Web User: Able to operate general Web pages and select to play a media.

(G3) Internet Expert: Able to use efficiently interactive online applications such as a search engine.

On the other hand, computer facilities are rated from several viewpoints and classified into 4 levels (None, Low, Middle, High) to setup media.

UI is provided differently according to computer skills and facilities. Table.1 shows 12 types of UI expressed in a matrix.

Computer beginners are supposed to select Broadcast Operation (BO) so as to play media according to the program without complicated operations. The user can get information just like watching TV because it is not necessary to operate any application software fundamentally. Choice Operation (CO) is intended for general Web users so as to select media only. But it takes user much time to select one from a lot of media. Search Operation (SO) is supposed to support Internet experts by providing a keyword search function.

Low power terminals are supported to play AA and text with only low graphics power and narrow bandwidth of network. Middle power terminals are to display contents such as combinations of still image and text. High power terminals play video requiring not only high power CPU but also high power Graphic device.

A layout is used to put media on UI and to specify the display region, display size and number of media for resolutions of the terminal device and the media. These relations enable a layout to specify the display position according to the display size and the number of media.

In order to introduce UIS, we focused on CO because willing users are supposed to perform this operation driven by necessity. On the other hand, they will not use any operation without CO. From this point of view, CO is applied to UIS switching from a current UI to desired one and controlling types of UI with buttons just like TV remote control.

Table 1. User interface according to user's operation a nd types of media

Operation	Media			
	AA (Ascii Art)	Text	Image&Text	Video
Broadcast	- No operation - Displaying a AA according to the program	- No operation - Displaying a text according to the program	- No operation - Displaying images and text according to the program	- No operation - Playing a video according to the program
Choice	- Selection - Displaying a AA according to the program	- Selection - Displaying a text according to the program	- Selection - Displaying selected images and text	- Selection - Playing a selected video
Search	- Keyword search - Displaying a AA according to the program	- Keyword search - Displaying a text according to the program	- Keyword search - Playing searched images and text	- Keyword search - Playing a searched video

5 IMPLEMENTATION

Our ideas were implemented as Flash applications running on a web browser as shown in Fig.3. These applications introduce the sightseeing area called the 'Keishouchi (=Splendid scenery)' contents providing the 12 UIs mentioned above. These UIs can be switched to a desired one using 'software remote controller (SRC)' as shown in Fig.4. SRC is supposed for general Web users and over so as to select a UI with simple button operation because other users would not like complicated operations.

6 EVALUATION

In order for evaluation, the web-based questionnaire survey system has been used to correct for the results of questionnaire sheets and to support following functions:

(ES1) Make a new questionnaire,
(ES2) Perform a questionnaire survey,
(ES3) Output the results of survey.

The system published contents [8] as shown in Fig.5 and was constructed on the following 4 types of software:

(FW1) Web server: apache 2.2.14 [10],
(FW2) Web Survey System: LimeSurvey 1.90 [11],
(FW3) Script language: PHP 5.3.1 [12],
(FW4) Database: MySQL 5.1.41 [13].

A questionnaire survey has been carried out for 5 elderly persons (over 70 years old) using the questionnaire sheet as shown in Fig.6. In the survey, the graduate student instructs them to operate the UI and fill out to the sheet. For this reason, none of them can do any computer operation. The results are shown in Fig.7. From the evaluation, we find that they can only use BO in order not to operate a general PC, but CO is preferred to BO using a tablet PC. Also, the information can be understood easily by video content regardless of its operation. But both of text and ascii art content are more difficult than other contents.

7 CONCLUSION

In this paper, we discussed the UI appropriate for low computer skills and facilities. Especially, we evaluated the 12 types of UIs for elderly persons. From the evaluation, elderly persons can only use BO in order not to operate a general PC, but CO is preferred to BO on a tablet PC. Currently, we are evaluating SRC and its UI for more persons. In near future, we will construct some types of content for evaluating UIS and other switching functions for UMA.

Toward Artificial Kansei Based on Mental Image Directed Semantic Theory

Tzu-Hsuan Huang Kaoru Sugita Masao Yokota
Fukuoka Institute of Technology
yokota@fit.ac.jp

Abstract

The authors have proposed a human mind model of human mind consisting of Stimulus, Knowledge, Emotion and Response Processing Agents and simulated human-robot communication based on it. This paper proposes 'Artificial *Kansei* (AK)', namely, *Kansei* for a robot as tight collaboration of Knowledge and Emotion Processing Agents of our mind model, and considers its application to a *Kansei* information system for Buddhism statues made to order.

1. Introduction

In recent years, there have been developed various types of robots in Japan. However, they are to play their roles according to programmed actions to stimuli and have not yet come to understand such a mental function of their human partners as is called *Kansei*. The authors have proposed a human mind model of human mind consisting of Stimulus, Knowledge, Emotion and Response Processing Agents (see Fig.1) and simulated human-robot communication based on it [1]. Besides this, we have tried to describe the meanings of *Kansei* expressions such as 'heart-calming', 'fantastic', 'soft', 'thick', 'grotesque', etc related to visual images of crafts and to retrieve them by these expressions as queries [4-6]. In this paper, we describe 'Artificial *Kansei* (AK)', namely, *Kansei* for a robot as tight collaboration of Knowledge and Emotion Processing Agents of our mind model, and verbalization of *Kansei* information so called '*Kansei* expression' by Response Processing Agent in the view of artificial or robotic individuality.

2. Multi-agent mind model

Figure 1 shows the multi-agent mind model proposed by the authors [1]. This is a functional model of human central nervous system consisting of the brain and the spine. The basic performances of its agents are as follows.

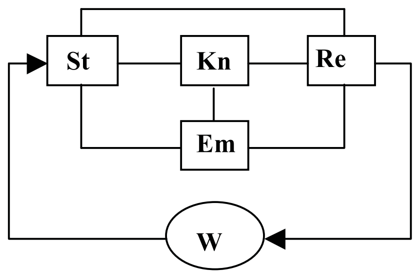
(1) **Stimulus Processing Agent** (**St**) receives stimuli from the world (**W**) and encodes them into mental images (i.e. encoded sensations) such as *"I sensed something oily."* (if verbalized in English.)
(2) **Knowledge Processing Agent** (**Kn**) evaluates mental images received from the other agents based on its memory (e.g. knowledge), producing other mental images such as *"It is false that the earth is flat."*
(3) **Emotion Processing Agent** (**Em**) evaluates mental images received from the other agents based on its memory (e.g. instincts), producing other mental images such as *"I like the food."*
(4) **Response Processing Agent** (**Re**) converts mental images (i.e. encoded physical actions such as *"I'll walk slowly."*) received from the other agents into real physical actions against **W**.

A *performance* ***P*** for a *stimulus* X with a *result* Y at each agent can be formalized as a function by the expression (1).

$$Y=\boldsymbol{P}(X), \tag{1}$$

where

P: a combination of ***atomic performances*** described later,
X: a spatio-temporal distribution of stimuli from **W** to **St** or a mental image for another agent, and
Y : a series of signals to drive an actuator for **Re** or a mental image for another agent.



St: Stimulus Processing Agent.
Kn: Knowledge Processing Agent.
Em: Emotion Processing Agent.
Re: Response Processing Agent.
W: World surrounding human mind, including his/her body.

Fig.1. Multi-agent model of human mind.

A performance ***P*** is assumed as a function formed either consciously or unconsciously. In a conscious case, a set of atomic performances are to be chosen and combined according to X by a meta-function, so called, '***Performance Selector*** (PS)' assumed as '***Conscience***'. On the contrary, in an unconscious case, such a performance as associated most strongly with X is to be applied automatically [8]

3. Mental image description

Mental Image Directed Semantic Theory (MIDST) has modeled mental images as "Loci in Attribute spaces" [3], [7]. An attribute space corresponds with a certain measuring instrument just like a thermometer, map measurer or so and the loci represent the movements of its indicator. The performance of 'Attribute space' is the model of '***Atomic performance***' introduced in Section 2.

A general locus is to be articulated by "Atomic locus" formalized as the expression (2) in first-order logic, where "L" is a predicate constant.

$$L(x,y,p,q,a,g,k) \quad (2)$$

The expression (2) is called "Atomic locus formula" whose arguments are referred to as 'Event Causer', 'Attribute Carrier', 'Initial Attribute Value', 'Final Attribute Value', 'Attribute Kind', 'Event Kind' and 'Standard Attribute Value', respectively.

The interpretation of (2) is as follows, where "matter" refers to "object" or "event".

"Matter 'x' causes Attribute 'a' of Matter 'y' to keep (p=q) or change (p ≠ q) its values temporally ($g=G_t$) or spatially ($g=G_s$) over a time-interval, where the values 'p' and 'q' are relative to the standard 'k'."

When $g=G_t$ and $g=G_s$, the locus indicates monotonic change or constancy of the attribute in time domain and in space domain, respectively. The former is called 'temporal event' and the latter, 'spatial event'.

For example, the motion of the 'bus' represented by S1 is a temporal event and the ranging or extension of the 'road' by S2 is a spatial event whose meanings or concepts are formalized as expressions (3) and (4), respectively, where the attribute is "physical location" denoted as A_{12}. We think that the verb 'run' used in S2 must reflect the motion of the observer's attention [4].

(S1) The bus runs from Tokyo to Osaka.

$$(\exists x,y,k)L(x,y,Tokyo,Osaka,A_{12},G_t,k)\wedge bus(y) \quad (3)$$

(S2) The road runs from Tokyo to Osaka.

$$(\exists x,y,k)L(x,y,Tokyo,Osaka,A_{12},G_s,k)\wedge road(y) \quad (4)$$

The expression (5) is the conceptual description of the English word "fetch", implying such a temporal event that 'x_1' goes for 'x_2' and then comes back with it, where 'Π' and '•' are instances of the tempo-logical connectives, 'SAND' and 'CAND', standing for "Simultaneous AND" and "Consecutive AND", respectively.

In general, a series of atomic locus formulas with such connectives is called simply 'Locus formula'.

$$(\exists x_1,x_2,p_1,p_2,k)\ L(x_1,x_1,p_1,p_2,A_{12},G_t,k)$$
$$\bullet (L(x_1,x_1,p_2,p_1,A_{12},G_t,k)\Pi L(x_1,x_2,p_2,p_1,A_{12},G_t,k))$$
$$\wedge x_1 \neq x_2 \wedge p_1 \neq p_2 \quad (5)$$

4. Artificial *Kansei*

It is well known that emotion in a human can be affected by his/her world, namely, ***W*** in Fig.1. For example, a person's evaluation of live image of an object (i.e. image output from **St**) expressed by such words as 'favorite', 'beautiful', 'tasty', etc can vary depending on his/her emotional bias such as 'hungry', 'depressed', etc.

Kansei is one of mental functions with emotion involved but has a more complicated phase than pure emotion originated from instincts or imprinting. For example, sweet jam may be nice on toast but not on pizza for certain people knowledgeable about these foods. For another example, people can be affected on their evaluation of an art by its creator's name, for example, 'Picasso'. These are good examples of *Kansei* processing as emotional performance affected by knowledge in humans.

Therefore, *Kansei* can be defined as human emotion toward an object affected by its information, so called, 'concept', including his/her intellectual pursuits, traditions, cultures, etc concerning it. In this sense, *Kansei* is assumed to be reasonable among the people sharing such concepts unlike pure emotion. These hypothetic considerations are formalized as (7) and (8).

$$I_P(x)= \boldsymbol{P_E}(S(x)) \quad (7)$$

$$I_K(x) =\boldsymbol{P_E}(S(x)\wedge O(x)) = \boldsymbol{P_E}(S'(x)) \quad (8)$$

where

$\boldsymbol{P_E}$(X): Performance of **Em** for mental image 'X',
I_P(x): Mental image as pure emotion for object 'x',
I_K(x): Mental image as *Kansei* for object 'x',
S(x): Live image of object 'x' from **St**,
O(x): Concept of object 'x' from **Kn**,
S'(x): Unified image of live image and concept.

Figure 3 shows an example of *Kansei* processing in our mind model, where perceived, induced and inspired images correspond to S(x), S'(x) and I_K(x), respectively, while Fig.2 is for pure emotion with I_P(x) as the inspired image.

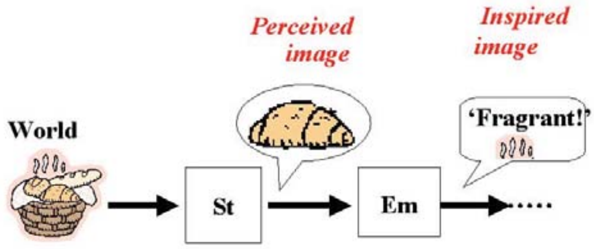


Fig.2. Example of pure emotion

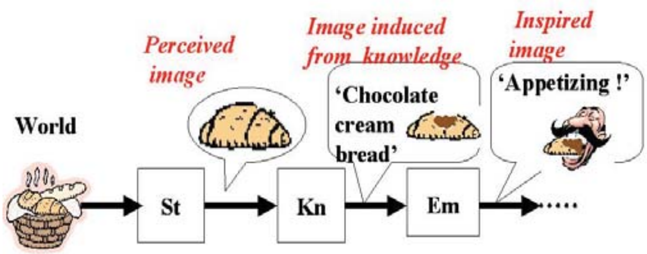

Fig.3. Example of *Kansei* processing

These two inspired images are to be verbalized in **Re** as 'Fragrant!' and 'Appetizing!', labeled in Fig.2, respectively. The essential difference between them is assumed to reside in whether or not they are affected by O(x), namely, the concept of 'chocolate cream bread', inferred by **Kn** from the shape and the smell. Whereas, pure emotion for an object can be a special case of *Kansei* processing without knowing or recognizing what it is.

In MIDST, the concept of an object 'x' is given as an integrated omnisensory mental image of its properties and its relations with other objects involved. For example, the concept of 'chocolate cream bread' can be given by (9), reading that x is bread, sweet due to chocolate cream, fragrant of itself, etc, where A_{29} and A_{30} refer to 'Taste' and 'Odour', respectively.

$$(\lambda x)chocolate\_cream\_bread(x) \Leftrightarrow (\lambda x\exists y,k_1,k_2)L(y,x,Sweet,Sweet,A_{29},G_t,k_1)\Pi\, L(x,x,Fragrant,Fragrant,A_{30},G_t,k_2) \wedge bread(x) \wedge chocolate\_cream(y) \wedge \ldots \quad (9)$$

5. Human language understanding in robots

For comprehensible communication with humans, robots must understand natural language *semantically* and *pragmatically*. Here, semantic understanding means connecting symbols to conceptual images of objects and pragmatic understanding means connecting symbols to real objects by unifying conceptual images with perceptual images. However, humans and robots can be equipped with sensors, actuators and brains of different performances and their vocabularies may well be grounded on quite different sensations, physical actions or mental actions. And in turn such a situation may bring inevitably different kinds of semantics to them, so called, "Natural Semantics (NS)" for humans and "Artificial Semantics (AS)" for robots.

For example, consider such a scenario as follows.

...A human 'Kate' and a humanoid robot 'Robbie' encounter at the terrace in front of the room where a Christmas party is going on merrymaking. Kate says "Robbie, please fetch me some nice food from the gaudy room." Robbie replies "OK, Kate."….

For a happy end of this dialog, Robbie must have a good knowledge of Kate's NS for *Kansei* and translate it into its AS appropriately enough to find out the real objects referred to by her words. In this case, Robbie needs at least to interpret Kate's statement as the expression (10) reading "If <u>*Robbie* fetches *Kate* some food nice ***for her*** from the room noisy ***for her*** (***E1***),</u> then consecutively <u>it makes *Kate* happier (***E2***)</u>". It is notable that (10) is the canonical form of the meaning of an imperative sentence.

$$\boldsymbol{E_1} \rightarrow_c \boldsymbol{E_2} \quad (10)$$

where

$$\boldsymbol{E_1} \Leftrightarrow (\exists x_1,x_2,k_1,k_2,k_3,k_4)\ (L(R,R,K,x_2,A_{12},G_t,k_1)\bullet (L(R,R,x_2,K,A_{12},G_t,k_1)\Pi L(R,x_1,x_2,K,A_{12},G_t,k_1))) \Pi(L(K,x_1,Nice,Nice,B_{08},G_t,k_2) \Pi\, L(K,x_2,Gaudy,Gaudy,B_{08},G_t,k_4) \wedge food(x1) \wedge room(x2)$$

$$\boldsymbol{E_2} \Leftrightarrow (\exists e_1,e_2,k_7)\ L(\boldsymbol{E_1},K,e_1,e_2,B_{04},G_t,k_7) \wedge e_2>e_1.$$

The special symbols and their meanings in the expressions above are:

'$X \rightarrow_c Y$' ='If X then consecutively Y', R='Robbie', K='Kate', B_{08}='*Kansei*' and B_{04}= 'Happiness (=degree of happiness)'.

As easily imagined, these values of the attribute *Kansei* (B_{08}) greatly depend on their standards (i.e. k_2 and k_4) that are most closely related to 'Individual' or 'Purposive' standard shown in Table 1 (see APPENDIX).

By the way, Robbie's task is only to make ***E1*** come true where each atomic locus formula is associated with his actuators/sensors. Of course, Robbie believes that he will become happier to help Kate, given by expression (11) where 'B_{03}' is 'trueness (=degree of truth)'and 'K_B' is a certain standard of 'believability'. That is *emotionally* to say, Robbie likes Kate. Therefore, this example is also very significant for intentional sensing and action of a robot driven by logical description of its belief.

$$(\exists p)L(R,\boldsymbol{E},p,p,B_{03},G_t,K_B) \wedge p>K_B \wedge \boldsymbol{E} = \boldsymbol{E_1} \rightarrow_c \boldsymbol{E_2} \quad (11)$$

6. Affective analysis of Buddhism statues

Many psychologists have claimed that certain emotions are more basic than others (Ortony & Turner, 1990). We have assumed that human emotion consists of 5 primitives representing the degrees of 1) Anger, 2) Disgust, 3) Anxiety, 4) Happiness, and 5) Superiority. For example, the degree of Happiness is measured by using such a word set as {anguish, distress, sorrow, gloom, content, joy, ecstasy}, whose each element is possibly arranged on a coordinate axis and fuzzified with a certain characteristic function. Therefore, we have assumed Kansei as a certain function to evaluate totally the loci in the attribute spaces of these primitives. Based on the 5 primitive emotional parameters, we have been analysing Buddhism statues as shown in Fig.4 in order to plot them in the attribute space of Kansei (B_{08}) with some purposive standard of Buddhism. Table 1 shows an example of such analysis, where H, M and L denote high, middle, and low in degree, respectively. These results are to be associated with Kansei words such as divine, gentle, reverential, noble, valiant, etc. analyzed in the same way and to be applied to the customer servicing interface of a Buddhism statue ordering system.

a) Dainichi-nyorai (DN) b) Fudo-myo-o (FM)

Fig.4. Samples of Buddhism statues

Table 1 Affective analysis of Buddhism statues

Sample	anger	disgust	anxiety	happiness	superiority
DN	L	L	L	H	H
FM	H	M	H	L	H

7. Discussion and conclusion

Our mind model is much simpler than Minsky's [2] but the locus formula representation can work for representing and computing mental phenomena fairly well [1, 3]. For realizing a plausible *Kansei*, it is most essential to find out functional features of **Em** and to deduce from them such laws that rule $\boldsymbol{P_E}$. The most important problems to be solved are how to realize the attribute space of *Kansei* and how to build its corresponding atomic performance. In order to solve these problems, focusing on Buddhism statues, we will consider the application of soft computing theories such as neural network, genetic algorithm, fuzzy logic, etc. in near future.
