Abstract

Several digital watermarking techniques for audio files have been proposed for hiding data in order to protect their copyrights. There is a tradeoff between the quality of watermarked audio and the tolerance of watermarks to signal processing methods, such as compression. In order to overcome the inevitable tradeoff, we previously developed an authentication method for digital audio. We have improved the method by determining the region to be authenticated in the audio data by using the fundamental frequency characteristics.

Keywords: Authentication, Audio, Copyright protection, Wavelet transform, Fundamental frequency.

1. Introduction

Recent progress in digital media technology and distribution systems, such as the Internet and cellular phones, has enabled consumers to easily access, copy, and modify digital audio. Several digital watermarking (DW) techniques for audio files have been proposed for hiding data in order to protect their copyrights. In general, there is a tradeoff between the quality of watermarked audio and the tolerance of watermarks to signal processing methods, such as compression.

In previous research,[1] to essentially overcome this issue, we developed an authentication method for digital audio to protect the copyrights. In contrast to DW, no additional information is inserted into the original audio by the previously proposed method, and the digital audio is authenticated using features extracted using a discrete wavelet transform (DWT) and characteristic coding of the previously proposed method.[1] However, the region to be authenticated in the audio data is decided by the fixed length and the fixed starting time from the beginning of the audio data. Therefore, the authentication tolerance to clipping of the audio data is insufficient for practical use.

In the present study, to overcome this issue, we have improved the method by determining the region to be authenticated in the audio data by using the fundamental frequency characteristics.

2. Observed Phenomenon Underpins the Authentication Method

The procedure and algorithm of our previously proposed method[1] is reviewed in this section, because it is very important for the present study.

It has been observed that when a DWT is applied to audio data, in the histogram of the wavelet coefficients of the multi-resolution representation

(MRR), the center of the distribution is very close to zero.[2] We exploited this phenomenon in order to develop an authentication method for audio data.[1] For further information on the DWT used, see Refs. 3 and 4.

3. Authentication Ratio

We set the authentication parameters as described below.[1,5]

In Fig. 1, $Th'(\text{minus})$ was chosen so that it divides the nonpositive wavelet coefficients (S'_m in total frequency) into two equal groups, and similarly $Th'(\text{plus})$ was chosen so that it divides the positive wavelet coefficients (S'_p in total frequency) into two equal groups. Next, the values of the parameters $T1'$ – $T4'$, which control the authentication precision, were chosen such that the following conditions were satisfied:

1) $T1' < Th'(\text{minus}) < T2' < 0 < T3' < Th'(\text{plus}) < T4'$.
2) The value of S'_{T1}, the number of wavelet coefficients in $(T1', Th'(\text{minus}))$, is equal to S'_{T2}, the number of wavelet coefficients in $[Th'(\text{minus}), T2')$, i.e., $S'_{T1} = S'_{T2}$.
3) The value of S'_{T3}, the number of wavelet coefficients in $(T3', Th'(\text{plus})]$, is equal to S'_{T4}, the number of wavelet coefficients in $(Th'(\text{plus}), T4')$, i.e., $S'_{T3} = S'_{T4}$.
4) $S'_{T1} / S'_m = S'_{T3} / S'_p$.

In the present study, the values of both S'_{T1} / S'_m and S'_{T3} / S'_p are set to 0.3, which is the same setting used for creating the code for the original audio data.[1] When preparing the authentication codes, the wavelet coefficients V' for each MRR sequence are divided as shown in Fig. 1 into three sets, which are defined as follows:

- $F = \{V' \mid V' \in V'^{AC}, V' < Th'(minus)\}$
- $G = \{V' \mid V' \in V'^{AC}, Th'(minus) \le V' \le Th'(plus)\}$
- $H = \{V' \mid V' \in V'^{AC}, Th'(plus) < V'\}$,

where V'^{AC} is the set of wavelet coefficients from the target audio data that is used to create the authentication code.

The wavelet coefficients V_i' are then classified according to the following rules with the flags f_i used in creating the original code ***C***:

When $f_i = 1$ and $V_i' \in G$, b_i' is set to 0.

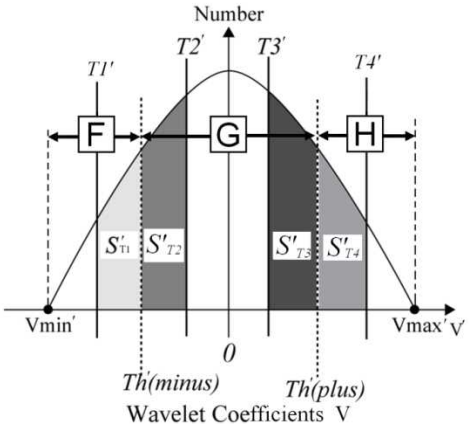

Fig. 1. Three sets (*F*, *G*, and *H*) of MRR wavelet coefficients used for authentication.[1]

When $f_i = 1$ and $V_i' \in (F \cup H)$, b_i' is set to 1.

When $f_i = 0$, b_i' is set to 0.5.

Note that the value 0.5 can be chosen arbitrarily, since the value of b_i that is the bit for creating the code for the original audio data[1] does not influence the method's performance. Finally, this sequence of b_i' values is used to form the authentication code *C'*.

The authentication ratio AR (%) is defined as follows:

$$AR = \frac{100 \sum_{i=1}^{N} f_i \left(1 - |b_i - b_i'|\right)}{\sum_{i=1}^{N} f_i}, \quad (1)$$

where N is the number of wavelet coefficients chosen to create the authentication code for the original audio data.[1] As can be seen in equation (1), neither b_i nor b_i' influences the value of AR when $f_i = 0$, which occurs when the corresponding V_i that is the wavelet coefficient of the original audio is not selected for coding in the original audio data.[1]

To use the proposed method, we need to store the flags f_i and the original code ***C*** for each copyrighted file that we want to protect. When calculating (1) in order to authenticate audio data, we do not use the original audio data; instead, we use the flags f_i and the code ***C*** for that file.[1]

4. Fundamental Frequency Characteristics of Audio Data

Fig. 2 shows the fundamental frequency of the first entry of the rock music genre category in the music database RWC for research purposes.[6] As shown, several local maximums

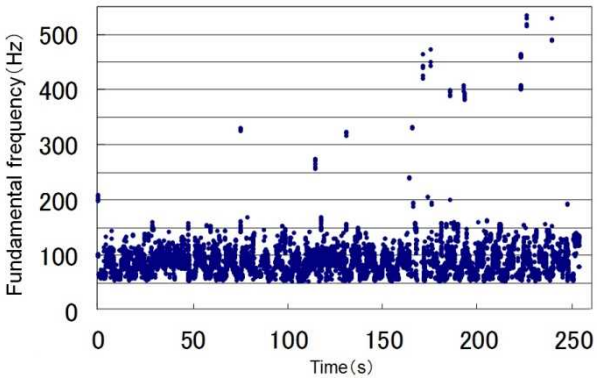

Fig. 2. Fundamental frequency of audio data.

of the fundamental frequency exist within the stream of the music. We have proposed a method for determining the region to be authenticated in the audio data by using local maximums of the fundamental frequency of the audio data, as described in the next section.

5. Proposed Method for Determining the Region to be Authenticated in the Audio Data

The audio data clipping procedure for the authentication is as follows:

Step 1: The fundamental frequency $f(i)(i=1,2,3\ldots,n)$ at the start time index i is measured every 0.01 seconds from the beginning to the end of T seconds of the original audio data, i.e., $n=100T$. Then, the absolute value of difference $ADF(i)=|f(i+1)-f(i)|$ is calculated for all $i(i=1,2,3,\ldots,n-1)$.

Step 2: The sum $S(i)=\sum_{j=0}^{999} ADF(i+j)$ is calculated for all $i(i=1,2,3,\ldots,n-999)$.

Step 3: The start time indexes i are determined by whether the value of $S(i)$ is among the top 10 of all $S(k)$ under the restriction $|i-j|\geq 1000$ for all j such that $S(i)<S(j)$.

Step 4: For the start time indexes i selected in Step 3, 10 seconds of audio data are clipped for the authentication.

6. Experiments

6.1 Conditions

An experiment was performed in the following computational environment: the personal computer was a DELL OPTIPLEX CF-SX1 (CPU: Core i7-2600 Duo, 3.40 GHz; main memory: 4.0 GB); the OS was Microsoft Windows XP; the development language was Microsoft Visual C++ 6.0.

Five music audio files, namely, the first entry of each of five genre categories—classical, jazz, popular, rock, and hiphop—in the music database RWC used for research purposes,[6] were copied from CDs onto a personal computer as WAVE files with the following specifications: 44.1 kHz, 16 bits, and monaural. For each music audio file selected from the database, 10 sets of 10-second clips of music audio were produced using the proposed method described in Section 5.

For investigating the authentication tolerance to clipping, audio test data were produced by clipping one region from each music audio file selected from the database. The clipped regions were specified by all combinations of the lengths 0.01, 0.1, 0.5, 1.0, 2.0, 3.0, and 4.0 seconds and the starting times 0, 5, and 10 seconds (from the beginning of the original audio data), resulting in 21 clipping conditions. Then, for each audio test data file produced from each original audio data file, 10 sets of 10-second clips of music audio were produced using the proposed method described in Section 5, and the authentication procedure was performed using the previously proposed method.[1] The highest value of the authentication ratio of the original audio data to the audio test data (hereinafter referred to as *HAR*) of AR as described in Section 3 among those of the 100 combinations of the 10 clips of the original data and the 10 clips of test data was calculated.

As another method for comparison (hereinafter referred as AMFC), we chose audio data from the classical music genre category and produced one 10-second clip whose starting time gave the highest fundamental frequency for 0.01 seconds among those in the audio data. Next, the clipping regions from the beginning of the original audio data were specified by the lengths 0.00001, 0.00005, 0.0001, 0.0002, 0.0003, 0.0004, 0.0005, 0.001, and 0.01 seconds. Then, the calculation of AR for the original audio data and the audio data after clipping by the above each length was performed for one 10-second clip whose starting time from the beginning of the audio data was decided by the above method for the original audio data. For the DWT, we used Daubechies wavelets. Level 8 was chosen based on an analysis of preliminary experiments.[1]

6.2 Results and discussion

Tables 1 and 2 respectively show the *AR* values for AMFC and the *HAR* values for the proposed method. As shown in Table 1, AMFC showed poor authentication tolerance to clipping: clipping 0.01 seconds of audio caused *AR* to decline to 65.88%. On the other hand, as shown in Table 2, the authentication tolerance to clipping of the audio data was improved by adopting the proposed method.

Table 1. *AR* with AMFC for clipping from the beginning of original classical audio data.

Clipping length (s)	*AR*(%)
0.00001	100
0.00005	100
0.0001	99.22
0.0002	96.84
0.0003	87.75
0.0004	84.98
0.0005	78.66
0.001	69.57
0.01	65.88

Table 2. *HAR* (%) with the proposed method under the 21 clipping conditions. Starting time for the test data from the beginning of the original audio data: (a) 0, (b) 5, and (c) 10 seconds.

(a)		Music				
		classical	jazz	popular	rock	hiphop
Clipping length (s)	0.01	100	100	100	100	100
	0.1	100	100	100	100	85.49
	0.5	98.82	99.60	99.17	99.61	78.04
	1.0	98.08	98.81	92.24	98.43	80.63
	2.0	73.12	86.67	99.17	95.29	80.63
	3.0	67.19	89.33	100	93.37	80.63
	4.0	94.25	90.40	95.01	69.41	71.76

(b)		Music				
		classical	jazz	popular	rock	hiphop
Clipping length (s)	0.01	95.62	98.82	96.40	99.72	94.90
	0.1	96.16	94.12	92.52	87.06	90.91
	0.5	82.75	89.02	93.91	84.71	83.40
	1.0	91.78	80.63	77.25	77.47	75.29
	2.0	86.03	74.67	75.10	95.44	73.52
	3.0	79.73	72.19	85.77	77.65	86.17
	4.0	64.38	71.76	76.28	74.12	73.12

(c)		Music				
		classical	jazz	popular	rock	hiphop
Clipping length (s)	0.01	100	100	100	100	100
	0.1	96.44	100	100	99.61	100
	0.5	97.65	99.61	98.42	97.63	99.60
	1.0	93.70	86.27	96.08	95.65	94.47
	2.0	88.77	66.40	91.70	93.73	88.54
	3.0	80.00	73.33	80.29	87.84	91.70
	4.0	64.84	73.87	79.45	79.61	76.28

When 5-second clip was used for narrowing the 10-second clip decided as the region to be authenticated in the audio data, *HAR* was much improved, being almost 100% for all the clipping conditions used in this experiment. Even for a clipping length of 4.0 seconds, *HAR* improved to 100% except under one condition for classical audio data: clipping from a starting time of 5 seconds from the beginning of the original audio data. In the exceptional case, *HAR* was 76.25%.

7. Conclusion

In general, there is a tradeoff between the quality of watermarked audio and the tolerance of watermarks to signal processing methods, such as compression. To overcome this inevitable tradeoff, we previously developed an authentication method[1] for digital audio using a DWT. In the present study, we have improved the method by determining the region to be authenticated in the audio file by using the fundamental frequency characteristics. The experimental results show that the method has a high authentication tolerance to clipping small parts from the audio data.
