#### Abstract

Herein, we report on the development of a system for agent facial expression generation that uses vowel recognition when generating synthesized speech. The speech is recognized using the Julius high-performance, two-pass large vocabulary continuous speech recognition decoder software system, after which the agent's facial expression is synthesized using preset parameters that depend on each vowel. The agent was created using MikuMikuDanceAgent (MMDAgent), which is a freeware animation program that allows users to create and animate movies with agents.

Keywords: MMDAgent, Speech recognition, Vowel recognition, Speech synthesis.

## 1. Introduction

In Japan, the average age of the population has been increasing, and this trend is expected to continue. Because of this, researchers have been studying ways of applying information technology (IT) to improving the medical and/or mental support provided to older adults, including persons with extreme psychiatric disorders.

In our previous study<sup>1</sup>, we developed a system for analyzing the facial expressions of a person obtained while answering interview questions posed by an animated agent. To accomplish this, we used MikuMikuDanceAgent (MMDAgent)<sup>2</sup>, which is a freeware animation program that allows users to create and animate movies with agents.

In this study, to make the agent's performance on a personal computer (PC) screen more human-like, we have developed a system for agent facial expression generation that uses vowel recognition when generating synthesized speech.

#### 2. Proposed System and Method

#### 2.1. System overview and outline of the method

Figure 1 shows the processing flow of this system, which consists of six processing units:

- creating facial expression data, recording voice utterances, automatic WAVE file division,
- speech recognition by the Julius high-performance, two-pass large vocabulary continuous speech recognition decoder software<sup>3</sup>,
- insertion of expressionless data, and
- the creation of facial expression motion.

The facial expression data are created in advance.

Fig. 1. Processing flow of system.

# 3. Development of facial expression synthesis system

## 3.1. Creating facial expression data

Expression motions are generated by combining the expression data of each vowel for each utterance motion. Facial expression data were created with MikuMikuDance<sup>4</sup>. In this study, in order to realize more human-like agent facial expressions, facial expression data were created for the vowels / a /, / i /, / u /, / e /, and / o / (Fig. 2).

## 3.2. Agent voice recording

In our system, utterance contents are input as text and used by the MMDAgent to output synthesized voice that

is then recorded by a stereo mixer inside a PC and saved as a WAVE file.

## 3.3. Automatic division of WAVE files

After all the utterances have been recorded, if there are multiple questions, the WAVE file is automatically divided for each question, and a new WAVE file is created for each question.

## 3.4. Speech recognition using Julius

The results of speech recognition using Julius are shown

in Fig. 3. From the recognition results, an output file is created that lists the vowels, and their start and end times (Fig. 4).

### 3.5. Inserting neutral agent motion data

In order to create more natural agent facial expressions, processing is then performed to insert a neutral facial expression when the vowel / a / is continuous. Figure 5 shows the insertion of neutral motion data executed when "0.00% c = 0.00" ("ikaga desu ka?"), which means, "How is it?", is spoken in Japanese. Since the vowel / a / is continuous when "ka" and "ga" are uttered, neutral data are inserted between them.

#### 3.6. Creating motion data for a facial expression

Figure 6 shows the flow of creating a facial expression motion. The facial expression motion data, in the form of a Vocaloid Motion Data (vmd) file, is created by composing the vowel vmd file based on the speech duration (Sect. 3.4, Fig. 4). First, the number of bones of the wire frame model to be used is calculated from the number of vowels and neutral frames, and the total number is written in the vmd file header. Next, the vowel voicing time is converted to the number of frames (1 frame = 1/30 seconds) in order to set each bone of the facial expression data and is then written to the vmd file.

#### 4. Experiment

Fig. 6. Flow of facial expression motion creation.

#### 4.1. Conditions

The experiment was performed on a Dell Inspiron 15 PC equipped with an Intel Core i7-6700HQ 2.2 GHz central processing unit (CPU) and 8.0 GB of random access memory (RAM). The Microsoft Windows 7 Professional operating system (OS) was installed on the PC, and Microsoft Visual C++ 2010 Express was used as the development language.

An animated agent that utters eight questions used in the initial diagnosis of depression by psychiatrists (Table 1) was created under two conditions (Condition 1: Created manually<sup>3</sup>, Condition 2: Created with this system). In addition, an animated agent that asked nine questions (Table 2) on the Hasegawa Dementia Scale<sup>5</sup>, which is used in the diagnosis of dementia, was also created using our system (Condition 3).

The content of the questionnaire is "How was the agent's mouth movements?" and the answer options were from a five-point scale (5: very natural, 4: natural, 3: normal, 2: unnatural, 1: very unnatural).

#### 4.2. Results and discussion

Table 3 shows the average impression evaluation values of all subjects under Conditions 1 and 2. In Table 3, headings "1" to "8" indicate items by question no., and

Table 1. Depression diagnosis test.

No.	Question
1	Do you get depressed or feel gloomy in a daily life?
2	Do you feel less motivated or lacking energy?
3	Do you get enough sleep at night?
4	How is your appetite?
5	Do you enjoy any hobbies on your day off?
6	Do you feel worthless for yourself or hopeless on your alive days?
7	How about concentration and attention to work?

© The 2020 International Conference on Artificial Life and Robotics (ICAROB2020), Jan. 13-16, B-Con Plaza, Beppu, Oita, Japan

8	Do you work efficiently?	
	2	

Table 2. Dementia diagnosis test.

No.	Question
1	How old are you?
2	What day of the month, what day, what day is it?
3	Where are we now?
1	Please tell me the three words you will say.
-	Please remember it later.
5	Please subtract by seven in continuous order
5	using 100 as the starting value.
6	Please tell me the numbers I will say from the
0	reverse. 6-8-2.
7	Please say the words that you learned earlier.
0	I will show you five items. Tell me what
0	happened because I'll hide it.
0	Please say as many vegetable names as you
9	know.

the "average value" is obtained by averaging over all questions. In the average impression evaluation values shown in Table 3, Condition 2 was higher than Condition 1 for all questions, and the "average value" was about 18% higher. From these results, we confirmed that our system (Condition 2) has an advantage over manual work (Condition 1).

Table 4 shows the average impression evaluation values of all subjects under Condition 3. In Table 4, headings "1" to "9" indicate items by the question no., and the "average value" is obtained by averaging over all questions. From this table, it can be seen that because the animated utterances of the dementia diagnosis questions also obtained high impression evaluation values, the versatility of our system has been demonstrated.

# 5. Conclusion

Herein, we reported on the development of a system for agent facial expression synthesis generation that uses vowel recognition when generating synthesized speech. The speech is recognized using the Julius highperformance, two-pass large vocabulary continuous speech recognition decoder software system, after which agent facial expression synthesis is performed using preset parameters depending on each vowel sound.

To create the agent, we used MMDAgent, which is a freeware animation program that allows users to create and animate movies with agents. To produce the agent's voice, we used the speech synthesis function setting built into MMDAgent. The impression evaluation values obtained from a questionnaire survey indicate that an agent produced by our proposed system is more natural than an agent created using preset parameters manually decided for each utterance. In the future, we plan to use this system for facial expression analysis and speech analysis experiments.

## Acknowledgements

The authors would like to thank Professor J. Narumoto of the Kyoto Prefectural University of Medicine for his valuable support and helpful advice during the course of this research. We would also like to thank the subjects of our experiments for their cooperation. This research was supported by COI STREAM of the Ministry of Education, Culture, Sports, Science and Technology of Japan.
