Abstract

The notion of PTT (Photon Transport Transistor) has been proposed in 1989 as an optical coupling device of light emitting diode (LED) and light receiving diode (Photo Diode, PD), where the carrier of the base layer is light (Photon) only. In this paper, in order to deal with the various applications of PTT circuit more theoretically, based on the approximate VI characteristic equation of LED and PD, we newly derive the h parameters in PTT emitter common circuit, while referring to the h parameter of Bipolar Junction Transistor (BJT).

Keywords: PTT, LED, PD, positive feedback circuit, amplification function, equivalent circuit, h parameters

1. Introduction

The notion of Photon Transport Transistor (PTT) has been presented by B. J. Van Zeghbroeck et al. at IBM Research Laboratories presented in 1989 {1}. The PTT consists of the optical coupling between Light Emitting Diode (LED) or Laser Diode and Photo Diode (PD). Moreover in 1996, it has been theoretically shown that the PTT can be a very low-noise transistor-like device with an amplification function in a positive feedback circuit [2].

Later, an audio amplifier prototype using PTT positive feedback circuit with optical coupling between high-brightness LED and PD was developed, and it was reported that the PTT even exhibited functions similar to those of a thyristor ([3], [4], [5], [6], [7], [8]). Also, while referencing the conventional studies on BJT ([9], [10], [11], [12]), authors have analyzed the current amplification function of the PTT based on experimental results ([13], [14]).

In this paper, in order to deal with the various applications of PTT circuit more theoretically, based on the approximate VI characteristic equation of LED and PD, we derive the h parameters in PTT emitter common circuit, while referring to the h parameter of Bipolar Junction Transistor (BJT) ([9], [10], [12]).

Moreover, from the similarities between PTT and BJT Ebers-Moll Model (EMM), we discuss the essential factors of amplification function in PTT and BJT.

2. PTT and BJT EMM in Emitter Common Circuit
2.1. VI Characteristic of PTT and BJT EMM

The PTT with fixed bias in emitter common circuit is illustrated in Fig. 1. Generally, the emitter common circuits are used for small signal voltage amplification. The VI characteristic equations for each of the PD and LED that make up the PTT are shown in Eq. (1) and Eq. (2), respectively ([13], [14]). Each meaning of the symbols in those equations is shown in Table 1. As for the BJT and BJT EMM, those circuits without fixed bias in emitter common are illustrated in Fig. 2(a) and Fig. 2(b). respectively. And, the VI characteristic equations of two diode parts of the BJT EMM are shown in Eq. (3)

Shimon Hattori, Osamu Matoba, Toshiki Tanaka, Yusuke Kawakami, Tetsuo Hattori

and Eq. (4), respectively, where α_0 of Eq. (3) means the current amplification constant.
Fig.1. PTT emitter common circuit.

$$I_C = \gamma^* I_E - I_{C0}\left(\exp(c_{PD} V_{BC}) - 1\right), \quad c_{PD} = \frac{q}{m_2 k T_{PD}} \quad (1)$$

$$I_E = I_{E0}\left(\exp(c_{LED} V_{BE}) - 1\right), \quad c_{LED} = \frac{q}{m_1 k T_{LED}} \quad (2)$$

Table 1. The symbol list of PTT characteristic formula.

I_{E0}	Reverse saturation current in Emitter (LED)	I_{C0}	Reverse saturation current in Collector (PD)
m_1	Ideality factor (LED)	m_2	Ideality factor (PD)
q	Charge	k	Boltzmann's constant
T_{LED}	Absolute temperature of LED	T_{PD}	Absolute temperature of PD
V_{BE}	Base-Emitter voltage	V_{BC}	Base-Collector voltage
γ^*	Proportional constant	---	----

(a)

(b)

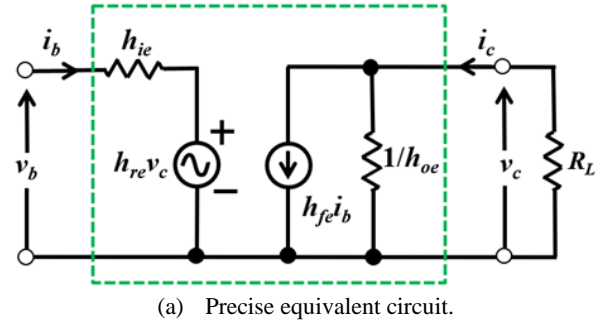
Fig.2. (a) BJT emitter common circuit for small signal voltage amplification. (b) BJT EMM without fixed bias where α_0 means the current amplification constant, and $I_E = I_B + I_C$.

$$I_C = \alpha_0 I_E - I_{C0}\left(\exp\left(\frac{qV_{BC}}{kT}\right) - 1\right) \quad (3)$$

$$I_E = I_{E0}\left(\exp\left(\frac{qV_{BE}}{kT}\right) - 1\right) \quad (4)$$

Comparing the pair of Eq. (3) and Eq. (4) with that of Eq. (1) and Eq. (2). we can expect that, the h parameters of PTT circuit using Eq. (3) and Eq. (4) will become the h parameters of BJT EMM by setting $\gamma^* = \alpha$, $m_1 = 1$, $m_2 = 1$. Then, we only have to find out the h parameters of PTT.

2.2. H Parameter for Small Signal Equivalent Equivalent Circuit

As is well known, for small signal amplification circuit of BJT in emitter common circuit, the small signal equivalent circuit with a set of h parameters (h_{ie}, h_{re}, h_{fe}, and h_{oe}) is used as shown in Fig. 3 ([9], [10], [12]).


(a) Precise equivalent circuit.
(b) Simplified equivalent circuit.

Fig. 3. Equivalent circuit of BJT emitter common with h parameters.

The equivalent relation equations in Fig. 3 are as follows.

$$\begin{bmatrix} v_b \\ i_c \end{bmatrix} = \begin{bmatrix} h_{ie} i_b + h_{re} v_c \\ h_{fe} i_b + h_{oe} v_c \end{bmatrix} = \begin{bmatrix} h_{ie}, & h_{re} \\ h_{fe}, & h_{oe} \end{bmatrix} \cdot \begin{bmatrix} i_b \\ v_c \end{bmatrix} \quad (5)$$

These h parameters are obtained from the total differential equation for V_{BE} and I_C, assuming the following functional relationship between f_1 and f_2.

Since we assume that $V_{BE} = f_1(I_B, V_{CE})$, $I_C = f_2(I_B, V_{CE})$,

$$
\begin{cases}
\Delta V_{BE}(\equiv v_b) = \left(\dfrac{\partial V_{BE}}{\partial I_B}\right)\Delta I_B + \left(\dfrac{\partial V_{BE}}{\partial V_{CE}}\right)\Delta V_{CE} = h_{ie} i_b + h_{re} v_c \\[2ex]
\Delta I_C(\equiv i_c) = \left(\dfrac{\partial I_C}{\partial I_B}\right)\Delta I_B + \left(\dfrac{\partial I_C}{\partial V_{CE}}\right)\Delta V_{CE} = h_{fe} i_b + h_{oe} v_c
\end{cases}
$$

$$(6)$$

First of all, as for h_{re}, we find the following relationship between the other h parameter, h_{oe}.

$$
h_{re} = \left.\frac{\partial V_{BE}}{\partial V_{CE}}\right|_{I_B = const} = \left(\frac{\partial V_{BE}}{\partial I_C}\right)\left(\frac{\partial I_C}{\partial V_{CE}}\right) = \left(\frac{\partial V_{BE}}{\partial I_E}\right)\left(\frac{\partial I_E}{\partial I_C}\right)\left(\frac{\partial I_C}{\partial V_{CE}}\right)
$$
$$
= \left(\frac{\partial I_E}{\partial V_{BE}}\right)^{-1} \cdot \left(\frac{\partial I_E}{\partial I_C}\right) \cdot h_{oe}
$$

$$(7)$$

Since

$$
\frac{\partial I_E}{\partial V_{BE}} = \frac{\partial I_{E0}\left(\exp(C_{LED}V_{BE}) - 1\right)}{\partial V_{BE}} = I_{E0} \cdot C_{LED} \cdot \exp(C_{LED}V_{BE})
$$
$$
= C_{LED} \cdot (I_E + I_{E0}) \approx C_{LED} \cdot I_E
$$

$$(8)$$

and

$$
\left(\frac{\partial I_E}{\partial I_C}\right) = \left(\frac{\partial(I_B + I_C)}{\partial I_C}\right) = 1
$$

$$(9)$$

then we have

$$
h_{re} = \frac{h_{oe}}{C_{LED}(I_E + I_{E0})} \approx \frac{h_{oe}}{C_{LED} \cdot I_E}
$$

$$(10)$$

Since $I_E = I_B + I_C$ in Eq. (1),

$$
I_C = \gamma^*(I_B + I_C) - I_{C0}\left(\exp(c_{PD}V_{BC}) - 1\right), \quad c_{PD} = \frac{q}{m_2 k T_{PD}}
$$

$$(11)$$

then

$$
I_C = \frac{\gamma^* I_B}{1 - \gamma^*} - \frac{I_{C0}\left(\exp(c_{PD}V_{BC}) - 1\right)}{1 - \gamma^*}
$$
$$
= \frac{\gamma^* I_B}{1 - \gamma^*} - \frac{I_{C0}\left(\exp(-c_{PD}(V_{CE} - V_{BE})) - 1\right)}{1 - \gamma^*}
$$

$$(12)$$

Therefore, we have the h_{fe} of PTT as in the following.

$$
h_{fe} = \frac{\partial I_C}{\partial I_B} = \frac{\gamma^*}{1 - \gamma^*} - \frac{I_{C0}}{1 - \gamma^*}\left(\frac{\partial \exp(C_{PD}V_{BC})}{\partial I_B}\right)
$$
$$
= \frac{\gamma^*}{1 - \gamma^*} - \frac{I_{C0}}{1 - \gamma^*}\left(\exp(-C_{PD}V_{CE}) \cdot \frac{\partial \exp(C_{PD}V_{BE})}{\partial V_{BE}} \cdot \frac{\partial V_{BE}}{\partial I_B}\right)
$$
$$
= \frac{\gamma^*}{1 - \gamma^*} - \frac{I_{C0}}{1 - \gamma^*} C_{PD} \cdot \exp(C_{PD}V_{BC}) \cdot h_{ie}
$$

$$(13)$$

Similarly, we have h_{oe} as shown in the following.

$$
h_{oe} = \frac{\partial I_C}{\partial V_{CE}} = \frac{\partial\left(\dfrac{\gamma^*}{1-\gamma^*}I_B - \dfrac{I_{C0}}{1-\gamma^*}\left(\exp(C_{PD}V_{BC}) - 1\right)\right)}{\partial V_{CE}}
$$
$$
= \frac{\left(\dfrac{-I_{C0}}{1-\gamma^*}\right)\partial \exp(C_{PD}(V_{BE} - V_{CE}))}{\partial V_{CE}}
$$
$$
= \frac{\left(\dfrac{-I_{C0}}{1-\gamma^*}\right) \cdot \partial\left(\exp(C_{PD}V_{BE}) \cdot \exp(-C_{PD}V_{CE})\right)}{\partial V_{CE}}
$$
$$
= \left(\frac{-I_{C0}}{1-\gamma^*}\right) \cdot \left\{ \frac{\partial(\exp(C_{PD}V_{BE}))}{\partial V_{CE}} \cdot \exp(-C_{PD}V_{CE}) + \exp(C_{PD}V_{BE}) \cdot \frac{\partial(\exp(-C_{PD}V_{CE}))}{\partial V_{CE}} \right\}
$$
$$
= \left(\frac{C_{PD} \cdot I_{C0}}{1-\gamma^*}\right) \cdot \left\{ 1 - \left(\frac{\partial V_{BE}}{\partial V_{CE}}\right) \right\} \cdot \exp(C_{PD}V_{BC})
$$
$$
= \left(\frac{C_{PD} \cdot I_{C0}}{1-\gamma^*}\right) \cdot \{1 - h_{re}\} \cdot \exp(C_{PD}V_{BC})
$$

$$(14)$$

As for h_{ie}, from Eq. (6), we have

$$
h_{ie} = \frac{\partial V_{BE}}{\partial I_B} = \left(\frac{\partial V_{BE}}{\partial I_E}\right)\left(\frac{\partial I_E}{\partial I_B}\right) = \left(\frac{\partial I_E}{\partial V_{BE}}\right)^{-1}\left(\frac{\partial(I_C + I_B)}{\partial I_B}\right)
$$
$$
= \left(\frac{\partial I_E}{\partial V_{BE}}\right)^{-1}\left(h_{fe} + 1\right) = \frac{\left(h_{fe} + 1\right)}{C_{LED}(I_E + I_{E0})} \approx \frac{\left(h_{fe} + 1\right)}{C_{LED} \cdot I_E}
$$

$$(15)$$

So far, we have obtained the following equations for the four parameters, h_{ie}, h_{fe}, h_{re} and h_{oe}.

Shimon Hattori, Osamu Matoba, Toshiki Tanaka, Yusuke Kawakami, Tetsuo Hattori

$$
\begin{cases}
h_{ie} = \dfrac{\partial V_{BE}}{\partial I_B} = \dfrac{(h_{fe}+1)}{C_{LED}(I_E+I_{E0})} \\[12pt]
h_{fe} = \dfrac{\partial I_C}{\partial I_B} = \dfrac{\gamma^*}{1-\gamma^*} - \dfrac{I_{C0}}{1-\gamma^*} C_{PD} \cdot \exp(C_{PD}V_{BC}) \cdot h_{ie} \\[12pt]
h_{oe} = \dfrac{\partial I_C}{\partial V_{CE}} = \left(\dfrac{C_{PD} \cdot I_{C0}}{1-\gamma^*}\right) \cdot \{1 - h_{re}\} \cdot \exp(C_{PD}V_{BC}) \\[12pt]
h_{re} = \dfrac{\partial V_{BE}}{\partial V_{CE}} = \dfrac{h_{oe}}{C_{LED}(I_E+I_{E0})}
\end{cases}
\tag{16}
$$

From Eq. (16), we can see the recursive relation between h_{ie} and h_{fe}, and another between h_{re} and h_{oe}. So, we derive those parameters in the details, as follows.

$$
\begin{aligned}
h_{fe} &= \frac{\gamma^*}{1-\gamma^*} - \frac{I_{C0}}{1-\gamma^*} C_{PD} \cdot \exp(C_{PD}V_{BC}) \cdot h_{ie} \\
&= \frac{\gamma^*}{1-\gamma^*} - \frac{I_{C0}}{1-\gamma^*} C_{PD} \cdot \exp(C_{PD}V_{BC}) \cdot \frac{(h_{fe}+1)}{C_{LED}(I_E+I_{E0})}
\end{aligned}
$$

So, we define the following K.

$$
K \; \square \; \frac{I_{C0}}{1-\gamma^*} C_{PD} \cdot \exp(C_{PD}V_{BC}) \cdot C_{LED}(I_E+I_{E0})^{-1}
$$

Then we have

$$
\begin{aligned}
h_{fe} &= \left(\frac{\gamma^*}{1-\gamma^*} - K\right) \cdot (1+K)^{-1} \\
&= \frac{\dfrac{\gamma^*}{1-\gamma^*} - \dfrac{I_{C0}}{1-\gamma^*} C_{PD} \cdot \exp(C_{PD}V_{BC}) \cdot (C_{LED}(I_E+I_{E0}))^{-1}}{1 + \dfrac{I_{C0}}{1-\gamma^*} C_{PD} \cdot \exp(C_{PD}V_{BC}) \cdot (C_{LED}(I_E+I_{E0}))^{-1}} \\
&= \frac{\dfrac{\gamma^* C_{LED}(I_E+I_{E0})}{1-\gamma^*} - \dfrac{I_{C0}}{1-\gamma^*} C_{PD} \cdot \exp(C_{PD}V_{BC})}{C_{LED}(I_E+I_{E0}) + \dfrac{I_{C0}}{1-\gamma^*} C_{PD} \cdot \exp(C_{PD}V_{BC})}
\end{aligned}
\tag{17}
$$

Similarly, as for h_{re}, we have the following equation.

$$
h_{re} = \frac{\left(\dfrac{C_{PD} \cdot I_{C0}}{1-\gamma^*}\right) \cdot \exp(C_{PD}V_{BC})}{C_{LED} \cdot I_{E0} \cdot \exp(C_{LED}V_{BE}) + \left(\dfrac{C_{PD} \cdot I_{C0}}{1-\gamma^*}\right) \cdot \exp(C_{PD}V_{BC})}
\tag{18}
$$

If we consider the case when V_{BC} approximately equals

0, then the term $\exp(C_{PD}V_{BC})$ nearly becomes 1.0. In this case we have the more simplified four parameters as follows that are corresponding to Fig. 3(b).

$$
h_{ie} = \frac{\left(\dfrac{1}{1-\gamma^*}\right)}{C_{LED}(I_E+I_{E0})} = \frac{\left(\dfrac{1}{1-\gamma^*}\right)}{C_{LED} \cdot I_{E0} \exp(C_{LED}V_{BE})},
$$

$$
h_{fe} \approx \frac{\gamma^*}{1-\gamma^*}, \; h_{re} \approx 0, \; h_{oe} \approx 0
\tag{19}
$$

3. Conclusion

We have newly derived the four h-parameters in the PTT small signal circuit, based on the VI characteristic equation of LED and PD that composes the PTT. From those computed h parameters, we find out that PPT functions the amplifier, because approximated and simplified h parameters are very similar to the case of BJT.

Abstract

For the arrangement processing of image using its histogram, we previously have presented a Histogram Matching method based on Gaussian Distribution (HMGD). However, in the case where the brightness histogram of input image has multiple peaks, the HMGD processing does not always bring good results. In this paper, we present an improved histogram matching method using the reference histogram that is made by appropriate moving average (HMMA) processing over the histogram of input image. Also in this paper, we show the experimental results.

Keywords: Image processing, Histogram matching (HM), Moving average, Kansei impression

1. Introduction

Recently, automated image arrangement processing such as enhancement of images that we have already reported is usually used in the various imaging devices, for example, Digital Camera, Smart Phone and so on [1], [2], [3].

In our previous papers, we have presented a Histogram Matching based on Gaussian Distribution (HMGD) processing for the image arrangement [4], [5], [6], [7]. And we illustrated that HMGD processing can improve feeling (or Kansei) impression of the original image [4], [5], [6], [7].

In this paper, we propose an improved Histogram Matching method using the reference histogram that is made by appropriate Moving Average (HMMA) processing over the histogram of input image [8]. Also, in this paper, we provide the experimental results for some color images and show its effectiveness of the proposed method.

2. Principle
2.1. Histogram Matching as Example of Gaussian Distribution [9]

In the section, we describe the principle of histogram matching method as an example of Histogram Matching based on Gaussian Distribution (HMGD).

Fig. 1 shows the conceptual image of HMGD. Let $f(x)$ and $h(y)$ be two probabilistic density functions (PDF) on real variables x and y, respectively. The PDF is corresponding to histogram of image brightness level which is discretely defined.

In addition, let $y=\phi(x)$ be a continuous and monotonic increase function corresponding to cumulative histogram of image brightness level between variables x and y. And let $y=\phi(x)$ be defined by Eq. (1).

$$y = \phi(x) + L\int_{0}^{x} f(x)\,dx \quad\text{................................ (1)}$$

At first, we have to expand brightness level of original image histogram and convert into uniform distribution histogram, because we aim to match Gaussian distribution. From Eq. (1) and Fig. 1, we can derive Eq. (2) and (3).

$$f(x) = h(y)\varphi'(x) = h(y)Lf(x) \quad\text{............. (2)}$$

$$h(y) = \frac{1}{L} \quad\text{... (3)}$$

Yusuke Kawakami, Tesuo Hattori, R. P. C. Janaka Rajapakse

We understand the histogram of original image $f(x)$ becomes uniform distribution $h(y)$ by Eq. (3). This means that brightness level of original image $f(x)$ is expanded to $h(y)$.

Then, let $g(z)$ and $\gamma(z)$ be the function that is defined by Eq. (4) and Eq. (5), respectively.

$$g(z) = \frac{1}{\sqrt{2\pi\sigma^2}} \exp\left(-\frac{(z-\mu)^2}{2\sigma^2}\right) \quad \text{............} \quad (4)$$

$$y = \gamma(z) = L\int_0^z g(z)\,dz$$

$$= \frac{1}{\sqrt{2\pi\sigma^2}} \int_0^z \exp\left(-\frac{(z-\mu)^2}{2\sigma^2}\right) dz \quad \text{...........} \quad (5)$$

Here, Fig. 1 shows the relationship between $y=\phi(x)$ and $y=\gamma(z)$. So we can be obtained following Eq. (6) and Eq. (7).

$$L\int_0^x f(x)\,dx = \frac{L}{\sqrt{2\pi\sigma^2}} \int_0^z \exp\left(-\frac{(z-\mu)^2}{2\sigma^2}\right) dz \quad \text{....} \quad (6)$$

$$\frac{d}{dx} L\int_0^x f(x)\,dx = \frac{d}{dz}\frac{L}{\sqrt{2\pi\sigma^2}} \int_0^z \exp\left(-\frac{(z-\mu)^2}{2\sigma^2}\right) dz. \quad \text{..} \quad (7)$$

If we perform Eq. (7),

$$L\varphi'(x) = L\gamma'(z), \quad f(x) \Rightarrow g(z) \quad \text{..........} \quad (8)$$

That is, we understand that $f(x)$ becomes Gaussian distribution $g(z)$ when we take the transform function as Eq. (1) and Eq. (5).

Thus, histogram matching processing is the function which defined by cumulative histogram transformation the original histogram into arbitrary histogram.

3. Experimentation

Fig. 2 and Fig. 3 show the example of results and the corresponding histogram respectively. In this case, we understand that HMGD image is very enhancing brightness and contrast than original image.

However, the touch of brush detail transforms unnatural in this image. Also we understand that HMMA image is enhancing contrast than original image and the color tone keeps and slightly brighter than original image.

Fig. 4 and Fig. 5 show another example of results and the corresponding histogram, respectively. In this case, we understand that the simple application of HMGD processing gives poor perspective impression. And HMMA image is enhancing its perspective and detail of rocks in this image than original.

From the experimental results, we consider that HMMA processing enhances the effect of the Kansei impression effect more than HMGD processing.
Fig.1 Conceptual image of histogram matching (example of HMGD).

4. Conclusion

In this paper, for the color image arrangement processing, we have described two histogram matching based methods: Histogram Matching based on Gaussian Distribution (HMGD) and Histogram Matching based on Moving Averaged histogram (HMMA).

And we have compared the two methods as to how each processing brings about the Kansei impression effect. Although the number of experimented images that we have shown in this paper is limited, from the results, we can find that the processing by HMMA more enhances the contrast, brightness, and detail of original image than by HMGD. That is, we consider that HMMA processing can improve the Kansei impression.

Since these evaluation of impression effects are subjective at this point, so we will objectively investigate the improvement of Kansei impression through questionnaire surveys and characteristics quantity in image, for future study.

Abstract

Recently, the necessity of integrated and comprehensive methodology for STEM (Science, Technology, Engineering and Mathematics) education is growing. In this paper, we propose an educational methodology utilizing the viewpoint of Equivalent Transformation Thinking (ETT) theory which has been proposed by Dr. Kikuya Ichikawa in 1955 as a principle of creativity. Especially, we show that the viewpoint is very useful not only for new technology invention but also for STEM Education in the sense that it deepens insights of the contents to be learned, motivates students to study further, and inspires their creativity.

Keywords: *STEM Education, Equivalent Transformation Thinking (ETT) Theory, Identification of Equivalence, 3-Dimensional Computer Graphics (3DCG).*

1. Introduction

Recently, the necessity of integrated and comprehensive methodology for Science, Technology, Engineering and Mathematics (STEM) education seems to be growing [1], [2], because the content of the STEM field is becoming increasingly sophisticated.

For the STEM education, we propose the methodology based on the viewpoint of Equivalent Transformation Thinking (ETT) theory which was advocated as a principle of creativity by Dr. Kikuya Ichikawa in 1955, after his investigation and analysis of the past discoveries and technological inventions.

In this paper, we briefly explain the ETT theory ([3], [4], [5], [6], [7], [8]) and describe that the viewpoint of ETT is very useful not only for new technology invention but also for STEM education. This is because the past inventions, discoveries and academic developments in STEM field can be explained according to the ETT theory.

Especially, we emphasize that the suitably combined use of dynamic visualization technology based on the viewpoint of ETT will be very effective for the students to deeply understand the learning contents, to promote their motivation, and to stimulate their creativity ([9], [10], [11]).

2. ETT Theory

As aforementioned, the ETT theory has been proposed as a principle of creativity by late Dr. Kikuya Ichikawa in 1955, after his investigation of the past discoveries and inventions to analyze how creation was done. And he revealed the investigation results that new technology developments and creations were produced along with the ETT process. Then he described the ETT process as a form of symbolic logical expression which is called "Equivalence Equation" as shown in Fig. 1.

Ao: original system, $B\tau$: transformed (or arrival) system, Σa: a set of special/peculiar properties and conditions that holds the system Ao, $c\varepsilon$: core essence or essential meaning that reasons the equivalence under some conditions, Σb: a set of necessary properties and conditions that hold the system, vi: viewpoint at a certain

Fig. 1 Equivalence Equation by Dr. Kikuya Ichikawa in his ETT Theory.

The description of "Equivalence Equation" means that, from a certain viewpoint vi, the original system Ao can be transformed to the system $B\tau$ according to the conditionalized essence $c\varepsilon$, where some properties and

conditions Σa in $\boldsymbol{Ao}$ are discarded, and new elements of property and condition Σb are added to the system $\boldsymbol{B\tau}$.

When Dr. Ichikawa presented "Equivalence Equation", he also showed the schematic flowchart of ETT. And he insisted that, if we make effort to develop something to be desired according to the ETT flowchart, creative achievement will be possible more efficiently.

As for the ETT theory, he mainly published papers at the Creativity Research Workshop that was held by Dr. Hideki Yukawa, the winner of 1949 Nobel Prize in Physics. Dr. Yukawa called this Dr. Ichikawa's theory as "Identification Theory" in his own words and highly praised it.

3. Application Examples of ETT Viewpoint
3.1. Cartesian Coordinate System

Looking back on history, it is possible to find out many facts that the act of ETT and/or Identification of Equivalence has made a progress of research in the field of STEAM (Science, Technology, Engineering, Art, and Mathematics), and that it has broadened our horizons and deepened our knowledge. Then, we consider that utilization of the viewpoint of ETT is also effective for STEM education.

For example, René Descartes provided "Cartesian coordinate system" that gives a correspondence between a point P on a plane and a pair of two numbers (x, y), where x and y are quantities based on the distances to two orthogonal axes (x-axis and y-axis), respectively, as shown in Fig. 2.
Fig. 2 Cartesian coordinate system.

As a result, taking a parabolic curve C for an example, it can be simply represented by a set of coordinates and algebra, without showing the procedure of geometric drawing, such as

C= {P(x, y) | y =ax^2, a: constant number}.

This is an example that ETT not only opens the new field of mathematics such as Analytic Geometry and Algebraic Geometry, but also brings about the new way of representation such as "Field" into physics, so we consider that it is worth to enhance the idea of ETT. Moreover, we should notice the viewpoint of ETT and appropriately point out the viewpoint of equivalence when teaching the subject of STEM.

3.2. Archimedes' Principle of Buoyancy
According to Archimedes' principle, floating power (or buoyant force) that operates on a body immersed in a fluid, is equal to the weight of the fluid in the same volume as the volume of body in the fluid (Fig. 3).

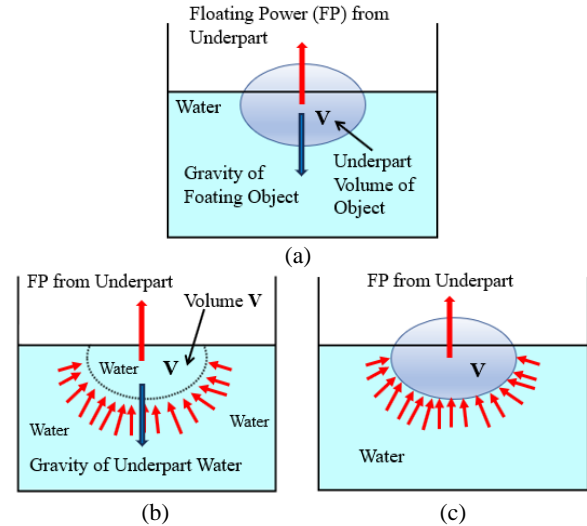
As shown in Fig. 3, if we imagine a situation that an object is quietly floating on the water, and if we think of that it is equivalent to the situation where the water in the same volume area of the object under the surface is quietly balanced (Fig. 3(c)), we understand that Archimedes' principle will be derived.


Fig. 3. Floating power (or buoyant force) that operates on a body immersed in a fluid. (a) An object is quietly floating on the water. (b) V means the same volume/area of the object under surface. (c) The water in the same volume area V is quietly balanced.

3.3. Mechanical Dynamic System (MDS) and Electric Circuit System (ECS)
For taking the relation between MDS and ECS as an example, we can deal with the equations of two systems (see Fig. 4) as equivalent equation from both meaning of mathematics and physics.

$$\begin{cases} m\dfrac{d^2x}{dt^2} + r\dfrac{dx}{dt} + \dfrac{x}{k} = \boldsymbol{F}_0 \quad \left(v = \dfrac{dx}{dt} \right) \\ L\dfrac{d^2q}{dt^2} + R\dfrac{dq}{dt} + \dfrac{q}{C} = \boldsymbol{E}_0 \quad \left(I = \dfrac{dq}{dt} \right) \end{cases}$$

Mass $\boldsymbol{m}$ $\Leftrightarrow$Inductance $\boldsymbol{L}$, Responsiveness $\boldsymbol{r}$ $\Leftrightarrow$Resistance $\boldsymbol{R}$, Compliance $\boldsymbol{k}$ (the inverse of spring constant) $\Leftrightarrow$Capacitance $\boldsymbol{C}$
(a)
Fig. 4. (a) Differential equations and their corresponding elements in MDS and ECS. (b) Conceptual image of MDS. (c) Conceptual image of ECS.

3.4. Explanation of Faraday's World First Motor

Faraday's world first electromagnetic rotating device is shown in Fig. 5, where the current flows from top to bottom into the left and right mercury containers. Viewing from the above, when the current flows, both of bar magnet and electrode (or conductor) rotate clockwise.

(a)   (b)

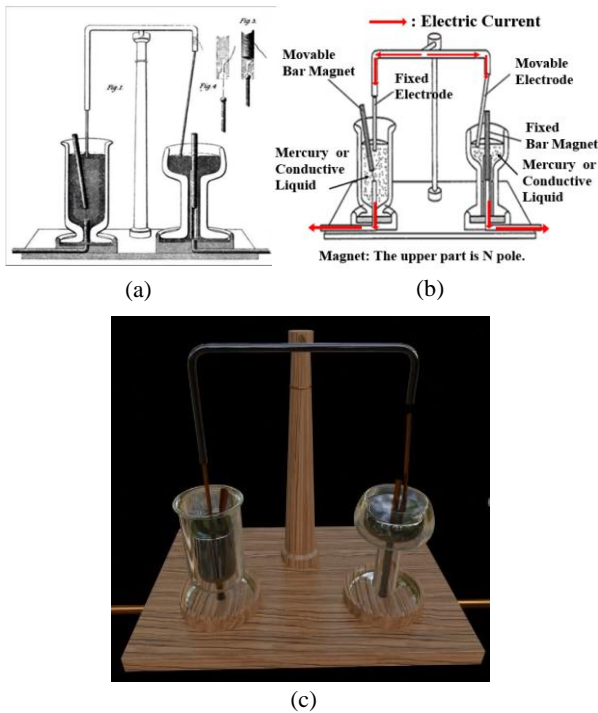
(c)


Fig. 5. Faraday's World's First Motor. (a) Documents left at the Royal Institution. (b) Explanation of each part and direction of current. (c) Motion view of the Motor made by 3-DCG "Blender".

As for the force that causes rotation, there are different explanations (or lectures) for the left and right sides. For the left side, the current flowing through conductor rotates the movable bar magnet by creating magnetic according to Ampere's law. On the contrary, for the right side, the the current in conductor rotates because it receives Lorentz force from the magnetic field made by the fixed bar magnet.

However, there is a unified explanation from law of action and reaction. In the left side, like the left side, the magnetic field caused by the current in conductor exerts a force on the fixed bar magnet, but since the bar magnet is fixed and the conductor is floating, then the the conductor rotates itself by the reaction force.

This unified explanation can be easily provided by 3-DCG video, referring that an electric current generates a magnetic field around it and receives a reaction force from the bar magnet via the magnetic field.

3.5. Recursive Programming

Recursive programming is useful, but it is not so easy to suitably write down. Taking the problem of "Tower of Hanoi" for example (Fig. 6), the problem is to move the tower consisting of n disks, from the place at pillar A (or start place) at the left end to the pillar C (or destination) at the right end, using the pillar B in the middle (as work place), under the constraints as below.
(i) Only one disk must be moved at a time, (ii) Do not go outside the three sections, (iii) Do not put a disk over a smaller disk.

(a)   (b)

Fig. 6. The "Tower of Hanoi" problem. (a) Initial state when the number of disks n=5. From the left end, we call three places as A, B, and C. (b) The smallest disk at A is moved from A to C, and the next small disk is on the way to move out.

For making the recursive program in the general case of n disks, we note a pattern of disk moving, that will appear clearly when the number of disks n=2. That is, the pattern is equivalent to what can be seen if we divide n disks into two parts: upper parts (n-1 disks) and lowest part (the bottom largest disk).

Imagine when the largest disk can be moved from A (start) to C (destination) under the constraints. Firstly, we must move the upper parts (n-1 disks) from the place A to B (workplace), after that, the largest disk (=lowest part) can be moved from A to C. As the next step, the upper parts (n-1 disks) are to be moved from B to C. This is the important turning point (Fig. 7).

(a)

(b)

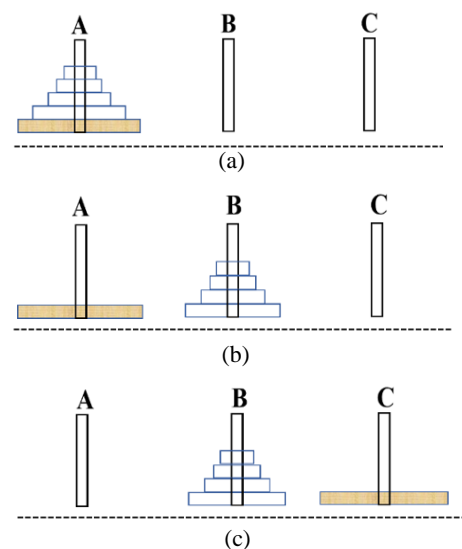
(c)


Fig.7. The turning point procedure of "Tower of Hanoi" problem in moving n disks from the place A to C using the place B. (a)Initial state. (b) and (c). The turning point when the top n-1 disks are moved from A to B, after that, largest disk left at A is moved to C.

Then, if we let TOH(n, S, W, D) represent a procedure of the "Tower of Hanoi" problem to move n disks from the start place S to destination D using workplace W, we obtain the following symbolic formulation as a recursive procedure.

TOH(n, A, B, C) =TOH(n-1, A, C, B) + Move the largest of n disks from A to C+ TOH(n-1, B, A, C).

The procedure TOH(n, S, W, D) is concretely, described by Excel VBA, as shown in the Fig. 8.

```
Sub main_Tower_of_Hanoi()
Dim n As Integer, Input_n As String
Input_n = InputBox("The number of disks ?")
n = Val(Input_n)
Call Hanoi_Tower(n, "A", "B", "C")
End Sub
'********************************
```
(a)

```
Sub Hanoi_Tower(n As Integer, S As String, W As
String, D As String)
  '/*Move n-1 disks from "S" to "W" via "D."*/
  If n >= 2 Then
       Call Hanoi_Tower(n - 1, S, D, W)
  End If
  Debug.Print "Move the top disk No. " & n & " : " & S
& "→" & D & "."
  '/*Move n-1 disks from "W" to "D" via "S."*/
  If n >= 2 Then
       Call Hanoi_Tower(n - 1, W, S, D)
  End If
End Sub
'**************************************
```
(b)

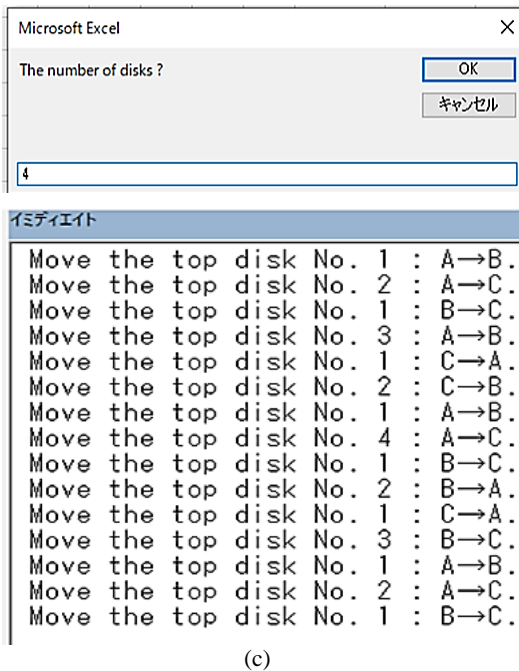
(c)


Fig. 8. Excel VBA program for the Tower of Hanoi. (a) and (b). The program list. (c) (upper) Inputbox where n=4 is input. (lower) The output at immediate window in the case n=4.

The necessary number of steps $a(n)$ to solve the problem of n disks is decided from the above algorithm.

$a(\text{n})=a(n-1) +1+a(n-1) =2a(n-1) +1$ $(n \geqq 2)$, $(a (1) =1)$.

Let $b(n)=a(n)+1$, then $b(1) =2$ and $b(n)=2b(n-1)$. Then,

$$b(n) = \frac{b(n)}{b(n-1)} \cdot \frac{b(n-1)}{b(n-2)} \cdots \frac{b(3)}{b(2)} \cdot \frac{b(2)}{b(1)} \cdot b(1) = 2^n$$

Therefore, $a(n)=b(n)-1=2^n-1$.

4. Conclusion

In this paper, we have proposed a methodology for integrated and comprehensive STEM education, based on the viewpoint of ETT. Moreover, we have presented some application examples of teaching way from the ETT viewpoint, in order to show the usefulness. We consider that the suitably combined use of visualization tool such as 3-DCG will be more effective.

As a further study, we are considering that the solution algorithm for the Tower of Hanoi problem can be represented as the tree generation in tree language notation. Then, we find out that the recursive algorithm may be described as an iterative algorithm equivalent to the recursive one, and that a fast solution algorithm can be obtained. We would like to report this on another opportunity.

Efficient Campus Shuttle Tracking and Management Mobile Application for College Campus

Andrea Tantay Gonzales
INTI International College Penang, Malaysia

Kavitha Thamadharan
INTI International College Penang, Malaysia

Neesha Jothi
UCSI University, Malaysia

Abstract

The purpose of this study is to address the current paper-based shuttle booking and tracking system at INTI International College, Penang. Shuttle Stalk, a Real-Time Campus Shuttle Booking and Tracking System was a proposed solution that enables the students to register for the shuttle service through the mobile application, reducing the administrative burden and tracking its current location in real-time, allowing them to plan their journeys more effectively. The application developed serves as a comprehensive solution for both students and administrators, providing real-time shuttle tracking and streamlined management capabilities. The development of this application is informed by extensive data collected through pre- and post-acceptance surveys, to ensure its effectiveness and alignment with user needs. The mobile application not only enhances the efficiency of shuttle services but also contributes to higher user satisfaction, improving the overall campus experience.

Keywords: Campus shuttle-tracking application, real-time shuttle location, Global Positioning System (GPS), Google Maps, Firebase, Mobile Application

1. Introduction

Shuttle services are a form of public transportation that respective schools and universities often provide to enable their students to travel from the pick-up point to the institution's location. However, there is no way to track and see the shuttle's arrival and departure time. According to a study [3], the drawback of public transportation (such as buses and shuttles) is that the commuter has an unknown amount of time to wait for their transport's arrival. This results in commuters opting for private vehicles, which adds consequences in environmental, social, and economic terms [7].

A study [7] shows that (from a survey sent to 3378 correspondence), 59% of the students opt for public transportation such as buses and shuttles. Distance, time, and economic capabilities are the most important factors when choosing a mode of transportation. With that in mind, the free transportation offered by some schools and universities (e.g., INTI International College and Universities) appeals mostly to students, as it meets the criteria of choosing a transportation mode. However, the lack of information regarding the transportation's arrival time, current location, and seat availability makes commuters or students reluctant to use public transportation [8].

Therefore, a shuttle booking and tracking system was proposed as a solution for the current paper-based shuttle management at INTI International College, Penang. It enables the students to book the shuttle service through the mobile application, where they can decide whether the registration may proceed or not depending on the seating availability in the shuttle. Moreover, the students will be able to track the shuttle's real-time location as well as efficiently mark their attendance when the shuttle is nearby. Lastly, the students will be able to receive notifications from both admins and drivers if the shuttle is unavailable.

Andrea Tantay Gonzales, Kavitha Thamadharan, Neesha Jothi

2. Literature Review

The current shuttle management system in INTI International College, Penang enables the students to use the shuttle through Google Form registration every new semester. Attendance marking and tracking were paper-based; the student's name and matriculation number must be written manually by the student after riding the shuttle. There was also no administrator dashboard for the overall management of the shuttle service on campus.

Fig. 1 shows the pre-acceptance survey which was sent out to 100 students with 63 respondents. Most of the students voted on having a real-time shuttle tracking application to help plan transportation ahead of time.

Would a real-time shuttle tracking application be helpful for you?
Fig. 1. Pre-acceptance survey result

A real-time location tracking application is a type of software application where the location data of any two or more devices are updated in each period to the database so that both devices' location data information synchronizes with each other. There has been much research about the implementation of real-time location tracking applications in a school and campus' public transportation system, each with different implementation methods and techniques.

Saad et al. [8] conducted research on a real-time on-campus public transportation monitoring system for Universiti Teknologi Malaysia. The researchers implemented a GPS receiver hardware and attached it to the campus bus, where it retrieves the latitude, longitude, and speed of the bus. The data is then synchronized to the student web application. This system is not as portable and accessible, however, since students mostly use mobile applications nowadays. The system must also adapt to the current design and UI trends. Lastly, each of the campus transportation vehicles must have GPS receiver hardware, which may add to the cost.

Hoque, et al. [1] developed a bus tracking system for the International Islamic University Chittagong in Bangladesh. Instead of using a physical GPS receiver, the researchers made use of an Android smartphone's embedded location-aware hardware, making the system cost and configuration time lesser. The system is mobile-based, therefore, improving student accessibility and access. There were also two added features in the system, namely the driver accident reporting and seat availability checking. These features are beneficial to students, however, the way that the seat availability checking was implemented may be hazardous (as the driver has to continuously accept/deny students' requests, even while driving). The UI for the application may also need a lot of time getting used to.

Shibghatullah, et al. [11] implemented Tracker, a real-time location tracking system that makes use of GPS-aware devices to track the current location of public transportation. It caters to a wider audience and is mobile-based. It has a much-improved UI with detailed information (e.g., real-time traffic conditions, error messages) which makes it easier for users to navigate through the application, as well as a notification feature, allowing the users to receive updates from the administrators. In terms of improvement, the application does not have a way to check seat availability, and the notification feature can be further improved by adding a push notification alert.

3. Methodology

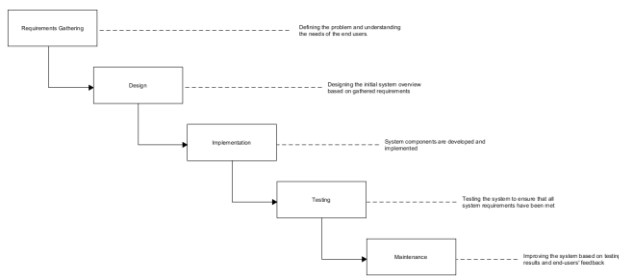
The research methodology used for this study was the Waterfall Methodology (as shown in Fig. 2). During requirements gathering, feedback regarding the current shuttle service on the campus was compiled from administrators and students alike. The design phase implements a non-working prototype of the application with the main features. Once the idea was confirmed, the working prototype was implemented based on the pre-acceptance survey result and the initial design of the application. Testing was done afterward, where the working application was sent to the end users for the purpose of gathering UI and feature-related issues and feedback. Lastly, the application was updated based on the result of the usability testing.


Fig. 2. Research Methodology

Fig. 3 shows the administrator website, where the admins can manage the campus' shuttle services. It contains various managerial features like shuttle and driver registration, where the admin can input the shuttle details (e.g., plate number, seating capacity) as well as create an account for the driver (to be used on the driver's side of the application). Route management is also included on the website, where the admin can assign a registered shuttle and driver to the route and enter its pickup/dropoff schedule and location. The admins can also view the number of bookings made by students, as well as the registered students.

Fig. 3. Administrator Website

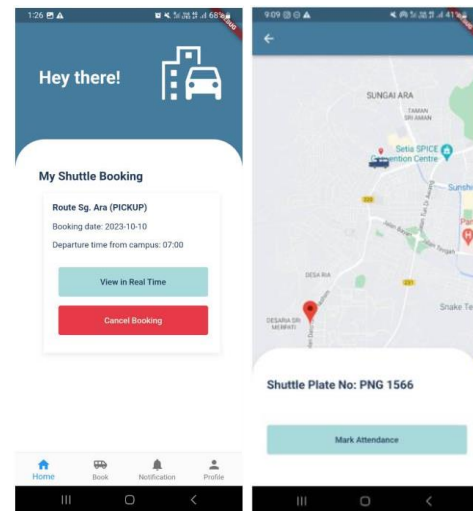
A student application was also implemented as shown in Fig. 4. It allows the students to book a shuttle based on the pickup/dropoff location, as well as view the shuttle's current real-time location. The application has a built-in attendance feature where the student can mark their own attendance if the shuttle is nearby. Unmarked attendance may result in the "no show" penalty embedded in the application that denies the student from booking the shuttle. Moreover, the student may book the shuttle as long as there is available seating in the vehicle. The student can also receive push notifications from administrators and drivers alike whenever there are updates regarding the shuttle service on the campus (e.g., shuttle maintenance). Lastly, an option to cancel the shuttle booking was also in place if the journey time was not within 2 hours.


Fig. 4. Student Application

Lastly, a driver application was implemented to foster communication between the student and the driver's location (refer to Fig. 5). A listing of all available and assigned journeys to the driver can be seen on the home page. When the driver starts a journey, the application saves the device's current location and updates the database with it whenever the shuttle or driver moves 100 meters from the last location. The driver application also has an emergency reporting feature that triggers whenever the driver cancels a journey or ends a journey early. The submitted report sends a push notification to the student's application side and cancels the journey without penalizing the student.

Fig. 5. Driver Application

4. Results and Discussion

For this study, the application underwent usability testing. Existing research [4], [5] shows that the amount of usability testers should be 5 testers (given that the study does not focus on quantitative results, in which case, 20 testers are required). A total of 8 participants, however, were compiled for this study as it ensures that almost all usability problems were covered as much as possible.

Table 1 below shows the result and overall feedback of the participants from the usability testing.

Table 1. Usability testing results

Participant no.	Feedback
1	- Some parts of the text instructions when logging in and registering are obstructed. - Overall, the application has nice features and is smooth and fast.
2	- Application is easy to use and straightforward with minimalistic design. - There should be an option for weekly booking of the shuttle.
3	- There should be a polyline location to track the shuttle route. - Improve the arrangement of the input boxes on the booking page.
4	- The application is easy to use as the layout is pretty similar to other applications. - There was a missing toast message for cancellation of shuttle booking.
5	- The application is easy to navigate around - More optimization in the future updates
6	- Overall application experience is smooth, and the interface is nice. - There should be more customization options for personalized application experience.
7	- There should be a password confirmation during registration. - Overall, the application is straightforward and easy to use.
8	- The application is not overwhelming to use. - It takes some time to load (optimization).

It can be seen from the table that the overall impression of the system was smooth, easy to navigate, and straightforward, with most of the participants liking its

minimalistic design and similarity in layout with other applications (thus contributing to its ease of use). Further improvements of the system focused more on optimization, minor element obstruction, and other requested features by the users (e.g., personalization, polyline for Google Maps).

5. Conclusion

In this paper, an efficient shuttle tracking and management application has been developed for INTI International College, Penang campus. The proposed system proved beneficial to both the campus administrators and students, especially when it comes to managing shuttle bookings and tracking the shuttle location, compared to its initial paper-based and manual shuttle management system. Furthermore, the application was a success in terms of user acceptance as proven by the result of the usability testing.

Abstract

This study focuses on schizophrenia, impacting 24 million people globally, characterized by distorted reality and delusions. We propose utilizing a GraphSAGE model and a Graph Convolutional Network (GCN) model on a task-based fMRI data to differentiate schizophrenia instances, with and without auditory-visual hallucinations, utilizing healthy participants for comparison. The study focuses on identifying specific auditory stimuli that can help significantly differentiate individuals experiencing hallucinations. The GraphSAGE model performed better by achieving an accuracy of 97% and 96% on the specified stimuli.

Keywords: Schizophrenia, Hallucination, Graph Convolution, GraphSAGE, fMRI

1. Introduction

Functional Magnetic Resonance Imaging(fMRI) has emerged as a powerful tool in unraveling the intricacies of mental disorders. Among the various types of fMRI, the task-based fMRI serves as an ideal method for understanding the functioning of neurons as it captures real-time brain activity as individuals perform specific cognitive tasks. In the context of schizophrenia, the analysis of task-based fMRI data has proven to provide valuable insights that in turn aid the diagnosis and treatment of this disorder.

Graph Convoluted Network (GCN) is a type of neural network architecture designed to process data structured as graphs. In these graphs, the nodes represent entities, and the edges represent the relationship between the entities. **GCN′s** leverage information from the neighboring nodes to perform traditional convolution operations. This methodology is suitable for analyzing fMRI data as they model dynamic changes in brain connectivity. In our investigation, we designate regions of interest (ROIs) as nodes, and the edges represent the functional connectivity between these brain regions. We leverage pertinent node attributes to encapsulate the variability in brain activity corresponding to specific stimuli, serving as distinctive features for our classifier. This methodology enables us to unveil patterns and relationships in brain connectivity, offering enhanced insights into the complex dynamics of schizophrenia and the responses of individuals affected by it to auditory stimuli.

2. Literature Review

This section provides concise information about prior literature which has been consulted as reference during the model preparation. The application of graph based neural networks in the analysis of neural activity is an emerging area of study. Saeidi *et al* [1] have proposed an end-end GCN network on the benchmark HCP dataset, which makes use of statistical features extracted from the connectivity matrices as a node feature. Additionally, standard node embedding algorithms such as NetMF, RandNE, Node2Vec and Walklets were used to extract node features and their performance was analyzed. The paper acknowledges the importance of individual differences in brain function by testing the model on a gender-based and gF score-based sub-dataset. The effect of batch size was also accounted for. The proposed framework achieved an accuracy of 97.7% and concluded that NetMF and RandNE algorithms outperformed the rest.

Li, X. *et al* [2] have employed a custom framework BrainGNN, composed of Ra-GNN and R-pool blocks which are responsible for generating the node embeddings. The node embeddings are aggregated with its neighbors and the updated representations are projected onto a learnable vector which is fed to a classifier. The model was utilized on two distinct datasets: the Biopoint Autism Study Dataset (Biopoint) and the Human Connectome Project (HCP) 900 Subject Release [3]. The primary objective for the Biopoint dataset [4] was the classification of autism affected individuals and healthy controls. Conversely, for the HCP dataset, the focus was on classifying seven

Tejaswini Thota, Reuben Stephen John, R Dhanush, Amutha S, Heshalini Rajagopal

cognitive and behavioral task states. BrainGNN demonstrates an enhancement in average accuracy ranging from 3% to 20% for autism classification. Additionally, it achieves an average accuracy of 93.4% for the classification on Human Connectome Project dataset.

3. Methodology

3.1. *fMRI dataset and preprocessing*

We obtained task fMRI data for 71 participants, 46 schizophrenic patients and 25 healthy controls subjected to three experimental conditions, word lists, sentence lists and reversed speech. White noise was the low-level control condition to which the task results were compared to. The schizophrenic patients are further classified into two classes, 23 subjects who experience auditory visual hallucinations (AVH+) and 23 subjects who do not (AVH-) (Table 1). The data was obtained using a 3T Philips Ingenia scanner employing a T2*-weighted echo-planar imaging (EPI) sequence. The acquisition consisted of 341 volumes, and the following parameters were applied: a repetition time (TR) of 2000ms, echo time (TE) of 30ms and a flip angle of 70°. The in-plane resolution was set to 3.5×3.5 mm, with a field of view (FOV) measuring 238×245 mm. The slice thickness was 3.5 mm, and an inter-slice gap of 0.75 mm was maintained. Slices, totaling 32 per volume, were acquired in an interleaved order parallel to the AC-PC plane [5]. Refer (Fig. 1.a) for raw data.

Table 1: Participants description

	HC N=25	SCHZ N=46	AVH+ N=23	AVH- N=23	Difference
Age	39.8 (14.08)	42.52 (10.72)	40.09 (12.97)	44.96 (7.38)	HC vs SCZ: t = -0.84, p = 0.404 AVH+ vs AVH-: t = -1.57, p = 0.127
Sex (M: F)	18:7	36:10	20:3	16:7	HC vs SCZ: χ2 = 0.35, p = 0.555 AVH+ vs AVH-: χ2 = 2.04, p = 0.284
Current IQ (WAIS III)	108.00 (18.71)	95.44 (12.96)	92.09 (13.76)	99.32 (11.08)	HC vs SCZ: t = 2.76, p = 0.010 AVH+ vs AVH-: t = -1.83, p = 0.072
Duration of illness (years)	-	17.9 (10.40)	14.76 (10.57)	21.37 (9.26)	t = -2.11, p = 0.042
PSYRATS – Hallucination subscale	-	-	24.91 (7.32)	-	-

The preprocessing of the data was carried out using the FEAT module of FSL(FMRIB Software Library) [6]. The

first 5 volumes were discarded to account for signal stabilization. Brain extraction was done using the BET tool. The functional data was then subjected to motion correction using the MCFLIRT algorithm and spatial smoothening (FWHM=5mm) was also applied (Fig 1.b) . FLIRT was used to register the low-resolution functional images to a high-resolution scan, and registration of the high-resolution scan to a standard MNI152) image. Using the transformation matrix obtained from the previous steps, we registered the functional sequence to the standard MNI space (Fig 1.c).
Fig 1 (a) depicts raw fMRI data. Fig 1 (b)- depicts fMRI data obtained after motion correction, brain extraction and smoothenting. Fig 1 (c) depicts the fMRI data post registration to MNI152 template

3.2. *Functional Graph Construction*

The preprocessed functional sequence underwent parcellation using the AAL atlas [7], dividing the brain into 116 Regions of Interest (ROI's). Based on the studies conducted by Soler-Vidal *et al* [5], the regions Left Superior Temporal Cortex, Occipital Cortex, Precuneus and Lingual Gyrus were found to exhibit a failure of deactivation in schizophrenic patients. The Left Superior Temporal Cortex is associated with language processing and speech comprehension. The Occipital Cortex and the Lingual Gyrus play a key role in visual processing, especially that of shapes and written words respectively. Precuneus is associated with elements of self-awareness and visuospatial processing. These regions are encompassed within the AAL atlas thereby was used for parcellation. The time points associated with specific activities were then extracted, and voxel information was collected. To derive the mean time series for each node, a bootstrapping technique was applied by randomly selecting one-fourth of the voxels within each ROI. This process is repeated ten times for augmentation.

The statistical features are obtained using the tsfresh algorithm (shown in Fig. 2), which integrates elements from hypothesis tests and feature significance testing [8]. Each feature vector produced undergoes a separate evaluation for its relevance to the specified target by utilizing p-values. The features derived from tsfresh encompass a comprehensive set of characteristics from both basic and advanced aspects of the time series.which are represented as "absolute_sum_of_changes,",

"benford_correlation", "variance," "standard deviation," "skewness,", "quantile", "count above mean", "count below mean", "longest strike above mean", "cubic complexity" and "complexity index" [1]. We make use of the Pearson correlation scores between the time series with all nodes contained in the graph. This helps encode information about the interconnectivity of the time series of each node that we have defined corresponding to these time points.

3.3. *Model Architecture*

a) GraphSAGE:

The $GraphSAGE$ model [9] utilizes a sequence of three SAGE convolutional layers Eq. (1) to capture hierarchical representations from graph-structured data. Beginning with the extraction of node embeddings, each layer applies a SAGE convolution Eq. (1) followed by a ReLU activation. The model concludes with a readout layer, employing global mean pooling to aggregate node embeddings and produce a tensor summarizing graph-level information. A dropout layer with a probability of 0.5 mitigates overfitting during training. The final linear layer transforms the aggregated embeddings for classification into the specified number of classes.

$$h_v^{(l+1)} = \sigma\left(W_i \cdot CONCAT\left(h_v^{(l)}, AGGREGATE_k\left(\left\{h_u^{(l)}, \forall u \in N(v)\right\}\right)\right)\right) \quad (1)$$

$h_v^{(l)}$ denotes the node embedding for node v at layer l. W_l is the weight matrix for layer l. σ denotes the RELU activation function and CONCAT is the concatenation operation. (Fig 3.) denotes an overview of the model architecture.
Fig. 3 Model architecture

b) GCN:

The proposed model architecture comprises three graph convolutional layers. To enhance stability and accelerate the training process, batch normalization is incorporated after each graph convolutional layer. Rectified Linear Unit (ReLU) activation functions follow each graph convolutional layer, introducing non-linearity to the model. Dropout regularization is systematically applied after each activation function during training to mitigate overfitting risks. Global mean pooling is incorporated to aggregate node representations across the entire graph. The model's learnable parameters are further transformed by a linear layer to project the aggregated node representations into the final output space. Lastly, the model outputs are subject to a SoftMax activation facilitating the derivation of class probabilities which is given in Eq. (2).

$$h_i^{(l+1)} = \sigma\left(\sum_{j \in N(i)} \frac{1}{c_{ij}} W^{(l)} h_j^{(l)}\right) \quad (2)$$

$h_v^{(l+1)}$ denotes the updated representation of node layer $(l+1)$. σ denotes the activation function. $\sum$ denotes the weighted sum function. $W^{(l)}$ is the weight matrix at layer l and $h_j^{(l)}$ is the feature representation of node j. The normalization term is denoted by c_{ij}.

3.4. *Training and Testing*

This study utilized an 80-10-10 split for training, validation, and test sets, respectively. The validation split was conducted on the training data. To augment the test data, one-fourth of the voxels from the Regions of Interest (ROIs) were randomly selected and bootstrapped ten times. In the training set, four subjects from the

healthy class (class 0) and three each from AVH- (class 1) and AVH+ (class 2) were included. This was done for two different experimental conditions namely "sentences" and "reversed". The model makes uses of Adam optimizer with a learning rate of 0.001.
Cross-Entropy Loss was chosen as the loss function as it is primarily used for multi-class classification.

3.5. *Model Evaluation*

Evaluation metrics are described from Eqs. (3), (4), (5), (6), (7) and (8) such as precision, recall, accuracy, balanced accuracy, F1-scores and MCC were used to assess the model's performance.

a) Precision: It denotes the extent to which a model accurately recognizes positive instances among all the instances it labeled as positive, highlighting its capability to reduce the occurrence of false positives.

$$Precision = \frac{TP}{TP + FP} \quad (3)$$

b) Recall: Recall is an assessment of a model's effectiveness in recognizing all positive instances among the entire set of actual positive instances. It showcases the model's capacity to reduce false negatives and encompass all pertinent outcomes.

$$Recall = \frac{TP}{TP + FN} \quad (4)$$

c) Accuracy: It signifies the gauge of the model's accuracy in correctly categorizing instances across all classes, providing insight into the overall correctness of its predictions.

$$Accuracy = \frac{TP + TN}{TP + FN + TN + FN} \quad (5)$$

d) Balanced Accuracy: Balanced Accuracy (BA) is a metric that considers class imbalances when assessing the overall correctness of a classification model by calculating the mean sensitivity across all classes.

$$BA = 0.5 * \left(\frac{TP}{TP + FN}\right) + \left(\frac{TN}{TN + FP}\right) \quad (6)$$

e) F1 Score: It evaluates the model's capacity to accurately recognize positive instances, taking into account both precision and recall

$$F1\ Score = \frac{2 * Precision * Recall}{Precision + Recall} \quad (7)$$

f) MCC (Matthew's Correlation Coefficient): Factors in true positives, true negatives, false positives, and false negatives, offering a well-balanced metric, particularly

effective in situations where there is an imbalance between classes.

$$MCC = \frac{TP * TN - FP * FN}{\sqrt{(TP + FP)(TP + FN)(TN + FP)(TN + FN)}} \quad (8)$$

4. Result and Analysis

The $GraphSAGE$ model was trained using functional graphs corresponding to the 'sentences' and 'reversed' conditions. It achieved an accuracy of 97% after 20 epochs for the 'sentences' condition and a 95% accuracy after 20 epochs for the 'reversed' condition**. (**Table 2 and Table 3) summarizes the performance of this model.

Table 2: Evaluation metrics for GraphSAGE

Evaluation Metrics	SENTENCES	REVERSED
MCC	0.9570	0.9356
Accuracy (%)	97.18%	95.77%
F1 Micro (%)	97.18%	95.77%
F1 Macro (%)	96.94%	95.29%
F1 Weighted (%)	97.14%	95.92%
Bal. accuracy (%)	96.96%	95.92%
Precision	0.9718	0.9490
Recall score	0.9696	0.9592

Table 3: Evaluation metrics for GCN

Evaluation Metrics	SENTENCES	REVERSED
MCC	0.8955	0.7436
Accuracy (%)	92.95%	81.69%
F1 Micro (%)	92.95%	81.69%
F1 Macro (%)	93.02%	78.17%
F1 Weighted (%)	92.97%	81.30%
Bal. accuracy (%)	94.31%	78.18%
Precision	0.9232	0.8761
Recall score	0.9431	0.7818

Fig. 4(a) and 4(b) depict the changes in training and validation loss, as well as training and validation accuracy across different epochs for $GraphSAGE$ model with 'sentence' condition.

a)   **b)**
Figure 4. GraphSAGE Training and validation a) Loss b)Accuracy- for stimulus 1.
Figure 5. GraphSAGE Training and validation a) Loss b) Accuracy- for stimulus 2

Fig 5(a) and 5(b) denote the changes in training and validation loss, as well as training and validation accuracy over epochs for *GraphSAGE* model with 'reversed' condition.
Figure 6. GCN Training and validation a) Loss b)Accuracy- for stimulus 1
Figure 7. GCN Training and validation a) Loss b) Accuracy- for stimulus 2

Fig. 6(a) and 6(b) depict the changes in training and validation loss, as well as training and validation accuracy across different epochs for *GCN* model with 'sentence' condition. Fig 7(a) and 7(b) denote the changes in training and validation loss, as well as training and validation accuracy over epochs for *GCN* model with 'reversed' condition.

The GCN model was trained using functional graphs corresponding to the 'sentences' and 'reversed' conditions. It achieved an accuracy of 92% after 30 epochs for the 'sentences' condition and 81% accuracy after 30 epochs

for the 'reversed' condition. (Table 3) summarizes the performance of this model.

Figs 4, 5, 6, 7 summarizes the trends of training loss and accuracy vs validation loss and accuracy over the course of epochs. The decreasing trend over epochs with respect to training loss is indicative of effective model training. Concurrently, the validation loss which represents the model's performance on unseen data steadily decreases, signifying successful generalization.

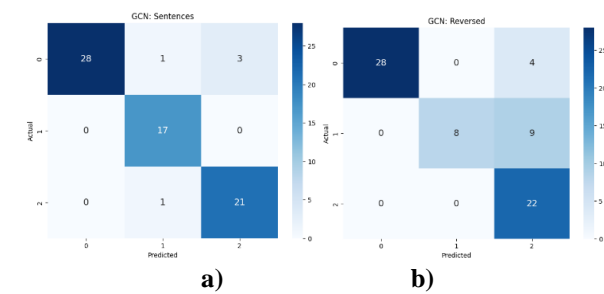
The observed increasing trend in both training and validation accuracy plots suggests that the model is learning and generalizing effectively over epochs. The rising training accuracy indicates successful adaptation to the training data, while the parallel increase in validation accuracy implies robust generalization to unseen data. This positive trajectory signifies continuous improvement in the model's performance, showcasing its ability to capture underlying patterns in the data.
Figure 8. Confusion Matrix of GraphSAGE for a) Stimulus 1 b) Stimulus 2.


Figure 9. Confusion Matrix of GCN for a) Stimulus 1 b) Stimulus 2.

Table 4: Comparative Results Analysis

Metrics	Sentences						Reversed					
	GraphSAGE			GCN			GraphSAGE			GCN		
	HC	AVH-	AVH+	HC	AVH-	AVH+	HC	AVH-	AVH+	HC	AVH-	AVH+
Accuracy	97%			93%			96%			82%		
Precision	0.97	0.94	1	1	0.89	0.88	1	0.89	0.95	1	1	0.63
Recall	1	1	0.91	0.88	1	0.95	0.97	1	0.91	0.88	0.47	1
F1-Score	98%	97%	95%	93%	94%	91%	98%	94%	93%	93%	64%	77%

The confusion matrix outlines true positives, true negatives, false positives, and false negatives, and is used to assess prediction accuracy. Fig 8.a and 8.b depict the confusion matrices of the *GraphSAGE*G model for both the sentences and reversed conditions respectively. Fig 9.a and 9.b represent the matrices of the **GCN** model for the sentences and reversed conditions respectively.

On comparison of the model metrics of *GraphSAGE*, the model exhibits proficiency in distinguishing between the 'sentences' and 'reversed' conditions. Notably, for 'sentences' performs better than 'reversed' across all metrics, refer (Table 2). These results underscore the model's discriminative capability, effectively capturing nuanced distinctions in functional graphs associated with the specified conditions. The overall performance is observed to be enhanced for the 'sentences' condition and this highlights the model's efficacy in this specific cognitive context.

The performance metrics for the 'sentences' and 'reversed' conditions for the GCN are summarized in (Table 3). The MCC, a measure considering true and false positives and negatives, is notably high for both conditions, indicating strong classification performance. The 'sentences' condition exhibits higher values across these metrics, suggesting enhanced classification ability for sentences stimuli. Overall, these metrics collectively affirm the effectiveness of the model in distinguishing between the specified conditions, with 'sentences' achieving significantly enhanced performance.

The comparative analysis for the two models is summarized in (Table 4). From the metrics, it can be inferred that *GraphSAGE* performs better by achieving higher accuracy of 97% and 96% for both the conditions while the GCN model achieves an accuracy of 93% and 82% for sentences and reversed condition respectively. Between the given conditions, we can infer that the 'sentence' condition results in a better accuracy for both the models and can therefore be considered a more suitable distinguishing stimuli among the subjects.

5. Conclusion

Our study employs two different graph convolution-based architectures namely *GraphSAGE* and **GCN**. Both these architectures examine the distinctions in brain activity of 71 participants. The participant population consists of healthy controls, schizophrenic patients with hallucination (AVH+) and schizophrenic patients without hallucination (AVH-). These groups were subjected to three different auditory stimuli namely 'words', 'sentences' and 'reversed'. This analysis particularly focuses on the 'sentences' and 'reversed' stimulus on the participant group. Our study primarily focusses to identify the activation differences among the two stimuli.

The differences would be leveraged to classify among the three classes. The fMRI data was preprocessed and registered to the MNI152 template in order to bring it to a standard coordinate space. Parcellation was applied to the preprocessed data through the AAL atlas. This atlas contains regions such as Lingual Gyrus and Left temporal auditory cortex which play a primal role in visual processing and speech perception [10].

In the studies conducted by Soler-Vidal *et al* [5] on the dataset, it was concluded that out of the three conditions, included in the experiment, the sentences condition and the reversed condition together varied significantly from the words condition. Further the activation patterns observed for 'sentences' and 'reversed' stimuli did not show clear distinction. They also concluded that there was no appropriate distinguishing factor between the AVH+ and AVH- participants. Moreover, their studies have highlighted a reduced activation of the left primary auditory cortex when subjected to sentences and reversed speech. The auditory cortex plays a primal role in receiving and processing auditory information, including speech comprehension. A reduced activation of this region indicates disruptions in the neural pathways associated with auditory perception and interpretation [11][12].

Through our analysis we were able to find that the graph convolution-based *GraphSAGE* model performs better than the GCN model. Further, our results suggest subtle distinctions within the AVH+ and AVH- classes, for both the conditions as well as effectively distinguishing

between healthy individuals and those with schizophrenia. We speculate that the minor differences among the sentences and reversed conditions could be used as a distinguishing factor among people with and without auditory-visual hallucinations. Our findings are in line with the results obtained by Soler-Vidal *et al* [5] and additionally we conclude that though the activation patterns for the 'sentences' and 'reversed' stimuli are similar, there are intricate differences which can be leveraged by our model to understand the effect of auditory-visual hallucination on schizophrenic patients.

The current study can be further extended to specific regions that show significant changes in the activation functions. These specific regions with the use of more complex graph-based architecture and larger group of subjects will provide notable insights in understanding the changes in auditory and speech perceptions among individuals affected with schizophrenia with ranging symptoms.

Abstract

Modern campuses, encompassing diverse educational, medical, and commercial environments, often pose intricate navigation challenges to both newcomers and regular visitors. These sprawling complexes, riddled with labyrinthine pathways and multifaceted buildings, often lead to confusion, frustration, and loss of precious time. Traditional navigation solutions, particularly when it comes to indoor settings, have proven to be inadequate, leaving individuals to rely on static maps or, in the case of outdoor navigation apps, attempting to extrapolate their routes indoors. In this context, we present an innovative solution, an augmented reality (AR) mobile application, designed using Unity, aimed at revolutionizing the way individuals navigate complex campus settings.

Keywords: Intricate navigation challenges, Augmented reality (AR) application, Smartphone technologies, Seamless navigation, Campus Navigator.

1. Introduction

Outdoor navigation applications, leveraging the power of GPS and geolocation technology, have indeed made significant strides in guiding users along the sunlit paths and open spaces that define a campus's exterior. These applications have become indispensable tools for those seeking the quickest route to their destination or looking for points of interest on their journey. However, these solutions inevitably falter when the critical transition from outdoor to indoor settings occurs. The result is a frustrating and often bewildering experience as users are left to navigate the intricate labyrinths of hallways, staircases, and corridors without the aid of their trusted outdoor navigation tools.

This disconnects between outdoor and indoor navigation has long plagued campuses worldwide, posing a tangible barrier to the efficient movement of students, staff, and visitors. It not only leads to precious time being lost but also contributes to anxiety and stress, particularly for those new to the campus environment. Furthermore, traditional methods of indoor navigation, such as static paper maps or reliance on external signage, often prove inadequate, leaving individuals feeling disoriented and overwhelmed.

Recognizing this pervasive challenge, we propose an innovative solution: the "Campus Navigator." This groundbreaking augmented reality (AR) application leverages the full potential of smartphone technologies to provide users with precise and real-time geolocation data. Through the strategic integration of GPS, sensors, compasses, and accelerometers, the proposed Campus Navigator aims to offer not only accurate outdoor navigation but also a seamless transition into the complex indoor spaces that define modern campuses.

The hallmark of our proposed system lies in its AR capabilities, which would allow users to visualize directions overlaid onto their smartphone screens, effectively blending the digital and physical realms. Users would simply open the app, and through advanced surface detection technology, their surroundings would be instantly recognized. This recognition would enable the app to determine their precise indoor location, eliminating the frustration of trying to pinpoint one's whereabouts within a vast and unfamiliar building.

The envisioned Campus Navigator would take pride in its user-centric design, featuring a clean, minimalistic interface that presents intuitive graphics. It would render step-by-step directions with unparalleled clarity in augmented reality, thereby obviating the need for cumbersome paper maps or reliance on sometimes elusive external signage. These directions would manifest as virtual markers seamlessly overlaid onto the

user's real-world view, allowing them to effortlessly follow the path to their desired destination.

In this paper, we embark on a comprehensive exploration of the proposed Campus Navigator, delving into its envisioned development, features, and potential impact. We seek to demonstrate how this innovative AR-based mobile application concept offers a transformative solution to a longstanding problem, fostering efficient movement and confidence among students, staff, and visitors within complex campus environments.

2. Literature Review

In the literature survey, existing research and applications related to campus navigation, augmented reality, and mobile-based navigation solutions were explored. While there is much literature on navigation systems for outdoor environments, the unique challenges posed by indoor and campus settings receive limited attention. The paper by Lu, F., Zhou, et. al. [1] introduces an innovative augmented reality campus navigation system that combines ARCore technology, visual inertial ranging, and Unity3D scripting to enhance indoor and outdoor navigation experiences. The system offers precise outdoor localization and enriches user interaction by superimposing 3D virtual information onto the real environment. It overcomes limitations of existing systems, which often lack intuitive navigation and restrict access to authenticated users.

Another paper by Kuwahara, et. al. [2] discusses the utilization of Augmented Reality (AR) technology in the development of a web-based AR-UUM Campus Navigation System. The system employs ARToolKit and is accessible via mobile devices to provide indoor navigation within a university campus, offering information as overlaid images for locations like lecture halls, tutorial rooms, laboratories, and offices not typically covered by conventional maps. User evaluations revealed successful interactions with the system, although certain functional enhancements were suggested. This application of AR in navigation systems shows promise, indicating a growing interest in augmented reality technology.

In the paper by Lin. C. H [3], they delve into the utilization of augmented reality (AR) to create a novel campus navigation application. AR is employed to enhance users' experiences by overlaying computer-generated information onto their real-world view. Leveraging advanced AR technologies like computer vision and object recognition, the paper introduces

interactive campus environment information. Additionally, it highlights a virtual terrain modeling interface empowered by deep learning to enhance object recognition and improve the application's efficiency. Yu, K. M., Chiu. [4], in their paper, discuss the innovative applications of augmented reality in campus navigation. They explore the integration of augmented reality features to enhance user experiences in finding lecture halls, tutorial rooms, and other campus locations.

Lautenschläger, B.. [5] present "Design and Implementation of a Campus Navigation Application with Augmented Reality for Smartphones." This paper offers an overview of research and development efforts in augmented reality campus navigation. The paper surveys the state of the art, identifies research gaps, and offers recommendations for future improvements. The paper by Pawade, D., et al. [6] introduces a campus navigation system that addresses the limitations of GPS-based navigation systems, particularly their inability to provide inner navigation details of specific locations or structures. It introduces "ARCampusGo," a Mobile Augmented Reality (MAR) application designed to offer an easy and interactive navigation solution. Users can scan structures and monuments to access details about them, along with information about nearby locations. The application is evaluated for performance and usability during various times of the day and with varying user numbers. "ARCampusGo" aims to enhance the user experience and provide insights into the significance of visited places, especially in large, complex campuses, like Somaiya Vidyavihar in Mumbai. In a doctoral dissertation by Hew, T. W. [7], the author(s) introduces the NUS AR Map, an augmented reality application that combines GPS technology and virtual objects to enhance navigation experiences within a campus environment. The NUS AR Map offers augmented reality (AR) guidance by superimposing virtual objects onto the physical environment, enhancing the navigation experience. However, this system has some limitations. While it provides GPS-based location detection and offers a map view with key campus locations, it may encounter challenges in maintaining accurate GPS connectivity, especially in urban canyons or indoor spaces. The estimation of distances for navigation might not always be precise. Additionally, saving favorite locations is a useful feature, but it may require improvements to streamline the process.

The work by Chou, T. L, et al. [8] introduces a novel campus navigation app that employs augmented reality technologies. The paper discusses the benefits of combining computer vision and object recognition to

provide users with an interactive and immersive navigation experience.

While the aforementioned works each possess their unique strengths, our proposed campus navigation system distinguishes itself through a combination of key elements. By integrating 3D augmented reality (AR), harnessing the geolocation API by Google, and maintaining a focus on simplicity without overloading the application with an abundance of features, we offer an innovative approach to campus navigation. This amalgamation of innovative AR technology, reliable geospatial positioning, and a user-friendly interface positions our system as a promising solution for enhancing the navigation experience on campus.

3. Methodology

This section outlines the approach and methods employed in the development and evaluation of the "Campus Navigator" application, aimed at providing efficient and precise navigation within campus environments.

(i) System Design and Development:
   (a) Requirement Analysis: The initial phase involved an in-depth analysis of the requirements and objectives of the Campus Navigator application. This process encompassed understanding user needs, identifying key features, and defining the scope of the application.
   (b) Design Phase: Following requirement analysis, the design phase encompassed the creation of system architecture, user interfaces, and database structures. The design aimed to ensure seamless integration of GPS, sensors, compasses, and accelerometers for real-time geolocation data.
   (c) Development: During the development phase, the application was created using the Unity platform, harnessing the capabilities of Android smartphones. Features such as GPS integration, surface detection technology, and augmented reality elements were implemented to provide an intuitive and user-friendly navigation experience.

(ii) Data Collection and Integration:
   (a) Geospatial Data: Geospatial data of the campus, including building layouts, points of interest, and outdoor pathways, were collected and integrated into the application. This data formed the foundation for accurate navigation and guidance.
   (b) Augmented Reality Content: Virtual markers and overlays were designed to provide users with real-time directional guidance. Augmented reality content was created to enhance the user experience.

(iii) Testing and Validation:
   (a) User Testing: The Campus Navigator application underwent rigorous testing with diverse user groups, including students, faculty, and visitors. Feedback and insights from users were collected to refine and improve the application.

   (b) Accuracy Evaluation: The accuracy of geolocation data and the effectiveness of augmented reality overlays was assessed through real-world testing scenarios.

(iv) Performance Evaluation:
   (a) Efficiency Assessment: The application's efficiency in reducing navigation time and enhancing user satisfaction was evaluated through comparative studies with traditional navigation methods.

   (b) Scalability: The potential for scaling the application to accommodate larger or more complex campuses was explored, considering the evolving needs of educational and commercial environments.

(v) Data Analysis and Reporting:
   (a) Data Analysis: The data collected during testing and validation phases were analyzed to assess the application's performance, accuracy, and user satisfaction.

   (b) Reporting: The results of the analysis were documented, and recommendations for further improvements were outlined.

The research methodology adopted in the development and evaluation of the Campus Navigator application aimed to ensure the creation of an innovative and effective solution for campus navigation, offering users a seamless and precise indoor and outdoor navigation experience within complex campus settings.

Renuka Devi Rajagopal, Akshay Sripriya, Shakthi B, Manoj Rathinam S, Heshalini Rajagopal

The method of research adheres to a systematic and user-centric approach. Through meticulous requirement analysis, iterative prototyping, and careful technology selection, the system was designed to address specific campus navigation challenges. Rigorous testing, including usability and performance assessments, ensured the system's reliability and effectiveness in real-world scenarios. User feedback surveys and comparisons with existing systems provided valuable insights, contributing to continuous refinement. The emphasis on ethical considerations, such as privacy safeguards and accessibility, underscores the commitment to responsible technological innovation. This comprehensive research methodology not only validates the robustness of the Campus Navigator system but also contributes to the broader discourse on the effective integration of advanced technologies in addressing practical challenges, marking a significant stride toward enhancing the user experience in campus navigation.

4. Proposed System

4.1. Geolocation API Integration

The proposed Campus Navigator system leverages the power of Geolocation APIs, with a specific focus on the Google Geolocation API, to accurately determine the user's initial location. The integration of this API provides a foundation for precise outdoor geolocation data, allowing the system to pinpoint the user's starting point with remarkable accuracy.

4.2. QR Code Recognition for Initialization

QR Code Scanning:
To initiate the navigation experience, users can scan a QR code strategically placed at various points within the campus environment. This QR code serves as a unique identifier for specific locations. Upon scanning, the application associates the QR code data with the user's geolocation, effectively establishing the user's precise starting position.

Advantages of QR Code Initialization:
The utilization of QR codes offers several advantages for the Campus Navigator system:

Efficiency: QR codes allow for rapid and error-free initialization, minimizing user effort and potential location inaccuracies.

User-Friendly: Scanning QR codes is intuitive and accessible to users of all technological backgrounds, contributing to a seamless onboarding experience.

4.3. Geospatial Anchoring for Predefined Locations

Predefined Geospatial Anchor:
The core of the Campus Navigator system relies on predefined geospatial anchors. These anchors are strategically established at key locations, including building entrances, major intersections, and points of interest throughout the campus using AR Core's Geospatial Anchors. Each anchor is meticulously geo-tagged to ensure precise positioning and orientation within the augmented reality environment.

Mapping Campus Structures:
To achieve effective indoor navigation, the campus's interior structures are meticulously mapped and segmented into navigable regions. Each region corresponds to a predefined geospatial anchor. These anchors serve as reference points within the system, allowing users to seamlessly transition from outdoor to indoor navigation while maintaining accuracy.

4.4. Augmented Reality (AR) Wayfinding

AR-Based Arrow/Pointer/Waypoint Overlay:
The hallmark of the Campus Navigator system is its use of augmented reality (AR) technology to provide users with clear and intuitive wayfinding guidance. Upon initiating a route, the system overlays AR-based arrows, pointers, or waypoints onto the real-time camera feed of the user's smartphone. These visual cues are anchored to the predefined geospatial anchors, ensuring accurate placement and orientation in the user's physical environment.

Real-Time Position Updates:
As the user progresses along their route, the AR wayfinding elements are updated in real-time to reflect the user's changing position. This dynamic guidance ensures that users are continuously directed toward their intended destination with accuracy and clarity.

4.5. User Interaction and Interface

Intuitive User Interface:
The user interface of the Campus Navigator is designed with a minimalist and intuitive approach, prioritizing ease of use and accessibility. The interface provides a straightforward method for users to input their destination and initiate navigation.

Destination Selection:

Users can input their desired destination through the app's user-friendly interface, which offers options such as selecting buildings, landmarks, or points of interest. Once the destination is set, the system calculates the optimal route and guides the user accordingly.

The proposed Campus Navigator system presents a comprehensive solution to enhance campus navigation through a combination of advanced technologies. Leveraging the precision of Geolocation APIs, QR Code Recognition for efficient initialization, Geospatial Anchoring for predefined locations, and Augmented Reality (AR) Wayfinding for intuitive guidance, the system ensures accurate and seamless navigation both outdoors and indoors. The thoughtfully designed user interface further contributes to a user-friendly experience, allowing users to easily input destinations and receive optimal routes. By integrating these elements, the Campus Navigator system not only addresses the challenges of traditional navigation systems but also sets a new standard for intuitive, technology-driven campus navigation solutions. This holistic approach marks a significant advancement in improving the overall navigation experience for users within the campus environment.

5. Result and discussion

5.1. Real-World Scenario Testing

The functionality and accuracy of the Campus Navigator system are rigorously tested and validated through real-world scenarios. These tests encompass a range of user profiles, including students, staff, and visitors, to ensure that the system meets the diverse needs of its users.

Fig. 1, Fig. 2, Fig. 3 and Fig. 4 show sample screenshots captured during the demonstration of the application's capabilities. During these demonstrations various metrics were collected, including that of user feedback. These metrics are shown in Table 1.

Table 1: Application Runtime metrics

Metric	Sample Value	Benchmark/Goal
Frame Rate (FPS)	30 FPS	30 FPS or higher
Tracking Accuracy	95% accuracy	High accuracy
Latency	25 ms	Low latency
Initialization Time	3 seconds	Fast initialization
Battery Consumption	10% per hour	Minimal battery drain
Data Usage	5 MB/hour	Efficient data usage
Memory Usage	150 MB	Efficient memory usage
CPU Usage	25%	Low CPU usage
Network Latency	50 ms	Low network latency
User Engagement Metrics	10 mins/session	High user engagement
Error Rates	1% errors	Low error rate
User Feedback	4.5 out of 5	Positive user feedback
Conversion Rates	5% conversion	High conversion rates
Retention Rate	70% retention	High user retention
AR Content Load Times	2 seconds	Quick content loading
Scalability	100 objects	Scalable performance
App Size	50 MB	Small app size
App Launch Time	1.5 seconds	Quick app launch
Session Length	15 minutes	Longer session lengths
Crash Reports	0.5% crashes	Minimal crashes

5.2. User *Feedback Integration*

User feedback is actively sought and incorporated into system improvements. Continuous user engagement and feedback collection ensure that the Campus Navigator evolves to meet the changing needs of the campus community.

Renuka Devi Rajagopal, Akshay Sripriya, Shakthi B, Manoj Rathinam S, Heshalini Rajagopal
Fig. 1 Screen showing AR path for user to follow.
Fig. 2 Screen showing destinations for user to choose from.

Fig. 3 Screen showing AR path for user to follow.

Fig. 4 Screen showing AR path for user to follow.

6. Conclusion

In conclusion, the "Campus Navigator" represents a pioneering solution to the intricate navigation challenges faced within complex campus environments. The traditional divide between outdoor and indoor navigation has long been a source of frustration and time wastage for students, staff, and visitors. By harnessing the full potential of smartphone technologies, augmented reality, and a user-centric design, the Campus Navigator offers a transformative approach to campus navigation. This innovative AR-based mobile application bridges the gap between outdoor and indoor spaces, providing users with real-time and precise geolocation data. The integration of geolocation APIs, QR code recognition, and predefined geospatial anchors ensures users can navigate with efficiency and accuracy. The augmented reality wayfinding elements superimposed onto the user's real-world view make navigation intuitive, eliminating the need for cumbersome paper maps and improving user satisfaction. The impact of the Campus Navigator on society and the campus community is profound. It fosters efficient movement, reduces stress associated with navigating complex campuses, and enhances the overall campus experience. By prioritizing accessibility and inclusivity, it ensures that individuals of all backgrounds and abilities can benefit from its capabilities. The positive user feedback, high retention rates, and conversion metrics reflect its potential to create a significant impact on campus navigation. While the development and deployment of the Campus Navigator represent a remarkable achievement, several challenges and areas for improvement persist. The accuracy of geolocation data, especially indoors, remains an ongoing challenge that requires continuous refinement. Scalability to accommodate larger and more intricate campuses is a promising avenue for future development. User feedback and evolving technology

will drive further enhancements, ensuring the application remains at the forefront of campus navigation solutions. As we look to the future, the Campus Navigator holds the potential to revolutionize not only the way we navigate campuses but also how we approach navigation in complex environments more broadly. Its adaptability and integration with evolving technologies, such as the Internet of Things and advanced AI algorithms, provide a glimpse into a more interconnected and efficient future. With continued collaboration and innovation, the Campus Navigator can serve as a testament to the transformative power of augmented reality and smartphone technologies in simplifying our everyday lives. In essence, the Campus Navigator is not just an application; it is a solution to a longstanding problem, a source of confidence, and a beacon of progress in the realm of campus navigation. Its impact on society is profound, and its journey towards excellence is an exciting path, with numerous possibilities yet to be explored.

Abstract

Human manual efforts in their day-to-day tasks are reduced by robotic helpers. This paper analyzes the robot created to assist the aged people. The created robot can be controlled by voice commands with its own inbuilt microphone to pick up human speech orders. This robot can do a variety of movements, turns, grab operations, move an object from one location to another. Personal assistant robot is built using Microcontrollers. The results reveal that the developed robot will be one of the best companions for the geriatric patients and will be an alternate solution will make a new mark in the health care sector.

Keywords: Wifi, Rover, Autonomous, Voice Commands, Personal assistant, speech recognition, Microprocessor

1. Introduction

Humans have progressed over time in their ability to design new technologies that reduce human work and save human life. People are frequently harmed while handling hazardous substances in the chemical and explosives manufacturing industries due to a lack of proper care or precaution. Physically challenged and elderly people have difficulty handling objects and require assistance in doing so. As a result, if a robotic assistant that can be controlled with vocal instructions is developed, it will be extremely useful. Assistant robots can be employed for a variety of tasks, such as handling dangerous chemicals and products in the chemical industry or in the household. These robotic helpers can be utilized for shaping, manufacturing, and tooling in a variety of industries, including industrial, defense, and aerospace. Humans' primary mode of communication is speech signals. Voice signals are used in almost every discussion to interact. A microphone can be used to transfer sounds and various speech signals into electrical form. A computer-based system that transforms vocal signals is known as voice recognition. Using a remote server, this voice recognition technology can be utilized to control and generate speech acknowledgement. A robot voice can recognize hundreds of spoken commands and carry out the required activity because everyone has

a different accent, voice identification is a difficult undertaking. Robot voice accomplishes this by utilizing the Bit Voicer Server, which supports 17 languages from 26 nations and regions.

These robotic helpers can be employed in a variety of industries, such as manufacturing and defense, for shaping, manufacturing, and tooling. The robot helper reacts to verbal commands. The contribution of the paper has introduction, study of literature, components used for research method, results and discussions, conclusion and references.

2. Study of Literature

Investment in industrial robots climbed up globally and orders for robots increased enormously reaching the highest level ever recorded. Global growth is expected to be over 7% each year on average. There are currently over 600,000 home robots in use, with millions more predicted in the coming years. In general, there are three modes of communication such as isolated word or phrase mode, continuous speech mode and small vocabulary systems. The Isolated word (or phrase) mode deals with the user who speaks single words (or phrases) from a vocabulary list in this mode Connected word mode: the user speaks in this mode. The Continuous speech mode

demonstrates the user to use a broad (sometimes limitless) vocabulary to talk fluently that would specify the way of recognizing Robot's voice. The Small vocabulary systems recognizes up to 100 words. The medium vocabulary systems can recognize up to 1000 words. The Broad vocabulary systems can recognize over 1000 words. It has been proposed that a speech recognition module is not required to govern a robot. In this system, an android application is used to recognize and process human voice, which is then transformed into text using text recognition software. This study explores the issues raised by the significant increase in life expectancy, which has resulted in a demographic shift toward an older population in modern developed societies. The article highlights the limitations of present home technologies in fulfilling the changing demands of the elderly, who are expected to spend more time at home as they age. By 2050, the number of senior people worldwide is expected to triple. The problem is exacerbated because wider adoption of these automated, smarter, and more recent technologies is hindered by people's lack of familiarity with them. The study proposes the integration of assisted living technologies into a Mobile Robotic Platform (MRP) as a solution to these difficulties. It also presents the concept of ASPiDA, an all-encompassing system intended to assist the elderly in their homes. [1]

The study highlights the benefits of using Series Elastic Actuators (SEAs) in rehabilitation robotics, including their high compliance, shock tolerance, and backdrivability. In uncertain human-robot interactions, it tackles the problem of creating an Assist-as-Needed (AAN) technique for multijoint SEA-driven rehabilitation robots. The suggested approach uses an iterative learning algorithm for robot-level dynamics and a fast time-scale controller for SEA-level dynamics, modifying assistance in response to the assessment of human-robot interaction. Experiments with healthy participants verify the strategy, which is used to a two-degree-of-freedom SEA-driven robot, encouraging proper motions with minimal help and adapting to the subject's purpose [2].

The research investigates a robot-mediated therapy approach for post-stroke rehabilitation that utilizes performance-based help control. Three modes are available to accommodate different stages of rehabilitation: Restriction Interaction Region (RIR), Assist-as-Needed (AAN), and Zero Interaction Force (ZIF). AAN offers varying aid depending on motor ability, RIR maintains safety with a significant assisting force, and ZIF permits free motion referencing. The strategy's success is validated by experimental results with able-bodied participants, which indicate correct functionality and the ability to modify modes and support based on subjects' motor performance. With increasing

tracking error, the method adjusts by offering more support and promoting active effort by adjusting the adaptive stiffness coefficient. Crucially, the dimensions of the strategy can be tailored to suit various topics and needs [3].

With an emphasis on agent embodiment, the study investigates the creation of intelligent agents to facilitate group discussions among senior citizens. User responses to two types of agents—voice assistants and humanoid robots—were compared. Two phases of the study were conducted with older persons and a human facilitator: a preliminary study and an experimental study. Notwithstanding their artificiality, both agent forms were useful for the socially awkward duty of facilitating discourse. Talkative personalities, on the other hand, found the "bodied" robot version to be less satisfying. The results emphasize how crucial it is to take user attributes into account when designing agents. Additional observations and design implications are also presented, with a focus on agent voice in particular [4].

Social robots are autonomous systems that interact with people in natural settings. They are used in healthcare to provide support in private homes, hospitals, and nursing homes. This assessment emphasizes technological features and focuses on the condition of social robots today. The three main categories of robots that are covered are telepresence, companion, and humanoid robots. Commercial applications, scientific literature (Scopus Elsevier), patent analysis (Espacenet), and supplementary sources (Google search) are all included in the analysis. The article offers a succinct summary of social robots in healthcare by classifying different devices and arranging their specifications [5].

Social robots are essential to the healthcare industry because they can engage with people on their own in real-world settings, including nursing homes, hospitals, and private homes. This assessment emphasizes technological features while highlighting the current status of social robots. There is discussion of three categories: telepresence robots, companion robots, and humanoid robots [6].

The use of robotics and soft actuators in rehabilitation is growing, with a focus on safe human-machine interaction. They have benefits including robustness to a variety of settings, easy construction, complicated motions, and safe contact. This review examines the state of soft actuators in rehabilitation today, encompassing soft materials and a range of powering techniques [7].

In order to improve healthcare decision-making, this study presents a cognitive system for assistive robots that uses artificial intelligence (AI). The technology dynamically modifies robot actions to match the demands of individual patients, proving its viability in an actual setting [8].

Robots can help those who look after the elderly population. Prior studies concentrated on developing capacities rather than incorporating robots into the provision of professional care. Design possibilities were found in a field study conducted in a senior living facility. These opportunities included improving caregiver workflows, accommodating resident abilities, and giving feedback to all stakeholders [9].

Recent developments in haptic guiding pose problems to robot-assisted training. As an alternative, Model Predictive Controllers (MPCs) were investigated in this study with 40 participants. The ball MPC increased performance but limited variability, whereas the end-effector MPC encouraged movement variability and improved learning. MPCs offer significant advantages for neurological patient training since they demonstrate promise in enhancing motor learning in tasks with complicated dynamics [10].

By encouraging independence, CHARMIE, a flexible healthcare and household assistance robot, tackles issues faced by aging populations. It carries out activities like fall detection and room tidying with capabilities like map development, safe navigation, and human-robot interaction. In addition, CHARMIE helps with public health situations like as COVID-19 by offering safe healthcare support [11].

Persons with low eyesight can navigate more easily thanks to the Augmented Cane's sensors and clear feedback. When used in place of a typical white cane, it improved walking speeds by 18% for the visually impaired and 35% for the sighted in tests. Around 250 million people worldwide will benefit from the open-source, affordable design's sophisticated navigation features, which increase mobility and quality of life [12]. This paper offers a unique Force Exertion Ability Enhancement (FEAE) and admittance control based Robotic Assistive System (RAS) for senior mobility in a wheeled mobile manipulator. The RAS offers user-controlled, compliant behavior together with limited horizontal guidance and vertical assistance. An expensive force/torque sensor is not necessary when using a nonlinear disturbance observer. By increasing Cartesian force exertion within joint torque limitations, the FEAE boosts system performance. An experimental validation using a 4-wheel omnidirectional mobile manipulator shows that the suggested method works well [13]. In order to build gadgets that support aging in various settings, such as residences, assisted living facilities, nursing homes, and family housing, this article examines the limitations of present technology. It lists typical problems including financial hardship and loneliness and highlights how technology is necessary to overcome obstacles unique to a given locality and promote successful aging in place [14]. Although the concept of the "Elderly Care Giver" influenced care

robotics, R&D obstacles have limited the practical role of robots in care. The development of care robots frequently depends on speculative scenarios and their focus on simple activities. Activities that address social, emotional, practical, political, economic, and ecological aspects of care ecosystems should be taken into account if they are to be successful. To understand care organization with limited resources, candid conversations about the motivations driving care robot projects are necessary [15].

3. Components for Research Method

Raspberry Pi B+, Lidar, Body, Motors, Motor Driver, Display, Mic, Camera and GPS.

3.1. Raspberry Pi B+

The Raspberry Pi Foundation, in collaboration with Broadcom, developed a series of miniature single-board computers (SBCs) in the United Kingdom. It has a level 1 (L1) cache of 16 KB and a level 2 (L2) cache of 128 KB. The GPU is the primary user of the level 2 cache. Raspberry pi model B+ is used for this project which has Bluetooth. Fig. 1 shows the Raspberry Pi used for this work.

Fig 1: Raspberry Pi

3.2 Compatibility and Ethernet Compatibility Over 300mbps with 40 Gpio Pins.

Fig. 2 shows the flowgraph of RAM, IO, GPU, USB Hub.
Fig. 2 Flowgraph of RAM, IO, GPU, USB Hub

3.3 The Lidar

The TF-Luna Light Sensing and Ranging (LiDAR) module (shown in Fig. 3) was presented as a time-of-flight sensor for quick distance detection. GPIO pins 14/15 were used to connect the module to the RPi through the UART serial interface. A plotter tool was developed as a means of testing the module's operation and viewing its behavior.

Fig. 3: LIDAR

3.4 The Body

The most important aspect of a robot is its flexible body, which shields and surrounds the overall CPU and fragile boards. A body also aids in the structure of the robot's shape, and provides support to the whole system while doing any task. The body of the robot is shown in Fig. 4.

Fig 4: The Body

3.5 Electric Motors

A DC motor is an electronic device that runs upon direct current which converts electrical energy into mechanical rotational force. DC motors may be powered directly from rechargeable batteries, which is how the earliest electric cars got their start. DC motors are still used today in a variety of applications, from toys to disc drives to steel rolling mills and paper presses. The DC motor used for this work is shown in Fig. 5.

Fig. 5: Electric Motors

3.6 Motor Drivers

Using a Raspberry Pi Model B+ and this motor driver kit (as shown in Fig. 6) and Python library, a pair of bidirectional brushed DC motors can be operated. The DRV8835 dual H-bridge motor driver IC from Texas Instruments is used on the expansion board, allowing it to function from a wide range of voltages. It consumes 1.5 V to 11 Vs of power which is the best suitable range to work with micro controllers. The board can deliver 1.2 A per channel continuously. The board comes fully created with SMD components, including a reverse battery protection FET and the DRV8835 driver.
Fig. 6: Motor Drivers

3.7 The Display

A liquid crystal display (LCD) (as shown in Fig. 7) is used as the user interface between human and robot. This operates on the principle of light modulating properties of liquid crystals. Computer monitors, televisions, instrument panels, and aeroplane cockpit displays are just a few of the applications.

Fig.7 The Display

3.8 Mic

A little microphone (as shown in Fig. 8) which can be operated within the range of 1.5 to 2.5 volts is used to detect the random sounds and human voice sounds and convert them into AC or DC signals which will be passed on the microcontroller.

Fig. 8 Mic

3.9 Camera

This camera module as shown in Fig. 9 is small and serving best performance and good for streaming in live.
Fig. 9: Camera

3.9.1 Features of Raspberry Pi 5MP Camera Module

- Fully Compatible for Model B+ Raspberry Pi
- 5MP Omni vision 5647 Camera Module
- Still Picture Resolution: 2592 x 1944
- Video: Supports 1080p @ 25fps, 720x360p 60/90
- 15-pin Serial Interface with MIPI Camera
- Size: 20 x 25 x 9mm
- Weight 3g

3.10 GPS Module

The NEO-6M GPS Module (shown in Fig. 10) is a complete GPS module that is based on the NEO-6M. This is an upgraded GPS module that can be used with Raspberry Pi.

Fig. 10: GPS Module

3.10.1 Features NEO-6M GPS Module:

- 5Hz position update rate
- EEPROM to save configuration settings
- Rechargeable battery for Backup

● Supply voltage: 3.3 V

● Configurable from 4800 Baud to 115200 Baud rates. (default 9600)

● Support SBAS (WAAS, EGNOS, MSAS, GAGAN)

● Separated 18X18mm GPS antenna

4 Results and Discussions

The robot's movement is controlled by speech commands. The robot recognizes the voice commands with mic and the internal op amp cuts off the noises and passes on the clear voice sound. The vocal stream is subsequently translated to text in real time via an internet cloud server. The hardware platform is made up of a moveable robotic arm incorporated within the robot's body. Two robotic hands make up the robotic arm. The arm is utilized to place the hands in their proper positions, and the hands are used to pick, hold and drop objects. It works similarly to human hands, with the robotic arm acting similarly to our arm and the robotic hands acting similarly to our hands. Two DC motors control the robot's body movements.

4.1 Modules used

4.1.1 Speech Recognition
The ability of a machine to listen to and recognise spoken speech is referred to as voice recognition. The uttered words can then be converted to text, a query can be made, and a response can be given using Python's speech recognition. With the help of computer programs that take in information from the microphone, process it, and convert it into a proper form, you may accomplish voice recognition in Python.

Speech recognition may appear futuristic, but it is already in use. You can shout out your query on automated phone calls, and virtual assistants like Siri and Alexa use speech recognition as well.

4.2 Process of speech recognition

Speech recognition starts by converting the sound energy into electrical signals using the microphone and we also use some noise cancellation techniques to acquire clear audio. After that, the electrical energy is transferred from analogue to digital, and then to text. It takes the audio data and breaks it down into sounds, then uses algorithms to

analyse the sounds to identify the most likely word that fits the audio. All of this is accomplished using Natural Language Processing and Neural Networks. By recognizing temporal patterns in speech, hidden Markov models can improve accuracy. The working model is shown in Fig. 11.
Fig. 11 Working Model

4.3 Procedure of Working

The working procedures of the robot are as follows:

● Build the robot's body first

● Connect the motors, chipsets, and limbs.

● Use WIFI to establish a reliable internet connection and local Network connection. Speak any of the pre-programmed commands to direct the robot's actions.

4.3.1 Voice Controls
Forward - The body moves forward.
Backward - The body moves backward.
Left - The robot moves to the left.
Right - The robot moves to the right.
Up – The robotic arm moves upward.
Down - The robotic arm glides downward.
Open - Robotic hands that are open
Close - Robotic hands are quite close together.
Bring Water - Brings a Water to you.

When a user speaks a command, the mic listens to it first, and the voice input is processed by the speech recognition module, The Google API is used to convert the speech to text format. The matching driver code of the code is executed if the text matches the commands list. When a user commands the robot to bring a given object, the object's coordinates should already be initialized, and the robot uses the GPS module interface to reach the coordinate and bring the object. The robot's arm picks the thing, and the Lidar

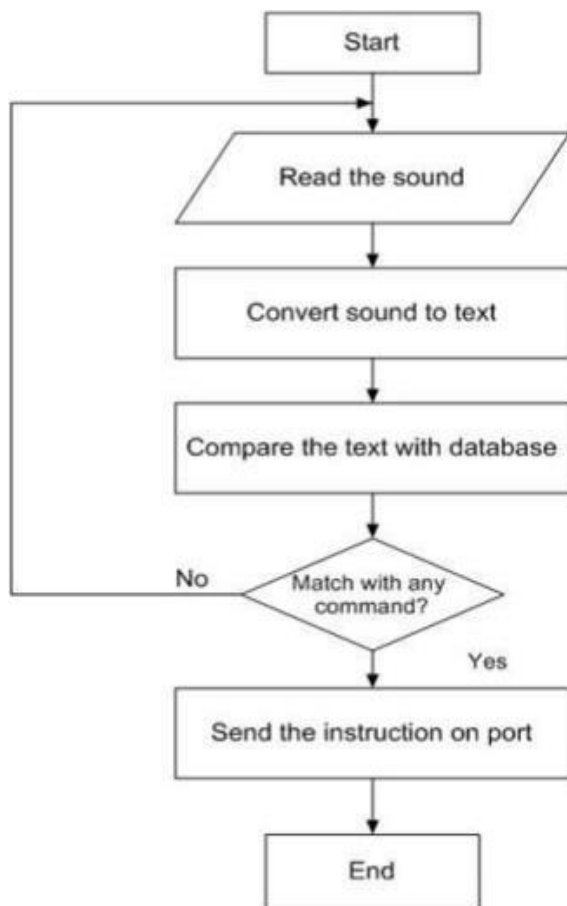
sensor is used to detect and avoid obstacles along the way. The workflow is shown in Fig. 12.


Fig. 12 Workflow

5 Conclusions

The personal assistant robot is built on a microcontroller platform and has the ability to track its present location. Improvements are also considered in terms of prospective uses in the home, hospitals that could aid the geriatric patients. Some of the areas that can be further investigated are the robot's mouth and microphone, its performance, and the effect of noise on voice to text conversion. The robot's functioning is unaffected by the speaker's accent since voice commands are handled by a cloud server that works regardless of the speaker's accent. Using renewable energy sources to power the robot would not only reduce the cost of the robot, but it would also be environmentally good. Another form of energy source is solar energy. The robotic assistant developed has a wide range of potential uses, from the chemical industry to a relaxing environment within a home wherein the elderly people can live happily and at ease.

Abstract

The number of restaurants has grown rapidly around the world, the awareness of managing it efficiently has increased. This necessity yields the idea to invent a restaurant management system (RMS). This RMS will bring several benefits such as greater management of a restaurant, reduced resources cost, raise profit, and time-saving by allowing the admin to manage the restaurant easily through the functionality provided in the system. The provided features include adding, updating, and deleting information, stock calculation and auto re-order stock items, ingredients management, and finance calculation.

Keywords: Restaurant Management System (RMS), Business Solutions, Administration System

1. Introduction

Throughout the years, businesses in various sectors had attempted to reach efficiency and gain the most profit through their efforts. Methods and strategies have been developed to overcome the problem of inefficiency. However, most of the time, the advancement of technology is the solution to those problems in activity and performance done by using the traditional system. Technology has shifted the way various task is executed and decreased the need for people that used to perform the task manually. This situation is likewise applicable to many restaurant owners who have tried to increase sales and satisfy their customers with excellent services.

A restaurant management system was developed to help owners manage personal operations such as customers, employees, ingredients, suppliers, and sales. Restaurant management system (RMS) simplifies the personnel's daily workload and fulfill various task in one integrated system using a software system and databases that keep all the operational and personnel details. RMS offers its benefits by providing functions to organize the details of employees and their payroll, keep track of ingredients based on their category, manage suppliers, keep sales history, retrieve information easily, and calculate profits [1]. Using RMS, restaurants can get the opportunity to speed up operations through the automated system, increase personnel efficiency due to decreased time required for ingredients checking and manual order taking, and lessen labor costs by lowering the number of employees needed. Thus, this project aims to develop a restaurant management system that eases daily operations, enhances performance, and solves the current inefficiency of restaurants across Malaysia. A survey will be distributed among Malaysian restaurant managers and owners to study their opinion and

Gabriela Maria Ancilla, Heshalini Rajagopal, Ismail Ahmed Al-Qasem Al-Hadi, Renuka Devi Rajagopal, Norrima Mokthar

acceptance of RMS, the current and previous implementation, and their perceived benefits of using RMS. Besides, the survey will also help to understand whether they have sufficient knowledge and resources to run and implement RMS.

2. Existing System

In the existing system, the operational and daily tasks of the staff all need to be done manually. Activities such as keeping details of the employees, suppliers, and inventories are taken by paper and pen which leads to paper wasting and overloaded document. Paper documents can easily get lost or damaged and may be hard to be found when needed. Besides, calculating and updating the ingredients stock manually can be very time-consuming and cause miscalculations. In certain circumstances, a restaurant can be running out of stock and miss the time to re-order the ingredients which can affect the restaurant's profits. Moreover, manually calculating the ingredients stock also require more manpower and increase labor cost. Hence, this proposed desktop-based restaurant management system is developed to overcome those issues that restrain restaurants to achieve efficiency. The system will combine several functional features in an integrated centralized system. The staff and supplier information as well as the detail of all ingredients will be stored inside the database which will ease information retrieval whenever needed. The stock of ingredients will be automatically ordered from the assigned supplier to avoid situations when the restaurant is running out of stock. In addition, the finance calculation of the restaurant will also be performed inside the RMS which involves calculating the employees' payroll, daily sales, overall expenses, and profit. Eventually, the proposed system aims to replace all the tasks that are regularly done manually with an automated system that can accelerate and ease the restaurant's daily operation and administration by executing several processes in one system. Table 1 shows the comparison between the existing and proposed system.

3. Prior Work

Various projects and studies related to restaurant management systems have been conducted, aiming to improve efficiency, customer satisfaction, and overall performance. Rainer Alt (2021) emphasizes the importance of supply chain management in restaurants to handle raw materials efficiently and maintain smooth operations [2]. Srikar Macha (2022) develops a web application using modern technologies like MVC and bootstrap to optimize restaurant management [3]. W. B. A. C. Piyatissa (2020) presents an online system for orders and reservations, offering convenience for customers and enhancing customer relationship management [4].

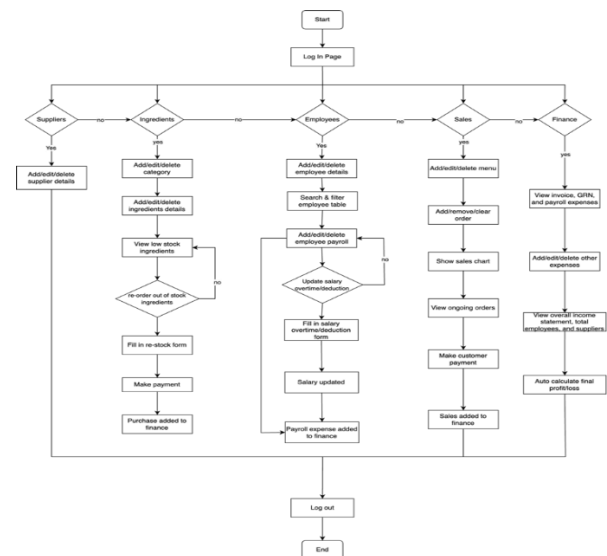
Emel Memis Kocaman (2021) highlights the widespread adoption of RMS in restaurants, positively impacting their operations and service standards, although it comes with significant technical costs [5]. Prudveer Karne (2022) introduces a web-based application to facilitate better communication between customers and staff, improving order management and overall efficiency [6]. Ivan Wanyama (2019) implements a web-based restaurant management system to enhance data organization and decision-making [7].

These projects and studies collectively contribute to the advancement of restaurant management systems, enabling better resource management, improved customer service, and enhanced overall performance in the foodservice industry. As technology continues to play a prominent role in daily life, the ongoing development of innovative restaurant management systems promises to revolutionize the way restaurants operate, making them more efficient, customer-oriented, and adaptable to changing market demands.

Fig. 1. Restaurant Management System Flowchart

4. Method

The methodology selected to develop this project is the Software Development Life Cycle (SDLC) which is a method used to develop software by going through several phases. The five phases of SDLC include planning, requirement of analysis, design, implementation, and testing.

The system consists of 5 tabs which are the employees, ingredients, suppliers, sales, and finance tabs that will be fully controlled by admin. First, in the employees tab admin can add/edit/delete employee details that consist of their personal information such as name, age, gender, etc. Admin can filter and search the employee's table by ID, name, and role. Then, the admin can manage the employee payroll as well as do adjustments for salary deductions and overtime. In the ingredients tab, the admin can add/edit/delete the details of each ingredient such as its name, price, quantity, etc. The ingredients will be grouped based on their category thus admin also can add/edit/delete the ingredients category. There is an ingredients table that the admin can search and filter based on its barcode, name, and supplier name. There will be a low-stock item button provided for the admin to check the low-stock ingredients for them to re-order and purchase the ingredient by filling in the re-stock form. Thirdly, the admin can add/edit/delete supplier details in the suppliers tab which details then will be used to identify which ingredients were produced by which supplier for re-stock purposes. In the sales tab, the admin can add/remove/clear the food item from the order table before adding it to the ongoing orders table. There is a show chart button provided for the admin to view the bar chart of the overall monthly sales of the restaurant. Then, the admin can view the list of ongoing orders, do customer purchases, and add/edit/delete the food menu within this sales tab. Lastly, on the finance tab, the admin can view the list of overall invoices, GRN, and employees' payroll expenses. Admin can likewise add/edit/delete other expenses such as electricity, water, internet, etc. In the income statement tab, all the total income, expenses, and final profit/loss as well as the total number of employees and suppliers can be viewed. Eventually, the admin can log out from the system by clicking on the logout button provided. The flowchart of the proposed system is shown in Fig. 1.


5. Result and discussion

The restaurant management system is implemented using Java with Java Swing library inside Netbeans IDE and MySQL for the database. The system consists of 5 main tabs which are the employees, suppliers, ingredients, sales, and finance tabs. Fig. 2 shows the add employee subtab allows the admin to save, update, and delete employee personal information from database. The admin must fill in all the text field there which includes name, age, phone number, email, and address as well as choose the radio button for gender. Fig. 3 is the Search employee subtab allows admin to view the table of information list of all the registered employees. Admin can search and filter the employee's information based on the employee ID, name, role, or all.

Fig. 2. Add Employee Subtab

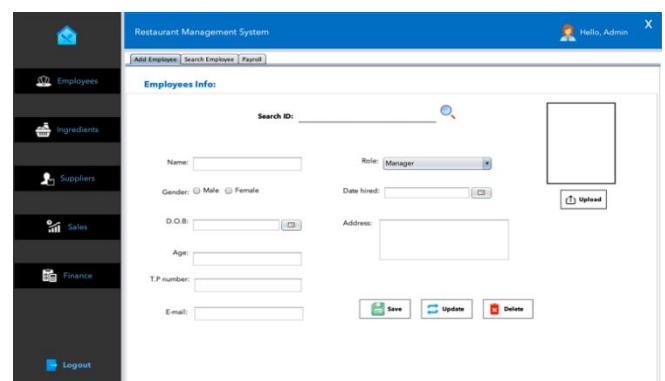
Gabriela Maria Ancilla, Heshalini Rajagopal, Ismail Ahmed Al-Qasem Al-Hadi, Renuka Devi Rajagopal, Norrima Mokthar


Fig. 3. Search Employee Subtab

Fig. 4 indicates the employee's payroll subtab where the admin can save, update, and delete the employee payroll by searching on the employee ID and clicking on the buttons provided. Besides, admin can alter the employees' payroll by clicking on the deduction or overtime button depends on the employee number of days absence or total overtime work hours.
Fig. 4. Payroll Subtab

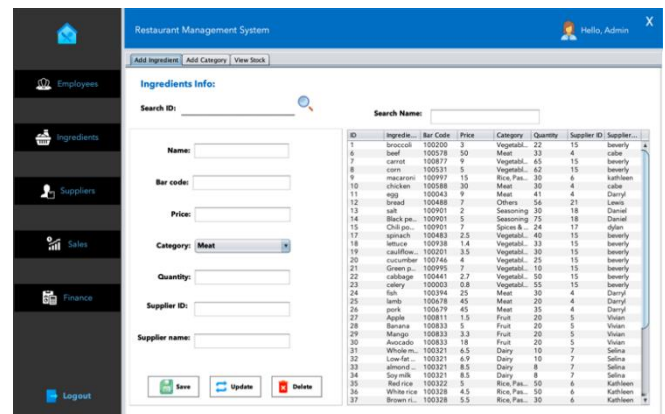
The add ingredient subtab in Fig. 5 allows the admin to save, update, and delete the ingredients detail from database. The admin must fill in all the text field which includes name, bar code, price, and quantity. The supplier ID and name will automatically appear after the admin select the ingredient's category to show where the supplier of the ingredient.


Fig. 5. Add Ingredient Subtab

The add category subtab indicated in Fig. 6 is provided for admin to save, update, and delete the ingredients category. Admin can do that by simply fill in the category name and the supplier ID will be automatically appear when admin select the supplier's name provided in the drop-down menu. Admin can likewise search and filter the category table based on the category name. The low stock item window in Fig. 7 is for admin to check the low stock item and re-order the stock by clicking on the re-order stock button. Fig. 8 shows the re-order stock form that will appear when admin click on the re-order stock button. Admin can simply key in the ingredient ID on the search field. Then, the admin can key in the desired re-stock quantity and the total price will appear.

Fig.6. Add Category Subtab

Fig. 7. Low Stock Ingredients Window

Fig. 8. Re-stock Ingredient Form

Fig. 9 shows the supplier tab which is generally used to manage the supplier's data such as their personal information. Admin can save, update, and delete supplier's personal information from database. The admin must fill in all the text field provided which includes name, phone number, email, and address.

Fig.9.Suppliers Tab

The add order subtab in Fig. 10 is primarily used to add the customer order. When admin key in the menu ID, the

food name and its unit price will appear. The total price will be calculated once the admin key in the quantity of the food. The add, remove, and clear button provided there is used to manage the table order. After adding the order, the total amount and quantity of the orders will be calculated and shown under the order table there. The show chart button in Fig. 11 will show the graph of the weekly sales of the restaurant.

Fig. 10. Add Order Subtab

Fig. 11. Monthly Sales Chart

Fig. 12 exhibits the ongoing orders tab is used to view the ongoing orders and its details. The table number will be used to identify which orders belong to which customer. When the customer wants to pay the bill, admin can click on the pay bill button. The pop-up window as exhibited in Fig. 13 shows the example when admin want to complete the order of customer from table number 3. Admin just need to key in the table number in the search field and the food items from that table will be listed out. Then, the total item and amount of the order will be calculated. After customer finish paying the bill,

admin can click on the add sales button to add the sales data to database.
Fig. 12. Ongoing Orders Subtab
Fig.13.Re-stock Ingredient Form

Fig. 14 shows the menu list sub tab where admin can save, update, and delete the restaurant menu item. Admin can just simply type the food name and its price in the text field provided.
Fig.14. Menu List Subtab

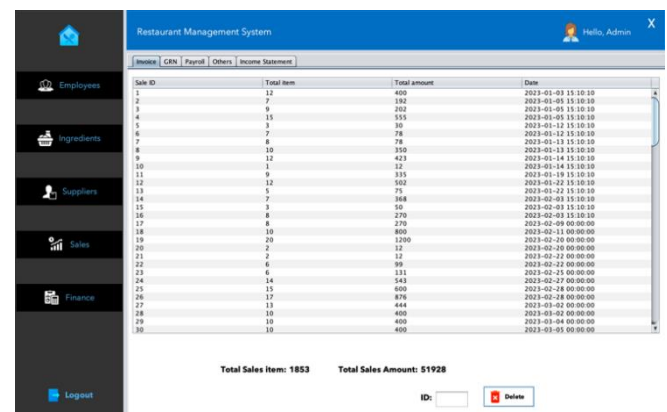
The invoice subtab in Fig. 15 is used to list out all the sales of the restaurant. It includes the sale ID, total item, total amount, and date. Admin can delete the sales when there is a mistake by key in the sale ID or clicking on the list and press on the delete button. The total of sales item and amount will be automatically calculated. The income statement subtab in Fig. 16 is where admin can see the total income, expenses, employees, and suppliers of the restaurant. The profit or loss will be automatically calculated based on the sales and purchase of the restaurant. Lastly, admin can logout from the system by clicking on the logout button provided at the bottom left of the system.


Fig. 15. Invoice Subtab

Fig.16.Income Statement Subtab

Based on the survey taken from 30 respondents of restaurant managers or owners, RMS has received positive feedback where all of them agree with the efficiency of using RMS and would like to use the system for their restaurant. Thus, this project can bring the solution to restaurant owners who wants to take the benefits of using RMS. Fig. 17 shows the positive feedback from users.
Fig. 17. User Acceptance Test Question on Willingness to Use the RMS

6. Conclusion

The proposed restaurant management system is developed to address the current issues in the existing system and reduce the manual process for restaurant daily operations. The traditional system that nowadays is still implemented in many restaurants is time-wasting, demands a high cost, and often cause human error which as a result cannot promote restaurant to perform in the best efficient way. Thus, the proposed restaurant management system is time-saving and error-free compared to the manual system. It aims to fulfill all the needs of the restaurant owners by developing a desktop application restaurant management system which able to ease the operational management of a restaurant,

increase management efficiency, minimize labor and resource costs, and enhance the performance of restaurant management. The system development is based on the SDLC methodology in a determined time and scope. User acceptance test is performed and has received positive feedback from users. Overall, the system is targeted to bring benefits to most restaurants and create efficiency by developing an integrated system that includes several functional features. This system can be enhanced and improved for future development by adding more functional features.

Abstract

The use of face recognition technology for attendance tracking has grown popular in recent years. Hence, the main goal of this project is to produce an accurate, fast, and robust face recognition based on an attendance system. The system detects the user's unique features, understand the identity of the user through face recognition technology, and thus records the attendance from the face recognition dataset to the user that matches the user, in an attempt to help the user automatically check in with real-time attendance date. The system includes features such as face detection, face recognition, distance estimation, and attendance recording.

Keywords: Face Recognition, Attendance, Convolutional Neural Network

1. Introduction

A face recognition based on attendance system uses machine learning techniques to identify individuals and track their attendance automatically [1]. It captures an image of the person's face, processes it to extract unique features, and compares it with the face recognition datasets to determine the known faces [2]. If the known face is detected, the system updates his or her attendance record. This technology is commonly used in workplace environments, educational institutions, and other organizations to streamline the attendance-taking process and reduce manual errors [3].

In the 1980s and 1990s, researchers started to use linear algebra for face recognition. This approach was based on the idea that faces could be represented as mathematical objects and compared using linear algebraic operations. The first linear algebra-based face recognition algorithm was introduced by Turk and Pentland in 1991 [4]. They proposed a method called "Eigenface" which used eigenvectors and eigenvalues to represent the face space. This method involved transforming the images into a lower-dimensional space where faces could be represented as points in space. This approach was later improved upon with the introduction of "Fisherface" in 1997 by Belhumeur, Hespanha, and Kriegman [5]. This method used linear discriminant analysis to transform the face space into a space where faces could be separated more easily. This made it possible to use face recognition in a variety of applications, including security and surveillance, border control, and airport security [5].

In the 2000s and 2010s, the development of mobile devices and the widespread availability of the internet paved the way for cloud-based face recognition systems, which allowed for easy access and use from anywhere in the world. This also paved the way for the development of mobile face recognition applications, which could be used on smartphones and other mobile devices. In education, face recognition systems were used for attendance tracking and to enhance student safety [4], [6].

However, many conditions can affect the face recognition attendance system, such as the camera angles, the lighting conditions of the environment, the quality of the image, and various other factors. In addition, the images will get low contrast and low brightness if they are captured under low light conditions [1]. There are several algorithms used by experts to improve face recognition attendance systems, such as the Eigenface algorithm, Principle Component Analysis (PCA), Fisherface algorithm, and Convolutional Neural Networks (CNNs) [5], [7], [8]. The choice of algorithm will depend on the specific requirements of the application. However, CNN is widely used in face recognition attendance systems due to their high accuracy and ability to learn complex features from large amounts of data.

Therefore, this project uses a built-in camera to capture video from the camera, presents automatic attendance tracking, develops a Graphical User Interface(GUI), prevents system warnings and wrong execution from unknown faces, and recognizes faces with high accuracy and fast speed. The expected outcomes aim to ensure that the system can recognize faces under the camera angles, the lighting conditions of the environment, and the quality of the image.

2. Prior Work

This section reviews the methods which were used in those studies to implement face recognition technology and the corresponding to their results.

Shuhui and Xiaochen (2022) compared different SOTA deep face recognition models to extract features from a face image even in the presence of masks. By using data augmentation, the masked face recognition system became more robust to variations in the face images. The result proved that an appropriate margin aided the model's establishment of flexible embedding [9].

Winarno et. al (2019) proposed a combination of CNNs and PCA to identify and verify the attendance of individuals. CNN was used to extract features from a face image while PCA was used to reduce the dimensionality of the data and reduce computational costs. The result showed that the combination of CNNs and PCA can lead to improved performance in face recognition compared to using PCA alone [10].

Cahyono et. al (2020) designed a face recognition system for automating the process of tracking employee attendance. The linear SVM was used to classify the faces of employees in real-time as they entered or left the workplace. K-fold cross-validation was used to evaluate the performance and accuracy of a model. As a result, the combination of FaceNet and SVM achieved 100% accuracy [2].

Qu et. al (2018) compared algorithms, such as PCA, LBP, and CNN algorithms, for handling recognition speed and accuracy. PCA was suitable for fast recognition but with reduced accuracy, while CNN was suitable for high-accuracy recognition but at the cost of computational resources. LBP was a good compromise between the two, offering a balance between recognition speed and accuracy. It was possible to implement a CNN on FPGA due to its high performance and low power consumption [7].

Early work by Ilyas et. al (2019) was concerned with the use of the Viola-Jones algorithm to detect faces in images. Histogram Equalization was used in image processing to enhance the contrast of an image. The result showed that the recognition method using the CMU PIE face database has a higher recognition rate than the Extended Yale B face database [11].

KB and J (2020) designed a real-time face recognition system using CNNs. Viola-Jones algorithm was used to capture real-time input images from a camera. Then, the AT&T database was used to detect faces in each image and crop the image to include only the face. It was possible to simplify the feature extraction process by having all images of equal size [12].

Rahouma and Mahfouz (2021) implemented a face recognition system that leveraged the capabilities of the API mobile vision for face detection. API Google's mobile vision was used to detect faces in the pre-processed images while Pearson correlation was used to compare two face representations and determine their similarity. As a result, the Pearson correlation spent less time but also produced a higher recognition rate than other recognition methods [13].

Sarwar et. al (2021) developed an LBPH-based face recognition system for visually impaired people. Haar Cascade Classifier worked as a pre-processing step to detect faces in an image or video frame. The use of the Euclidean distance helped to determine the similarity between two faces and decide whether they belong to the same person or not. The result showed that LBPH gained higher average accuracy than the Fisherface algorithm [14].

Wang et. al (2020) compared algorithms, such as SGD, RMSprop, and Adam for evaluating the accuracy of the face recognition system. ReLU allowed the network to

model complex features in the input images, such as the shapes of eyes, noses, and mouths. The result proved that CNNs have significant practical application potential when used for face recognition [15].

Early work by Wandzik et. al (2018) was concerned with the use of an SVM classifier to distinguish between real faces and morphed faces. SVMs were able to handle high-dimensional data and can work well with noisy data. The Euclidean distance was used to compare the features of two faces and determined if they were significantly different. The result showed that the performance of CNN-based approaches dramatically increased [16].

3. Method

The face recognition based on attendance system goes through five stages:

(1) Set up the hardware: This involves installing the cameras and other necessary hardware components to capture the images and process them in real-time.

(2) Collect and prepare the training data: A large dataset of face images is collected and processed to extract the features needed for training the face recognition model.

(3) Train the face recognition model: The extracted features are used to train a deep Convolutional Neural Network (CNN) or other machine learning model to recognize faces.

(4) Integrate face recognition system with attendance system: The face recognition model is integrated with the attendance system so that the attendance of individuals can be recorded and tracked in real-time.

(5) Test and evaluate the system: The system is tested on a variety of real-world data to evaluate its accuracy and performance. Any essential modifications are performed to raise the system's efficiency.

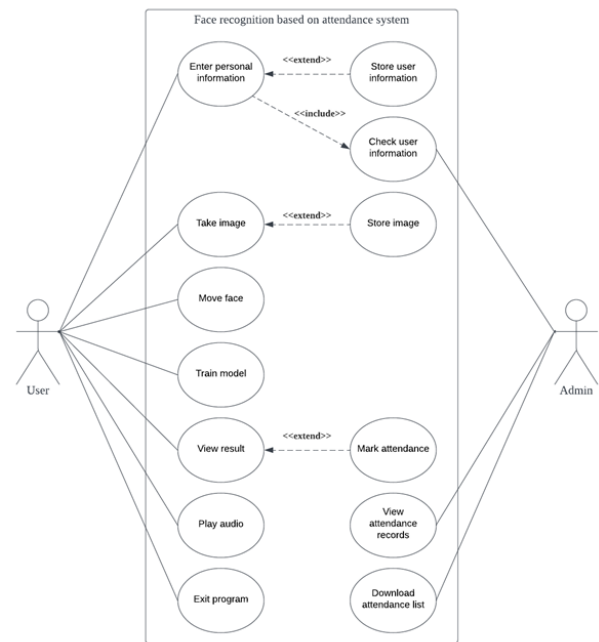
Fig. 1 represents two actors: the user and the admin. A user can enter his or her personal information, such as name, id, and course code. This information will be stored in the system. Besides that, users can take face images, train a model, view the result, or play an audio file. If the username matches the result, the system marks user attendance automatically. Users can exit from the program after using the system. On the other hand, an admin can check user information, view the attendance records, and download an attendance list.


Fig. 1. Use Case Diagram

4. Result and discussion

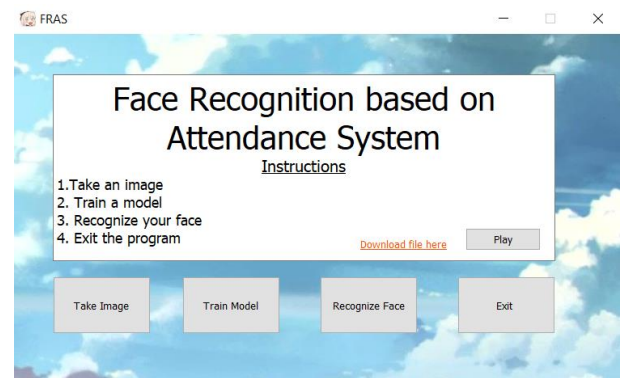
There is an interface design of face recognition based on attendance system, as shown in Fig. 2. It is designed to be simple to use and user-friendly for end users of all ranges.


Fig. 2. Graphical User Interface (GUI) using QT Designer

The system includes six main functions, such as:

1. Play button: The user can click the play button to play an audio file. This audio file introduces the instructions should follow to complete all the processes.

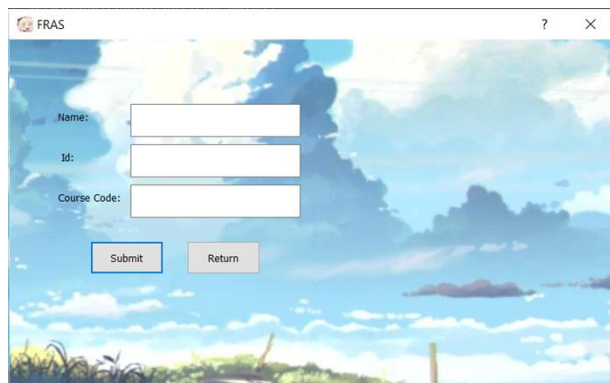
2. Take image button: The user can click the take image button to register their faces. This button will bring the user to another window, as shown in Fig.3.


Fig. 3: Take image window

3. Train model button: The user can click the train model button to train a CNN model. The training process runs on the back-end interpreter. Please give a few moments of patience until the window pops up a success message.

4. Recognize face button: The user can click the recognize face button to recognize his or her face. The result shows the name, id, and the distance between an individual and the built-in camera. The system will automatically record the name, attendance date, and time.

5. Download link: The user can click the download file here to select the file to download and select the destination folder to store the file. The system will automatically download files in the destination folder.

6. The user can click the exit button to exit from the program immediately.

The system converts the images to grayscale, equalizes the histogram, and normalizes pixel values between 0 and 1., as shown in Fig. 4.

Fig. 4. Preprocessing images

Next, the system preprocesses the data, creates the model, applies image augmentation, and starts the training loop, as shown in Fig. 5.

Fig. 5. Train CNN model

After the CNN model is trained, the model is evaluated on the test set to find the test score and test accuracy, as shown in Fig. 6.
Fig. 6. Test Score(Loss) and Test Accuracy

Then, the system uses focal length calculation to estimate the distance of the recognized face from the camera, as shown in Fig.7.

Fig. 7. Focal Length Calculation

After that, the system predicts images from each detected face in the frame, as shown in Fig. 8.

Fig. 8. Predict Image

Lastly, the system updates the CSV file every time a face is recognized, as shown in Fig. 9.

Fig. 9. Attendance records

The testing and evaluation phases are crucial for the developed system. The system is tested on a variety of real-world data to evaluate its accuracy and performance. Any essential modifications are performed to raise the system's efficiency. This project covers unit testing, functional testing, and user acceptance testing.

Unit testing involves testing individual components of the system to ensure they function correctly. In this project, the unit testing helps to check the images are captured successfully, as shown in Fig. 10. Besides that, this testing helps to check the model has been trained successfully, as shown in Fig. 11. Moreover, it helps to check the face recognition done successfully, as shown in Fig. 12.
Fig. 10. Capture Image Completed
Fig. 11. Training Completed
Fig.12. Testing Completed

Functional testing involves testing the system as a whole to ensure that it meets the specified functional requirements and performs correctly. In this project, the system recognizes known faces and unknown faces, as shown in Fig. 13. Moreover, the system downloads an attendance file in the destination folder.
Fig. 13: Known face and Unknown face

5. Conclusion

In conclusion, face recognition based on attendance system provides a functional solution for tracking attendance automatically. The system includes features such as face detection, face recognition, distance estimation, and attendance recording. It exploits a pre-trained Convolutional Neural Network (CNN) model for face recognition. Moreover, the system can recognize faces with high accuracy and fast speed. Furthermore, the system can accurately recognize known faces and unknown faces. In addition, the system stores attendance records in a CSV file, making it easy to manage and track their attendance. Besides that, the system works on a graphical user interface to interact with end users easily.

Abstract

In today's technology-driven era, there is an increasing emphasis on efficient and user-friendly methods to elevate user satisfaction. UCSI University, Kuala Lumpur, currently relies on a manual facility reservation process, necessitating either in-person or email submissions. This outdated approach frequently leads to double bookings and underutilization of resources. Thus, this project endeavours to create a web-based facility reservation system called U-Reserve, employing the prototype methodology. U-Reserve was crafted using HTML, CSS, JavaScript, and core Java (JSP and Servlet), while its database is administered through phpMyAdmin. Additionally, U-Reserve places emphasis on incorporating preferred colour tones and font types of the target users, aiming to enhance user experience and satisfaction. Through U-Reserve, the reservation request and cancellation processes are streamlined, and a data-driven dashboard facilitates informed decision-making regarding facility management.

Keywords: facility reservation system, web-based system, colour tone, design principle, data-driven decision-making, user permission management

1. Introduction

UCSI University's ongoing expansion has posed challenges in keeping facilities' information up-to-date, leading to students and staff being unaware of available resources. The Group Logistics Management Office (GLMO) depends on a manual reservation process, requiring students to email GLMO admin for facility availability confirmation, leading to a three-day response time. Subsequent booking procedures exacerbate inefficiencies, risking overlapping reservations and increasing the administrative workload.

Additionally, the manual confirmation process for Block B's discussion rooms at the library counter exacerbates these challenges, leading to time wastage and increased workload for library admins. This inefficiency significantly impacts the overall experience and satisfaction of students, staff, and lecturers at UCSI University, potentially impeding academic performance and participation in extracurricular activities [1], [2].

Therefore, this project introduces U-Reserve, a web-based facility reservation system aiming to address the issues associated with the current reservation process at UCSI University. The system has been developed using HTML, CSS, JavaScript, and core Java (JSP and Servlet) to establish its functionality. For database management, phpMyAdmin is used alongside the MySQL database management system. The primary objectives include streamlining the reservation process, enhancing security measures, and enabling data-driven resource optimization, which will benefit students, staff, lecturers, and administrators at UCSI University.

The remainder of this paper includes sections on system comparison, literature review, development methodology, conclusion, and future work, offering a comprehensive overview of the development process, system features, and potential areas for further improvement.

2. System Comparison

Comparison among four (4) existing facility reservation systems—Bookeo [3], MRBS [4], Reservator [5], and RoomBooker [6] highlights commonalities and distinctive features, detailed in Table 1. These systems share fundamental functionalities, enabling users to make reservations, check reservation history, and granting administrators slot management capabilities. These essential features eliminate manual processes, prevent double bookings, and ensure efficient slot control, forming the foundation for U-Reserve. Table 1 illustrates that Bookeo, MRBS, and Reservator offer reporting tools for analyzing reservation trends. U-Reserve utilizes graphs for visualizing data, aiding in decision-making. Bookeo, MRBS, and RoomBooker send email notifications to requesters—an absent feature in Reservator. U-Reserve ensures prompt updates for users upon request approval or rejection. Furthermore, MRBS and Reservator display booked slots, whereas Bookeo and RoomBooker exhibit available slots only. U-Reserve

Esther Chong Jun Lynn, Neesha Jothi, Ismail Ahmed Al-Qasem Al-Hadi

combines both, providing a comprehensive Home Page table for clearer planning. Additionally, RoomBooker features admin reservation management and user-friendly slot searches—attributes adopted by U-Reserve for enhanced control and convenience.

Table 1. Features Comparison Between Different Facility Reservation Systems and The Proposed System.

Features	Bookeo	MRBS	Reservator	RoomBooker	U-Reserve
Make reservation.	√	√	√	√	√
Reservation history checking.	√	√	√	√	√
Slot management.	√	√	√	√	√
Report and analytics.	√	√	√	×	√
Email notifications.	√	√	×	√	√
Table showing booked slot.	×	√	√	×	√
Reservation management.	×	×	×	√	√
Search for available facilities or slots.	×	×	×	√	√
Batch reservation.	×	√	×	×	√
Track reservation details.	×	×	×	×	√
View announcements and contact information.	×	×	×	×	√

Moreover, MRBS introduces batch reservation options for weekly, monthly, and yearly bookings. U-Reserve customizes this feature for weekly reservations, offering users flexible date selection to minimize unnecessary bookings. Furthermore, U-Reserve empowers administrators to track reservation details, ensuring seamless user contact. Users can also access department announcements and contact information, streamlining communication.

In summary, U-Reserve integrates functionalities from Bookeo, MRBS, Reservator, and RoomBooker, while incorporating unique elements to provide a comprehensive solution.

3. Literature Review

3.1. *Security*

User Permissions: Managing user permissions is a critical and multifaceted aspect within web-based systems, serving as the cornerstone for security, privacy protection, web personalization, and access control. As emphasized in the referenced scholarly works, adopting Role-Based Access Control (RBAC) models and permission-based mechanisms equips web-based systems with essential tools for handling user permissions. The benefits are extensive, encompassing the mitigation of security risks, safeguarding user privacy, tailoring user experiences, and facilitating secure, controlled resource access. In the evolving landscape of web-based systems' influence on our digital lives, effective user permission management remains a pivotal component. It ensures system integrity, operational efficacy, and fosters trust among both users and administrators [7], [8], [9], [10].

3.1.1 Data-Driven Resource Optimization

Resource Management: Web-based systems have revolutionized resource management, particularly in domains like facility management. These systems provide a comprehensive platform for data analysis, decision support, accessibility, and collaboration. In the context of facility management, they enable quantitative and conceptual analysis, data sharing, remote accessibility, and secure data management. Ultimately, adopting web-based systems for resource management empowers businesses to optimize their operations, reduce costs, enhance safety, and improve overall efficiency. By leveraging the capabilities of these systems, organizations can ensure that their resource management processes are both effective and efficient, ultimately contributing to their success and competitiveness [11], [12].

Decision Making: Web-based systems have revolutionized the decision-making landscape for businesses by offering tools and frameworks that empower organizations to make informed, data-driven decisions. Decision support systems, business intelligence, analytics, interactive decision aids, and provenance-based strategies all contribute to more effective and efficient decision-making processes. In the era of big data and data science, web-based systems are essential for organizations aiming to stay competitive and improve business performance. The effective harnessing of data is a key driver of success, with web-based systems playing a pivotal role in achieving this goal [13], [14], [15].

3.1.2 Design Principle

System Design: It's the core foundation for web-based systems, addressing resource allocation, reliability, security, usability, and learning system design. Its critical role ensures reliable performance, secures sensitive data, enhances usability, and promotes effective web-based learning. Good system design is essential for seamless operation and user satisfaction in digital environments, be it large-scale enterprises or local host websites [16], [17].

Colour Theory: Color tone is a potent tool in web design, influencing users' perceptions, emotions, and behaviours when used intentionally. With a well-matched colour scheme that complements content, designers craft visually appealing designs and guide users effectively. This approach fosters trust, improves user experience,

and drives engagement and satisfaction in web-based systems [18], [19], [20].

Visual Appeal: Crucial in web system design, the layout establishes flow and hierarchy, guiding users effectively. Applying visual principles and aesthetics, designers craft engaging, user-friendly systems, contributing to satisfaction and success [21], [22].

3.2 Applications of Security, Data-Driven Resource Optimization, and Design Principle on U-Reserve

Table 2. Applications of Security, Data-Driven Resource Optimization, and Design Principle on U-Reserve.

Area	Applications
Security.	● A role-based security system prevents errors and safeguards system integrity.
Data-Driven Resource Optimization.	● Decision support design for administrators: comparing requests and enhancing efficiency. ● Dashboard presenting visualised data for data-driven facility management. ● Downloadable Excel report providing valuable insights into facility utilisation.
Design Principle.	● User preferences on colour tones and font types are gathered for UI design. ● Logical page structure, consistent navigation bar, and organised content ensure coherence. ● Font size variations create a clear visual hierarchy on pages.

4. Development Methodology

The project was completed using the prototype methodology, as illustrated in Fig. 1. This approach was selected due to its capacity to involve users in identifying missing functionalities at an early stage [23].
Fig. 1 Prototype Methodology [24]

4.3 Planning

Location of Study: All research activities were conducted at UCSI University, Kuala Lumpur, Malaysia, and remotely via Microsoft Teams using an Internet connection.

Target Population: Students, lecturers, staff, and admins of UCSI University, Kuala Lumpur.

Sampling Methods: Purposeful sampling entails preselecting participants based on specific criteria to ensure diverse insights into various system aspects. Snowball sampling recruits additional participants meeting specific criteria, allowing respondents to refer others.

Data Collection: Primary data collection involves identifying functional and non-functional requirements, as well as preferences for colour tone and font type for U-Reserve. Secondary data from sources such as journals guides the acquisition of user requirements, supporting project insights and results.

4.4 Analysis

Functional and Non-functional Requirements Analysis: A total of seventy-five (75) users actively participated in this survey via Google Forms, providing valuable insights and feedback.

Functional requirements include checking availability, making reservation requests, checking request status, request history, and tracking reservation details. All highlighted functional requirements identified by respondents are integrated to enhance user satisfaction. Priority will be given to enabling users to check availability, make reservation requests, and check request status, as these received the highest percentages: 93.33%, 86.67%, and 74.67%, respectively.

Moving to non-functional requirements, feedback on the ease of use of a facility reservation system shows that 73.33% prefer high user-friendliness. U-Reserve prioritizes easy navigation and efficient user interactions in line with this preference. The next query assesses reliability and security, with 53.33% rating them as very important, guiding U-Reserve's robust security design. The importance of 24/7 availability is evident, with 65.33% considering it crucial for user convenience and efficiency. Lastly, 70.67% emphasize scalability's importance for a reservation system's effectiveness. Despite its local host development, U-Reserve needs to meet availability and scalability as vital non-functional requirements when adopted by UCSI University.

User Interface (UI) Preferences Analysis: The feedback received from these one hundred (100) users via Google Forms provided insights on their preferred colour tones and font types for U-Reserve.

Four (4) commonly used colour tones - blue, red-violet, green, and red - were selected for the user interface (UI) of U-Reserve. Respondents could choose their preferred colour tone for each questionnaire question. Blue, linked to familiarity and professionalism, emerges as the top choice across multiple criteria: visual appeal (32%), suitability (39%), calming effect (42%), professionalism (34%), modernity (30%), and accessibility (47%). This preference for blue aligns with research highlighting its universal appeal, trustworthiness, and readability in digital environments. Notably, cool colours like blue and green consistently dominate preferences (60.83%), reflecting users' preference for calming and trustworthy associations. Emphasizing the importance of contrast in U-Reserve's UI, achieved through thoughtful design considerations, is crucial for readability and enhancing the overall user experience [25].

Additionally, respondents were asked to select a font type—Josefin Sans + Dosis, Sans-Serif, Verdana, Arial, or Georgia—based on suitability, readability, and aesthetic appeal for the UI design. Verdana emerges as the top choice, favoured by 38% for suitability, 48% for readability, and 49% for aesthetic appeal. Sans-Serif and the combination of Josefin Sans + Dosis also receive varied support. The consistent preference for Verdana aligns with research emphasizing its screen-centric design, readability advantages, and aesthetic appeal, making it the optimal font type for a user-friendly experience in a facility reservation system [26].

4.5 Design

System Design:

The following figures show the main pages of U-Reserve.

Fig. 2 displays a login page with ID number and password fields. Regardless of their role, users must provide the correct ID number and password for authentication.

Fig. 2 Login Page of U-Reserve

After a successful login, the home page, as depicted in Fig. 3, is displayed, showcasing a navigation bar, announcement slides, contact information, and an availability table for facility reservations.

Fig. 3 Home Page of U-Reserve

Fig. 4 Block B Facility Checking and Reservation Page of U-Reserve

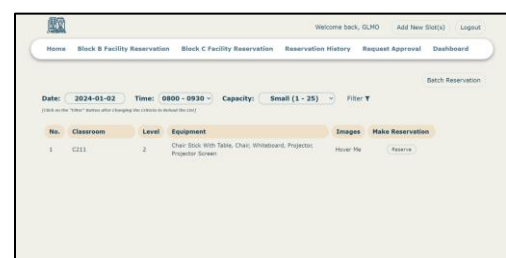
Users can check availability by viewing the cell's colour and make reservations by clicking on the cells. Additionally, users can navigate to specific facility reservation pages for Block B, as illustrated in Fig. 4, or Block C, as illustrated in Fig. 5.


Fig. 5 Block C Facility Checking and Reservation Page of U-Reserve

After selecting a facility, users are redirected to the reservation page, as depicted in Fig. 6 which is used to fill in the details. Additionally, users can review their reservation request list and check the status from the reservation history page, as shown in Fig. 7. Finally,

admins can approve or reject reservation requests on the reservation approval and checking page, as illustrated in Fig. 8.

Fig. 6 Reservation Page of U-Reserve

Fig. 7 Reservation History Page of U-Reserve

Fig. 8 Reservation Approval and Checking Page of U-Reserve

Use Case Diagram:

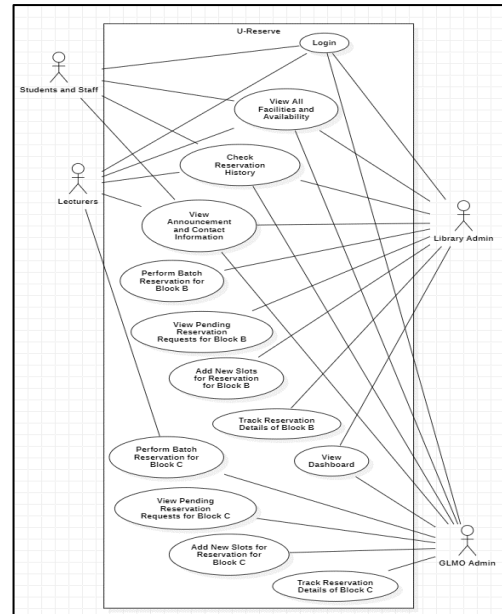
The U-Reserve use case diagram delineates three user roles: students and staff, lecturers, and administrators (Group Logistics Management Office (GLMO) and library admin), illustrated in Fig. 9.


Fig. 9 Use Case Diagram for U-Reserve

Students and staff possess various capabilities, including logging in, password management, accessing announcements and contact details, checking facility availability, making reservations, reviewing reservation history, and canceling reservations. Additionally, lecturers enjoy extended privileges, allowing batch reservations specifically for Block C classrooms. GLMO and library admins have the highest permissions, sharing fundamental functionalities with students and staff while also conducting batch reservations, adding new slots, and overseeing reservation requests. GLMO admins can access a dashboard and download usage reports for Block C classrooms, whereas library admins focus on managing discussion rooms in Block B, significantly contributing to efficient oversight and management.

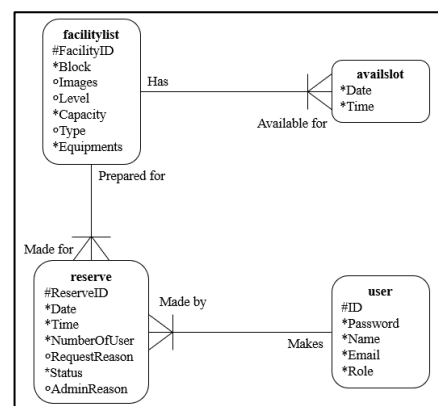
Entity Relationship (ER) Diagram:


Fig. 10 ER Diagram for U-Reserve

In the ER Diagram displayed in Fig. 10, four entities are represented: "facilitylist", "availslot", "reserve", and "user". The "facilitylist" entity stores data about all facilities, utilizing "FacilityID" as its unique identifier, and includes mandatory attributes like "Block", "Capacity", "Equipments," as well as optional attributes such as "Images", "Level", and "Type". The "availslot" entity comprises mandatory attributes "Date" and "Time." Identified by "ReserveID," the "reserve" entity contains mandatory attributes like "Date," "Time," "NumberOfUser," and "status," along with optional attributes like "RequestReason" and "AdminReason". The "user" entity, marked by "ID," encompasses mandatory attributes like "Password", "Name", "Email", and "Role". Relationships are established using UID bars: a facility can have multiple available slots, each uniquely linked to a facility through the "FacilityID" attribute. Similarly, a facility can be prepared for multiple reservations, each associated with a facility through the same "FacilityID". Finally, a user can make multiple reservations, with each reservation linked to a user through the "ReserveID" attribute.

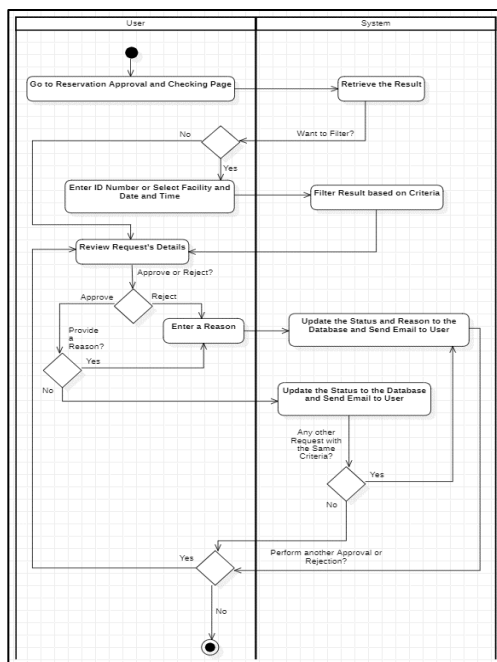
Activity Diagram:


Fig. 11 Activity Diagram for U-Reserve – Approve or Reject Reservation Requests

In Fig. 11, users handle reservation requests by accessing the reservation approval and checking page through the "Request Approval" link. Here, they can browse and filter pending reservation requests by ID number, facility, date, and time. Users review request details and decide to approve or reject. Giving a reason for rejection is necessary. The system updates the status and notifies requesters via email. Approved requests prompt the system to check for similar ones,

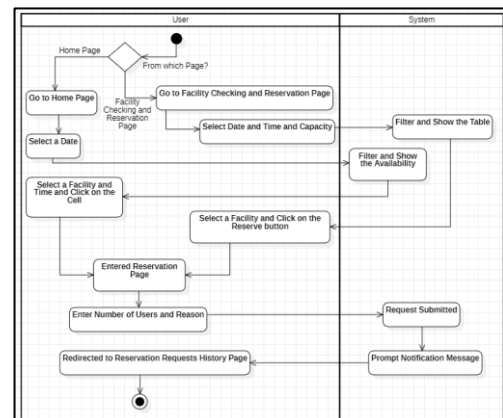
automatically rejecting them, updating the status, and sending notifications.


Fig. 12 Activity Diagram for U-Reserve – Make Reservation

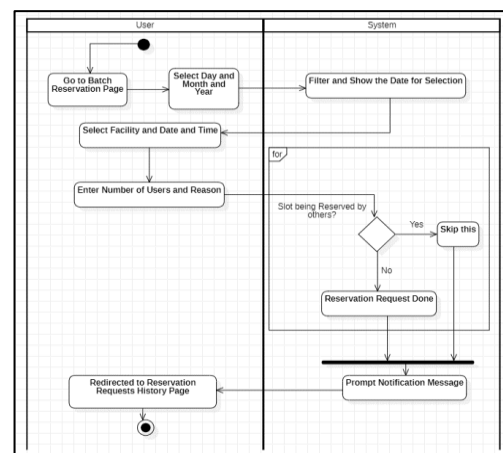
As per Fig. 12, users reserve through two methods: via the home page's availability table or Block B/Block C facility checking and reservation page. To reserve from the home page, users scroll, pick a date from the date picker, check facility availability, select time and facility, and click a cell. This redirects to the reservation page where they input user count and reason, get confirmation, and are sent to the reservation history. Alternatively, from the facility checking and reservation page, users choose Block B/C, set date, time, capacity, select a facility, and click "Reserve". This proceeds to the reservation page following the same steps.


Fig. 13 Activity Diagram for U-Reserve – Batch Reservation

In Fig. 13, users perform batch reservations on the batch reservation page. Here, users select the day of the week, month, and year. The system retrieves corresponding dates from the database and presents them. Users then pick the facility, date, and time, enter user count and reasons, and submit the request. The system checks for existing reservations for the selected slots. If available,

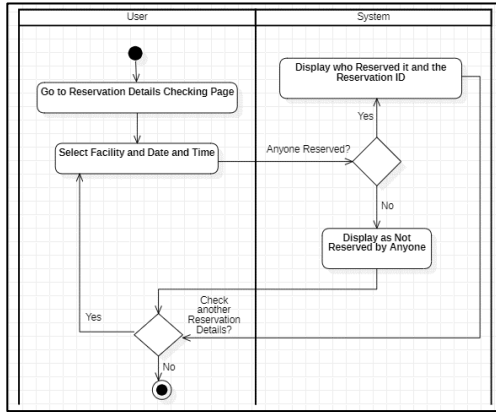
the system adds the new reservation request to the database; otherwise, it skips it. This cycle repeats for each selected date until completion. Users are notified of the submitted requests and redirected to the reservation requests history page.


Fig. 14   Activity Diagram for U-Reserve – Track Reservation Details

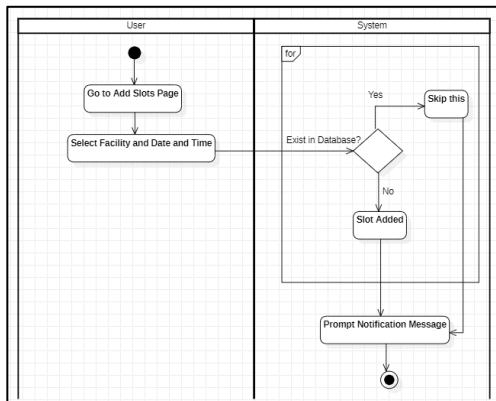
In Fig. 14, users can monitor reservations for a particular facility, date, and time via the reservation details checking page. They choose the desired parameters, and the system scans the database for reservations that match the criteria. If found, the system displays the Reservation ID and requester's ID number; otherwise, it indicates no reservations.


Fig. 15   Acytivit Diagram for U-Reserve – Add New Slots

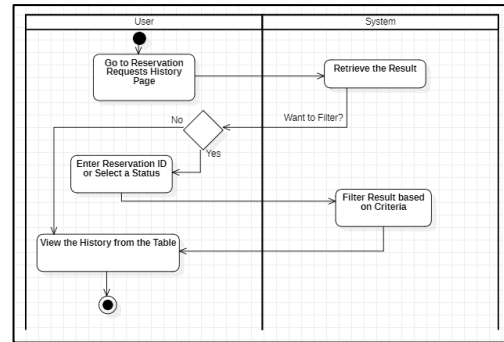
In Fig. 15, admins can include reservation slots by clicking the "Add New Slot(s)" button to access the Add Slots page. On this page, they select the facility, date, and time, and submit the details to the system. For each slot, the system verifies its existence in the database; if already present, the system skips that slot. Upon completion of the loop, the system informs admins about the number of submitted slots.


Fig. 16   Activity Diagram for U-Reserve – Check Reservation History

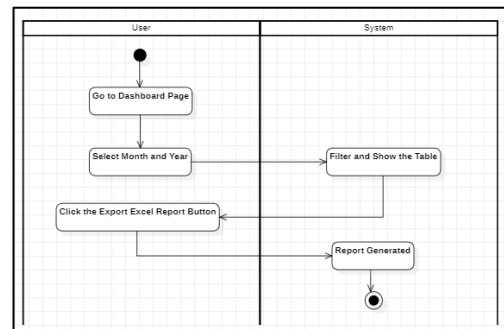
Users can access their reservation request history by clicking the "Reservation History" link on the navigation bar, as depicted in Fig. 16. Upon reaching the reservation requests history page, users can observe all their reservation requests. They have the option to input the Reservation ID, select a status, or both to refine the history. Subsequently, the system connects to the database, filters the results based on the provided criteria, and displays them to the users.


Fig. 17 Activity Diagram for U-Reserve – Export Excel Report

In Fig. 17, users can generate an Excel format utilization report from the dashboard page by clicking the "Dashboard" link on the navigation bar. They choose the preferred month and year, and the system filters and displays the corresponding data. Clicking the "Export Excel Report" button prompts the system to generate and download the report.

4.6 Development and Implementation

Table 3 displays the tabulated data from the user acceptance test (UAT) forms, utilising a Likert scale ranging from 1 for strongly disagree to 6 for strongly agree, as suggested by research [27], as shown in Fig. 18. The analysis used the arithmetic mean technique, following the methodology of [28]. A comprehensive evaluation of different sections can be accomplished by calculating the mean rating for all items within each section. A mean rating exceeding five (5) indicates user agreement. In this three-scale representation of

Esther Chong Jun Lynn, Neesha Jothi, Ismail Ahmed Al-Qasem Al-Hadi

agreement, encompassing 4 - Agree, 5 - Somewhat Agree, and 6 - Strongly Agree, five (5) serves as the midpoint.

Fig. 18 Likert Scale [27]

Table 3 User Acceptance Test (UAT) Result.

Item	1	2	3	4	5	6	Mean Rating
User Interface Design [27]							
Appropriate colour tone.	0	1	1	5	10	13	5.1000
Appropriate font type.	0	0	0	3	9	18	5.5000
Appropriate font size.	0	0	0	3	7	20	5.5667
Navigation is easy.	0	0	0	3	7	20	5.5667
Navigation is clear and concise.	0	0	0	1	8	21	5.6667
Perceived Usefulness [29]							
Using the system in my job/study increases my productivity.	0	0	0	4	9	17	5.4333
Using the system enhances my effectiveness in my job/study.	0	0	0	1	10	19	5.6000
I find the system to be useful in my job/study.	0	0	0	2	11	17	5.5000
Perceived Ease of Use [29]							
My interaction with the system is clear and understandable.	0	0	0	1	13	16	5.5000
Interacting with the system does not require a lot of my mental effort.	0	0	0	1	10	19	5.6000
I find the system to be easy to use.	0	0	0	1	8	21	5.6667
I find it easy to get the system to do what I want to do.	0	0	0	1	10	19	5.6000
Output Quality [29]							
I have no problem with the quality of the system's output.	0	0	0	3	11	16	5.4333
I rate the results from the system to be excellent.	0	0	0	2	9	19	5.5667
Result Demonstrability [29]							
The results of using the system are apparent to me.	0	0	0	1	11	18	5.5667
I would have no difficulty explaining why using the system may be beneficial.	0	0	0	4	11	15	5.3667
Behaviour Intention [29]							
Assuming I had access to the system, I intend to use it.	0	0	0	0	10	20	5.6667

In addition, Table 3 presents survey results indicating a favourable user perception of U-Reserve across various aspects, such as UI design, effectiveness, ease of use, output quality, result demonstrability, and behavioural intention. The system meets user expectations and preferences satisfactorily. However, potential areas for improvement have been identified, and several suggestions are currently under consideration. In essence, U-Reserve stands as a well-developed system proficient in efficiently managing facility reservations for UCSI University while assisting university staff in handling lecturers' timetables.

5. Conclusion and Future Work

In conclusion, the development of U-Reserve, UCSI University's web-based facility reservation system, followed a prototype methodology involving planning, analysis, design, and implementation. This approach successfully engaged users early in the process, incorporating feedback from user acceptance tests to modify and enhance the system. Notable contributions include streamlining the reservation process for students, staff, lecturers, and administrators, reducing workloads, and improving facility management through data-driven analyses.

U-Reserve meets user preferences for colour tone and font type, fulfilling functional and non-functional requirements. It stands out from existing systems by integrating their features while introducing unique elements like tracking reservation details and offering announcement and contact information. Moreover, the comprehensive project report lays the groundwork for implementing the facility reservation system at UCSI University, signifying a substantial achievement for the institution and its users.

Future improvement suggestions for the facility reservation system at UCSI University include redesigning for formality and consistency, migrating to a cloud-based or hosted server, implementing approval periods for reservation requests, integrating with central databases and the IIS, expanding reservation options, and enhancing the password reset mechanism. These enhancements aim to boost the system's functionality, security, and user experience, aligning it with the evolving needs of the university community.

Ismail Ahmed Al-Qasem Al-Hadi, for their invaluable support, guidance, and mentorship throughout this project. Their patience and expertise have played a crucial role in shaping the direction and scope of this study, and I am truly thankful for their contributions. I also want to express my sincere gratitude to the lecturers, administrators, staff, and students of UCSI University for their cooperation in conducting the user acceptance tests (UATs) and providing valuable feedback. Special thanks to Assistant Professor Ts. Dr. Ghassan Saleh for helping me in finding more lecturers and staff to participate in my UATs. Additionally, I acknowledge the support of my friends, who assisted me in collecting details and images of the facilities.

Authors Introduction

Ms. Esther Chong Jun Lynn

She is currently a degree student at UCSI University, Kuala Lumpur, Malaysia, studying for a B.Sc. (Hons) in Business Information System.

Dr. Neesha Jothi

She received her PhD from the School of Computer Sciences, Universiti Sains Malaysia in 2020. She is currently an Assistant Professor in UCSI University, Malaysia. Her research interest areas are Data Mining in Healthcare and Health Informatics.

Dr. Ismail Ahmed Al-Qasem Al-Hadi

He is a highly qualified and experienced Assistant Professor who is currently working at UCSI University in Kuala Lumpur, Malaysia. He has a strong background in computer science, with a PhD in Intelligent Computing and a Master's degree in Computer Science. He also holds a Bachelor's degree in Comp Science.

Dr. Sook Fern Yeo

She is an Assistant Professor at the Faculty of Business, Multimedia University, Melaka. She is currently holding the position as of the Deputy Dean for Research & Industrial Collaborations. Her current research areas are service innovations, consumer behaviour, social media marketing, branding, supply chain management, healthcare management and tourism marketing..

Abstract

This study focuses on the challenges and potential for Intelligent Document Processing (IDP) with Artificial Intelligence (AI) to manage unstructured data. A large amount of data in many different forms, such as information from the IoT, cybersecurity and more are produced during this modern Digital Age which has been widely distributed through a wide range of unformatted formats. IDP utilizes AI technologies like Machine Learning (ML), Natural Language Processing (NLP), and Computer Vision (CV), with the aim of converting unstructured data into structured, usable information. The IDP, are explored in the findings and discussion section that emphasizes its capability to automatically perform redundant tasks, reduce operating costs as well as improve employee productivity.

Keywords: Artificial Intelligence (AI), Natural Language Processing (NLP), Document Processing, Computer Vision (CV)

1. Introduction

In today's world, everything is connected to a data source, and digitization has made it possible to record everything. The current electronic era has an abundance of data available in various forms including the Internet of Things (IoT) data, cybersecurity data, smart city data, business data, smartphone data, social media data, health data, COVID-19 data, etc. This data can be structured, semi-structured, or unstructured [1].

With the emergence of new communication platforms and diverse applications such as social media, mobile applications, and digital marketing, the data delivered lacks a typical format or predefined schemas like the standard data and is unmanageable with the relational database models. Data is generated in various forms like text, audio, videos, emails, and images, which are categorized as unstructured data. Unfortunately, such data lacks structure and standardization, which leads to difficulty for most organizations to edit, search, and analyze [2].

Based on Forbes statistics, it reported that 95% of business organizations struggle to analyze unstructured data due to they do not have the required expertise to deal with unstructured data [2]. In a business company, 80% to 90% of data is in the form of unstructured format (Sukrutha, 2023). Business companies face significant challenges in effectively processing such unstructured data. In addition, the process of unstructured data analysis is always time-consuming and costly for any organization [2].

However, all organizations are required to extract valuable information from unstructured data to access functional information. Thus, automated analysis is crucial in helping the organization manage and access useful information in a structured manner. By automating the unstructured data kept in digital formats, organizations are allowed to quickly gain insight into their businesses, increase their competitive edge, improve productivity, and drive innovations. Artificial Intelligence-based (AI-based) technologies are critical for organizations that would like to adapt to automation solutions [2].

Intelligent Document Processing (IDP) is the conversion process of unstructured data such as email, images, and PDF documents to functional data. Intelligent Document Processing is one of the processes carried out by artificial intelligence (AI) and AI technologies are one of the best automation processes of the next generation. It involves Computer Vision (CV), Deep Learning (DL), Machine Learning (ML), etc. for data extraction [3].

The field of Artificial Intelligence (AI) is widely renowned as one of the most exciting and promising areas in the technology landscape. Analysts believe that AI will play a vital part in any business sector and industry. Besides that, the potential for value creation across the economy with machine learning (ML), a major subset of AI, is vast. It not only affects consumers, but it also transforms the way businesses operate aTsyapewtheoxlet . [4].

The increasing demand for the effective use of unstructured data necessitates the development of an AI-based unstructured document processing framework. This framework can aid organizations in extracting valuable insights from unstructured data automatically. Therefore, this research area is considered a significant and an important research topic [2].

Extracting insights from unstructured data can be challenging due to the lack of a predefined schema or format. Therefore, it is more challenging to analyze and process. Besides that, it also required the users to have a certain level of understanding to utilize the AI technologies and techniques. Thus, the main research objectives of this study are listed as below:

- To review the advantages and disadvantages of IDP with AI-based techniques for unstructured data.
- To understand the challenges with IDP to manage unstructured data.

Intelligent Document Processing (IDP) is a powerful technology that can transform unstructured and semi-structured data into a structured format. By leveraging advanced AI technologies like machine learning (ML) and natural language processing (NLP), IDP can capture, classify, and extract even the most complex and challenging data. This extracted data can then be validated and automatically entered into existing applications using Robotic Process Automation (RPA) technology [5].

According to [4], although advanced analytics and ML have been shown to provide a competitive advantage, many enterprises still struggle with their adoption. The lack of a clear AI strategy, talent, and data are major barriers, along with soft factors like leadership, decision- making, and company culture. According to

[6], it is shown that there are some potential issues and challenges with using machine learning, such as collecting sufficient and relevant training data. Besides that, another challenge is the development methods to automate document processing using machine learning, particularly for complex documents. Moreover, it requires efficient and effective technology and techniques to process and analyze fast streams of unstructured data. The complexity of unstructured data poses challenges for information extraction, especially for streaming data. Structural variation and differences in data formats are the critical obstacles associated with unstructured big data [7]. To fully leverage the IDP and gain access to valuable insights, organizations must go beyond simply knowing about it and actively incorporate it into their management and utilization of data.

Extracting insights from unstructured data can be challenging due to the lack of a predefined schema or format. Therefore, it is more challenging to analyze and process. Besides that, it also required the users to have a certain level of understanding to utilize the AI technologies and techniques. Thus, the main research objectives of this study are listed as below:

- To review the advantages and disadvantages of IDP with AI-based techniques for unstructured data.
- To understand the challenges with IDP to manage unstructured data.

2. Literature Review

Intelligent Document Processing (IDP) is one of the most popular technologies in this modern era with a high demand focused on the automation of the way humans work with different types of documents on a daily basis. Besides, Digital transformation is also one of the trending topics nowadays as Robotic Process Automation and other AI technologies such as ML work toward automating the ordinary operations performed by users. These AI technologies work together to process documents intelligently with limited human involvement [8].

The possibilities of electronically exchanging structured information continue to rise significantly. Nevertheless, a large amount of business processes continue to center on the sending, receiving, and processing of unstructured documents. According to Prasad (2020), only 20 % of data in enterprises is structured and the rest of it is unstructured data with most of it locked in documents. Companies with the adaptation of an automated document processing solution reported a reduction of 50% in their staffing and labor cost [9], while processing time is reduced to less than 20 % compared to manual processing time. It shows that

automation of business document processing is the key element for businesses to be more cost-effective and cost efficient.

Robotic Process Automation (RPA) refers to the automation of service tasks to perform repetitive human tasks precisely with the assistance of AI. The developer set the task instruction with the use of some form of screen recording and defining variables. Logging into applications, copying and pasting data, opening emails, filling forms are some of the examples of tasks. Different from the traditional automation method, RPA mainly emphasizes element identification instead of screen coordinates or XPath selections which results in better intelligent interaction with the user interface [9].

An alternative to the manual processing of documents is necessary to limit human involvement, minimize error rates and manage the time and cost efficiently and effectively. In this case, the research of automatic document processing has become one of the trending topics in recent years. RPA, also known as digital employee, has become a powerful tool to facilitate the automatic processing of business documents. RPA shows its effectiveness by enabling simple configuration of robots to handle high-volume and repetitive tasks automatically based on predefined rules which not only limits the human errors, but also improves the efficiency and cost reduction [10].

AI-based approaches are capable of extracting useful information from unstructured documents automatically. AI-based approaches are used in numerous applications such as invoice digitization, health record extraction, metadata extraction, machine translation, text summarization, insurance claims processing, and contract analysis [2].

Natural Language Processing (NLP) is one of the subfields of Artificial Intelligence that focuses on empowering computers to understand and process human languages, bringing them closer to human-like language understanding. Named Entity Recognition (NER) is an important component of NLP systems, which involves the process of automatic identification of named entities in a given text or document. Named entities refer to real-world objects such as people, location, date, and time. Recognizing and extracting real named entities is vital for various research areas, including Question Answering and Summarization Systems, Information Extraction, Machine Learning, Semantic Web Search, Video Annotation, and etc [11] According to [12], significant improvements have been made in extracting information from free text using NLP techniques based on AI. NLP uses syntactic rules to automatically scan and extract named entities like names, locations, organizations, dates, and invoice numbers from unstructured text using NER. The main steps in NER involve text pre-processing, extracting

NER features, then training and classification. In text pre-processing, the given text will be formatted to be understandable for machine learning algorithms. Then, features are extracted to create a numerical representation because the NLP model could not work on the text data. Lastly, the NER model will classify and categorize words and phrases. [2].

Computer Vision (CV) is also a component of AI that enables systems to identify and extract useful information from scanned document images and other visual inputs. The goal of computer vision is to extract meaningful information from images with the development of technology that enables computers or systems to understand and recognize digital images [13]. Machine Learning (ML) is a type of data-driven AI that provides the ability to learn about a system without explicit programming [14]. AI Algorithms and Machine Learning (ML) approaches have been effectively used in real-world scenarios which include the digital services, industry and commerce throughout the years. ML acts as the teacher of the machines which "teach" the efficient data handling skills by simulating the learning concept of rational beings. It can be achieved with AI algorithms that reflect diverse rational paradigms including connectionist, genetics, statistics and probabilities, based on cases, etc. The integration of AI algorithms and the ML approach provide a possibility for the exploration and extraction of information to perform tasks such as classification, association, optimization, grouping, prediction and pattern identification. [9]

Since a large amount of enterprise data these days is usually unstructured data which has no predefined schema or format, it is more complicated and challenging for users to collect, process and analyze the data without proper structure [2]. In this case, Intelligent Document Processing with AI is proven to be essential and necessary for the processing of unstructured documents.

However, there are several challenges and limitations that might affect the performance of which need to be addressed. There are major challenges regarding the use of Unstructured Data. Inaccurate text data is added by OCR text extraction in the form of noisy data sometimes. This is a key problem related to data. Unstructured data originating from multiple sources are not standard and have different formats of data. The lack of a sufficient supply of data and insufficient quality is also another challenge in data processing with unstructured data. Moreover, it is difficult to obtain information in a language that is complex such as Arabic, without the creation of dictionaries. It is difficult with information extraction methods to describe the semantic and contextual relationships among named entities in this ambiguous language.

Raenu Kolandaisamy, Heshalini Rajagopal, Indraah Kolandaisamy, Glaret Shirley Sinnappan

Another challenge is posed by domain specific entities. For example, the biomedical datasets are different from any other dataset in terms of domain specific entities [2]. As the business process requires handling and processing different types of unstructured documents from the clients or suppliers such as invoices, ID cards and application forms, it poses a challenge as these documents differ in type, form and layout which require classification based on their type and nature. Therefore, the AI technologies used for document processing should be able to extract the relevant fields from the particular documents with the application of either template-based or template-free approach. Moreover, AI technologies should be able to process and improve the quality of scanned documents, which is often submitted with low quality scanners or mobile devices. The collection of relevant target data from documents is complicated when it comes to managing multi-pages of unstructured documents which consist of tables with data that span across different pages [2].

3. Method

A case study method will be used for this study due to various data and information gathering have been undertaken to study this topic. A case study is a research methodology that assists in phenomenon exploration in a certain context via various data sources. Besides, it embarks on the exploration of phenomena from different perspectives to uncover various aspects. In the case study, the study is conducted in real-time within its naturally occurring context, with the consideration that context will influence the outcome [15].

According to [16], case study research is a qualitative approach in which the investigator explores real-life, recent cases over time involving detailed data collection from numerous sources of information, and reports a case description. To present the complexity of the issue being examined, various methodological approaches will be used. A case study will include a case study database, a clear evidence chain, and multiple sources of data from research. The depth and richness of the case study description allow readers to have a better understanding of the case and to determine the applicability of findings beyond the setting. The evidence sources for case studies include questionnaires, interviews, documentation, direct observations, participant observations, archival records etc. Therefore, case studies involve trustworthy information and act as a reliable research method since case study research is an in-depth and intensive research methodology [15].

4. Result and discussion

A questionnaire is conducted to review and understand about this study and research objectives. The questionnaire results from the respondents are shown in the Fig. 1.

Fig. 1 Results from the questionnaire

RPA is the automation technology that strives to automate human tasks including business processes by utilizing software robots that interact with systems through their user interface. It can help to increase efficiency, decrease costs and efforts that humans spend on repetitive tasks [17]. One of the advantages of RPA is that it can automate numerous processes smoothly and decrease operational costs significantly due to it can handle repetitive tasks and time-saving as well as resource-saving. Besides that, prior programming knowledge is not a must to set up and implement RPA, leading to accessibility to employees who are without any programming knowledge and experience. Moreover, RPA supports most of the regular business processes with error-free automation and reduces the need for human intervention. Furthermore, software tools are scalable and do not get exhausted [2]. RPA can handle tedious and redundant tasks, thus employees can concentrate on more complicated and valuable tasks that contribute more value to the company. The employees

with more meaningful tasks can invest more time to develop new skills to be more qualified for their job [18].

On the other hand, RPA might be limited when it comes to reading unstructured documents with various layouts and formats. The documents need to be in the same format for software bots to read accurately. In addition, even minor changes in the automation application also require reconfiguration of the RPA software bot [2]. Moreover, it can be disruptive and less effective if without the appropriate tools although it seems like a good idea for a company to shift to a more advanced business system [19].

Even though it has been proven that a competitive advantage can be achieved with the use of advanced analytics and ML, enterprises nowadays are still facing significant challenges in the adoption of ML due to lack of clear strategy for AI, insufficient time and limited data available. Soft aspects which include leadership, decision making, and company culture are also some of the challenges which affect the adoption of ML [4].

It is possible to achieve adoption through the creation of a tangible business value. However, as part of product or process innovation, the main challenge is to find the right purpose and to deliver the technology in a compliant manner. In these circumstances, for the development of business value it is imperative to have deep experience in processes and a good understanding of commercial requirements. Efficiency can be achieved by automation and an increased pace of implementation of business processes, saving costs at the same time. Effectiveness refers to higher business process quality which consists of fewer errors and compliant process execution [4].

ML is expected to address the clear business needs and integrate them into the business process so that it can deliver efficiency, preferably in the form of an end-to-end automation, simplifying the access of business users to technology. In this respect, 'everyday AI' which is capable of functioning without long data preprocessing and training activities is expected. In order to achieve this simplification, it is possible to integrate the technology into the process where the data is stored and improve the user experience [4].

In addition, access to data and its quality are two of the key elements that contribute to the success of ML. Firstly, it is necessary to consider the aspects of data gathering, access and transfer, anonymisation, annotation, curation, secure storage and deletion. Nevertheless, strict observance is required in the areas of legal frameworks and general regulations. When more data is created or collected, AI must be trained and evolved over time. The algorithms are expected to learn directly from user behavior, which is then used to internalize their knowledge. ML is currently still

considered as an assistance system which coexists with humans, and processes the data provided by humans. This is expected to happen automatically, in a way that human correction is used to improve algorithms and that this knowledge is not forgotten by the machine. This can be described as continuous learning. As a result, users will be able to anticipate increasing accuracy over time, build trust and depend on the results.

Furthermore, culture also plays an essential role in the introduction of machine learning and therefore needs to be adequately climate governed by innovation principles, resources, time, etc. The leadership's mindset and employees' willingness to accept change are the main reasons for this. It will have to be derived from and integrated with the proper strategy. It seems that enterprises with pragmatic and hands on attitudes tend to be more agile. They are aware of business needs, have well defined use cases, and provide the necessary environment for implementation such as fewer organizational obstacles, empowerment of staff, no fear of losing control or jobs. In fact, there seems to be a reluctance and much slower adoption by customers who are deeply entrenched in bureaucracy and hierarchies of managers without an explicit innovation culture [4].

5. Conclusion

The study focused on the potential and challenges of Information Document Processing with Artificial Intelligence techniques to manage unstructured data or documents. The prior study conducted by the researchers on IDP with AI techniques indicated that there are numerous benefits and challenges for AI-based techniques, but it is still a very popular and trending technique that most companies are adapting and utilising. According to the findings of this study, AI techniques such as RPA and ML have various benefits to companies, such as increased efficiency, reduced costs, and support for error-free automation of business processes. In addition, they are also facing some challenges, such as a lack of AI strategy, insufficient data, and culture, in the adoption process for the IDP with AI techniques. However, it can be overcome through value creation, integration, data considerations, and fostering an innovation-driven culture. IDP with AI techniques has been growing and increasingly important in each industry. Therefore, it is vital for companies to emphasise, adopt and utilise the current technologies to improve their business performance.

Abstract

Over the decades, the forms of cyber-attacks have evolved from disruption level, cybercriminal, followed by cyber espionage and lastly threatening level. Digital security has played a significant role in protecting enterprises from any form of cyber-attacks, especially in today's era of digitalization. Aligning with the global effort in emerging the concept of Industrial Revolution 4.0 (IR4.0) in organizations, where sensitive data and confidential information can be accessed at a fingertip of an employee. This paper discusses the difficulties of implementing digital security solutions in an enterprise in terms of external potential cyber threats, internal cyber security roadblocks within the organization and how Covid-19 pandemic imposed challenges towards cyber security in the organizations.

Keywords: digital security, cyber security, cyber-attacks, cybercriminal, cyber espionage, business organizations

1. Introduction

The Information System has changed our lifestyle over the past decades among banking systems, education, transportation, business, tourism, shopping. The rise of internet consumption has dramatically increased by organizations and individuals with massive global international trade and changes of human interaction in the young generation. Digital economy can refer to integration of new business models, goods, services and markets established on a basic business infrastructure with digital technologies. Digital technologies can be defined as consolidation of communication, computing, information, and connectivity technologies that are driven by storage, software applications, sensors and bandwidth to the next generation of digital economy through cloud computing [1].

The rapid development of science and technology is far more than that such as the internet of things (IoT), artificial Intelligence (AI), augmented reality (AR), drones, additive manufacturing (3D printing), robotics and others. These latest technologies work from extracting data from sensor conditions of physical devices, spreading and storing it rapidly on cloud to analyse it in real time by using advanced big data analytics for generating useful information of integrating services, products and processes, and making decisive influence on existing business models. Meanwhile, approximately 90% of business managers in developed countries like the U.K. and U.S. forecast information technology and digital technologies contribute strategic values to the entire economy in the future. On the other aspect, information technologies will uncover a variety of new threats of cyber security challenges and risks when more companies foster innovation by increasingly popularizing new digital technologies, while security information technologies are changing and evolving to become a complicated threat (cyber security). Furthermore, information security cases might have caused a minor technical problem 10 or 15 years ago, but today advanced and intentional cyber attacks are challenging us that might cause large-scale events as a result of direct and indirect consequences affecting business's strategy and competitive advantage [2].

Browsing the internet, reading digital books, social networking, searching content, and online shopping are transforming our lives to better, efficient and productive

Raenu Kolandaisamy, Heshalini Rajagopal, Indraah Kolandaisamy, Glaret Shirley Sinnappan

ones. However, most of the netizens and organizations lack cyber security awareness and relevant knowledge of internet hazards. Individuals and business organisations have limited knowledge to protect their devices and servers from cyber hazards such as financial fraud, sensitive information theft, website spoofing, Internet of Things (IoT) hacking, malware, distributed denial of service attack (DDoS) as well as ransomware. Cyber hazards come from the work of hackers also known as "black hats" who committed cyber crime on their own or with an organized criminal group. Large-scale breach of cyber security has been rated by the World Economic Forum as one of the five most

critical threats confronting the world today where the scope of threat globally is spreading rapidly and cost an estimated US$6 trillion by 2021 [2]. Nevertheless, studies show that installing protective tools on the computers from factories does not maximize cyber security generally. Hence, this paper examines the challenges faced while implementing cyber security solutions into organizations' systems in various different perspectives.

2. Result and discussion

According to the Internet Crime Report published by the Cyber Division of the Federal Bureau of Investigation (FBI) in the year of 2020, losses exceeding USD 29 mil resulted from 2,474 ransomware attacks registered worldwide has been recorded [3]. The fact that cyber crimes against enterprises have increased tremendously over the years has shown that the digital security systems or practices within the organizations still remained susceptible and vulnerable towards cyber attacks in any form or even worse, could not keep up with the growing pace of these cyber threats. Thus, the roadblocks or difficulties to carry out the implementation of the cyber protection have to be discussed thoroughly in terms of external cyber hazards, internal cyber security challenges in organization and challenges of digital security during Covid-19 pandemic in order to improve, correct and make changes towards the current situation of cyber security support in the right direction.

2.1. External Potential Cyber Hazards

The Internet has improved the standard of living of IoT users, but every pillar has two sides. Everything can be done smoothly by one click as the same goes with cybercrime. That could so easily invade valuable information of individual and business organizations by

various cyber hazards such as malware, phishing, distributed denial-of-services attack (DDoS), man-in-the-middle attack (MMIT), ransomware and insider threats [4]. Every cyber attackers' intentions are different, but mostly demanding for money, financial information, personal information and even the business infrastructure. Cyber attacks target individuals and business organizations that have less cyber security awareness and protection tools because they always have key assets to be exploited by criminals. According to "PricewaterhouseCoopers survey", organizations that undergo cyber attack relevant matter vanished 2.1% of its value and lost more than 1.6 billion USD per case on average [2]. Understanding the motive of cyber attackers and hazards is essential for internet users to prevent financial loss and irreversible consequences. There are three aspects of motive to be proven as crime which are motive, means, and opportunity that can be treated as a conventional crime. Means refer to an attack tool or technical expertise to execute the attack, motive is the aims, intention, purpose or reason of the attacker selecting a target, opportunity can be seen as a timing, vulnerability and weakness in the network of the target [5].

Ransomware is a kind of malicious software that encrypts files of business organizations by demanding ransom in exchange for a decryption key [6]. It is very difficult to detect hijacked files and data before a cyber attacker initiates the attack. There are only 2 options for users to solve the problem which are to pay ransom in exchange for a decryption key to retrieve files and data or disconnect the internet and format the computer [4]. However, it is nearly impossible for internet-based business organizations to get rid of ransomware by formatting all data in digitized generation because it is the foundation and infrastructure of the company. In 2012, Reveton is one of the recognised ransomware trojans that ransom nearly $130,000 fines from victims who believed that they have been charged for participating in illicit online activities. Business organizations weren't too worried about the attack because it was affecting mostly individuals. By the end of 2016, an estimated $1 Billion was paid to the ransom hackers from Cryptorlocker and CryptoWall. It gave a huge profit trajectory to the hackers, something big known windows exploits were on the way from the National Security Agency (NSA). The worst and largest ransomware attack that ever happened before in 2017, "WannaCry" (Fig. 1) ransomware attacked more than 230,000 computers of various industries which were universities, government organization, hospital, bank, logistic, telecommunication companies, railways companies and business organizations across 150 countries [7]. According to research from "SonicWall Capture Labs", ransomware cases have risen by 20%,

with up to 121 million attacks recorded around the world in the first half of 2020 [8].

Working of ransomware (Fig. 2) will be introduced into 4 steps. First, the ransomware starts with an unsolicited email usually designed to trick the victim into clicking on an attachment or visiting a webpage. Second, ransomware leverages flaws in the computer's command-and-control server and forces it to download a public key for running ransomware code. Third, important data is encrypted on the system and demands a ransom payment using cryptocurrency by providing ransom fee instructions. Lastly, the decryption key will be given by the attacker once the ransom is paid [4].

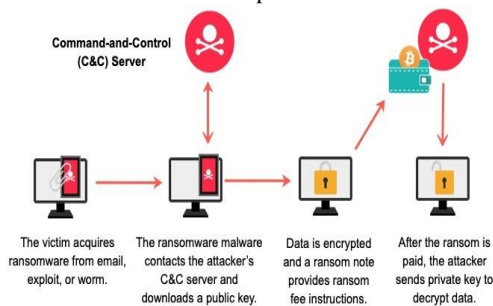
Fig. 1 Activation of "WannaCry" on victim's computer


Fig. 2 Ransomware mechanism

Phishing attacks (Fig. 3) is a social engineering technique to bypass computer security and human defence by using social networks, emails, mobile apps, instant message, business email compromising or search engine poisoning to steal user's data, sensitive information, credit card number and code, as well as login credentials to make the victim perform an action. There are more than 30% of cybercrime caused by phishing attacks and cost at least 8 billion USD according to Verizon Data Breach Investigation (DBIR). There are some technical countermeasures to mitigate risk of phishing such as anti-phishing, email malware detection, data loss prevention and spamming tools.

However, it's not effective because these technical countermeasures are unable to analyze and differentiate between phishing and general email. Furthermore, business organizations provide phishing attack awareness training to their employees against phishing techniques, tactics, and procedures (TTPs) through email security guidelines and standard operating procedures to increase cyber awareness [9].
Fig. 3 Phishing attack mechanism

Distributed Denial of service attack (DDoS) attack is one of the most common cyber crimes faced by business organizations when a group of botnets, server or numerous connected internet devices flood the capacity limit and resources of a targeted system as a result in service degradation and unavailability by disrupted normal traffic. Attacker will control his resources to overwhelm the capacity limit of the server by sending numerous requests to the targeted IP address of the website in a short time that trigger a crash. DDoS attacks could stay as long as 24 hours and up to days to retain access to the unavailability of the company's server that lead to reputation damage and profit minimization. There are vulnerabilities in the system that are exploited by the hackers although various protections and prevention are applied.

DDoS attacks (Fig. 4) are conducted with private networks of internet-connected machines and any kinds of IoT devices. Attackers can remotely control the networks that are constituted by computers and devices that are malware infected. These infected devices can be called bots (or zombies), and a botnet where a group of bots is connected in a network. Attackers are allowed to send attack instructions to each bots when the botnet has been established. When each bot sends requests to the victim's IP address, possibly causing the server of the website to be down where limit traffic is triggered during a short period as a result of denial-of-service to normal traffic. Because the server is difficult to identify attack traffic and normal traffic from each bot is considered a legitimate internet device [10].
Fig. 4 DDos attack mechanism

Types of DDos Attack

- Ping of Death (POD) attack
  POD attack exploits the particular characteristic based on the maximum size of the packet of transmission control protocol (TCP)/ internet protocol (IP) can be up to 65,535 bytes in normal cases. Generally, in the case of a large IP packet, it will be splitted into numerous fragments and reassembled into a complete packet to the recipient host. However, POD attack exactly exploits the reassembling packet size of 65,535 bytes greater than its maximum to maliciously manipulate overflow of memory allocated as a result of denial of service[11].

- Hypertext Transfer Protocol (HTTP) Flood Attack
  HTTP flood attack is another method of resource consuming by manipulating the HTTP GET and HTTP POST requests while connecting with the victim's machine [12]. HTTP works as a request-response protocol and designs to allow communications between servers and clients. HTTP GET and POST are the two most common methods where GET requests data from a particular resource and POST sends data to a server to update or create a resource [13].

- Domain name system (DNS) Flood Attack
  DNS is the "contact list" of the internet which allows devices able to view the content of websites. It sends a huge amount of DNS requests to the target device in order to overload it and reduce the speed of traffic. Attack will be done by the botnet to generate a large volume of traffic [12].

Cloud computing attack (CCA) is a malicious activity that involves data breaches, manipulating, account hijacking or eavesdropping from a user's virtual machine on the physical server by injecting malware from the hacker. Once the cloud system is deceived, hacker can gain unauthorized access to the user's cloud storage without permission and awareness. CCA could be conducted by various methods such as structured query language (SQL) injection attack, DDoS attack, malicious insider, side channel attack, man-in-the-middle (MITM) attack and abuse of cloud services. Cloud computing attack is the most economically significant threat in the world of virtualization technology, confidential data breach is one of the key diminish potential revenue loss and customer trust [11]. In fact, a massive cyber attack in Sweden in July 2017, a high confidential data stored at cloud system was breached, causing irreversible consequences that exposed national secrets, national security, international wrongdoing, and resignation of ministers. In fact, a massive cyber attack in Sweden in July 2017, a high confidential data stored at cloud system was breached, causing irreversible consequences that exposed national secrets, national security, international wrongdoing, and resignation of ministers. In June 2017, British Airways cloud system was being disrupted by hackers as a result of financial loss at 114 million EUR due to over 100 flights being cancelled from London airports [2].

SQL injection (Fig. 5) attacks is a common attack where an attacker inserts malicious code to unauthorized access to a backend database to gain sensitive information that was not intended to be disclosed or private company data. Generally, SQL injection attacks require an attacker to figure out the vulnerability of a webpage or web application to perform unauthorized access without an official account. For example, a logical user's account coupled with usernames and passwords that are registered at the database, attacker could input malicious code like username = '1' or 2>1 -- ' and password = '111' to bypass source code of the web application [14].
Fig. 5 SQL Injection mechanism

MITM (Fig. 6) occurs when an attacker establishes independent connection with separate ongoing conversations to different third parties by misleading them with the aim to inject, steal or exchange information to manipulate the result. Third parties are not aware that the attacker has control over the ongoing conversation between both parties. All of the message sent by one party to another will go through the attacker and it allows the attacker to tamper the information to mislead both parties [14].
Fig. 6 MITM mechanism

2.2. Internal Cyber Security Challenges within the Organization

Other than external cyber security challenges in the form of various cyber threats, there are seven internal challenges in implementing or improving the cyber security in an organization where these challenges could be grouped into three different categories or foundations for the organizations which are the three pillars of People, Process and Technology [6]. Indeed, human resources or employees are important assets to the organization, however, also one of the internal factors that drive the organization to the risks of exposing them to the emerging and evolving cyber threats when the employees are lacking cybersecurity skills, demonstrating irresponsibility and conducting human error while dealing with sensitive data and processes [6]. Firstly, the lacking of cybersecurity skills is said to be one of the challenges of cybersecurity in an organization and getting worse four years in a row since 2017 where this crisis has impacted almost 70% of the organizations globally according to the fourth annual global study by both the cybersecurity professionals, the Information System Security Association (ISSA) and independent industry analyst firm, the Enterprise Strategy Group (ESG) [15]. In fact, there are numerous factors that lead to such cybersecurity expert shortage crisis which could impose significant cybersecurity risk to the organizations, they are mainly due to global worker shortages, limited hands on skills as well as experience in handling cyber attacks and threats, the increasing workload of employee resulting in lesser time to acquire the relevant skill set, the incompetence of the employees to learn or utilize the cybersecurity technologies to the fullest potential, etc [16]. Thus, it is clearly evident that lack of skills in cybersecurity is one of the most challenging concerns in implementing cybersecurity measures under the pillar of 'People' within the organizations. Besides cybersecurity talent shortage, the irresponsible behaviour of the employees towards cybersecurity is also one of the challenges faced by the organizations in implementing the relevant measures. Most of the employees in an organization would intend to push the responsibility of the IT staff only, whereby the cybersecurity implementation is not solely IT departments responsibility, but all employees from operational level to management level within the

ecosystem of the organization [17]. Thus, with such irresponsible behaviour, the employees tend to put lesser attention onto the data handling which leads to the ignorance attitude towards the basic cyber security practices and possibly violating the compliances of cyber security. Not only that, employees' careless work behaviour such as inappropriate sharing confidential information with third parties without permission, inappropriate use of IT resources, losing their own devices storing company data, etc. could lead to a significant financial loss to the organization [18]. This could be evident when the result from the IT Security Risks Survey 2017 has indicated that almost 11% of the cyber attack incidents are due to careless and uninformed employees as shown in Fig. 7 below [18]. Hence, proven that the irresponsible act of the employees could definitely lead to hard time for the organization to implement the cybersecurity measures.

Fig.7 Most serious cyber attack vectors over the 12
months in 2017.

Furthermore, human error has also contributed as an obstacle towards the implementation of digital security in an organization [6]. This could be proven from a survey conducted by IBM in 2018, indicating that the misconfiguration of cloud servers due to human error is the biggest risk in cyber security in cloud computing with 62% of survey participants made up of IT and security professionals, while 55% of them noting misuse of employee credentials and improper access as one of the human error contributing to challenges while implementing cyber security measures, followed by insecure interfaces at 50% [19]. In fact, misconfiguration of systems usually allows cyber criminals to access large data platforms consisting of usernames, passwords, credit card data, health data, national identification numbers, email addresses, etc. which could possibly be used to request for ransom from the organizations. For example, one of the significant cyber attack incidents happened due to misconfiguration of system and human error in 2018, where a well-known marketing firm in the US, Exactis was reported leaking approximately 340 million files to the public including sensitive personal details ranged

from national identification number to hobbsies by making them available through a server accessible to anyone [20]. This incident has definitely shown that human error within an organization especially involving data handling and system configuration will definitely lead to big loss to the organizations regardless of financial or reputation.

The processes, which is the second pillar of an organization, has played an important role in cybersecurity implementation. There are three cyber security challenges identified under the pillar of 'Process' in a recent research, which include the lack of implementation plans for cyber security measures execution, the misplaced human resources and the lack of budget allocated for cyber security efforts within the organization [6]. The readily compliance and regulations governed nationally such as cyber security guidelines used in Malaysia including Information Technology Instructions 2007, ICT Security Policy 2010, Electronic Government Act 1987, Public Sector Cyber Security Framework 2016, etc., would need a good implementation plan within the organization in order to apply the guidelines into processes and enforce the cyber security strength of the organization [6]. However, most of the organizations do not emphasize cyber security planning which ultimately leads to a higher risk of monetary loss and reputational damage [21]. The mentioned phenomenon could be proven by the results of the survey conducted by The Department for Digital, Culture, Media & Sport (DCMS) in the UK on 1,500 businesses from October to December 2017, where only 38% of the businesses is aware of the new incoming data protection law, while only 27% from these businesses have made the changes on the organization processes and less than half of these businesses made changes to the cyber security practices within the organization, leading to a total of 43% of these businesses in the UK experienced cyber threats in 2017 [22]. The lack of implementation plan could involve cyber security governance, protection measures, hardware maintenance plan, incident response plan, evaluation plan, documentation including policies, Standard of Procedures (SoP), Work Instruction (WI), etc. where the effectiveness of the cyber security implementation is directly affected by the quality of these elements [21]. Therefore, detailed construction of the implementation plan is indeed important to ensure the cyber security measures are being implemented and executed accordingly in order to reduce the risks of exposing the cyber physical asset of the organization towards potential cyber hazards.

The next digital security challenge in an organization under the pillar of 'Process' is poor human resource management. For instance, new arrangements for cyber security talents in the workplace due to promotion to managerial positions, assignments to new departments or even the failure to retain cyber security talent would lead to the reduction of trained and experienced talents that could counteract cyber threats in an organization [6]. Due to talent loss, more time would need to be consumed to acquire capable talents, to train and nurture the replacement, etc which would cost a knowledge gap in terms of cyber security in the organization, leading to the risks of cyber invasion [23]. In fact, a survey conducted on cyber resilience by IBM Security and the Ponemon Institute has shown that 75% of the survey respondents found it difficult to hire and retain skilled cyber security professionals in respective organizations, while 48% of them has also pointed out the complexity in operation due to various type of security tools being implemented, causing the weakening in cyber resilience due to the skill and abilities gap between existing talents and tools deployed within the organization [24].

The sixth challenge in digital security within an organization is the limited budget allocated for the implementation and enforcement [6]. A detailed cyber security budget allocation should include risk analysis cost, technology acquisition or software licensing costs, training charges, insider threat reduction cost, etc. to reduce the potential risk of cyber internal breach and external threats [25]. However, most of the top management in the organizations especially small and medium enterprises do not prioritize cyber security because they would be willing to maximize the profitability instead of spending on cyber protection measures for incidents that may not happen, but they did not consider the possibility of cyber security failures which would cost the organizations even more [26]. For example, RiskIQ estimated financial loss of $17,700 per minute will be imposed on the victims due to phishing attack while Accenture estimated Malware rates up to $2.6 million at most and Ransomware rates up to $646,000 on average [27]. Not only that, organizations with improper cyber security could also be fined as it would induce insecurity within users, for instance, Google was fined at a cost of $57 million in 2019 due to the failure in complying with General Data Protection Regulation (GDPR) in France [28]. Thus, limited budget allocation as a roadblock in cyber security of an organization would definitely cause larger amounts of financial and reputational losses in the future as the risks from organizations internally or cyber threats externally are not being mitigated sufficiently.

Lastly, business organizations are facing cyber security challenges when the technology advancement is evolving too fast, so does the advancement in cyber threat vectors [6]. In fact, the cyber threats are characterized as asymmetrical and multi directional, making the organizations being reactive instead of proactive while facing the new form of cyber attacks[6].

Also, as the world is currently accelerating towards IR4.0, the organization especially in manufacturing industry which adopting technologies such as Robotics and Automation (R&A), Artificial Intelligence (AI) and Machine Learning (ML), Big Data Analysis (BDA) and Cloud Computing (CC), etc, where these technologies adapted are actually associated with the risks of being attacked by cyber criminals [29]. For example, Booz Allen Hamilton has pointed out the largest potential risk of AI and ML algorithms that worry the most is the possibility of leaking the training data to cyber criminals as this training data is sufficient enough to rebuild the original AI model via reverse engineering [30]. Thus, it is clearly shown that the benefits from ever evolving technologies aligning with IR4.0 are always associated with greater risk of cyber hazards invasion.

Recommendations are proposed in terms of the three main pillars which are people, process and technology, in order to help overcome the internal challenges faced by the organizations while implementing cyber security measures.

Firstly, human resources (HR) directors should play a key role or even a leader to keep the organizations safe from internal cyber breaches and employee-imposed cyber threat risks. As a HR director, a HR team should be formed to work with the IT or cyber security department to align the expectations ensuring the digital security measures and policies to be implemented is practical, ethical and appropriate. Besides, the HR director and the team should also take ownership of the security risk posed by employees by providing sufficient education regarding the impact of the employees behaviours towards the cyber security of the organizations as well as identifying employees who may be insiders allowing risks of external cyber threats to be imposed on the company. Overall, the HR team plays a vital role in shaping the workplace culture where the employees are following the reviewed cyber security measures and policies to help reduce the risks of cyber attacks. [31]

Secondly, in terms of processes, the management systems within the organization are vital in combating cyber security breaches. A proper management system must be adopted to ensure all the employees are aware of their duties and responsibilities as well as to adequately manage the level of competence and interest of the employees in cyber security. Besides that, a series of enterprise cyber security governance activities should be conducted from time to time to continuously improve the strength of the cyber security, where the activities include adopting enterprise risk management (ERM) to prevent data loss, and also, conducting threat,

vulnerability and risk analysis tests within the organization to access the sustainment of the cyber security governance. Moreover, the policies, SOP and WI related to cyber security measures and practices should be comprehensive enough and made available to every employee to ensure these guidelines or documents are clear and easy to understand to avoid miscommunication as well as guiding the employees in their decision making process when facing issues

like cyber attacks attempts. Vendor management is also one of the important processes to be focused on regarding cyber security because the vendors may potentially serve as a medium for external cyber threats invading the organizations, thus, it is important to ensure the vendors engaged are equipped with the same level of security. [32]

Lastly, in the aspect of technological advancements, organizations are suggested to adopt AI-based cyber security management systems where the systems allow to leverage up-to-date global cyber security knowledge and industry specific threats to make significant prioritization decisions as well as prompt incident response when exposing to cyber threat, keeping track of all organizations' IT assets in a domain to perform breach risk prediction and generating comprehensive reports on recommendations and analysis of the decisions proposed to all the involved stakeholders. [33]

3. Conclusion

In this paper, cyber security challenges faced by the business organizations have been discussed and analyzed in two different perspectives including the external potential cyber threats and internal factors within the organizations. Notable external cyber hazards such as the Ransomware, Phishing Attacks, DDoS Attacks as well as Cloud Computing Attacks comprises SQL Injection Attacks and Man-in-the-middle have been introduced and their mechanism also have been discussed in this paper. Seven internal cyber security challenges within the organizations have also been highlighted in terms of three different elements which are people, process and technology, where by the challenges discussed include the lack of cyber security skills, irresponsible behaviour of employees, human error, lack of digital security implementation plan, poor human resource management, constraint of budget allocation for cyber security implementation and lastly technology advancement. Indeed, both the internal and external cyber security obstacles faced by the organization have allowed many digital security breaches and invasions to happen, which leads to critical negative impacts to the organizations, corporate

and national such as breach of trust, data, privacy, financial or economical losses as well as the damage of reputation and public image. Therefore, further broad researches and detailed studies on cyber security especially the method of combating cyber threats and enhancing the strength of cyber security in organizations are recommended so that the readers could be provided with useful insights and ideas as well as emphasizing the importance of everyone's role in ensuring the success of implementing effective and efficient digital security measures in the organizations to instill the supportive behaviours and foster the cyber security culture within the companies.

Abstract

E-waste is piling up at an alarming rate, which results in our environment's pollution, while only a few are being disposed of correctly. This research aims to discover people's awareness of e-waste and how to handle it. An online survey was done among 75 respondents, who were asked about their general knowledge of e-waste. Most respondents are aware of the effects of e-waste but lack knowledge on how to tackle them, including questions concerning e-waste management and its causes. In conclusion, the general public must be educated on e-waste to reduce and dispose of e-waste efficiently and effectively.

Keywords: E-waste, Technology, Online Survey, Environment

1. Introduction

The 20th century was rich with pivotal technological advancement, from the birth of the television to the creation of personal computers. Technological advancement kickstarted the tech industries towards more innovations that are rapidly improving, which led to inventions such as the iPhone that paved the way for modern-day smartphones. Technology these days has become mainstream. Statistics show an uphill trend regarding the adoption of technologies in a household. For example, colour TV use increased exponentially, recording a 10 per cent adoption in 1966 to 96 per cent in 1990 and a fairly stable adoption rate moving towards the 21st century, staying around 90 per cent. The adoption of computers has also shared the same prosperity, skyrocketing from 20.70 per cent in 1992 to 89.30 per cent in 2016. The biggest winner of all this is the smartphone. Since its introduction around the 21st century, its adoption has rapidly increased, from 35 per cent in 2011 to 73 per cent in 2016. Its predecessor, the cellular phone, is the only factor stopping the adoption of smartphones from growing further since it also has an increase of adoption from 10 per cent in 1994 to 93 per cent in 2016 [1].

There are a multitude of factors feeding the growth of the usage of technology. The role of the government and human nature to favour efficiency are the pivot of this swift growth of technology usage. The government have been emphasizing Vision 2020 lately, which includes an objective to establish a scientific and progressive society that is not only a consumer of technology but also a contributor [2]. Another thing to note is the term Industry 4.0, which aims to create a smart factory environment. Alternatively, technology is known to ease day-to-day tasks. Due to this, technology has infused into our lives and become an ongoing trend. To make it clear, if the five big tech companies are combined, they would have a higher revenue (up to 802 billion) compared to Saudi Arabia, which has the 19th highest GDP at 684 billion [3].

Unfortunately, there is always a catch. The ever-increasing demand for technology causes tech companies to manufacture more and people to upgrade their technologies. All of this causes a domino effect, which leads to e-waste. Electronic waste or e-waste could be defined as any electrical and electronic equipment disposed of without considering it being repurposed. The term covers any objects with screens, temperature-related equipment like refrigerators, lamps, large or small electronic appliances such as a vacuum or dishwashers, and portable electronics ranging from Global Positioning System (GPS) to calculators [4]. As with any production, the manufacturing of technologies is not proportionate to its recycling work. As of 2016, 44.7 million metric tons of e-waste were produced,

comparable to 6.1 kilograms per inhabitant (kg/inh), which increased compared to the 5.8 kg/inh amount in 2014 [5]. In other words, the perception of people regarding e-waste remains uncertain. Therefore, this study aims to investigate the general public's perception of e-waste in Klang Valley.

2. Background

2.1. Overview

Electronic waste and electronic waste identify mechanical and digital products that have been discarded. These wastes are also regarded as appliances deemed refurbishable, recyclable, disposable and saleable. The processes involved when managing e-waste are burdensome, as they cause pollution and negatively impact human conditions, especially in developing countries.

2.2. Definition

E-waste or digital waste is generated after completing its useful life when an electronic item is discarded. The rapid expansion of innovation and the economy powered by usage contributes to producing a large amount of e-waste every minute. The European WEEE Directive classifies electronic and electrical equipment for waste management purposes into ten categories namely large household appliances (e.g., refrigerators, washing machines), small household appliances (e.g., toasters, coffee makers), IT and telecommunications equipment (e.g., computers, phones), consumer equipment (e.g., TVs, radios), lighting equipment (e.g., lamps, fluorescent tubes), electrical and electronic tools (e.g., drills, saws), toys, leisure, and sports equipment (e.g., video game consoles), medical devices (e.g., X-ray machines, pacemakers), monitoring and control instruments (e.g., thermostats, smoke detectors), and automatic dispensers (e.g. vending machines).

2.3. Current Situation of E-Waste

Electronic waste keeps growing. Today, people are buying more electronic devices, which are being quieted faster. For example, cell phones generally have a short lifespan of one to two years. People use most of their incomes to buy electronics yearly. According to a study, more than 20 million tons of e-waste are produced annually.

The environmental impact of e-waste is a growing concern in today's society. With the widespread use of electronic devices and rapidly advancing technology,

people constantly upgrade to more efficient electronics, contributing to the ever-increasing e-waste problem.
The old electronic devices are thrown away without considering the toxic materials from the electronic devices released into the environment. The groundwater, soil and air affect land and sea animals, causing harmful substances to seep into groundwater. When e-waste is released, toxic chemicals are released into the air, damaging the atmosphere.

Numerous electronic devices contain hazardous materials like lead and barium. In particular, the release of lead into the environment can result in adverse health effects, including damage to the human blood, kidneys, and peripheral nervous system.

2.4. Amount of Electronic Waste Worldwide

Increasing technological changes, media developments (tapes, computers, MP3), affordable market prices and the deliberate design of short life span technologies have culminated in a rapid buildup of accumulation of e-waste internationally. An achievable countermeasure has been developed, but in most situations, it is necessary to implement it to work legally in the real world, which is time-consuming even in the most advanced nations, especially due to the bureaucracy.
Different models and versions of TVs, processors, storage units, and audio modules have varying lifespans. Among these, screen systems and processors are commonly affected by electronic waste. Screen systems are often discarded without attempts at repair, whereas processors see a continuous influx of new and improved versions to meet the demands of ever-advancing video gaming graphics.

2.5. Environmental Impact

The methods used to manage e-waste in developing countries are often questionable. It has caused many issues that have an unfortunate effect on Mother Nature. These range from airborne or liquid-borne material leakage into the atmosphere, soils, water and foods, affecting animals, humans and plants.

2.6. Electronic Waste Substances

Many electronic parts can be recycled in manufacturing new computer devices, while others are reduced to materials that can be reused for industries as diverse as building, flatware, and jewelry. Large-scale materials include fiberglass, PVC, fabrics, gold, iron, copper, quartz, beryllium and oil. Almost all electronics contain lead-tin (as solder) and copper.

2.7. Effects

It is known that 13 percent of e-waste is processed in developing countries. Yearly, e-waste is generated at a large sum (around 40 million metric tons) worldwide. According to the United Nations Environment Program (UNEP), the European Union contributed up to 22.5 percent of the e-waste. Meanwhile, in China, the Philippines, Pakistan, India and Vietnam, unconventional ways of the procession of e-waste are largely practiced, with 50-80 percent of the e-waste procession. The processes involve dismantling, burning and shredding the items in backyards. These actions cause bi-products that have been proven impactful (in a bad manner) to mother nature and humans alike. Their action, however, is also due to the large amount of e-waste flowing in since they are handling e-waste domestically and internationally.

2.8. Methods Used to Reduce E-Waste

The production of devices and the use of the materials that go into their manufacturing represent a major way of embodied energy. Reducing the e-waste helps protect the resources and minimizes the required total energy taken from the earth.

- Recycling
  Recycling the highly valuable materials of old electronics rather than making or mining new materials for new devices.
- Stem the Spread
  Before buying a new electronic device, think twice. We can use the old electronic as an MP3 player or GPS device. Please do not throw it away.
- Sell and donate old electronics.
  The best and easiest way to minimize the electronic waste footprint is to sell or give it away to the people who need it. Giving out an electronic device to poor people is a good example of reducing e-waste; not only that, but it also makes us feel good.

- Educate and organize
  We may also educate our neighbors and local businesses on recycling. Returning these electronics to the recycling flow will lower the pressure on the mining, refining, manufacturing, and transportation industries and reduce pollution. Make a much more affordable trip to the local recycling centre to organize a group project to clean up old electronics. For example, Green Citizen.com organizes pickups for those in the San Francisco Bay area and provides mail-in services to those who cannot make it.

- Recycle and dispose of e-waste properly.
  Inappropriate throwing of e-waste is a more hostile problem as we speak, as its volume is increasing every year. For this reason, major business brands provide their customers with a platform to recycle their old electronics.

- Maintain the electronics.
  Effectively taking care of electric gadgets and appliances is a way of killing two birds with one stone since it could halt the production of e-waste and, at the same time, save money since it could function longer.

- Store data online
  Cloud services are effective in minimizing environmental effects. By keeping data online, we can access the data from any place all over the globe. There is no need to take other storage devices.

3. Methodology

This study is based on an online survey. The questionnaire was prepared with multiple-choice questions that comprised general information about the respondents (age and gender) and knowledge in regards to the topic, such as the proper e-waste disposal technique, country produces the most e-waste, e-waste hackable after being thrown away, country hosts the biggest digital dumping ground, the main causes of e-waste, its effect on children within the proximity of the dumping ground, environmental pollution and the main victim of e-waste. The data obtained from the survey was computed in Microsoft Excel for analysis. The statistics of each question were presented in the form of tables, pie charts and bar charts, as shown in the next section.

4. Result and discussion

In total, 75 respondents took this survey. 69.3 percent of the respondents were male, and 30.7 percent were female. Therefore, most of the respondents are males. The survey was taken by people ranging from the age of 19 and below or 20 to 49. None of the respondents over 50 years old participated in this survey. About 74.7 percent of people aged 19 and below took this survey, while 25.3 percent of respondents aged 20 to 49 took this survey. Seventy-six per cent of respondents choose to give to a reliable e-waste company. Moreover, 18.7 percent of respondents choose to throw e-waste in the

Raenu Kolandaisamy, Heshalini Rajagopal, Indraah Kolandaisamy

rubbish bin, while 4 percent throw e-waste by throwing it in the streets, and 0.3 percent of respondents choose to burn e-waste. The right answer is to give it to an e-waste company, as shown in Fig. 1. Based on a study, Switzerland and Germany tackled the e-waste problem efficiently. All these countries have a specialized company that handles it, such as the Public Waste Management Authorities (PuWaMa) of Germany or the Producer Responsibility Organization (PROs) of Switzerland [6].

Fig. 1: Respondents way of disposing E-waste
Fig. 2: The Country that produces the most E-Waste

Based on Fig. 2, respondents think China produces the most E-waste, with 58.7 percent of respondents, USA at 25.3 percent, and Canada and Ghana, gaining 8 percent of respondent choices. Unsurprisingly, China produces the most e-waste, amounting to 7.2 tons per annum. However, it is also worth noting that Norway tops it all in kg per capita, at 28.3 [7].
Fig. 3: Result of respondent regarding the prospect of E-Waste being hackable

Fig. 3 represents respondents' view on whether they think e-waste are possibly hackable once thrown away. As we can see, 72 percent of respondents said yes while 28 percent of respondents said no. Fig. 4 illustrates the percentage of people's predictions on which country would have the largest digital dumping ground. Brazil was the most chosen, at 41.3 percent, followed by Ghana, which had 25.3 percent of the respondents' choices. Mexico came in third, sharing 18.7 percent, while Kenya received 14.7 percent. Most respondents
chose Brazil as the world's biggest digital dumping ground.

Fig. 4: People's view on who shares the biggest E-Waste dumping ground

Fig. 4 illustrates the percentage of people's predictions on which country would have the largest digital dumping ground. Brazil was the most chosen, at 41.3 percent, followed by Ghana, which had 25.3 percent of the respondents' choices. Mexico came in third, sharing 18.7 percent, while Kenya received 14.7 percent. Most respondents chose Brazil as the world's biggest digital dumping ground. However, statistics showed Ghana is the worlds' largest digital dumping ground [8].
Fig. 5: Main causes of E-Waste

Based on the above Fig. 5, our respondents regarded improper disposal as the main cause of e-waste, gaining 44 percent of the responses. On the other hand, 11 percent of respondents chose population growth, 8 percent chose pollution, and 37 percent assumed due to technological advancement. In truth, the main contributor to e-waste is the failure to dispose of it effectively. Countries usually lack appropriate infrastructure, legislation, quantification measures and funding, resulting in a mass accumulation of e-waste [9].
Fig. 6: Effect of E-Waste on children near the digital dumping ground

The pie chart in Fig. 6 shows respondents' views on the effect of e-waste on children near digital dumping grounds. 29.7 percent of the respondents chose the answer of the possibility of the children getting sick. 51.4 percent chose the answer of children getting chronic diseases, 17.6 percent of children would get a chance to learn technology, and 1 per cent would get money. Children exposed to e-waste are highly likely to get a chronic illness or disease. It could harm the nervous, immune, reproductive and digestive systems. Due to this, they would have permanent, irreversible damage to their body (World Health Organization [10]. The pie chart in Fig. 7 below shows the possible types of pollution e-waste can do to the environment. 50.7

percent of respondents chose soil pollution,17.3 per cent chose water pollution, and 32 per cent chose air pollution, concluding that soil pollution is the main pollution mostly caused by waste. E-waste produces all types of pollution. It affects the air from the open burning and dust emitting into the air, while water is polluted when chemicals used are improperly treated and let out into the normal world. However, soil pollution is the most harmful form of pollution caused by e-waste [11], [12]. Toxic chemicals would be absorbed into the soil, which later would be used for farming. This would then grow harmful foods that humans would consume. In other words, it slowly and silently kills people who ate the food produced.
Fig. 7: Respondents' view on the possible pollution due to E-Waste
Fig. 8: People affected by E-Waste

The types of people affected by e-waste are shown in Fig. 8. 62.2 percent of respondents chose that workers working at digital dumping grounds are affected most

27 percent of respondents chose people who dispose of their e-waste, and 10.8 percent of respondents chose people who recycle e-waste. In conclusion, workers working at digital dumping grounds are affected the most by e-waste. The people that are most affected are those who work near the dumping ground. As stated before, e-waste causes air, water and soil pollution. Therefore, anything they do has a chance of being contaminated, thus harming them, especially in the long term.

5. Conclusion

E-waste is one of the rapidly growing environmental problems around the world. This is because of the lack of awareness and appropriate information on disposing of these wastes. Another reason for the rapid growth of E-waste is technological advancement. As technology advances, the old technologies will be left out because they are outdated. Furthermore, because of the ever-growing rate of technological advancement, we are creating more waste than ever every day. Most of these wastes are hazardous to the environment, and due to the growing amount of waste, we are damaging the ecosystem more and more every day [13]. Moreover, very few authorities are making any necessary moves yet. We hope the government can create more campaigns and talk about e-waste, its destructive properties and what we can do to stop this environmental crisis. The school authorities must also create awareness in kids and young adults so they would not even destroy the future. We hope the government and school authorities take immediate action to reduce this environmental crisis.

Abstract

The rise of social networking websites has been seen in recent years. Everyone will be spending most of their time on social networking websites such as Facebook, Instagram and Whatsapp. The great advantage that this social networking website offers benefited many of the users. It can help people to promote themselves or their business to gain more popularity and also customers through these social networking websites. There are many cybercrimes that can be identified which are identity theft, hacking, fraud and so on. The emergence of cybercrimes has created an awareness so that the users will know what the common attacks are and how they can be prevented from being lure and being a victim of this attack. This research will discuss about the attacks and how these attacks can be prevented by the users.

Keywords: Social Network, Cybercrimes, Digital World

1. Introduction

Social network has been growing in the 21st century and has become one of the trend that people use to communicate everyday. Social network is connecting with different individuals using the internet through social media websites [1]. It allows many individuals to be connected to each other and thus allowing many people to have communication with each other around the world. Social networking has been so popular because of the great ability and the features that it offers. The number of social networking sites has been growing from time to time. Some of the popular social media application and websites are Facebook, Whatsapp, WeChat, Instagram, Twitter, Google + and Skype. An example will be Facebook that have over 2 billions of active users each month based on Fig. 1 as of June 2017 [2].

Each of the social media platform have different features and design in it. There are many reasons why social networking has gain so much popularity over the years. The first reason will be the opportunity to meet new people. We live in a world that is full of different culture and environment thus meeting new people from different countries all over the world is indeed a great joy for many of us.
Fig. 1: Monthly users of social media applications

The second reason will social networking sites are user friendly and thus is easy to use. Most sites are developed with a very user friendly interface and is easy to navigate which require a little knowledge to learn. The third reason is that it is available to use on many platforms such as desktop computers, tablets and also smartphones with different operating system. The fourth reason is that social networking sites are free of charge to use and therefore many users will certainly want to try and use it [3]. Through gaining popularity to this sites, many also get the opportunity to advertise their product and services thus making social networking a good place to start and grow your business. The fifth reason is that social networking sites create the opportunity for graduates, businessmen and also

Raenu Kolandaisamy, Heshalini Rajagopal, Indraah Kolandaisamy

professionals to find their ideal jobs and also to meet the people that have the same interest as theirs.

The rise of social media certainly has a great impact on the community and the great benefits it has to offer but there also dangers in using social networking because of the large community it possesses and thus making user vulnerable to security threat and attacks. It can be shown that in recent years through social media that many have faced attacks such as scam and conned by users on social networking sites trying to impersonate another person seeking for donation and other personal information such as bank details and so on. There are very dangerous in the society and unaware users might be lured so this studies to help to increase the awareness of cybercrime in social network.

Cybercrime can be any activities that compromise on the security of the users and try to exploit another user using the internet. It is an illegal activity that involves the use of computer and the internet through a platform like social networking to gain or to cause destruction to another user on the that network. Cybercrime is the greatest attack based on the Fig. 2 that shows the motivation of the attackers [4].
Fig. 2 Motivation behind attacks

Cyber criminal can be categorized into many aspect. It can be broken down into a few different parts which are

- A website lure a users to click on an image or a link to visit another website that can spread malware to the users computer to take control and gain information from the users computer.
- A scammer try to claim to impersonate someone to be a bank staff to gain personal information such as password or even donation by creating a fake account.
- The hackers hack your social networking account to use as a way to get details from close people like family.

The danger to the victim here is that, they can lose their information in a matter of minutes. It will be a big problem to many society and what's more dangerous is that one victim can lead another victim to be a victim. For example, a victim receive an email regarding a free gift that can be obtained if they follow the steps to complete it on a website, but he or she sends it to her many friends on Facebook thus making them to be a victim as well because of the person doing things unknowingly.

2. Literature Review

2.1. Detecting Compromised Accounts on Social Networks

Social networking is one of the most used website in today's internet world. Social networking is a website that uses the internet to bring people together to share information, ideas and also make new friends. This can also be known as social media. Everyone loves to use social media because it is convenient and free. Social media websites such as Facebook, Instagram, Twitter and Whatsapp can all be accessed on various platform such as smartphones, tablets and computers. This has been a great advantage to many users around the world. Social networking has been very demanding and popular but the ever increasing of cyber criminals activities are also increasing as well making it very dangerous.

The study on detecting compromised accounts on social networks by Manuel Egele, Gianluca Stringhini, Christopher Kruegel and Giovanni Vigna will be discussed. The act of compromising on social network accounts has been a great and profitable job that has benefit the cyber criminals. The reasons here is because the speed and reliability of social medias account. By targeting a social media account of a famous artist that have many followers and by sending out fake messages can be able to scam many thousands of users that have follow that famous artist. It is very dangerous because once an attacker managed to compromise a social network account, the person can use it for many purposes such as sending out spam messages to people or even phishing web sites link. It is a higher benefit for attackers to target large and popular company that has large amount of followers like news company.

Fake accounts and legitimated hacked accounts have different characteristic so the system is harder to detect because it is not the fake accounts that is created by a user, it has been a good standing account but it is being compromised. This research introduced COMPA which is basically a detection system that is designed to identify compromised social network accounts. COMPA is use to monitor the habits of the user in a social network account [5]. A person who uses social media like Facebook usually have a fairly stable behaviour from the messages that is being send or the amount of time that the person is active. How this works that COMPA will actually build a behavioural

profile for social network accounts and then it will start to monitor and compare the new messages that is being sent by the account, if it looks different from what it usually is then Compa will flag it as being compromise. There are two common use to detect compromise account and the first is call suspicious group. Suspicious group are those that send and do more than what the accounts normally do. For example, account A usually send out 50 messages a day and averages about 45 per month, but that particular month itself, it exceeded the regular threshold by sending over 500 messages a day. It can be easily be detected especially if the amount raise too significantly.The second is call bulk application. Bulk application are the one that send out large amount of messages with the same amount of text and words.

The studies have evaluated both social media websites which are Facebook and Twitter. The data collection method was to collect real time tweets from Twitter and ran Facebook experiments on a large dataset crawled in 2009. The advantages of COMPA is able to identify groups of compromised accounts that are to distribute malicious messages on this accounts.

The limitation of this studies is that if the attacker is aware of COMPA, the attacker learn about the victim's behaviour before compromising so that COMPA cannot detect the unusual behaviour of the account because of the similarity of the action that is being possessed by the attacker that imitate the action of the victim. Besides that, social networking sites are harder to gather data.

2.2. Cyberbullying detection in the Twitter network

The rise of social networking websites has been such a great impact to many users in the world. Many use this opportunity to gain new friends, establish new relationship and also to connected with family and friends. Although it has been seen by many as a benefit but the use of social networking websites has been so popular that many have use it in the wrong manner to abuse it and gain advantages over it but causing harm to another. The discussion in this literature review is by Mohammed Ali Al-garadi , Kasturi Dewi Varathan and Sri Devi Ravana which is about the experimental case of cyberbullying detection in the Twitter social network[6].

Firstly cyberbullying can be defined as the use of information and communication technology on the internet and it can on any social media platform for example Facebook, Twitter, Google+ and also Instagram to harass another user. This research and studies is to focus on how cyberbullying happens on Twitter. The study is to improve the detection rate on

detecting cyberbullying on Twitter that has been done by detecting the use of offensive language on Twitter. The detection of of abusive language can include the use of acronyms and words that can increase the cyberbullying classifier. Cyberbullying can be also associated with the aggressive behaviour of the users on Twitter. As certain words can be harder to detect because the words needs to be read as a whole sentence to know whether it is offensive or not. In this case, plenty of information that needs to be utilized to achieve and accurate detection to says that the particular tweet is dangerous and abusive. The detection of vulgar words can also be used as this also a signal of offensive behaviour. The cyberbullies can also use many ways to tweet and of way is to use abbreviation or acronyms to shorten the sentence. The studies uses machine learning algorithms to detect the words with various method. They are four different ways that has been used which are NB, LibSVM, random forest and KNN. This are all the method that is used the various results and conclusions has showed that the study of abusive language and cyberbullying will required the machine to adapt and new learn words as time goes on because new vulgar words with abbreviation may be form and thus making it difficult to detect. The studies suggest that using other social medias can also improved the learning process of the system so that cyberbullying can be resolved and reduced in the community of social networking users.

2.3. Organised crime goes online: realities and challenges

The Internet is like a vast galaxy of interconnected networks that allows many transactions and events taking place virtually from the whole world - including cyber crimes and also Internet-facilitated organized crime. The study of the realities and challenges of organised crime online by the author Anita Lavorgna will be discussed.

Cyber crimes are known as a group of criminals that uses ICT infrastructure to commit crimes, such as phishing, malware injection, Denial of Service, and so more. However, in this world we are living in, organized crime groups (OCGs) have existed for long time and have conducted crimes offline. This paper mostly discussing on how these OCGs make use of Internet or online presence to evolve themselves in today's situation where everyone is more Internet-dependant.

The data for this paper are from interviews and also data collected from law-enforcement officials and experts researchers in the United Kingdom, United States, and the Netherlands. 120 case studies regarding crime with

the usage of Internet are also taken into the analysis of this paper.

This paper focuses on two types of OCGs, one is traditional business-style groups, the other is mafia-style groups. The type crimes committed by these business-style OCGs are identified - mostly on trafficking activities such as wildlife, human, psychoactive substances (drugs), and also fake medicines. These criminal activities are more to businesses motive and thus using the Internet to facilitate online. With the use of online social forums, instant messaging feature for example, it is easier for these crime groups to conduct and also expand their businesses ties with the client.

Mafia-style groups, however, were found to be still grasping on the use of Internet technologies for their criminal activities. Trafficking and gambling activities were their main focus. However, mafia-style groups as are mostly depend on a territorial and political trust, hence face-to-face interactions are needed. The highest hierarchy of this group were found to be mostly leaded by a leader who are not fancy of the use of the Internet. However, as these groups keeps evolving in the future, the usage of Internet in their criminal activities are to be expected as new generations will lead in the future.

The previous points discusses the reality of these OGCs. The challenges however, observed on legislation and policies for these Internet-mediated crimes. It is found that the regulatory policies regarding these crime activities via the Internet are not enough to control them. The instantaneous and universality of the Internet makes these inhibits these regulatory policies to fully take effect. Other challenges found for legislation and policies are such as different approaches applied in different countries as some of these countries have difference in experience in regards to tackling online crimes and carrying out investigations. [7]

2.4. Privacy and Security Issues in Social Online Networks

Social networking has becoming a necessity in today's society as more people in the world are having easier access to the Internet. However, this new necessity can bring a potential danger especially to new and also "naive" users of online social networks, especially teenagers. In this paper by Radhika Bhagat, Rajvi Modi, Palaumi Patel, and Harshil Joshi discusses about the potential privacy and security threats in social online networks today.

Users of online social networks were discussed in this paper. Most of the users using social network sites (SNS) to get informations and happenings all around them instantaneously. Personal information were propagated by them using SNS. Users of SNS tend to

take security lightly and this poses security and privacy threat upon their account.

Among the security issues discussed in this paper are, firstly, identity theft. It is defined as an action of acquiring someone's identity without permission and misusing it for malicious purposes, such as fraud. The author(s) suggested that users of SNS should not simply accept unknown friend requests and check the requesting account beforehand for safety.

Secondly, phishing is also a security issue found in SNS. Preparators of phishing uses 'mock-up' websites to lure users into logging in and thus exposing their sensitive credentials such as login credentials. Author(s) suggested users to always use trusted devices to log in to accounts and be wary of unknown websites. Other security issues found in SNS are such as brute force attack, Sybil attack, and Trojan attack.

Privacy issues in SNS were also discussed in this paper. Privacy settings is said to be always overlooked by most SNS users therefore this poses a huge privacy risk to them as social networks get to hold users sensitive data. It is found that some users even share their sensitive data, whether aware or unaware.

Among privacy threats discussed are such as cyber stalking, whereby most SNS has made it easy for these lurkers to stalk users' profiles without adding them as friends. Author(s) suggested users to keep their profiles privacy mode hidden and only to be shown to trusted parties only. Secondly, cyberbullying also a privacy threat found in SNS. Cyberbullying example are such as commenting illicitly on people's photos or posts and also tarnishes one's reputation online, mostly anonymously. Author(s) suggested users to keep things shared on SNS away from third party users and also be wary of them.

Other privacy threat includes profile cloning, whereby preparators create another account with similar information as the users', and therefore performing malicious actions online to the victim's friends.[8]

2.5. Cybercriminal Networks, Social Ties and Online Forums: Social Ties Versus Digital Ties Within Phishing And Malware Networks

As we are living in a digital age, everything is adapting to it. Not just people, and organizations as a whole, but even cyber criminals too. The usage of digital means such as Internet, and its platforms such as forums, social networking services, has made it easier for individuals to get together and communicate anywhere and anytime. This paper, authored by E. Rutger Leukfeldt, Edward R. Kleemans and Wouter P. Stol, discusses about

cybercriminal networks applying social ties and/or digital ties for their activities and recruiting.

A social network usually formed by actor to another actor with ties between them that defining their connection and relationship. A social tie are usually formed via social contact, for example, meeting in a specific place such as cafes, to engage social activity. Digital tie can be formed virtually online without social contact such as using forums.

Social relationships are crucial in criminal networks. However, social relationships are highly clustered with existing relationships such as contacts from former workplace, friends, family, and these relationships are said to yield less opportunity. With Internet, the boundaries of traditional social network are blurred and "specific offender convergence setting" can take place via online forums where these cybercriminals can get together and share information online from different places and also recruit new members or enablers.

The origins and growth of cybercriminal groups were mostly investigated in this paper. The data for this paper is taken from 18 Dutch police files on cybercrimes that provides them with knowledge cybercriminal networks and its members.

Four models of growth were developed in this paper. It is found that cybercriminal networks' growth are associated with recruitments of enablers - professional and/or recruited. These enablers provides services to cybercriminals to give them access to useful and relevant information such as credit card information and postal information details. The four models of growth consists of the first stage, that is "entirely through social contacts", second stage "based on social contacts; forums for recruiting specialists", third stage "based on forums, with social contacts used to recruit local criminals" and fourth stage that is "entirely through forums".

It is found that most of the cybercriminal networks uses social contacts entirely (first stage) to grow their network and does not use online forums. However, in future, forums may become a more common place for the growth of cybercriminal networks in this digital era. [9]

3. Methodology

The methodology used in this paper are are as follows:
- Questionnaire
  A set of questionnaire created in Google Forms is distributed online for respondents to fill in. The respondents sample size is taken among students of UCSI University as a representative of the public society. The questionnaire would help to analyze the approaches and actions

taken by the society in dealing with online social networks, especially in situations that may cause cyber crimes to take place.
- Social network visualization
  A Facebook dataset from Stanford Network Analysis Project (SNAP) are used to demonstrate and visualize how actors are connected in social network such as Facebook. [10] Social network analysis visualization tool used is Gephi.

4. Result and discussion

We have found that the problem with cybercrimes will continue to increase as more users increase in the use of social media. This is because the great number of users can be a good target for the hackers and attackers because it can be very lucrative if the hacker is being able to compromise millions of users at once. That is why online social media has also been a dangerous platform to know friends because of the use of a device and a face to face conversation has not been done and that makes it very difficult to know the real person's identity. The person can be a boy on Facebook talking to another person, but in reality she is a girl. That is really a very dangerous act and it can cause many unwanted things to happen on social media websites. Nowadays, because people are also attracted by free stuff and gifts only, it can be such an easy way to cheat people because of the lack of knowledge the users possess and thus it is very dangerous for users to click on links that link to malicious website that can harm the user's computers.

To find out how actors connected to each other in a social network, we have used a social network analysis tool software Gephi to visualize the network based on a dataset collection from Stanford Network Analysis Project (SNAP). This dataset is particularly from Facebook. As shown in Fig. 3 this is the result of the visualization projected from the dataset. The type of the dataset is undirected, it has 4039 nodes, and 88234 edges.

Raenu Kolandaisamy, Heshalini Rajagopal, Indraah Kolandaisamy
Fig. 3 Result of the visualization projected from the SNAP dataset

Fig. 4 shows our simulation on how a group of "rogue actors" can affect the social network. These "rogue actors" nodes are represented in color red. This shows that a small group of them can have quite a spread impact on the network. Note that this dataset is not a full dataset from Facebook - it is collected from SNAP survey participants on Facebook. However, a small dataset can be observed quite complex.
Fig. 4 Simulation on how a group of "rogue actors" can affect the social network

The questionnaire was distributed online and conducted via Google Forms. Over 35 respondents responded to the questionnaire. Questions asked were about their online social network service they are using, how do they use, how many connections they have, how do they react with unknown person on social network, and so on. The results are shown in the charts and graphs below. Based on the chart above in Fig. 5 asking about social network that is being used by the respondents and Facebook has the highest amount of users based on the survey done. It clearly shows that Facebook is still the most popular social network website that is use among the people.
Fig. 5 Social Media used

The pie chart above in Fig. 6 shows that many people have many friend on social networking website and it can be clearly seen that many spend time on social networking site making new friends.
Fig. 6 Number of friends on social networking site

Fig. 7 shows that most of the respondents accepts friend requests even if they don't know the person well. Although the difference between those who answered Yes and No is quite minimal, this shows that there are people still doing that practice.
Fig. 7 Friend request acceptance

Fig. 8 shows that most of the respondents do get a private message from unknown person on online social networks.
Fig. 8 Receiving private messages from unknown person on online social networks

Fig. 9 shows that many messages that is being sent to the user are mostly an advertisement with a link attached to lure the users to go to another website. The next is the attempt to get to know you more which is very common in social networking sites because is a platform to get to know more new friends. The last is just a simple link without any description.

If yes, how is the message typically be?
28 responses

- An advertisement (with a link attached)
- An attempt to get to know you more
- Just a link without any description
Fig. 9 The typical messages

Fig. 10 shows that many users will still click on the link even is a banking website. It shows that many users will click if the link looks trustworthy. Which the yes has the highest user.

Would you click links that appear to be a website that you familiar of such as banking website, even if its coming from your friend?
35 responses

- Yes
- No

5. Conclusion

Social networking has been really a good way to communicate with friends and family and thus make life happier and more joyful. This is because of the convenience that is offer and many users love using it and have spend hours and hours a day just to go through social media and looking at post posted by others. The security of this social medias websites has improved over the years but there are still many loopholes that be compromised by the hackers because of the lack of knowledge that the users have and thus making users more vulnerable to attacks. One common mistakes that

most users make is to create a password that is similar to their birthday date or telephone number and that makes easy for many to easily compromise his or her account. Besides that, talking to an unknown stranger can also be very dangerous especially those who are seeking for new friends and are desperate, they tend to do things without thinking of the danger.

From the findings gathered in the previous section, it is apparent that because of the way on how online social networks users uses the platform, it contributes to the emergence of the cyber crime in online social networks.

Abstract

Music is an important part of human life and culture, and it can affect people's emotions and moods. However, choosing music from a large library can be a challenging and time-consuming task. In this paper, we propose a facial expression recognition-based music recommendation system that can recommend suitable music which matches the user's current mood. The system uses a camera to capture the user's face and a convolutional neural network model which trained facial emotion recognition database to recognize seven basic emotions: anger, disgust, fear, happiness, sadness, surprise and neutral. The paper contributes to the research of facial emotion recognition and music recommendation and provides a convenient way for people to enjoy music.

Keywords: Facial Emotion Recognition, Music Recommend Systems, Convolutional Neural Network

1. Introduction

With the development of the Internet of Things (IoT) technology, various smart homes are entering the public eye, and AI voice assistants used to unify the management of various smart home appliances have also emerged. People control the use of various electrical appliances and furniture in the same network by giving commands to the AI voice assistants with their words, while many AI voice assistants have added many other functions in addition to the basic home control functions in order to increase the diversity of functions, such as music recommendations. When people are looking for music to listen to, they are often confused about the choice of music and are looking for some suggestions to help them choose, since it is often difficult to choose the most suitable music from a large library of thousands of songs, and music recommendations are one such feature that can reduce the difficulties users have in choosing music [1]. However, the music recommendation function sometimes does not meet the user's needs, and there are often situations where the recommended music conflicts with the user's current mood, such as recommending sad songs when the user is happy, or recommending songs with a strong rhythm when the user needs to calm down [2]. Therefore, how to make the computer quickly and accurately recommend the right song to the user is a problem that needs to be solved. It should be noted that facial expressions account for two-thirds of human communication and are one of the most important means of expressing human emotions. In the absence of facial expression recognition, AI is sometimes unable to give correct and rapid feedback through speech alone. For example, the same phrase what's up may have different meanings depending on the emotion, it may be a greeting between acquaintances, or it may be a concern to ask what difficulties you are experiencing, so people hope that computers will be able to understand human emotions and give correct feedback, bringing people a better experience with more intelligent human-computer interaction [3].

For this problem, we will use a camera to capture the user's image, use python deep learning based facial expression recognition technology to identify the user's current mood, and select the music that matches the user's current mood from the music categories in the database that apply to different moods to recommend music to the user, thus trying to reduce the user's anxiety in choosing music and improve the user's experience

2. Literature Review

Communication is a bridge to build interpersonal relationships, people send or obtain information through communication, and facial expressions are an important means and factor to help people understand the information conveyed by others in communication, according to the survey [4] the non-verbal component of communication reaches about 55% of interpersonal communication, and as an important category of non-verbal component, the study of human facial expressions is not only in medicine and psychology, its

wide application prospects have also led to its widespread interest in computer science [5].

As early as 1971, two American psychologists, Ekman and Friesen, had systematically studied facial expressions and in 1978 developed and defined the Facial Action Coding System (FACS), a system for recognizing various human emotions by representing different facial expressions in terms of different facial muscle changes. The system encodes specific facial muscle changes, called Action Units (AUs). Fig. 1 shows the main types of Aus.

Action Unit	Description	Facial Muscle
AU0	Neutral Face	
AU1	Inner Brow Raiser	frontalis (pars medialis)
AU2	Outer Brow Raiser	frontalis (pars lateralis)
AU4	Brow Lowerer	depressor glabellae, depressor supercilii, corrugator supercilii
AU5	Upper Lid Raiser	levator palpebrae superioris, superior tarsal muscle
AU6	Cheek Raiser	orbicularis oculi (pars orbitalis)
AU7	Lid Tightener	orbicularis oculi (pars palpebralis)
AU8	Lips Toward Each Other	orbicularis oris
AU9	Nose Wrinkler	levator labii superioris alaeque nasi
AU10	Upper Lip Raiser	levator labii superioris, caput infraorbitalis
AU11	Nasolabial Deepener	zygomaticus minor
AU12	Lip Corner Puller	zygomaticus major
AU13	Sharp Lip Puller	levator anguli oris (also known as caninus)
AU14	Dimpler	buccinator
AU15	Lip Corner Depressor	depressor anguli oris (also known as triangularis)
AU16	Lower Lip Depressor	depressor labii inferioris
AU17	Chin Raiser	mentalis
AU18	Lip Pucker	incisivii labii superioris and incisivii labii inferioris
AU19	Tongue Show	
AU20	Lip Stretcher	risorius
AU22	Lip Funneler	orbicularis oris
AU23	Lip Tightener	orbicularis oris
AU24	Lip Pressor	orbicularis oris
AU25	Lips Part	depressor labii inferioris, or relaxation of mentalis or orbicularis oris
AU26	Jaw Drop	masseter; relaxed temporalis and internal pterygoid
AU27	Mouth Stretch	pterygoids, digastric
AU28	Lip Suck	orbicularis oris
AU41	Lid Droop	relaxation of levator palpebrae superioris
AU42	Slit	orbicularis oculi
AU43	Eyes Closed	relaxation of levator palpebrae superioris
AU44	Squint	orbicularis oculi, pars palpebralis
AU45	Blink	relaxation of levator palpebrae and contraction of orbicularis oculi, pars palpebralis.
AU46	Wink	levator palpebrae superioris; orbicularis oculi, pars palpebralis

Fig. 1. The main types of Aus

It is well-known that human beings have six basic emotions (BEs), namely happiness, surprise, anger, sadness, fear and disgust, on the basis of which Du et al [6] have proposed 22 compound emotions (CEs) made up of combinations of basic emotions with each other, and different combinations of AU classify these facial emotions to facilitate identification, e.g. AU combinations 1, 4, 20, 25 can be identified as fear

emotions. Fig. 2 shows the main types of human facial emotions represented by the various AUs combinations.

Category	AUs	Category	AUs
Happy	12, 25	Sadly disgusted	4, 10
Sad	4, 15	Fearfully angry	4, 20, 25
Fearful	1, 4, 20, 25	Fearfully surprised	1, 2, 5, 20, 25
Angry	4, 7, 24	Fearfully disgusted	1, 4, 10, 20, 25
Surprised	1, 2, 25, 26	Angrily surprised	4, 25, 26
Disgusted	9, 10, 17	Disgusted surprised	1, 2, 5, 10
Happily sad	4, 6, 12, 25	Happily fearful	1, 2, 12, 25, 26
Happily surprised	1, 2, 12, 25	Angrily disgusted	4, 10, 17
Happily disgusted	10, 12, 25	Awed	1, 2, 5, 25
Sadly fearful	1, 4, 15, 25	Appalled	4, 9, 10
Sadly angry	4, 7, 15	Hatred	4, 7, 10
Sadly surprised	1, 4, 25, 26	-	-

Fig.2. The AUs combinations that can be observed in different human facial emotions [5]

3. Method

This system implements a music recommendation system based on facial expression recognition on the PC. Fig. 3 shows the steps for facial recognition.

Fig.3. Steps for facial emotion recognition

The aim of this system is to use the computer's powerful computing resources to quickly and accurately understand human emotions and recommend more appropriate songs to the user, bringing a smarter experience to people.

The system was developed on a PC with Windows 10, 64-bit operating system, Intel-i7-10510U CPU, 16G Byte RAM, PyCharm 2022.2.2, OpenCV-3.4.4.19 compilation environment and python as the main programming language. Tests of the system were also carried out on this machine.

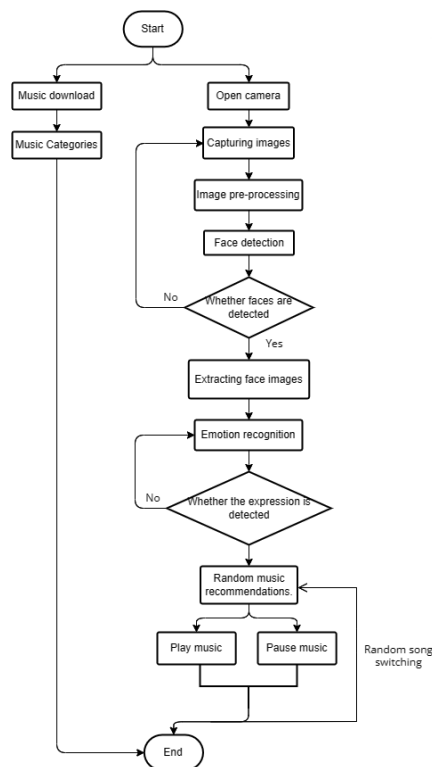
The process of using this system can be simply summarized as capturing the user's image using the local camera, using deep learning based facial expression recognition technology to identify the user's current mood, and recommending music that matches the user's current mood from the downloaded music that has been categorized into different mood folders, thus trying to reduce the user's anxiety in choosing music and improve the user's experience. Fig.4 shows the workflow of this system.


Fig. 4. System workflow diagram

According to the need, the design of this system as shown in Fig. 5 is mainly divided into seven modules such as Image pre-processing, Face detection, Emotion recognition, Music download, Music classification, Music recommendation and Music playing:

1) Image pre-processing module: the image captured by the local camera is pre-processed, the pre-processing process is mainly to convert the colour image into a grey scale image, which is convenient for face detection.

2) Face detection module: face detection is performed on the grayscale image, after the face is detected, a rectangular box is drawn on the original colour image to frame out the face, in preparation for expression recognition.

3) Emotion recognition module: The detected face image is fed into the expression recognition model for expression recognition. The recognition model is a convolutional neural network model with parameters trained to recognize the face expression and return the result.

4) Music download module: The crawler crawls the MP3 file of the searched music from the music playing website and downloads it to the local area, while crawling the corresponding lyrics and saving them in txt format, so as to prepare for music classification.

5) Music classification module: count the emotion value of each emotion word in the text according to the emotion dictionary, and classify the music files corresponding to the lyrics according to the emotion value.

6) Music recommendation module: according to the expression recognition result, a song is randomly loaded from the local music folder of the corresponding emotion

7) Music playing module: play or pause the loaded song.

Among them, the core function of the system is Emotion recognition, the recognition result will be directly related to the quality of the system, the appropriateness of the recommended music.
Fig.5. Structure diagram of the system modules

3.1. User Interface Design

A clean and aesthetically pleasing user interface (UI) provides a good user experience and helps users to interact easily with the software system. Here the UI is designed by using PyQt5, a GUI framework for the Python programming language, which makes it easy to implement powerful user interfaces using a variety of UI controls. The main controls used in this system are Label, Button, Line Edit and Timer.

Fig. 6 show the design blueprint of the UI and screenshots of the actual UI interface respectively, with the functions of each UI control as follows:

1) close_btn: Button control, used to close the whole system.

2) title_label: Label control for scrolling the name of the currently playing music file.

3) result_label: Label control, used to display the result of face expression recognition.

4) camera_btn: Button control for turning the local camera on and off.

5) play_btn: Button control to control the playing and pausing of the currently loaded music.

6) next_btn: Button control for randomly loading a piece of music from the folder matching the expression recognition result.

7) detect_btn: Button control that detects the user's current expression, returns the result and displays it in the result_label.

8) searchMusic_LEdit: Line Edit control for entering music names in preparation for music downloads.

9) download_btn: Button control for crawling and downloading mp3 files and lyric content of the music entered by the user.

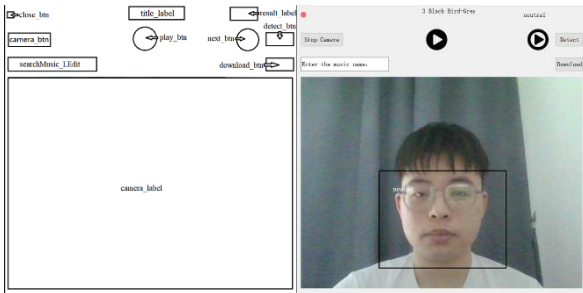
10) camera_label: Label control to display the image captured by the camera.


Fig.6. Design of the UI

3.2. *Design of Convolutional Neural Networks*

The design of the network structure affects the model performance and the accuracy of the classification. A good network structure can extract features more efficiently and reduce the training time. This system uses the convolutional neural network structure designed by Zhou [7] as the basis for classification. It achieved good recognition results on both the FER-2013 test set and the dataset [8]. The structure of this convolutional neural network consists of a 48×48 input layer and a 1×1 convolutional layer to form the first group of layer sets, and two consecutive convolutional layers with filter sizes of 3×3 and 5×5 followed by a 2×2 maximum pooling layer to form the second and third group of layer sets. Each convolutional layer uses ReLU as the activation function. The second group of layers has one more convolutional layer than the first group, which means that further refinement of features can be learned based on the first group of layers. The detailed structure of the network parameters is shown in Fig. 7.

Layer	Number of filters	Filter size	Stride	Padding	Feature image size
input	0	0	None	None	(48,48,1)
conv1-1	32	1×1	1	0	(48,48,32)
conv2-1	64	3×3	1	1	(48,48,64)
conv2-2	64	5×5	1	2	(48,48,64)
pool2	0	2×2	2	0	(24,24,64)
conv3-1	64	3×3	1	1	(24,24,64)
conv3-2	64	5×5	1	2	(24,24,64)
pool3	0	2×2	2	0	(12,12,64)
fc1	None	None	None	0	(1,1,2048)
fc2	None	None	None	0	(1,1,1024)
output	None	None	None	0	(1,1,8)

Fig.7. Network structure parameters [7]

3.3. Design and implementation of the main functions of the system

The music recommendation system based on facial expression recognition is divided into seven modules, and the main functions of each module are briefly introduced above.

Image pre-processing module

In order to ensure consistency in face size and position as well as face image quality in face images and to improve the efficiency and accuracy of face recognition, the images acquired by the camera need to be pre-processed prior to face detection, which can significantly reduce the computational effort of the device. The main task of pre-processing is image greyscale, which means that the image is unified into a grey-scale map of a specified size. In actual use will meet the image acquisition effect is not good, such as lighting and other factors cause image results are not good, and ultimately affect the recognition results, and the grayscale process can effectively remove these noise influence, after the grayscale, the influence of the noise is reduced to a minimum.

The method first normalises the input raw face image, scaling the pixel value range from 0-255 to between 0-1, then scales the raw face image to a specified image size of 48×48 and generates a set of face images of different sizes and orientations, providing more information for subsequent tasks such as face recognition and expression recognition, thus improving the accuracy and robustness of the algorithm.

The greyscale of the images is achieved using the COLOR_BGR2GRAY method in OpenCV.

Face detection module

The prerequisite for expression recognition is that the recognized image contains a face component, so face detection is a powerful guarantee for expression recognition. This module uses the face_detection_front.tflite and face_detection_back.tflite models from [8] for face detection.

The method first initialises the face detector, uses the detectFaces() method which from detector to detect faces in the input image, and returns a detection result containing the bounding box, key points and scores for each detected face. Finally, the returned detection results are used to obtain and return the absolute coordinates of the face bounding boxes.

Emotion recognition module

Emotion recognition is the core function of this system, image pre-processing, face detection modules are all paving the way for the implementation of this module.

In this method we first load a pre-trained facial emotion recognition model, read the video frames from the local camera using the capture.read() method in the OpenCV computer vision library, resize the video frames and greyscale them. Next, the faces returned by the face detection module are recognized for their emotions using the predict() method, and the predicted results are annotated in the original image and displayed in the control camera_label.

Music download module

The music download module mainly uses python's powerful crawler function to crawl music from music websites. The module consists of three main parts: music search, music crawling and music saving. Firstly, the searchSong() method is used to send an HTTP GET request to the url with the search content, and return a list of songs in JSON format to be prepared for the music download.

Then the MusicDownload() method uses the returned JSON list of songs to extract the song information for the first song in the list, including the song name, artist and song ID. Then the downloadSong() method is called and passed the extracted song information.

Finally, in the downloadSong() method, a request is sent to the url consisting of the song ID and a response is received. The music content is found in the JSON format response, read and saved as an MP3 file in the local download folder, thus completing the download of the music and also preparing the music for classification.

Music classification module

In the music classification module, we will classify the downloaded music according to the corresponding emotion and transfer the files to the corresponding emotion folder. For this function we rely on a sentiment dictionary from [9], which assigns sentiment values to each English word and the corresponding Chinese word for eight basic emotions (anger, fear, expectation, trust,

surprise, sadness, joy and disgust) and two emotions (negative and positive), and saves them in a csv file for easy searching. We used this sentiment dictionary to analyse the lyrics of the song to find the emotion with the largest sentiment value among all the emotions in the text of the lyrics as the final classified emotion, thus determining the sentiment classification of the song.

The code first read the sentiment dictionary and map the words to their corresponding sentiment values. Then the classify_sentiment() method below counts the number of each sentiment word in the input text and the total sentiment value based on the sentiment value of the word in the dictionary, thus returning the sentiment with the highest sentiment value as the result.

Music recommendation module

The music recommendation module is mainly based on the result of face emotion recognition, the music in the emotion folder corresponding to the recognition result will be played randomly using the method in the random library in python. The next_song() method in this module is also bound to the control next_btn, which is also a method for randomly switching music.

The code first opens the path to the folder where the emotional music of the category is stored based on the results of the face emotion recognition, searches the folder for files ending in '.mp3', '.wav', '.ogg ' or '.m4a' extension, saves the path to one of the files at random, and finally loads and plays the music using the method in the pygame library.

Music playing module

The Music playing module is used to control the playing and pausing of loaded music, and is implemented by the methods provided in the pygame library.

This method uses the Boolean variable ‘playing’ to determine if the music is playing and to control the playing and pausing of the music. When the playing variable is false, the music is not playing and can be played via the button, when the playing variable is true, the music is already playing and can be paused via the button.

4.   Result and discussion

4.1. *Under different light conditions*

The tests were first carried out under different lighting conditions and the results are shown in Figs. 8

and 9. As can be seen from the above diagram, under different lighting conditions, Fig. 8 shows the condition of insufficient lighting and Fig. 9 shows the condition of sufficient lighting, it can be seen from the figures that the function of the system expression recognition is not affected by the lighting, but the accuracy of expression recognition may be affected and reduced as a result.
Fig.8. Insufficient light
Fig.9. Sufficient light

4.2. *Testing at different distances*

The next test was conducted for different distances, with the face being closer to the camera and further away. The test results are shown in Figs.10 and 11.
Fig.10. Distance from camera 0.3m
Fig.11. Distance from camera 2m

Fig. 10 shows the results of the test at a distance of 0.3m from the camera and Fig. 11 shows the results of the test at a distance of 2m from the camera. After testing, it was found that the recognition of faces within two metres from the camera would not be affected; however, once the face is more than two metres away from the camera, the recognition will be affected and the face may not be detected, so when using this system, the user needs to be as close to the camera as possible so that the face can be better captured for recognition.

4.3. *Recognition accuracy test*

In this study, the 7 categories of "neutral", "surprise", "happy", "angry", "sad", "fear" and "disgust" were made in turn as shown in Fig. 12. The first five expressions matched the actual expressions, while the last two did not match the actual expressions. The highest recognition accuracy was achieved for the "happy" and "surprise" expressions, with over 90%, and for the "neutral", "sad" and "angry" expressions, with over 60%. The intended "fear" expression was identified as "sad" and the intended "disgust" expression was identified as "fear". The reason for this may be, on the one hand, the low recognition rate of these two expressions by the model, and on the other hand, the ambiguity of these two expressions, which could also be identified as "sad" and "fear" if judged by the human eye.
Fig. 12 (a) Neutral, (b) Surprised, (c) Happy, (d) Sad, (e) Anger, (f) Fear, (g) Disgusted expressions

5. Conclusion

Facial expression recognition has application needs in many scenarios, and today more and more fields have introduced expression recognition technology, such as the education field and the medical field. In order to meet the requirements of a facial expression recognition based music recommendation system, a convolutional neural network model based on the FER-2013, JAFFE, CK+ expression datasets was used in this project. A music recommendation system based on facial emotion recognition was successfully designed and implemented in the PyCharm development environment using the python programming language. It mainly includes seven

modules: image pre-processing, face detection, emotion recognition, music download, music classification, music recommendation and music playing. After the design was completed, the system was also tested in actual use. The results showed that the system has a high accuracy rate of expression recognition and is highly practical. However, the expression recognition function in this system is still inadequate for the occlusion, side face and distance cases. At a later stage, it is considered to add the expression images for the occlusion and side face cases to the existing dataset to improve the face detection rate and thus the expression recognition rate. In addition, the music classification function of the system designed in this project is limited to classifying music with lyrical content. In the future, the authors will consider improving the music classification algorithm and adding the classification of pure music without lyrics to the music classification module of this system.

A Model of Reaction-diffusion phenomena with Multiset Processing

Yasuhiro Suzuki

Nagoya University, Furocho, Chikusa-ku, Nagoya, 464-8601, Japan

Abstract

We propose a model of reaction-diffusion phenomena using Abstract Rewriting System on Multisets ARMS, which is a model of Multiset Processing. Although proposed model is simple, computer simulations confirm that the Turing pattern is generated.

Keywords: Reaction-Diffusion, Activator-Inhibitor, Multiset Processing , Abstract Rewriting System on Multisets, ARMS

1. Introduction

A reaction-diffusion system is a mathematical model of how the concentration of one or more substances distributed in space changes under the influence of two processes: local chemical reactions, in which substances change each other, and diffusion, in which substances spread in space. One of the most famous reaction-diffusion systems is that proposed by Alan Turing. Turing showed a system that is locally stable but destabilized by diffusion. The spatio-temporal pattern that occurs in this system is called the Turing pattern [1].

The reaction diffusion model, which Alan Turing proposed is one in which two oscillators are coupled by diffusion (Eq. 1), where the two oscillators mutually activate and inhibit each other.

$$\frac{\partial u}{\partial t} = f(u, v) + D_u \nabla^2 u,$$

$$\frac{\partial v}{\partial t} = g(u, v) + D_v \nabla^2 v, \tag{1}$$

In the equation (1), $u \equiv u(\boldsymbol{r}, t), v \equiv v(\boldsymbol{r}, t)$, f, g are reaction terms, D is a diffusion coefficient and ∇^2 is Laplacian.

2. Methodology

We model a system that performs activation and inhibition by diffusion coupling with two oscillators by a multiset rewriting system, Abstract Rewriting System on Multisets, ARMS.

2.1. Abstract Rewriting System on Multisets, ARMS

Abstract Rewriting System on Multisets, ARMS is a multiset rewriting system [2]. A multiset is defined as a simple set and a map, which returns the duplication of element. We denote the duplication (multiplicity) of an element as M (a), for a $\in$ A and in case c $/\in$ A, M (c) = 0; for example M (a) and M (b) of {a, a, b, b} are 2, and M (c) = 0; in the mathematical description, a multiset is described as; < sup, M () >, in which sup is a simple set of elements, in this paper we describe a multiset by denoting the same alphabet in its number of multiplicity such as {a, a, b, b} or a vector w =(M (a1) M (a2) . . . M (an)).

The union of two multisets M1, M2 is the same as the union of simple set and in vector description, the union of multisets is addition of vectors w1 and w2. And inclusion of sets is also the same as the simple set, when M1(a) $\le$ M2(a) for all a $\in$ A, the multiset M1 is included in M2 and we write M1 $\subseteq$ M2.

A reaction rule is a pair of multiset, we denote A# as a set of all combinations of multisets over A and in the combinations, an empty multiset is included. A reaction rule l $\rightarrow$ r, l, r $\in$ A# is described as a pair of multiset likewise chemical equations or a pair of its vector expression; and in some case, we can describe a reaction

rule as a vector r, r = −l + r, it is simple and good for examining the dynamics of an ARMS, but this description can not illustrate when there are the same species of element in the left-hand side and right-hand side such as a, b → a, c; in this case l = (1, 1, 0) and r = (1, 0, 1) and r = −(1, 1, 0) + (1, 0, 1) = (0, −1, 1).

A reaction is described as the rewriting of a multiset, if the left-hand side of a reaction rule is included in a multiset, these elements in the multiset are excluded and the right-hand side of the rule is merged to the multiset; the case when the multiset is a, a, b, b and the reaction rule is a, b → c, d, the left-hand side of the rule is included in the multiset, {a, b} ⊆ {a, a, b, b} so the {a, b} is excluded from the multiset and it is transformed to {a, b} and the left-hand side of the rule {c, d} is merged to the set and we obtain {a, b, c, d} by this reaction. By using vector ex- pression, a reaction is the addition of vectors as w − l + r,

in which l and r are vector expression of a reaction rule; the case when M = {a, a, b, b}, w = (2, 2, 0, 0) and the reaction rule is a, b → c, d, ({1, 1, 0, 0}, {0, 0, 1, 1}); and the reaction is denoted as {2, 2, 0, 0} − {1, 1, 0, 0} ={1, 1, 0, 0} and {1, 1, 0, 0} + {0, 0, 1, 1} = {1, 1, 1, 1}.

2.2. Activator-Inhibitor model

In the activator-inhibitor model, activator X increases themselves by autocatalytic reaction (Eq. 2); X → X, X. The reaction of activator X produces inhibitor Y is, X -> Y, X. X is put in both reaction equations because X does not increase by this reaction, while only Y increases. X, Y -> Y describes the inhibition of increasing X by Y, where X decreases while Y does not change. Y → ∅ denotes the decreases of Y, ∅ illustrates an empty set. We give reaction coefficients for each rule. We give reaction coefficients for each rule as k_1, k_2, k_3, k4. Each coefficient gives the probability of firing of the rule.

$$X \xrightarrow{k_1} X, X : \text{r\_1},$$

$$X \xrightarrow{k_2} Y, X : \text{r\_2},$$

$$X, Y \xrightarrow{k_3} Y : \text{r\_3},$$ \hspace{1cm} (2)

$$Y \xrightarrow{k_1} \emptyset : \text{r\_4}.$$
Modelling diffusion :

The Eq. 2 above does not include diffusion. So, we need to consider diffusion separately. Why does diffusion occur? If we put a drop of ink on clean water and watch it for a long time, the ink spreading on the water's surface

will eventually dissolve into the water. No matter how long we keep looking at the surface of the water where the ink has dissolved, there is no return of the drop of ink when the dissolved ink is dropped on the surface of the water again. In other words, diffusion is the process of homogenizing things.

If the state quantities of cells i and j are x_i and x_j, and diffusion occurs between these cells, the amount of diffusion from cell j to cell i can be expressed as d=(x_j - x_i)×D. D is called the diffusion coefficient. For example, let us consider a sequence of cells [2,3,1,2]. (The sequence of cells is indicated by enclosing the amount of state in each cell). For the cell with state 1, the state to the left of this cell is 3, and the state to the right is 2. The state of this cell is less voluminous than the left and right states. Therefore, an inflow occurs from the left and right cells to this cell, changing its state. The degree of inflow is determined by d=(x_j - x_i)×D. If the diffusion coefficient D is 0.1, the inflow from the left neighbour d_left=(3-1)×0.1=0.2 and the inflow from the right neighbour d_right=(2-1)×0.1=0.1. Thus, the sequence of cells [2,3,1,2] becomes [2,2.8,1.3,1.9] due to this diffusion. (Here, only the cell with state one is shown, but in reality, other cells change in parallel as well.) In this way, the state of each cell is averaged by diffusion.

2.3 Diffusion in a two-variable system

The active/inhibited system of Eq (2) consists of two variables, X and Y. Therefore, we will use a one-dimensional sequence of X-only cells and a one-dimensional sequence of Y-only cells. For example, if the sequence of cells representing the state of X is [2,3,1,2] and the sequence of cells representing the state of Y is [0,0,1,0], the states of X and Y in the cell located second from the leftmost are (1,1). When the diffusion coefficient of X is 0.1, and that of Y is 0.3, if diffusion occurs in cell (1,1), the state of the cell changes (Again, only cell (1,1) change is shown).

3. Results and Discussion

We assume that the rightmost cell is connected to the leftmost cell; the ten cells are considered to be connected in a ring. We show the result of simulation whose initial states are;

X=[0,10,0,10,0,10,0,10,0,10,0,10],

Y=[0,10,0,10,0,10,0,10,0,10,0,10].

We set the reaction coefficients are k_1=k_2=k_3=k_4=0.01. The state quantity is first updated by diffusion, as described in the previous section. Next, reaction rules are applied in parallel to update the state quantities. The update by diffusion and the update by reaction rules are repeated, and this process is repeated.

When the diffusion coefficients of X and Y are D_X=D_y=0.0, when there is no diffusion, there is no change from the initial state. Such a state is called an equilibrium state (equilibrium means "balanced"). As will be explained in detail in the next section, if X=Y (the amount of state of X is equal to the amount of state of Y), neither the amount of state of X nor the amount of state of Y will change in this reaction system. Therefore, since X=Y holds in the corresponding cell in the initial state, the system would remain in the initial state if there were no diffusion.

What would happen if diffusion were to occur in a state where the reaction is in equilibrium (X=Y)? First, assuming that X and Y diffusion coefficients are the same with D_X=D_y=0.1, X and Y change but always remain X=Y. In other words, the reaction is always in equilibrium. Eventually, X and Y are homogenized by diffusion, and the entire reaction reaches equilibrium. This is true even if the diffusion coefficient is changed as D_X=D_y=0.2,0.3···.

Next, when X's diffusion coefficient is more significant than Y's with D_x=0.3 and D_y=0.1, X and Y become homogenized and almost X=Y, and the reaction approaches equilibrium. On the other hand, when the diffusion coefficient of Y is more significant than X's with D_x=0.01 and D_y=0.3, Y becomes homogenized. However, a larger or smaller pattern appears in X (Fig. 1) shows an example of the results). In this case, X does not equal Y, and X and Y continue to change (increase).
Fig.1 Turing Pattern like behavior, where the diffusion coefficient of X is 0.01, while Y, 0.1.

4. Conclusion

The reaction-diffusion phenomenon has been modelled and investigated as a partial differential equation by modelling the activator-inhibitor system. We used ARMS by modelling the activator-inhibitor system and confirmed that the ARMS model shows Turing pattern-like behavior.

Abstract

We proposed the Tactile Score to describe time-varying tactile sensation by the time variation of vertical force. Tactile quality is essential in hardness/softness, roughness, and temperature. Hardness and softness can be extracted from the shape of the Tactile Score. Roughness can be extracted from the pattern of hardness and softness. The arbitrary time series data can be interpreted as a tactile score by considering the time variation of the vertical force, and the hardness and softness are extracted from the time series data interpreted as the tactile score. This method can extract different features from conventional data science methods.

Keywords: Data Science, Time series data, Tactile of Data, Tactile Score

1. Introduction

Sensitivity differs from person to person. The same greeting of "Good morning" may be perceived as cheerful by some and noisy by others. There is no correct answer to sensitivity, nor can it be generalized.

We can generalize if we take the average of many people's sensitivities. Sensitivities that deviate from the average should not be ignored or directed toward sensitivities closer to the average.

A general sensitivity search system is a system in which evaluation criteria for content are modelled for each individual through instructional learning, and each user's evaluation criteria model is used for searching.

The following algorithms have been used in a sensory search; color histogram A method to extract features of images and videos; impression analysis using the SD method A method to quantify the impression received from contents by assigning degrees to impression words, learning correspondence between impression words and contents, extracting correlation coefficients between contents, and Extracting correlation coefficients, the distance between contents Projecting the quantified impression words and features of contents onto the feature space and measuring the distance between them.

2. Tactile Score

Why do we feel "cheer" from the children's "Good morning"? What is the difference between them? The difference is "the way you say it. How we say it can be characterized by the pitch and volume of our voice, but let us look at the volume of our voice.

Yasuhiro Suzuki

When we think back to the children's "Good Morning," their voices gradually became louder and louder. So, let us describe the change in "loudness" by using the music notation. In musical notation, the higher the note is, the lower the note is, and the higher the note is, the lower the note is. The middle line (the third line) is the "normal" volume, and the lower the volume, the higher the volume, and the higher the volume, the lower the volume. The "rhythm of speech" is represented by the notes as they are. We call this notation to describe tactile sense as the Tactile Score [1] (Fig. 1).

Fig. 1 Tactile Score

2.1. *Tactile Quality*

There are several essential factors in the sense of touch, the most crucial being "hardness" and the second most important being "roughness. These properties are called "tactile qualities. Is it possible to describe these tactile qualities in tactile notation?

Think of two kinds of "springs": a stiff spring and a soft spring. The softer spring will expand and contract more when these springs are pushed and pulled with the same force (difference in elastic force). Therefore, we call a tactile spring with a slight change in size "hard" and a tactile spring with a significant change in size "soft". If we consider this as a way of saying "good morning," "hard" is a way of saying "no intonation," and "soft" is a way of saying "full of intonation.

Now we can describe the most critical tactile quality, "hardness," in tactile notation. What remains is roughness. Roughness is described as "smooth" when there is little change in hardness and "rough" when there is a significant change in hardness (Fig. 2). If we are walking on the grass in a park and the hardness of the grass is constant, we will feel "smooth".

3. Extract tactile qualities from time series data
Fig. 2 Roughness, read from Tactile Score

When we press a key, the piano makes a sound as it is. It is impossible to adjust the sound later, as with a violin or trumpet. So, are all piano performances the same? Of course not. Even the same music can sound very different depending on the pianist. One crucial element that makes a difference in piano playing is the "sense of touch. It is often referred to as "the touch of the piano". The word "touch" includes the meaning of "tactile sensation". The sound of the piano, as this expression suggests, is the sound of the sense of touch.

We examine the time series data of piano play and compare Arthur Rubinstein [1887 - 1982] and Stanislav Stanislavovich Bunin [1966-] playing Chopin's Polonaisein A-flat major, Op.53 with WAV format file.

We split the data by 0.1 seconds each and used the mean of the differences in the data as the hardness and the standard deviation of the differences in the data as the roughness.

4. Discussion and Conclusion

Rubinstein is one of the foremost authorities on Chopin. On the other hand, Bunin's style of playing is extremely unique and different from Rubinstein's (Fig. 3).

Fig.3. Tactile qualities of piano play, above) R. Stein, bottom) S. S. Bunin, where the vertical axis illustrates softness (the graph origin shows the hardest and far more upper shows softer and the horizontal axis illustrates roughness, the origin is the smoothest and far from origin means rougher.

Tactile quality analysis of sounds distinguished the differences in play style. In original music analysis, for example, the power spectrum of sounds cannot clearly show the difference (Fig. 4).
Fig.4. Spectrum distribution of piano play, above) R. Stein, bottom) S. S. Bunin, where the vertical axis illustrates frequency, and the horizontal axis illustrates power.

Wojciech Kocyan is a Polish pianist. He is most well known for his performances of Chopin, and for his 2001 album, which was named as one of the 50 best classical recordings ever made by Gramophone in 2007. He mentioned about the play style of Bunin.

"there are laureates of the First Prize whose performance style does not fit easily into what would otherwise seem to be a quite clear picture of the stylistic preferences of Chopin Competition juries. They are the Russian pianists Stanislav Bunin (11th Competition, 1985) and Yulianna Avdeeva (16th Competition, 2010)." (from [2] p32).

Healthcare applications of vibrotactile stimulation developed by Tactile Score

Yasuhiro Suzuki

Nagoya University, Furocho, Chikusa-ku, Nagoya, 464-8601, Japan

Abstract

We constructed a system to convert the tactile score into vibratory tactile sensation. We conduct basic biological experiments on electronic tactile stimuli and apply the results to medical and healthcare applications. We use two types of electronic tactile stimuli. One is direct vibrating tactile stimulation, and the other is airborne vibrating tactile stimulation. Verification experiments of this system have confirmed cosmetic effects such as skin collagen aggregation, improvement of hypertension and diabetes, and reduction of pain and nerve paralysis. In addition, a clinical study was conducted in which patients with dementia were exposed to vibrotactile sensation (low-frequency sound) via air vibration and an improvement in cognitive function was confirmed.

Keywords: Healthcare, vibrotactile, Tactile score

1. Introduction

Our hands have great power. There is a word in Japanese called, "Te-arte [1]". This word is the English term for "hand healing," or healing by laying one's hands on someone. In Japan, hand healing has been valued since ancient times.

It seems which is not limited in Japan. Dr. Abraham Varghese, a physician and professor at Stanford University Medical School, gave a TED Talk in 2011 titled "A doctor's touch," in which he emphasized that, the importance of healing through the doctor's touch. He addressed that:

"*the most important innovation in medicine, to come in the next 10 years, that is, the power of the human hand -- to touch, to comfort, to diagnose and to bring about treatment* [2]".

The sense of touch is the earliest of the five senses to develop, which is developmentally and biologically fully formed at birth. A baby's sense of touch at birth, is said to be superior to that of an adult.

However, the science and technology of the sense of touch is, still in its developmental stage compared to the other senses. For example, the senses of audiovisual, smell and taste have their own "products". What about touch? Can you think of some products based solely on the sense of touch? There is a product that people have used since time immemorial, across cultures and customs, that is based solely on the sense of touch. It is the massage. The mural paintings on the tombs of doctors from the Egypt period, depict a massage that is familiar to us today. We may have yet to develop massage techniques for more than 4000 years.

2. Methodology

We have studied massage and proposed a method for describing the sense of touch called the Tactile Score. In our previous research, we found that tactile sensation can only be expressed by the change in vertical force. So, we decided to describe only the change in vertical force over time. It is like describing music only in terms of pitch changes.

2.1. Tactile Score

Why do we feel "cheer" from the children's "Good morning"? What is the difference between them? The difference is "the way you say it. How we say it can be characterized by the pitch and volume of our voice, but let us look at the volume of our voice.

Yasuhiro Suzuki

When we think back to the children's "Good Morning," their voices gradually became louder and louder. So, let us describe the change in "loudness" by using the music notation. In musical notation, the higher the note is, the lower the note is, and the higher the note is, the lower the note is. The middle line (the third line) is the "normal" volume, and the lower the volume, the higher the volume, and the higher the volume, the lower the volume. The "rhythm of speech" is represented by the notes as they are. We call this notation to describe tactile sense as the Tactile Score [3] (Fig. 1)

Fig. 1 Tactile Score

2.2. Transform Tactile Score into Vibrotactile

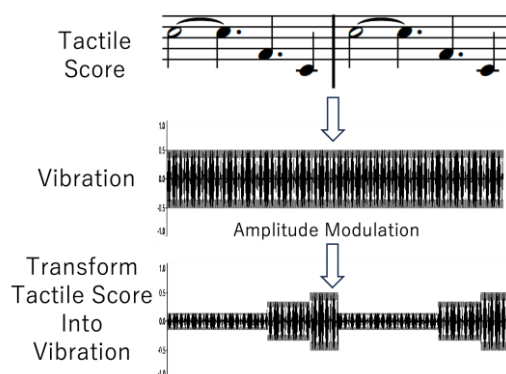
Tactile score was for mainly hand massages. Hand massage has long history, and its effectiveness has been confirmed. However, its effectiveness would be affected by skill of technician and even if well trained and experienced technician, it is impossible to give massage to more than two persons at the same time. And also, it is also very difficult to confirm that the technician gives exactly same tactile stimulations to patient.


Fig. 2 Transform Tactile Score into vibrotactile

To solve the difficulties, we transform the Tactile score into vibrotactile. Since the Tactile score denotes the strength of force, we transform the force into the amplitude of vibration. Hence, we found that applying amplitude modification with the Tactile score can

transform a Tactile score into a vibrotactile. Since a vibrotactile is a very low-frequency sound, we can record it as a music file in WAV or MP3 format. Hence, we can exchange a vibrotactile translated from a Tactile score via the Internet of electrical files.

By this Tactile score - vibrotactile translation, we can transform tactile stimulation by human hands into electrical data; this technique gives us the way to the digital transformation of tactile sense, tactile DX.

We obtained a Tactile Score, which is converted to vibrations. In order to confirm that this transformation works correctly, the biological responses of the vibration transformed from a Tactile score were compared to a hand massage using the same Tactile Score. Then, we confirmed that the transformed vibration shows almost the same biological response. So, we obtained a method which allows a skilled technician's massage to be converted to a vibratory massage using the Tactile Score (Fig. 2).

We had a method to convert tactile sensations into vibrations but no general-purpose equipment to replay the vibrations. Therefore, together with electrical and audio equipment manufacturers, we developed a general-purpose, face-shaped vibration presentation device (Fig. 3). This device allows users to receive massages by distributing tactile sensations online. We are starting a pilot service of internet delivery of vibration massage around 2019, and more than 1,000 users are already using the service.
Fig. 3 General-purpose vibrotactile display players; left) for face, right) for body.

With using this equipment, in order to verify the effectiveness of the vibrating massage, we compared the skin condition before and after the treatment. We examined that collagen fibers had agglomerated on the skin surface. It has known that the collagen fibers sink from the surface of the skin due to ageing and other factors, but by applying transformed vibration, they rose to the surface of the skin.

3. Preliminary Results

We are now analyzing test data from users of our Internet massage delivery system who visit hospitals for hypertension and diabetes before and after receiving the vibration massage service. We have just started the analysis and are surprised at the results. One user who was taking medication for hypertension, had stopped taking the user's hypertension medication. Because the user's blood pressure became lower and felt terrible after the user started the vibration massage. Now, the user's blood pressure has stabilized in the normal range without medication. We have confirmed several such cases. Since blood pressure is subject to seasonal fluctuations, we will continue to monitor it over a long period.

In addition, users who had high blood glucose levels and were scheduled to apply insulin, have stabilized their blood glucose levels at normal levels, after starting vibration massage. We have monitored this user's blood glucose levels regularly. We have observed that when the user skips the use of vibratory massage, the blood glucose levels rise again.

4. Conclusion

Our survey of past literature shows that when wounded soldiers were transported in horse-drawn carriages for long periods during the Greek period, their wounds healed faster. Also, in the 18th century, it was confirmed that patients with Parkinson's disease improved their motor functions when transported in a carriage for long periods.

From the survey, our findings in preliminary results would be a rediscovery of the wheel. Vibrotactiles had been utilized in medicine before World War II and were once forgotten. However, in the 21st century, vibrotactile has been rediscovered and applied in medical treatments; at Tronto University, a vibration chair has been used to treat patients with dementia and Parkinson's, and also vibroacoustic therapy has been used in northern Europe or Germany.

The main difference between our method and others is the Tactile score. Other methods have focused on sound or music, while we have been interested in tactile stimulation. Hence, we have focused on how to design the tactile stimulations.

Abstract

In recent years, in Japan, with the decline in the working population, there has been a noticeable shortage of labor at construction sites and offshore operations. On the other hand, with the aim of realizing a GX society, it is expected that offshore wind power generation platforms will rapidly increase and be deployed offshore. Since it is not easy to access offshore platforms, it is necessary to automate equipment inspection work, and it is expected that the use of AUVs will be particularly desirable for underwater inspection work. The most basic inspection work is assumed to be to collect images of underwater structures. Therefore, in this study, we created an AUV and conducted an image collection experiment using a pier owned by our university as an example to confirm its functionality.

Keywords: Offshore wind firm inspection, AUV, Underwater image

1. Introduction

In recent years, the worldwide development of wind-power generation has been expanding and the development of offshore wind power is booming in some areas because the construction site of onshore wind power is saturated. For example, in Europe, due to saturation of onshore wind power sites, it is expected that the installation capacity of offshore wind firms will continue to increase, under the condition that the European Union aims at reaching about 100 GW of offshore wind capacity by 2030 [1].

In Japan, the goal of either reducing greenhouse gas emissions to virtually zero or becoming carbon neutral by 2050 was set by the Cabinet recently. In 2020, the government released its "Green Growth Strategy for Carbon Neutrality by 2050", which sets 14 action plants that Japanese industries should start making efforts to realize the net zero society. Under this strategy, wind power is considered very important and set as one of the 14 action plans, with the goal of introducing 10 GW of offshore wind power by 2030 and 30–45 GW by 2040. Since Japan's topography has few open plains, to achieve this ambitious goal, accelerated development of offshore wind firm is required [2] and many offshore platforms will be installed off the coast of Japanese islands.

These offshore wind power platforms will be located far from the shore and accessing many platforms will not be easy. Generally, when maintaining offshore wind power facilities, some specialized crews have to be transferred to the platform using a CTV (Crew Transfer Vessel). If one platform can generate 10MW power, then around 4000 platforms must be installed to achieve the 40GW goal. In that case, it is not hard to imagine that maintenance costs will become huge because an operator must hire CTVs which goes around those platforms. So our concept is such that each platform should be equipped with a unmanned inspection robotic system which performs base inspection menus like taking images from underwater structures to up water windmill structures.

Image collection is one of the basic inspection menus for offshore structures such as harbor structures [3]. Underwater structures are damaged by long-term use and may be corroded by salty sea water. So, inspection process should be performed to check the safety of the structures. The regular safety inspection is very important to prevent collapse accidents. The conventional inspection of harbor structures used to be carried out by professional divers. However, recently, the aging of professional divers and the lack of successors have become a very critical issue in Japan. Also, while port structure is shallower than approximately 20m, structure of an offshore wind platform like a semi-sub column is likely to be deeper than 30m, which makes divers limit their activities in both time and space.

ROVs are widely used for offshore platform inspection [4], where it is assumed that an operator will operate the

Keisuke Watanabe, Koki Amano, Shingen Urano, Yasutaka Taniguchi, Konosuke Watanabe

system by monitoring underwater camera images. In out concept, the inspection procedure must be performed unmanned, so even if the vehicle has a tether cable, the system should be developed as autonomous.

2. AUV System Development

2.1. *System architecture*

An external view of the developed AUV is shown in Fig. 1. It has two pressure-tight vessels, one for the control system and the other for the battery. A total of 6 thrusters are installed, 2 each in the Surge, Sway, and Heave directions. The camera to capture images of the structure is installed inside the acrylic window in front of the upper hull and has a tilt mechanism. It is equipped with sonar to detect obstacles in front and to the sides. A DVL is attached to its bottom to measure altitude above the ocean floor and speed over the ground. The battery is stored in the lower hull, and buoyancy material is placed above to improve self-stability in roll and pitch. This AUV is a prototype for developing various control programs through experiments at sea, and was designed to have an air weight of approximately 120N to make it easier to handle on land. The dimensions of the AUV is shown in Fig. 2.

The architecture of the control system is shown in Fig. 3. This AUV is equipped with two microcomputers. One computer was designed to mainly control input and output of sensors and actuators, and the other computer was designed to control trajectory generation, control mode switching, and image acquisition. It has both wireless LAN and wired LAN, and when a tether cable is attached, it can be used so that it can be connected to a USV or land-based computer and operated in ROV mode. When surfacing and GNSS is available, it navigates using GNSS coordinates, and when it starts diving, it uses dead reckoning from the GNSS coordinates just before diving.

2.2. *Control algorithm*

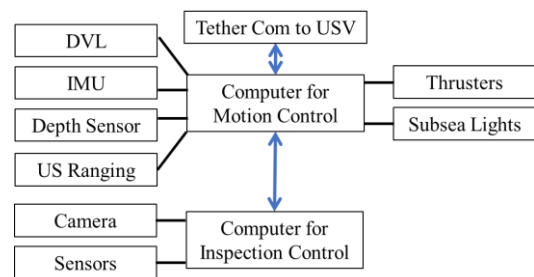
To implement the control algorithm, we assumed that the motion in the horizontal plane and the vertical motion can be separated because when the velocity is small, the
Fig. 1. External view of the AUV
Fig. 2. Dimension of the AUV


Fig. 3. Control system architecture
Fig. 4. The coordinate system for horizontal motion

motion in the heave direction has little effect on the motion in the horizontal direction. The coordinate system is set as shown in Fig.4. The coordinate system is a space-fixed coordinate system (O-XY) based on latitude and longitude, and a vehicle-fixed coordinate system (G-xy). G is the vehicle center of gravity. The longitudinal direction of the vehicle is the x-axis and the north is the x-axis. Let the angle formed by the X-axis and the x-axis be the azimuth angle ψ. ψ is positive when clockwise from the north. Space fixed Z axis and vehicle fixed z axis is set as vertically downward to form the right-handed system.

The AUV's equation of motion includes a second-order fluid force term and is nonlinear, but since the speed here is slow, the fluid force is linearized by a representative speed, and the linearly approximated equation of motion is used as the dynamics model. Based on the linearly approximated dynamics model, an optimal control

system of 1-type servo was designed and implemented. Here, the system matrix depends on the coordinate transformation matrix which consists of ψ. Since the coordinate transformation matrix changes according to the motion of the vehicle, it is controlled by solving the LQR problem for each step while updating the system matrix at each control step[5], [6].

2.3. *Sea experiment result*

To verify all functions we designed and implemented, we conducted a sea trial experiment at Tatsugo fishing port in Amami Oshima Island. The experiment site is shown in Fig.5. We set a trajectory along the quay of Tatsugo fishing port as shown in the blue line in Fig.5, and conducted an experiment in which we controlled the depth and azimuth while following this trajectory. The results of this experiment are shown from Figs.6 to Fig.9. The following control modes as shown in Table 1 were set for the trajectory tracking control, and the control mode was changed when the error from the control target value became less than the allowable value as shown in the column of the transition condition.

Table 1. Control modes set for the experiment.

Mode	Target	Transition condition
0	Azimuth ψ= 150 deg Depth = 0.5 m (X,Y)=(7.5cos ψ, 7.5sin ψ)	Error of (X,Y)<=1.0m Depth<=0.1m Then go to mode1
1	Azimuth ψ= 150 deg Depth = 0.5 m (X,Y)=(15cos ψ, 15sin ψ)	Error of (X,Y)<=1.0m Depth<=0.1m Then go to mode2
2	Azimuth ψ= -30 deg Depth = 0.0 m (X,Y)=(15cos ψ, 15sin ψ)	Error of (X,Y)<=1.0m Azimuth<=10 deg Then go to mode3
3	Azimuth ψ= -30 deg Depth = 0.5 m (X,Y)=(7.5cos ψ, 7.5sin ψ)	Error of (X,Y)<=1.0m Depth<=0.1m Then go to mode4
4	Azimuth ψ= -30 deg Depth = 0.5 m (X,Y)=(0,0)	Error of (X,Y)<=1.0m Depth<=0.1m Then go to mode5
5	Termination	Stop all thrusters

Fig.10 Concrete image captured by the AUV

As shown in those Figures above, despite model errors, all functions of the AUV operated smoothly, and the control mission set as shown in Table 1 was successful. Fig.10 shows an example of captured images of the harbor concrete structure. Because the sea was highly transparent, we were able to obtain relatively clear images. We plan to conduct further research and improve AUV functionality.

3. Conclusion

In this research, we developed an AUV platform and conducted trajectory tracking and image acquisition experiments with the goal of unmanned inspection of offshore wind power generation platforms. It was confirmed that trajectory tracking, azimuth, and depth control all functioned smoothly, and image acquisition surveys could be carried out by setting a trajectory.

Abstract

Researchers are conducting physical surveys by diving and swimming to study the effects of microplastics and global warming on coral reefs. The area, time, and water depth that can be investigated by diving are extremely limited. In addition, to collect microplastics, it is necessary to tow the nets, but chartering a ship is expensive. Therefore, the authors are developing a system that simultaneously operates a USV and a UUV to simultaneously observe the sea surface and underwater. In this paper, we conducted a conceptual design, carried out fluid force measurements, trajectory tracking experiments, and image recognition using AI, with the aim of realizing a lightweight USV that can be divided during transportation to coral reef areas and reassembled on site for operation.

Keywords: USV/UUV combined, Disassembly-reassembly type USV, Coral reef monitoring, AI image processing

1. Introduction

In recent years, marine plastic waste has been widely recognized as a global environmental problem. Because most plastics undergo very slow chemical or biological degradation in the environment, debris can remain in the ocean for years, decades, or even longer [1]. The term microplastic refers to very small and ubiquitous plastic particles less than 5 mm in diameter. They have been separated into different fractions: large (1–5 mm) or small (1 μm–1 mm) microplastics and the fraction below 20 μm (20 μm–1 μm) [2], [3]. Microplastics can adsorb and carry hydrophobic chemicals that can have biological and toxicological effects on the environment [4]. Therefore, a clear understanding of the interactions of small microplastics with the environment, especially living organisms, is essential to assess potential health hazards. To this end, it is important to have accurate methods to quantify the mount of such particles in natural environments. By monitoring the amount and characteristics of particles over time, along with the coordinates from which they were collected, it will be possible to define the extent of the effects they cause.

Additionally, by collecting small microplastics and identifying them at the single particle level, it will be possible to create some indicators regarding the potential impact of microplastics on marine biodiversity and their distribution in the ocean. Currently, there are two methods for collecting microplastics in coral reef waters: chartering a ship and towing the nets, or having people swim and tow the nets. The former requires the ship to be routed from the port to the collection site, and costs such as chartering fees are incurred. While the latter can be accessed directly from the beach, the area in which it can be retrieved is very limited.

With the goal of improving these shortcomings and efficiently collecting more microplastics in coral reef waters, we are developing a disassembly-reassembly type USV, which we will introduce in this paper. The USV under development will tow the net while automatically following a set trajectory by a biologist to collect microplastics. The time and trajectory of microplastic collection will be recorded by GNSS data. Since the work is intended to be carried out even on remote islands, we designed a structure that could be disassembled, transported by aircraft, etc., and reassembled on-site.

2. USV System Development

2.1. *System architecture*

An external view of the developing USV is shown in Fig.1. The dimensions of the USV is shown in Fig.2. As shown in Fig.1, this USV consists of four hulls. The size of the hull was determined to fit within the typical packaging size used in typical Japanese delivery services. As shown in Fig.2, the thruster, computer, and GNSS antenna are attached to the aluminum frame. The center of the hull has a large opening so that the USV can collect microplastics while navigating, and a net for collecting microplastics is attached to the rear of the USV. The hardware components of control system is shown in Fig.3. This USV is equipped with two microcomputers. One computer is for motion control, and the other is for image acquisition and processing. Image processing is supposed to be used for collision avoidance when the tide is low and the reef is exposed above the sea surface. As for the algorithm of trajectory tracking, we hire optimal control based 1-type servo [5].

2.2. *Drag force measurement of a hull*

In order to estimate the maximum speed of the USV and construct a nominal model for designing the optimal control system, it is necessary to estimate the drag force coefficient. Therefore, as shown in Fig. 4, the hull was set in a circulating water tank and the drag force was measured by varying the flow velocity and angle of attack. The flow velocity was increased every 0.2 m/s and was measured from 0.4m/s up to 1.0 m/s. The measurement results are shown in Fig.5. As the graph shows, it is almost parabolic, confirming that the drag force is proportional to the square of the flow velocity. The drag force coefficient when moving forward is estimated using the equation, where D is drag force, ρ is water density, A is representative area of the hull, u is velocity.

$$C_d = \frac{D}{\frac{1}{2}\rho A u^2} \qquad (1)$$
Fig. 1. External view of the USV
Fig. 2. Dimensions of the USV
Fig. 3. Control system architecture
Fig. 4. Hull drag force measurement.
Fig.5 Drag force result

The drag force coefficient became 0.18 in average.

3. Image Recognition Experiment Using AI

Since it is necessary to avoid obstacles during automatic navigation, we are considering an image object recognition function. We conducted an experiment using YOLOv5 using our university's pier column as an example. Fig.6 is an example of an image of the "pillar" labeling that YOLO is trained to learn. About 100 photos were taken to show the different shapes of the pillars on the quay and the changes in the exposed parts of the pillars due to the ebb and flow of the tide, and were used as training data. Fig.7 shows the results of image recognition based on the above learning. It can be seen that the pillars at the bottom of the quay could be recognized, but the probability of recognition was only about 60%, and when sailing from an angle, it was often not possible to recognize them. Fig.8 shows the results of learning by adding additional training data, including images from diagonal directions. The recognition rate was over 80%, and the pillars could now be recognized even in images viewed from an angle. Image recognition using AI is extremely important as a function of USV, and in addition to detecting obstacles, it may also be applied to recognizing coral reefs using underwater cameras in coral reef surveys. YOLO is a very powerful tool, but it is necessary to prepare various images as training data, and how to obtain images for learning at the first site is a future issue. One possible solution would be to fly a UAV (Unmanned Aerial Vehicle) in the research area and use the images captured by the UAV as learning data. Floating debris such as large pieces of wood or plastic bottles can break the microplastic mesh if the USV swims over them, so it must have a function to find them ahead and avoid them.

Fig.6 An image example for pillar labeling

Fig.7 An example of image recognition results

Fig.8 Improved recognition result after more learning

4. Trajectory Tracking Experiment

In order to confirm the resolution of GNSS and confirm the trajectory tracking performance, we conducted a trajectory tracking experiment using a catamaran-type USV that has been developed in our laboratory, rather than the USV currently under development. The results are shown from Fig. 9 to Fig.11. Fig.9 is a map of the trajectory in the actual ocean area. Fig.10 shows the results of thrust forces. Fig.11 shows converting the latitude and longitude to the XY coordinate system with the starting point as the origin. It was set to sail to the (-10,10) point and then return to the origin. On the day of the experiment, the wind was strong and there was some deviation from the straight trajectory, but we were able to confirm that it had sufficient performance to collect microplastics.

Fig.12 The total image of the USV

5. Summary

In this study, we designed a USV with the goal of automating and reducing the cost of microplastic collection in coral reef waters, which is currently done manually. A split-assembly type USV was designed to facilitate transportation to remote islands. The conceptual design drawing is shown in Fig.12. In order to realize the obstacle avoidance function through image processing, we implemented an object detection system using AI. In order to construct a nominal model for control system design, the hull's fluid force coefficient was identified through experiments using a circulating water tank. Through trajectory tracking experiments using existing USV, we have confirmed that trajectory tracking is possible within an error range of approximately 1m. We plan to conduct microplastic collection experiments.

Abstract

Aiming at the problem that the robustness of the classic visual SLAM system is greatly affected by dynamic target feature points in the environment, a method is proposed to use a target detection algorithm to identify and eliminate dynamic target feature points. First, use the target detection algorithm YOLOv5 to identify the collected environmental images, and select the surrounding environment. Objects identified as dynamic targets in the environment, and then the target detection results are integrated into the feature extraction of the visual SLAM front-end, the feature points belonging to the dynamic target part of the extracted image feature points are removed, and the remaining static feature points are used to map Construction and positioning, and finally testing on the TUM data set. The results show that after using the target detection algorithm to eliminate dynamic feature points, the root mean square error of the absolute trajectory error of the visual SLAM system in highly dynamic scenes is reduced by 97.89%, effectively improving the positioning accuracy and robustness of the system.

Keywords: Visual SLAM, Deep learning, Feature detection, Position estimation, YOLOv5

1. Introduction

With the development of autonomous mobile robot platforms, robots are widely used in areas such as search and rescue operations or delivery services required at industrial sites and hotels. In these scenarios, the robot needs to understand the entire area and the precise location of the target object in the map based on the map to complete autonomous navigation. In order to achieve autonomous navigation, mobile robots need to complete two tasks: attitude estimation and map construction. Therefore, Simultaneous Localization and Mapping (SLAM) is one of the research hotspots in the field of mobile robots. It is a robot that only relies on its own sensors to obtain external information of the unknown environment to complete pose estimation and build an environment model. Technology. This technology is currently widely used in agriculture, disaster relief, auxiliary medical and other robotic fields. According to the different sensors used, SLAM is divided into visual SLAM and laser SLAM. Visual SLAM uses cameras mounted on the robot as sensors, including monocular, binocular and depth cameras. Compared with lidar, cameras are cheaper and more convenient to install and debug. Moreover, cameras can collect more semantic information in the environment. Therefore, visual SLAM has gradually become a major research hotspot in the field of autonomous navigation of mobile robots.

2. Problem Description

2.1. *Overview of visual SLAM technology*

In recent years, various visual SLAM (Simultaneous Localization and Mapping) techniques have emerged, such as ORB-SLAM, ORB-SLAM2, VINS Mono, RTABMap, PTAM, LSD-SLAM, DSO, among others, playing a crucial role in the field of autonomous robot navigation [1]. The general algorithmic process of visual SLAM begins with the acquisition of images using a camera to generate a sequence of images. Subsequently, features are extracted from adjacent frames, and the motion of the camera is estimated by minimizing pixel intensity values through feature point matching. Pixel matching methods between images include optical flow and direct methods. Optical flow involves extracting image feature points and estimating camera motion using triangulation or Epipolar Geometry. Direct methods, on the other hand, directly use pixel blocks or extract image corner points to calculate motion estimation based on grayscale values.

Following the motion estimation, noise is filtered from the data to obtain the optimal pose estimation. Maximum a posteriori probability is then used to estimate the global map. Campos et al. [2], building on the research by Artal et al., released ORB-SLAM3 in 2020, which is a feature-based SLAM system and currently represents a notable approach in the field.

2.2. *Impact of Dynamic Points on Visual SLAM*

ORB-SLAM3, as one of the classic algorithms in visual SLAM, consists of two main components in its algorithmic pipeline: the front end and the back end. The front end, also known as visual odometry, processes captured images through feature extraction and matching. It solves the Epipolar Geometry relationship between corresponding feature pixels, thereby estimating the pose parameters of camera translation and rotation. The back end includes nonlinear optimization, map estimation, and loop closure detection. Nonlinear optimization, differing from the previous use of Kalman filtering, employs Bundle Adjustment (BA) to simultaneously optimize the six degrees of freedom of camera pose parameters and the poses of landmarks in space.

The effectiveness of the Bundle Adjustment (BA) method in optimizing camera pose results depends on whether the extracted matching feature points from the captured images exclusively static object features are. However, real-world robot operating environments often include dynamic objects. In scenarios with dynamic targets, both feature-based SLAM algorithms and direct methods SLAM algorithms struggle to differentiate between feature types in regions with moving objects. The matching points of dynamic target feature points can lead to misalignments, resulting in reduced accuracy in the front-end visual odometry's estimation of camera pose. This, in turn, causes a loss of camera pose tracking, leading to significant deviations between the robot's motion trajectory and the constructed environmental map.

3. Elimination of the dynamic points

3.1. *Dynamic SLAM based on geometric methods*

Currently, there are two main methods for mitigating the impact of dynamic target feature points in detection scenes. One approach is the traditional geometric-based method. Sun et al. [3] detect moving objects by comparing differences between adjacent frames, but this method suffers from poor real-time performance. Wang et al. [4] filter matching feature points in adjacent frames using Epipolar Geometry. They also perform clustering on depth images collected by RGB-D cameras to identify independent dynamic objects in the scene. The accuracy of this algorithm is significantly influenced by the pose transformation matrix between adjacent frames. If there are many highly dynamic objects in the scene, it can lead to substantial algorithmic errors. Lin et al. [5] use a fusion of image depth information and visual ranging to detect moving objects. While this approach can determine the position of moving targets in the scene, the algorithm's accuracy is compromised due to the uncertainty of depth information and cumulative errors in calculating the transformation matrix between adjacent frames.

The underlying principle of these methods assumes that the feature points of dynamic objects deviate from the standard constraints obtained in a static scene through processes such as triangulation, fundamental matrix estimation, epipolar lines, and reprojection error. During the pose estimation process, these dynamic feature points are treated as outliers. The correctness of feature matching can be determined by examining whether the extracted feature points violate these constraints, and dynamic points are subsequently excluded. However, the accuracy of this method depends on the proportion of static feature points in the scene. In scenarios with a high density of dynamic objects, it can significantly impact the reliability of pose estimation and the accuracy of map construction.

3.2. *Dynamic SLAM based on deep learning*

With the development of deep learning, many researchers have introduced deep learning algorithms into visual SLAM to mitigate the impact of dynamic targets and improve its accuracy. The DynaSLAM (Dynamic SLAM) algorithm proposed by Berta Bescos et al. [6] optimizes ORB-SLAM2 using Mask R-CNN (Region-based Convolutional Neural Network). By combining geometry with deep learning, DynaSLAM filters out dynamic feature points in the scene. The algorithm has shown excellent results on the TUM dataset, but its use of Mask R-CNN for pixel segmentation leads to low real-time detection efficiency, limiting its practical application in real-world environments. DDL-SLAM (Dynamic Deep Learning SLAM) [7] uses DUNet (Deformable Unity Networking) and semantic masks obtained through multi-view geometry to detect dynamic objects. It then employs an image restoration strategy to reconstruct the background obscured by dynamic objects. Since the calculation of dynamic object masks occurs at the pixel level, this method also falls short of achieving real-time performance. In contrast to Mask R-CNN, another more efficient object detection model is YOLOv5 (You Only Look Once Version 5) [8]. YOLOv5 achieves detection speeds of up to 45-155 frames per second (fps), which is 9-30 times faster than the maximum 5 fps achieved by Mask R-CNN. If the results of YOLOv5's object detection can be integrated into dynamic visual SLAM algorithms, it can partially compensate for the low efficiency of Mask R-CNN.

To address the issue of reduced localization accuracy and robustness of visual SLAM in dynamic environments due to the influence of dynamic targets, this paper introduces a target detection thread based on the ORB-SLAM3 algorithm to detect dynamic targets. Using the YOLOv5 target detection network to identify objects in input images, the semantic information of dynamic target objects in the images is determined. Additionally, while visual SLAM extracts feature points in the front end, a module is added to the tracking thread of visual SLAM to eliminate dynamic feature points based on the results of

target detection. Finally, only the remaining static feature points are used to estimate the pose change matrix between adjacent frames, reducing the impact of dynamic targets. This ultimately achieves high-precision estimation and localization of the environmental trajectory. The improved algorithmic flowchart is shown in Fig.1.

4. Experimental verification and result analysis

4.1. *Experimental environment construction and data set selection*

his experiment involved testing the optimized visual SLAM system proposed in this paper using video sequences from the TUM dataset. The experimental results were analyzed to evaluate the localization accuracy of the SLAM system. The experiments were conducted on the Ubuntu 20.04 operating system, with a 12th Gen Intel(R) Core(TM) i9-12900H 2.50GHz CPU, an NVIDIA GeForce RTX 3060 GPU with 12GB of VRAM, and the PyTorch deep learning framework. The algorithm's performance was tested on the fr3_walking_xyz, fr3_walking_half, and fr3_walking_static dataset sequences. The fr3_walking_xyz dataset depicts two individuals walking and conversing in a fixed scene, with both the camera and people in motion, representing a high-dynamic scene. The fr3_walking_half dataset builds upon this by having the camera move along a semi-circular trajectory in the air. The fr3_walking_static dataset, on the other hand, features relatively stationary objects, representing a low-dynamic scene.

4.2. *Visual SLAM front-end feature extraction effect after integrating YOLOv5*

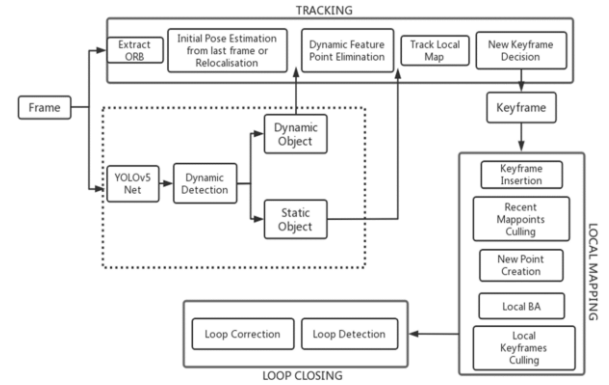
Capturing a frame for comparison with the original ORB-SLAM3 algorithm's front-end feature extraction, the results are illustrated in Fig. 2. The lower image shows the feature extraction before integrating YOLOv5, while the upper image demonstrates the effect after fusion. It is evident that the visual SLAM front end, after integrating YOLOv5, accurately identifies objects such as people and computers. It successfully removes feature points on the dynamic target "person" while retaining feature points on the static object "computer" within the detected bounding box of the dynamic target. This refinement enhances the precision of the results.


Fig.1 Algorithm framework

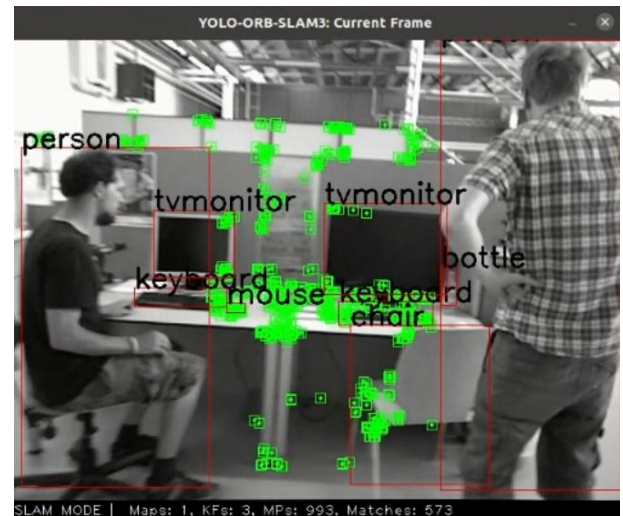
4.3. *Experimental data indicator analysis*


a.   Fusion algorithm

b.   Original algorithm

Fig.2. Comparison of front-end feature extraction results before and after integrating YOLOv5

Absolute Trajectory Error (ATE) describes the difference between estimated poses and ground truth poses, providing an intuitive expression of the algorithm's

Yufei Liu, Kazuo Ishii

global performance and accuracy. Relative Pose Error (RPE) calculates the differences in pose at the same timestamps, typically used for estimating odometry errors. The Root Mean Square Error (RMSE) is then employed to compute the overall value of this error. ATE and RPE are two parameters that reflect the robustness and stability of a visual SLAM system [9]. A lower RMSE value calculated from ATE and RPE indicates a better fitting performance.

Capturing a frame for comparison with the original ORB-SLAM3 algorithm's front-end feature extraction, the results are illustrated in Fig. 2. The lower image shows the feature extraction before integrating YOLOv5, while the upper image demonstrates the effect after fusion. It is evident that the visual SLAM front end, after integrating YOLOv5, accurately identifies objects such as people and computers. It successfully removes feature points on the dynamic target "person" while retaining feature points on the static object "computer" within the detected bounding box of the dynamic target. This refinement enhances the precision of the results. The improvement of the ATE and RPE performance of this algorithm compared with the original ORB-SLAM3 algorithm is shown in Table.1 and Table.2.
Table.1 ATE performance comparison
Table.2 RPE performance comparison

This indicates that the proposed algorithm not only enhances the detection capability in dynamic environments but also preserves the accuracy of map construction and localization in static scenes, as achieved by the original ORB-SLAM3 algorithm.

Abstract

Based on the study of the kinematic limitations of the rigid manipulator structure and the characteristics of the existing flexible manipulator in different categories, this paper proposes a structure assumption of flexible manipulator based on the advantages of high load of rigid joint and high flexibility of flexible manipulator. This paper designed a flexible manipulator structure driven by wires. Using the forward kinematics analysis, the sport model of the structure. The motion range of the end of the manipulator arm and the length changes of the wires were simulated with the movement of the model.

Keywords: Flexible manipulator, Wires driven, Kinematic model

1. Introduction

With the development of science and technology, rigid robot devices have been widely used in social production activities. It is well known that the industrial robot is applied in the manufacturing industry. The rigid manipulator consists of a rigid connecting rod connected by a rigid motion pair, which can quickly and accurately complete the corresponding control tasks [1]. However, due to the rigid structure of the manipulator, its flexibility is poor, and it cannot work properly in the complex and changeable environment. Its structural characteristics limit its application in dangerous and complex environments, such as exploration and disaster relief, nuclear power hazard management, space missions and other environments. If the manipulator is to be applied to the above engineering fields, it needs to meet the requirements of safe interaction between the machine and the environment, safe human-computer interaction, high flexibility and intelligence. The flexible manipulator is made of soft materials. Compared with the rigid robot, the manipulator has the characteristics of multiple redundant degrees of freedom, flexibility and safe human-computer interaction. Its characteristics greatly make up for the shortcomings of rigid robots, so it has been widely concerned and studied by scholars and institutions [2].

2. Classification of prior research

The development status of flexible manipulator is introduced according to the driving mode classification. The flexible manipulator is divided into the following driving modes: SMA driven, pneumatic - hydraulic driven, and wire driven, etc.

2.1. SMA driven

SMA, full of Shape Memory Alloys, can be heated to eliminate the deformation of alloys at a lower temperature, making it revert to the initial state and achieving the effect of "memory". It can be driven by direct heating of current, and its deformation can be controlled by heating and cooling. It has been widely used in aerospace and industrial intelligent manufacturing. As shown in the Fig.1, the manipulator can realize large spatial bending and complete the grasping action of different positions.

Fig.1 SMA flexible mechanical arm [3]

2.2. Pneumatic-hydraulic driven

Pneumatic or hydraulic driven respectively use compressed air and hydraulic oil as the power source of the mechanical arm bending. Pneumatic - hydraulic driven manipulator is usually made of elastic material as the main body, surrounded by a driving cavity. The bending of the manipulator can be realized by changing the volume deformation of the driving cavity by changing the input of the power source as showed in Fig.2. When the inner rubber air bag is filled with compressed air, the internal pressure rises, the inner rubber air bag expands along the radial direction, and then the force transmission

effect of the outer fiber is transformed into the axial contraction force to achieve the driving effect.

Fig.2 Pneumatic driven flexible manipulator [4]

2.3. *Wire driven*

Wire driven is a popular driving method for flexible manipulator. The bending motion of the flexible arm is generally realized by the stretching of the wire driven by the motor. The wire driven flexible manipulator is driven by the wires embedded in the interior of the flexible manipulator to realize the deformation movement of the flexible manipulator as showed in Fig.3. Usually, mechanical equipment such as motor is used to generate traction on the wire. The wire embedded in the flexible manipulator with eccentric eccentricity generates axial force on the manipulator while generating bending moment on the neutral surface, making the flexible bending motion of the manipulator.
Fig.3 Wire driven flexible manipulator [5]

3. Model scheme

The flexible robot arm is composed of three layers of single-section robot arm, the height of the single-section robot arm is 200mm, and the height of the entire robot arm is 600mm. The central flexible column is a soft plastic material with good flexibility and bearing capacity. The hardness and elastic modulus of soft plastics can be controlled by additives to adapt to different application scenarios. The flexible column is used as the main body

of the flexible manipulator. The flexible column is non-stretchable, incompressible and can be twisted arbitrarily. Bend the flexible column by tensing and relaxing the three driving wires to tilt the support plate. The outer part is covered with a spring to protect the flexible manipulator. The single-section mechanical arm is shown in Fig. 4. Integrated model scheme is showed in Fig.5.
a.   A single segment robotic arm in an upright position
b.   A single segment robotic arm in a bent position
Fig.4 Single segment robotic arm
Fig. 5. Integrated model scheme

4. Kinematic analysis of model

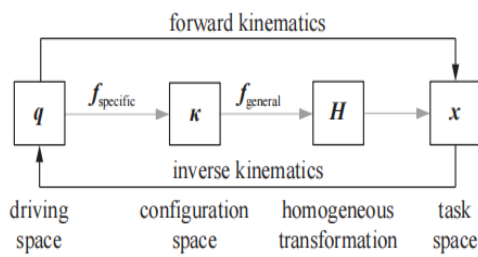
The spatial mapping relationship of the robot arm is shown in Fig.6. This paper analyzes the kinematics model of the flexible manipulator through forward kinematics. The forward kinematics analysis of the manipulator arm is to calculate the end pose of the manipulator arm according to the information of the driving space.


Fig.6 Spatial mapping of kinematic [6]

4.1. *The mapping relationship from driving space to configuration space*

According to the length variation of three wires, the bending angle θ and the rotating angle α and radius of curvature R of the mechanical arm are solved by geometric method. The solution method is to establish a set of equations by using bending angle θ, rotating angle

α and curvature radius R to represent the corresponding arc length and chord length of the projection of the line from the anchor point of the lower support disk to the curvature radius of the single-section mechanical arm, so as to obtain the array of bending angle $θ$ and rotation angle $α$ and curvature radius R represented by the length of the driving wires .The mapping relationship from driving space to configure space is Eq.(1).

$$\begin{cases} \alpha = \arctan\dfrac{\sqrt{3}(H_1 - H_2)}{H_1 + H_2 - H_3} \\ \theta = \arcsin\dfrac{\sqrt[2]{H_1^2 + H_2^2 + H_3^2 - H_1H_2 - H_2H_3 - H_3H_1}}{6r} \\ R = \dfrac{(H_1 + H_2 - H_3)r}{2\sqrt{H_1^2 + H_2^2 + H_3^2 - H_1H_2 - H_2H_3 - H_3H_1}} \end{cases} \quad (1)$$

4.2. *The mapping relationship from configuration space to task space*

Solving the mapping relationship between configuration space and task space that is the homogeneous transformation matrix from local reference frame to global reference frame is solved. Matrix elements are composed of configuration variables α、 θ and R. The solution is to use the D-H method, and the transformation relationship between the coordinate system from the lower support disk to the upper support disk is regarded as a series of sequential rotation and translation results.

D-H method (Denavit-Hartenberg method) is a matrix general method for establishing the relative position and attitude relationship of serial robots. It uses four parameters of connecting link length, joint angle, link offset and link twist to describe the structure and kinematic relationship of the series mechanism. These four parameters are collectively referred to as D-H parameters. The spatial geometric relation of each link relative to the fixed reference coordinate system is described by homogeneous transformation, and the spatial geometric relation between two adjacent links is expressed by homogeneous transformation matrix. The equivalent homogeneous coordinate transformation matrix of the end actuator coordinate system relative to the base coordinate system can be derived by the homogeneous transformation, and the kinematics equation of the robot can be established [7]. Generation steps of homogeneous transformation matrix is showed in Fig.7.
Fig. 7 Generation steps of homogeneous transformation matrix

The final homogeneous transformation matrix from configuration space to task space is Eq. (2), Eq. (3) is the rotation matrix. Eq. (4) is the translation matrix.

$$H(k) = \begin{bmatrix} \theta(k) & \Psi(k) \\ 0 & 1 \end{bmatrix} \quad (2)$$

$$\theta(k) = \begin{bmatrix} cos^2\alpha cos\theta + sin^2\alpha & cos\alpha sin\alpha(cos\theta - 1) & cos\alpha sin\theta \\ cos\alpha sin\alpha(cos\theta - 1) & sin^2\alpha cos\theta + cos^2\alpha & sin\alpha sin\theta \\ -cos\theta sin\alpha & -sin\alpha sin\theta & cos\Theta \end{bmatrix} \quad (3)$$

$$\Psi(k) = [Rcos\alpha(1 - cos\theta) \quad Rsin\alpha(1 - cos\theta) \quad Rsin\theta] \quad (4)$$

5. Flexible manipulator motion space simulation analysis:

The motion space diagram of the single-section flexible manipulator is shown in Fig.8.
Fig. 8 Space analysis diagram of flexible manipulator motion

The red part OO_1 of the circular arc represents the continuous flexible body. The head end point O is the fixed point, and the end point O_1 is the free moving end. Let the length of the continuous flexible body (spring) be L. The arc OO_1 corresponds to the chord length d. When the continuous flexible body is not subjected to external forces, its initial state is reconnected with the Z-axis. The angle between the projection of arc OO_1 on the *X-O-Y* plane and the positive direction of the *Y*-axis is set as α, and the angle between string d and the positive direction of the *Z*-axis is set as θ.

The free end point O_1 of the center line of the flexible arm is obtained. The expression in the coordinate system is Eq.5. The bending Angle is 0 to 90° and the rotation Angle is 0 to 360°.

$$\begin{cases} x = \dfrac{L}{2\theta}(1 - cos2\theta)sin\alpha \\ y = \dfrac{L}{2\theta}(1 - cos2\theta)cos\alpha \quad (5) \\ z = \dfrac{L}{2\theta}sin\theta \end{cases}$$

The length L of the prototype single section flexible arm in the natural state is set to 200mm, and the end point motion relation is obtained by using MATLAB to get the end point motion range diagram (Fig.9).
Fig. 9 Flexible manipulator motion space simulation

6. The simulation of length changes of the wires:

The vectors representation of the driving wires is obtained by superposition of the vectors, and then the maximum wire length variation of the single flexible arm is obtained by solving the modulus of the vector. The activity limit of the initial single-section mechanical arm is the rotation angle 0°-360° and the bending angle 0°-90°. Through simulation analysis in Fig.10, when the bending angle is 90° and the rotation angle is from 0° to 360°, the length of the drawstring changes the most. The simulation results are shown in the figure below. The maximum variation value of wires length of single section manipulator is about 95mm-265mm.
Fig. 10 The simulation of length changes of the wires

Abstract

Drowsiness driving will pose a serious threat to the lives of drivers and others. Determining the state of the driver through face recognition has the advantages of low cost and convenience. Therefore, this study deploys the face recognition model to the mobile phone, and finally realizes the recognition of the driver's Drowsiness by the front camera of the mobile phone. The whole research is divided into three parts. The first part is to train the face 68-keypoints recognition model based on the YOLO face algorithm. The second part is to deploy the trained model to the mobile phone using ONNX and NCNN. The third part is to calculate EAR and MAR using several facial key points, and finally complete the recognition of the driver's drowsiness state using EAR and MAR.

Keywords: YOLO face, ONNX, NCNN, EAR (Eye Aspect Ratio), MAR (Mouth Aspect Ratio)

1. Introduction

Nowadays, the car has become an indispensable means of transportation, but at the same time, driver drowsiness driving this dangerous driving behavior is common, the driver himself and others have brought indelible damage. Drowsiness driving is due to the driver's high-intensity, long time driving, resulting in excessive energy and physical exertion, and then the reaction ability and control level decreased, affecting the normal driving operation of the situation. The probability of a driver causing a traffic accident in drowsiness increases dramatically. In Canada, more than 20% of traffic accidents involve drowsiness driving. Surveys also show that 20% of traffic accidents in the United States involve drivers who are in drowsiness [1]. Therefore, it is important to study driver behavior and state recognition methods to alert and intervene when dangerous situations occur, to ensure the safety of drivers themselves and other people and vehicles on the road.

The current objective detection methods for drowsiness driving are mainly divided into based on driver physiological parameters; based on driver operating behavior; and based on vehicle driving information. In 2007, Yamaguchi et al. extracted amylase from the driver's saliva and determined whether the driver was in a drowsiness state by analyzing the changes in its composition [2]. In 2013, Mbouna et al. extracted the driver's eye state and pupil movement state as driver fatigue features and used SVM to classify the driver's drowsiness state, achieving a good recognition effect [3].

Mott G E et al. concluded that the angle of the driver's steering wheel and the lateral position of the vehicle had the highest correlation with drowsiness driving by comparing 87 vehicle parameters related to drowsiness driving in waking and moderate fatigue states [4].

As far as current research is concerned, recognition and early warning through physiological parameters is easy to interfere with normal driving and affect the drowsiness change process; identification through vehicle driving information is subject to factors such as driver skills and road conditions, and the recognition accuracy is relatively low. The drowsiness recognition method based on the driver's behavior and state has the characteristics of low equipment cost and non-invasiveness. At present, the recognition of driver characteristics is mainly concentrated in areas such as eyes, mouth and so on. At the same time, the use of cameras for face recognition also needs to consider the impact of changes in light on the recognition ability of the model.

Methods of drowsiness recognition based on face can be divided into two types. One is based on the entire image. In this method, the model will infer and recognize the entire image, and then crop the different facial feature areas. The other is based on facial feature points. The model will annotate the specified number of key points on the entire image, and then infer facial features based on the relationship between key points. Currently, the most common key points annotations include 98 key points, 68 key points, and 29 key points. This study chooses to use the most common 68 key points for model modification and dataset building.

Shi Puwei, Kazuo Ishii

In summary, this study aims to recognize the facial feature points of drivers through computer vision methods, establish a driver fatigue recognition method, and complete the deployment of the model on the smartphone side.

2. YOLO Face-based Face Recognition Model

2.1. *Yolo Face*

YOLO is a classic one-stage target detection algorithm based on CNN (Convolutional Neural Network). The original YOLO algorithm does not contain key points detection. It can only annotate target objects on images with bounding boxes. Later, some authors developed YOLO pose for human pose detection based on YOLO. YOLO pose adds 17 human body key points detection based on YOLO. The YOLO face used in this study is based on YOLO pose, changing the 17 key points to five key points regression. YOLO face treats face detection as a general target detection task. Therefore, its network structure is not much different from the overall YOLO pose, using only some special network modules to replace the modules in the original structure [5].

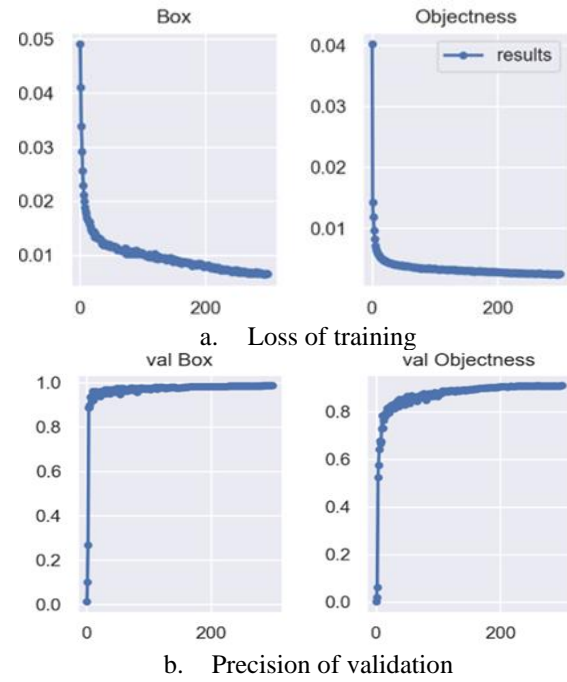
The original YOLO face includes only 5 key points detection. This study chooses to use 68 key points for extracting face-related features. Therefore, the original YOLO face needs to be modified. The modification is mainly reflected in the data structure. The data structure of each target in the original is a vector of length 16. The length of data vector modified is 138.

2.2. *Dataset for training*

This study combines the 300w-3D dataset and the LaPa dataset to build training and validation sets for the face recognition model [6], [7]. Among them, the 300w-3D dataset has the characteristics of large data volume, accurate annotation, gender balance, age distribution balance, and bright/dark balance. However, the open/closed eye data in the 300w-3D dataset is not balanced, especially the closed eye data is relatively small. This will lead to poor model generalization ability, and eventually fail to detect closed eye data. Therefore, this study screened out the closed eye data from the LaPa dataset and combined it with the 300w-3D dataset to form a new dataset. The model is trained and validated using this new dataset.

2.3. *Training Result*

YOLO-tiny is selected as the network structure. After training for 300 epochs, the model has basically converged (Fig. 1).

a. Loss of training


b. Precision of validation
Fig. 1. Result of training

The detection performance of the model is evaluated in terms of mAP (Mean Average Precision). mAP@0.5 represents the change of mAP when the IOU threshold is 0.5, and mAP@0.5:0.95 represents the change of mAP when the IOU threshold gradually increases from 0.5 to 0.95. These two mAPs are both greater than 0.9 after the end of training, and the training effect is good (Fig. 2).
Fig. 2. mAP (Mean Average Precision)

To verify that the model still has good detection capabilities under different lighting conditions, several images are selected, and new images were obtained by decreasing the average brightness of every image by 50 in turn, and they were sent to the model. The results show that the model also has good detection ability in low brightness conditions (Fig. 3).

Fig. 3. Face Detection under Different Brightness

3. Android Smartphone Model Deployment

This study uses ONNX and NCNN as "intermediate representations" to build an inference engine based on the NCNN framework to deploy the trained face recognition model on Android phones.

In general, deep learning models rely on related frameworks and environments, which are not suitable for installation in mobile phones and other environments. In addition, deep learning models require a lot of computing power, which is difficult to run on phones without optimization. ONNX and NCNN as "intermediate representations" can solve this problem. ONNX (Open Neural Network Exchange) was jointly released by Facebook and Microsoft in 2017 for standard description of model structure and parameter calculation graphs. It can optimize network structures and reduce environmental dependencies. NCNN is a lightweight neural network inference framework developed by Tencent for mobile platforms [8], [9]. In short, the trained model needs to be converted into ONNX form and then into NCNN form before it can be deployed to a smart phone. (Fig.4)

Fig. 4. Model transformation process

The effect is shown in Fig. 5, the experimental device is an Android phone equipped with Snapdragon 888Soc (in strong light and low light environments, respectively).
Fig. 5. The effect of the model running on a mobile phone

4. Drowsiness Detection Method by face key points

4.1. *Eye and mouth state recognition based on EAR and MAR*

After completing the extraction of facial feature regions or feature points, it is necessary to study the relationship between the open and closed state of the eyes and mouth and drowsiness based on these characteristics. The relationship was investigated in this study using EAR (Eye Aspect Ratio) and MAR (Mouth Aspect Ratio). They are based on the same principle, the value of them can reflect the opening and closing status of the eyes and

mouth visually. Taking eye as an example, among the 68 facial feature points, each eye occupies 6 feature points, distributed as shown in Fig. 6. [10]
Fig. 6. Feature points of eye

When the eyes are open and closed, the relative position of P1~P6 changes greatly, especially the vertical coordinate changes between the P2/P6 and P3/P5 point pairs are more obvious, and the horizontal coordinate distance between the P1/P4 point pairs basically does not change when the eye state changes. According to the change law of the relative distance between the 6 feature points when the eye state changes, the current state of the eye can be clearly extracted, and the specific calculation is as Eq. (1).

$$EAR = \frac{\|P2 - P6\| + \|P3 - P5\|}{2\|P1 - P4\|} \quad (1)$$

4.2. *Experiment for drowsiness detection based on EAR and MAR*

This study uses the dataset from NTHU Computer Vision Lab for related experiments and analysis. EAR and MAR are computed for each frame of all the videos in the training subset of the dataset. To minimize the effect of noise on the data, exponential smoothing filter and Gaussian filter are applied to the EAR and MAR of each sample respectively. The EAR and MAR graphs can be obtained as shown in Fig.7 and Fig. 8. The downward spike in the graph of EAR is the process of winking, and the upward spike with a certain width in the graph of MAR is the process of yawning.

By analyzing 142 video samples (71 drowsiness samples and 71 non-drowsiness samples), it can be found that the change in the frequency of winking does not reflect the drowsiness state, because there are individual differences in winking habits, and the frequency of winking rises in the drowsiness state of some people and decreases in other people. But there is always a longer period of eye closing when people are in the drowsiness state. Therefore, the presence of significantly longer than normal winking time for eye closing time can be used for drowsiness detection (Fig. 9). In addition, for MAR, the n-sigma rule can be used to distinguish between yawning and normal speaking (Fig.7 and Fig. 10). The existence of yawning can also be used for drowsiness detection. In summary, drowsiness detection methods can be constructed based on yawning and longer eye closing time.

Fig. 8. MAR of a non-drowsiness sample
Fig. 9. EAR of a drowsiness sample
Fig. 10. MAR of a drowsiness sample

5. Conclusion

In this study, a 68-keypoints face recognition model was implemented based on YOLO face, after which the model was deployed to Android phones through ONNX and NCNN frameworks, and finally EAR and MAR were calculated by key points and their relationship with driver drowsiness driving was studied. According to the experiment, it was concluded that based on yawning and longer eye closing time can be used as a standard for drowsiness determination. In the future, it is planned to add this standard into the Android inference engine, and the network structure of the face recognition model is adjusted to improve performance.

Abstract

In fields such as logistics, robots are required to have efficient mobility. There are various types of rollers used in mobile robots. Among them, omni-rollers have excellent omnidirectional mobility and are easy to control. In this study, mechanism kinematics has been proposed that assumes arbitrary changes in the roller arrangement position on a circular mechanism and the roller arrangement has been evaluated from the viewpoint of speed efficiency. Furthermore, we aim to evaluate the mobility of mobile robots by focusing on their translational components. Moreover, we have examined the behavior of the area of the area generated by the end point of the robot velocity vector and evaluated the velocity efficiency.

Keywords: Omni-roller, Translational motion, Motion analysis of mobile robot

1. Introduction

In recent years, industries such as logistics require efficient mobile robots for object transport. Development of such mobile robot vehicles has attracted great attention among the research community. The degrees of freedom for omnidirectional movement (if holonomic properties are provided) is three, expressed as the sum of a translational component of 2 degrees of freedom and a rotational component of 1 degree of freedom. The holonomic movement mechanism is easy to control and has excellent maneuverability in all directions due to the independent drive characteristics of the wheels.

In particular, there are many moving mechanisms equipped with three omni rollers, and the kinematics for these mechanisms have been derived [1]. The three-roller arrangement of this mechanism has a basic structure of an equilateral triangle.

This basic arrangement is also used in the soccer robots of RoboCup Meddle-sized-reague, such as RV-infinity [2], Musashi 150 [3], and NuBot [4]. Thus, a regular polygon with the highest degree of symmetry among triangles was used, and no theoretical research had been conducted. However, recently, researchers have started focusing on the kinetic energy of drive rollers for moving mechanisms [5] and spherical conveyance [6].

In a movement mechanism using a sphere as wheels (or a mechanism using a sphere as a conveyance object), the optimal angle of the sphere rotation axis with respect to the movement direction [7] and the placement location of the two drive rollers that drive the sphere should be determined. The optimal location has been identified to be on the equator [8]. In a mechanism using rollers as wheels, a transformation matrix is defined that associates the input roller speed with the output robot speed (translation/rotation), and the "Image volume" and "Orthographic area" are used as an evaluation function for movement efficiency. The roller arrangement was evaluated in a previous study [9].

The present study focuses on sectional area by considering the kinetic energy of a mobile robot in the line-symmetric roller's arrangement which has one-dimensional of freedom. Focusing only on the robot's translational motion, we derive a relational expression between velocity efficiency and roller arrangement, and subsequently analyze the behavior of the end point region area of the robot velocity vector.

The rest of this study is as follows: Chapter 2 discusses the kinematics of mobile robots. Chapter 3 derive sectional area function. Chapter 4 conducted the simulation. Finally, we present the summary and future tasks.

2. Kinematics of Transfer Mechanism in case of isosceles triangle three rollers arrangement

In a previous study, we have defined "Image volume" and "Orthographic projection area" as evaluation functions analysis roller contact location ([9]).

Section 2.1 introduces only on the robot translational motion and analysis robot motion.

Section 2.2 discusses kinematics for a mechanism that adapts three omni-rollers in line symmetry roller's arrangement.

2.1. *Liner Transformation mapping for correspondence of roller speed and robot speed*

As shown in Figure 1(a), the mobile robot that has a common radius of all omni-wheels adapted the *i-th* rollers ($i = 1,2,3$) contact point P_i on a circle. $X-Y$ is the global coordinate system (origin O). The robot translation speed is $V = [V_x, V_y]^T$ and φ denotes robot direction. Robot rational speed $L\dot{\phi}$ ($\dot{\phi}$: robot angular velocity) roller peripheral speed v_i are decomposed as translation and rotational components. Contact point P_i are adapted angle θ_i on the circle that has a radius L. Thus, the correspondence of $[v_1, v_2, v_3]$ and $[V_x, V_y, \dot{\phi}L]$ is represented in Figure 1(a).

As shown in Figure 1(b), linear transformation mapping $f_A : [V_x, V_y, \dot{\phi}L]^T \rightarrow [v_1, v_2, v_3]^T$ and $f_A(W) =$Image$f_A \in \mathbf{R}^3$ is a parallelepiped domain from cubic domain W.

In this study, we represented a sectional area of $f_{A^{-1}}(W)$ for a horizontal plane as follow:

$$f_{A^{-1}}(W) \cap \{V_x V_y - \text{plane}\}$$
$$= \{(V_x, V_y, 0)| \ |v_1|, |v_2|, |v_3| \leq 1\} \quad (1)$$

Where

$$f_{A^{-1}}(W) = \{(V_x, V_y, L\dot{\phi})| \ |v_1|, |v_2|, |v_3| \leq 1\} \quad (2)$$

$$W = \{(v_1, v_2, v_3)| |v_1|, |v_2|, |v_3| \leq 1\} \quad (3)$$

2.2 *Kinematics for isosceles triangle three rollers arrangement*

In our previous work [9], we derived kinematics for arbitrary roller arrangement position as $(\theta_1, \theta_2, \theta_3)$. In this study, we restrain an isosceles triangular roller arrangement (line symmetry roller's arrangement) in Eq. (6) of the previous study [9]

Substituting $\theta_1 = \theta$, $\theta_2 = 360° - \theta$ and $\theta_3 = 0°$ with $(\theta_1, \theta_2, \theta_3)$ in Eq. (6) of [9].

Inverse kinematics ($[v_1, v_2, v_3]^T$ is determined from $[V_x, V_y, L\dot{\phi}]^T$) is represented as follows:

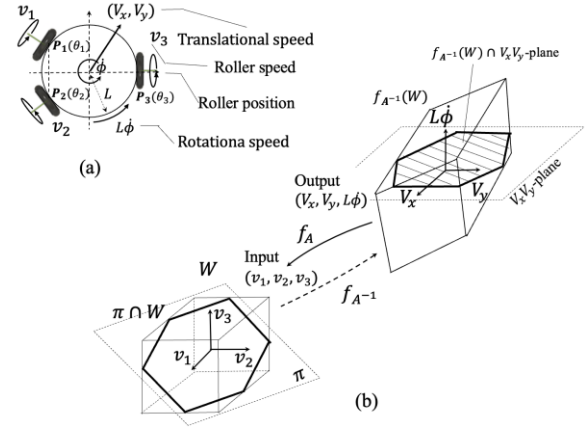
$$\begin{bmatrix} v_1 \\ v_2 \\ v_3 \end{bmatrix} = \begin{bmatrix} -\sin\theta & \cos\theta & 1 \\ \sin\theta & \cos\theta & 1 \\ 0 & 1 & 1 \end{bmatrix} \begin{bmatrix} V_x \\ V_y \\ L\dot{\phi} \end{bmatrix} \quad (4)$$


Figure 1 Correspondence between three omni-rollers speed $[v_1, v_2, v_3]^T$ and $[V_x, V_y, \dot{\phi}L]^T$ (robot mobile speed (V_x, V_y) rotational speed $\dot{\phi}$). (a) mobile robot and (b) translation mapping.

Forward kinematics ($[V_x, V_y, L\dot{\phi}]^T$ is determined from $[v_1, v_2, v_3]^T$) is represented as follows:

$$\begin{bmatrix} V_x \\ V_y \\ L\dot{\phi} \end{bmatrix} = \begin{bmatrix} -\dfrac{1}{2\sin\theta} & \dfrac{1}{2\sin\theta} & 0 \\ -\dfrac{1}{2-2\cos\theta} & -\dfrac{1}{2-2\cos\theta} & \dfrac{1}{1-\cos\theta} \\ \dfrac{1}{2-2\cos\theta} & \dfrac{1}{2-2\cos\theta} & -\dfrac{\cos\theta}{1-\cos\theta} \end{bmatrix} \begin{bmatrix} v_1 \\ v_2 \\ v_3 \end{bmatrix}$$
$$(5)$$

3. Derive sectional area function

In this section, we calculate area using Eq. (1). Section 3.1 shows analysis of roller's speed space, while Section 3.2 shows analysis of robot speed space.

3.1. *Analysis of roller's speed space*

(A) *Setup for Cubic domain*

As shown in Figure 2(a), the cubic domain is composed of the following eight apexes: $B_1 = (1, 1, 1)$, $B_2 = (-1, 1, 1)$, $B_3 = (-1, -1, 1)$, $B_4 = (1, -1, 1)$, $B_5 = (1, 1, -1)$, $B_6 = (-1, 1, -1)$, $B_7 = (-1, -1, -1)$, $B_8 = (1, -1, -1)$. Additionally, sectional domain denoted by π is symmetrical with respect to the origin O. For the sectional shape to be hexagonal like Figure 2(a), six dots $P(p, -1, 1)$, $Q(-1, q, 1)$, $R(-1, 1, r)$, $S(s, 1, -1)$,

T $(1, t, -1)$, U $(1, -1, u)$ (real parameter : $-1 \leq p, q, r, s, t, u \leq 1$) should satisfy the following condition.

$$p = s, q = t, r = u \tag{6}$$

As the two faces, $B_1 B_2 B_3 B_4$ and $B_5 B_6 B_7 B_8$ (face to face), are parallel, side PQ and TS are parallel and have same length.

(B) Plane representation as roller speed existent set

Focusing on $L\dot{\phi}$ -component of Eq. (5), only transrational motion is equivalent to $\dot{\phi} = 0$.

$$v_1 \sin \theta + v_2 \sin \theta - 2 v_3 \sin 2\theta = 0 \tag{7}$$

Eq. (8) represents a plane equation including origin by three-dimensional combinate $[v_1, v_2, v_3]^T$.

$$\pi = \{(v_1, v_2, v_3) | v_1 \sin \theta + v_2 \sin \theta - 2 v_3 \sin 2\theta = 0\} \tag{8}$$

(C) Normal vector of plane

Eq. (7) is equivalent to following expression.

$$\sin \theta \langle \begin{bmatrix} 1 \\ 1 \\ -2\cos\theta \end{bmatrix}, \begin{bmatrix} v_1 \\ v_2 \\ v_3 \end{bmatrix} \rangle = 0 \tag{9}$$

Thus. $[1, 1, -2\cos\theta]^T$ is normal vector of plane π. Also, $\sin \theta > 0$ and $-2\cos \theta > 0$ for all $90° \leq \theta < 180°$.

Figure 2(b) shows a section of the cubic domain with respect to rectangle $(B_1 B_3 B_7 B_5)$. It can be observed that normal vectors shift counterclockwise direction from v_3-axis (when $\theta = 90°$) to line $B_3 O$ (when $\theta = 180°$). Thus. $\pi \cap W$ satisfies the following property.

Property
(i) Sectional shape is symmetrical with respect to origin
(a) $\theta_1 = 90°$ $\Leftrightarrow$ Rhomb
(b) $90° < \theta_1 < 180°$ $\Leftrightarrow$ Hexagon

(ii) When $\theta_1 = 120°$ it has minimal area.

3.2. Analysis of robot speed space

Using Eq. (5), image of $\pi \cap W$ by transformation mapping $f_{A^{-1}}$ can be represented as follows:
Figure 2 Sectional shape of roller's speed space $\pi \cap W$ in case of an isosceles triangle roller arrangement. (a) Isometric view. (b) Sectional view.

$$f_{A^{-1}}(W) \cap \{V_x V_y - \text{plane}\} = \tag{10}$$

$$\{(V_x, V_y) | v_1 \acute{A}_1 + v_2 \acute{A}_2 + v_3 \acute{A}_3, |v_1|, |v_2|, |v_3| \leq 1\}$$

where

$$\acute{A}_1 = \begin{bmatrix} -\frac{1}{2\sin\theta} \\ -\frac{1}{2-2\cos\theta} \\ \frac{1}{2-2\cos\theta} \end{bmatrix}, \quad \acute{A}_2 = \begin{bmatrix} \frac{1}{2\sin\theta} \\ -\frac{1}{2-2\cos\theta} \\ \frac{1}{2-2\cos\theta} \end{bmatrix}, \quad \acute{A}_3 = \begin{bmatrix} 0 \\ \frac{1}{1-\cos\theta} \\ -\frac{1}{1-\cos\theta} \end{bmatrix} \tag{11}$$

From Eq. (6) and property of transformation mapping $f_{A^{-1}}$, $f_{A^{-1}}(\pi \cap W)$ is decomposed as three parts.

$$f_{A^{-1}}(\pi \cap W) = 2 f_{A^{-1}}(\triangle OPQ) \tag{12}$$

$$+ 2 f_{A^{-1}}(\triangle OQR) + 2 f_{A^{-1}}(\triangle ORP)$$

Where

$$\pi \cap W = 2(\triangle OPQ + \triangle OQR + \triangle ORP) \tag{13}$$

Thus. Sectional area of $f_{A^{-1}}(W) \cap \{V_x V_y - \text{plane}\}$ is represented as following.

$$D_{Sec}(\theta) = \| f_{A^{-1}}(P) \times f_{A^{-1}}(Q) \|$$

$$+ \| f_{A^{-1}}(Q) \times f_{A^{-1}}(R) \| + \| f_{A^{-1}}(R) \times - f_{A^{-1}}(P) \| \tag{14}$$

Where $P(p, -1, 1)$, $Q(-1, q, 1)$, $R(-1, 1, 0)$

Kenji Kimura, Kazuo Ishii

$$p = \frac{\sin\theta - \sin 2\theta}{\sin\theta}, q = \frac{-\sin\theta - \sin 2\theta}{\sin\theta} \qquad (14)$$

4. Simulation

This section presents the simulation findings, including the evaluation values of "horizontal cross-sectional area: D_{Sec}"

Simulations were performed at the various symmetric roller arrangement (Eq. (14) in $90° \leq \theta < 180°$).

As shown in Figure 3, $D_{Sec}(90°) = 4.05[m/s]^2$ and $D_{Sec}(180°) = \infty \ [m/s]^2$. minimum value is $D_{Sec}(120°) = 3.85[m/s]^2$. Thus. The worst efficiency roller arrangement in only translational motion is the equilateral triangular shape.
Figure 3   Behavior of Area of domain of end point of robot speed $D_{Sec}(\theta)$ ($90° \leq \theta < 180°$).

5. Conclusion

In this research, we focused on the translational motion of mobile robots. Furthermore, we derived the area of the region where the end point of the robot's velocity vector exists as an evaluation function, investigated its behavior, and determined the minimum value. We get fact that worst efficiency roller arrangement is the equilateral triangular shape.

This is a one-parameter problem because the roller arrangement is given as an isosceles triangle.

Abstract

With the extensive use of robots in recent years, an age of co-existence between humans and robots is expected to arrive in the future. Therefore, providing robot education in the early stages of elementary and junior high school is necessary to stimulate students' interest in robots. Furthermore, educational institutions are becoming more active in robot education as a part of their contribution to the local community. For elementary school students, a Beauto Racer (Vstone) has been adopted as a teaching material for robot education, and teaching materials have been developed for teaching line tracing. In this study, we will develop educational materials for junior high school students on maze exploration using a Beauto Rover (Vstone). The students of Matsue National College of Technology took the initiative in this activity. The purpose is to improve their teaching skills.

Keywords: Robot education, Programing, Maze search, Student-based educational activities

1. Introduction

AI robotic research is being promoted at an accelerated pace, as obvious from RoboCup's goal of "building an autonomous robot team that can beat the world champion soccer team in 2050" [1]. Thus, an era in which humans and robots will live together in harmony is expected in the near future; therefore, providing a strong awareness regarding robots to future children at an early age is critical. As shown in Table 1, many lesson designs use commercially available microcomputers.

As an example of robotic education using Lego Mindstorms NXT, the company offers numerous courses in robotic education for students belonging to first to sixth grades. This includes student-centered robotic contests centered on line tracing [2].
Furthermore, robotic education using Beauto Racer (Vstone) is being developed as a curriculum for elementary school students to learn programing on the theme of line tracing [3].
In a junior robotic contest, participants used Lego Mindstorms EV3 to perform line tracing for simulating tomato harvesting [4].
Moreover, embedded programing using Lego Mindstorms NXT was employed to teach maze exploration programing [5].

Table 1 Commercial microcontrollers for robotic education

Commercially available microcontrollers	Lesson content	Literature
Lego Mindstorms NXT	Line trace Maze Search	[2][5]
Beauto Racer (Vstone)	Line trace	[3]
Lego Mindstorms EV3	Line trace	[4]

While most of these efforts are faculty-led, there are also student-led collaboration activities in the community that are aimed at improving the basic skills of students and other members of society ([6]).

A student-led working group was organized in this study to produce educational materials that will enable students to quickly and easily learn maze search programming.

The rest of this study is as follows: Chapter 2 introduce information on lesson design and microcontrollers to be used for maze exploration programming . Finally, we present the summary and future tasks.

Kenji Kimura, Youta Takano

2. Planning and Preparation

2.1. View trovers and educational equipment

A Beauto Rover (Vstone) was used as the microcontroller for robotic education. To organize multiple wiring, a body is designed for it, as shown in Figure 1. It was designed using Slid Works (Figure 1(a)), prepared for processing by SPACEGEAR-U44 (MAZAK) (Figure 1(b)), and laser was processed using an acrylic plate (Figure 1(c)). This plane has a rectangular shape with dimensions of 90 [mm] × 125 [mm], and an image of the microcontroller after attaching the protective cover is provided in Figure 1(d).

As shown in Figure 2, a single infrared sensor (①) was mounted on the head of the mechanism. First, the power switch of the microcontroller (②) was turned on, and then a program created by an application on a PC was sent to the CPU board (③) by connecting it to a USB connector (④). Finally, the program proceed button (⑤) to execute the program is turned on, and the front tires (⑥) rotate to perform the motion on execution.

Figure 2 Function of each part of the robot

2.2. Lesson design for maze exploration programing

Assuming that we have lectured on how to transfer a program to the microcontroller and execute it, we will prepare problems 1–5, which are the key problems to be solved in a maze search. Table 2 shows the maze search programing materials (powerpoint-slide) prepared for the lecture.

The first problem is "1 second forward" and "turn right (90-degree rotation)." Participants were asked to think about the number of rotations and how much they have rotated with respect to time (Figure 3(a)).

For problem 2, the exercise is to repeat problem 1 four times, where the useful "loop" function is taught and guidance is provided (Figure 3(b)). For problem 3, students are taught about conditional branching by helping them understand the relationship between senders and the IF function (Figure 3(c)).

A driving program is given as a mission in problem 4 to avoid obstacles when they are placed in predetermined positions (this would use the knowledge from problems 1-3) (Figure 3(d)).

Problem 5 is implementing a program that will work with different placements of obstacles (note the difference from problem 4) (Figure 3(e)).

Table 2 Class design

	(data) item	Notes on the Guidance
Question 1	Actions for going straight and turning right.	Understand the relationship between the number of revolutions and time required to make a 90° turn (relationship between the number of revolutions and angle of the turn)
Question 2	Iterative operation	Ability to use the loop function.
Question 3	IF Function	Ability to use the role of sensors and IF syntax
Question 4	Traveling along an approximate known route	Summary of stationary, straight ahead, right/left turn (basic driving)
Question 5	Unknown Maze Running	Understand the difference between driving on an approximate known pathway

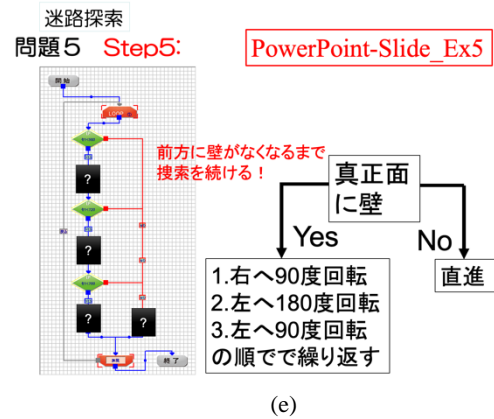
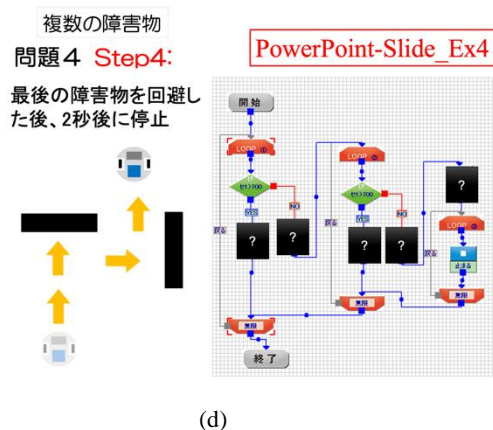
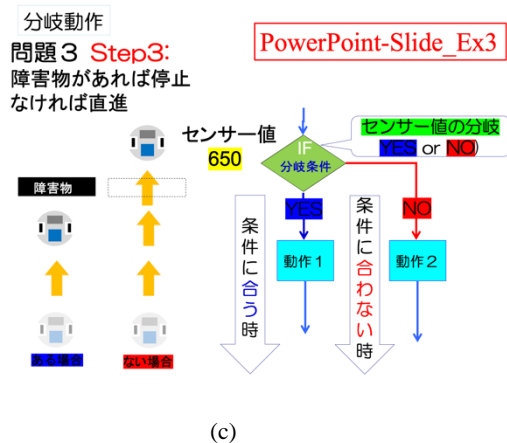
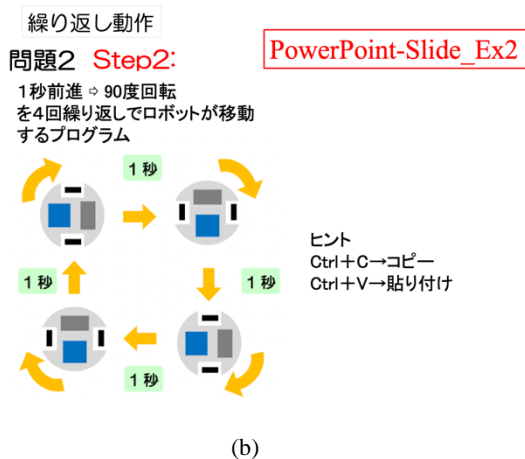
(e)








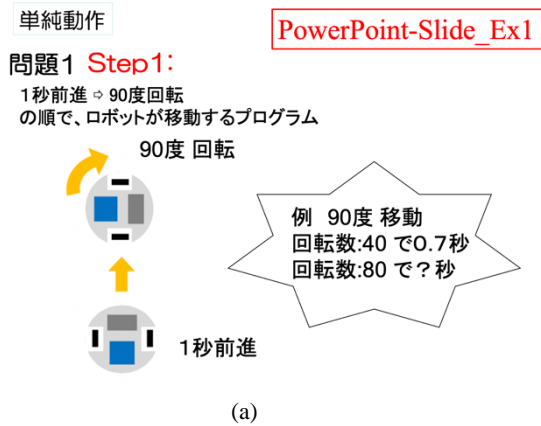


Figure 3 Maze search programming materials (powerpoint-slide for lecture) and five Processes. (a). Basic driving, such as going straight, turning right, and turning left. (b). Iterative operations, (c). IF syntax, (d). multiple obstacle avoidance, and (e). maze search.

2.3. Maze selection

Obstacles were selected to create a maze, and three materials used for creating a maze are listed in Table 3. First one is recycling boxes, which are all around us and have a flat surface. They are relatively responsive to sensors, but their nonuniform size makes it difficult to freely change the maze path (Figure 4(a)). Further, in the case of paper cups, the size is uniform and its unit price is low. However, its shape resembles a part of a cone, and the infrared sensor light reflects irregularly and penetrates the gap between neighboring paper cups (Figure 4(b)). Finally, the sensors responded well in the cubic box case dimensions: 100 mm × 100 mm × 100 mm). This is because they have flat surface, and the infrared sensor responded relatively well because of its uniform size. Furthermore, with cubic box, it is easy to freely change the maze path (Figure 4(c)). Based on the above, cubic boxes were adopted as the obstacle for preparing maze.

The maze corridor's width should be set at 200 mm, which is equivalent to the width of two cubes. This allows the robot to turn right and left in the passageway.

(c)

Figure 4 Maze production choice: (a). recycled box, (b). paper cup, and (c). cube box

Table 3 Three candidates for maze production

Candidate obstacles	Advantage	Disadvantage
Recycling bin	Gather easily	Uneven size
Paper cup	Low unit price Uniform size	Sensor recognition is unstable
Cube box [100 mm per side] (commercially available)	High degree of freedom for placement Uniform size	High cost

3. Conclusion

In this study, a Beauto Rover (Vstone) was used as the microcontroller for robot programing. With only one infrared sensor attached to the back of its head, this microcontroller can be easily operated by junior high school students. To make robot programing learning feasible, we produced programing materials that provided steps for realizing a successful maze exploration.

We plan to conduct several workshops at our university using the developed robot programming material for future research projects. In addition, we plan to conduct pre- and postlecture questionnaires to investigate changes in interest and awareness on maze exploration and to evaluate the educational materials we have developed.

Abstract

The Ministry of Education, Culture, Sports, Science and Technology (MEXT) has been promoting cross-curricular learning including STEAM education in its educational policy for 2021. The purpose of this study is to have students experience not only control engineering but also basic programming techniques, and to have them become interested in mathematical subjects in general, which are the basis for control engineering. The educational design and accompanying software were designed using Beauto Balancer2 (Vstone) educational robot and Scratch, a visual programming editor developed by the Scratch Foundation. In addition, workshops were conducted, and the lesson design was evaluated by a questionnaire.

Keywords: Robot education, Control engineering, Visual Programming, Beauto Balancer

1. Introduction.

The Ministry of Education, Culture, Sports, Science and Technology (MEXT) has made programming education mandatory for elementary and junior high schools starting in 2021. The purpose is to develop children's programming abilities, discover their hidden potential, and create opportunities for them to play an active role in society in the future [1].

In addition, the Ministry of Education, Culture, Sports, Science and Technology (MEXT) promotes STEAM education and other cross-curricular learning to apply learning in each subject and other areas to discovering and solving problems in the real world. This is aimed at fostering problem-solving skills that transcend subject boundaries [2].

Hirata developed an experimental teaching material that enables students to identify control objects in both the time and frequency domains and to design control systems while considering the relationship between them [3]. This teaching material is intended for beginning students of control engineering.

Kato conducted an objective verification of educational effectiveness through robot building and robot contests. Here, as an objective method of measuring effectiveness, criteria for behavior evaluation were established and implemented, and the behavior of the subjects was evaluated by TAs [4]. This study cites education in the setting of a robotics class for elementary and junior high school students.

In recent years, it has become necessary to use some form of programming in controlling robots. However, there are few educational materials for elementary and middle school students that can help them understand and become interested in programming and control engineering concepts. There have been no control engineering-related studies targeting elementary and middle school students or aiming to educate them about new concepts through robotics.

In this study, we will develop extensions to existing educational robots and plan lessons that will enable elementary and junior high school students to become interested in a wide range of fields and challenge themselves to learn. The robot used in this study, "Beauto Balancer2 (Vstone)," is a teaching material aimed at learning control. Therefore, it is necessary to develop new software to use it as a teaching material for programming classes.

2. Creation of home-grown software

2.1. *Examination of specifications for home-grown software*

In this study, Beauto Balancer 2 (Vstone) will be used.
Beauto Balancer 2 comes with the factory software (Balancer 2 Programmer).

Youta Takano, Kenji Kimura

The objectives sought for the home-made application used in this study are as follows.

· To have the robot embody the behavior envisioned by the subject.
· The difficulty level of the application should be such that elementary and junior high school students can operate it without difficulty.
· Use of libraries (written in C) provided by Vstone

To achieve these goals, we have defined the functions to include or coexist with the functions of the original software (Balancer 2 programmer) and to introduce the concept of visual programming so that elementary and junior high school students can easily operate the software.

To achieve this, the following three compositions and description methods were considered.

A   Desktop application only (written in Python)
B   Console application (written in C)
C   Scratch script + console application.
       + Genuine software (written in C)

Table 1   Study table for the software specification

	advantage	disadvantage
A	Use of external libraries facilitates UI tuning	The stock library needs to be re-written in advance. Even if the library is ported to Python, there is no guarantee that the serial communication system will work properly.
B	User operation unit (so-called front end) and the language of the internal processing part (i.e., the bag-end) Uniformity is possible, allowing for flexible design and description.	The nature of console applications limits UI tuning. High degree of difficulty in introducing visual programming concepts.
C	Troubleshooting is easier because software is created or diverted by dividing functionality.	Software tends to be somewhat cumbersome to configure, as software is divided by function, which is less consistent than other proposals

Table 1 shows the results of the study and review of the specifications (A, B, and C). Initially, we adopted proposal A, giving priority to the user interface (UI). However, the communication problems could not be solved, and the development process would have been too large, so we gave up on it. Next, they decided to adopt proposal C and develop it in earnest, as it was judged to be more effective in terms of man-hours among the three proposals.

2.2. *Software Development*

As a result of the study in section 2.1, we adopted C and produced two applications. The overall system configuration and process flow are shown in Figure 1. The first is a visual programming editor produced using Scratch 3.6. The second is a communication software written in C.

The flow of the entire system, its usage, and its structure are described. First, a txt file was generated from the visual programming editor, and using Scratch's original block definition function, a block was created to add a string to the list according to the contents of the action (e.g., forward, stop). After the participants created their own actions, we had them generate them using Scratch's txt file output function for the list contents.

Next, we asked participants to start up the communication software. To reduce the burden on the participants, we implemented the software so that it could be automatically loaded and executed by simply clicking on the application to open it.

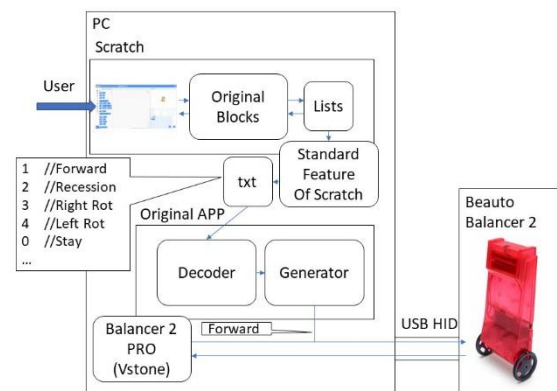
When the communication software is opened, it automatically establishes USB HID communication and reads the txt file. At this time, we designed the software to read the txt file sequentially and issue communication commands according to the contents of each line.


Figure 1   Overall system design

3. Mock Class for Experiments

3.1. *Design of mock class*

A mock class was conducted for elementary and junior high school students (hereinafter referred to as participants). The evaluation was based on the results of the participants questionnaires. The dates of the experiments were as follows Table 2.

Table 2   Planning mock classes

Date	participant
December 16, 2023	4 persons (Breakdown: Fourth grade. 2 students, (one each in sixth grade and eighth grade))
Title. Student-centered lectures and hands-on practice ♪ 〜Let's feel mathematics, physics, and control by using butte balancer! 〜	

The author was the instructor and one teaching assistant (TA), and the maximum number of participants was set at five. Each mock class was held as a part of a craft class hosted by the school, and participants were recruited from the public through posters distributed to elementary and junior high schools in Shimane Prefecture. The aim of the classes was to encourage students to become interested in mathematics, physics, and all other fields by experiencing the mechanisms that make objects move as desired. The mock class consisted of three steps (Step.1-3).

Step.1 "Let's get used to the robot! "
After giving the students the course materials and explaining how to use the robot and its software, we ask them to touch the robot. Since this is the first time for the participants to touch the machine, we ask them to touch it for the time being to familiarize themselves with it. At this point, we ask them the question, "What is gain? and asked them to answer the question while touching the genuine software. Figure 2 is a slide showing how to use Beauto Balancer 2.
Figure 2   Slide of Class Step 1

Step.2 "Let's feel physics and mathematics! "
Next, mathematics, physics, and control engineering were explained to elementary school students in an easy-to-understand manner using specific examples. At first, basic knowledge and concepts of mathematics and arithmetic (functions, derivatives, and integrals) were explained as necessary knowledge to explain physics concepts. Figure 3 shows a slide explaining integration.
Figure 3   Slide of Class Step 2

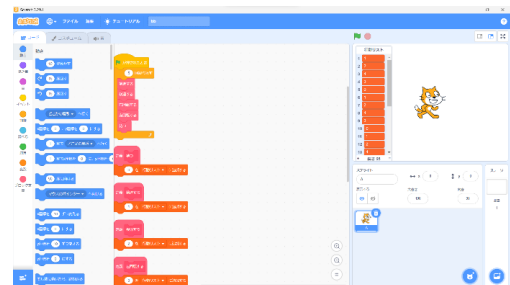
Step.3 "Move the robot as you wish! "
We defined the movements we wanted the subjects to perform with the robot and asked them to perform them in sequence. This was done using special software. The explanation was given while displaying the Scratch screen Figure 4.


Figure 4   Demonstration of Class Step 3

3.2. *Evaluation of mock class*

To test the effectiveness of the program, a pre-class questionnaire and post-class questionnaire are administered to the subjects. Subjects were asked 5 questions before and after each class. The questionnaire was given on a 5-point scale, with the higher the number, the more positive the evaluation. Table 3 shows the contents of the pre-lesson questionnaire and Table 4 shows the post-lesson questionnaire.

Table 3   Pre-Class Questionnaire

Q1: Do you like mathematics?
Q2: Do you like science?
Q3: Can you visualize the control?
Q4: Are you concerned about what math and arithmetic. learned in school is used for?
Q5: Wha science is used for in school. Are you curious?

Youta Takano, Kenji Kimura

Table 4   Post-Class Questionnaire

Q1: Have you developed an interest in mathematics?
Q2: Were you interested in science?
Q3: Did you have an interest in control engineering?
Q4: Did you want to know more about what math and. arithmetic is used for in school?
Q5: What is the science you learn in school used for? Do you want to know more about it?

Figure 5 shows the results of the questionnaire. The horizontal axis represents each question 1-5 in the questionnaire and the vertical axis represents the average of the response results.
Figure 5   Questionnaire results

3.3. *Discussion of Verification Results*

From Figure 5, the percentage increase in the survey results was calculated and is shown in Table 5. As a result, there is a large increase in some areas. However, Q4 can be taken as showing a decrease.

Table 5   Percentage increase in survey results

	Q1.	Q2.	Q3.	Q4.	Q5.
Rate of increase [%]	29	29	39	- 6	7

Due to the nature of the mock classes held this time, it is difficult to conduct a long-term survey such as a follow-up survey, and the shortcoming is that it is inevitably a short-term survey. In addition, because the recruitment method was open-ended, the results were likely to be influenced by the characteristics of the subject population. For example, if the subjects were junior high school students planning to take entrance exams to difficult-to-enter private high schools, the results of the survey would have changed significantly. Therefore, it is necessary to gather subjects with similar characteristics and ages, and to conduct long-term observation using their parents' and academic records.

4. Conclusion.

In this study, we developed software for robot education for elementary and junior high school students and planned and verified mock classes. The results of the verification showed that the level of interest and concern increased.

In the future, we plan to conduct mock classes with subjects with similar characteristics. In addition, we plan to conduct a long-term post-lesson survey.

Abstract

Visual inspection of products in manufacturing plant is usually conducted by workers. However, that inspection process by workers occasionally happen oversight due to careless check, so that automatic visual inspection system is needed from manufacturer. Products made of low-reflective material are difficult to inspect by light reflection because contours of defect areas are got blurred. To solve this problem, we propose to inspect products utilizing of a string shadow. Form our research, a string shadow was different between contours of defect area and its of non-defect. On the other hand, former research did not success to detect defect area due to determination algorithm for defect. In this paper, we apply linear approximation of a string shadow to defect detection. From the experimental results, we succeed in detecting defects.

Keywords: Visual inspection system, low-reflective material, string shadow

1. Introduction

In the manufacturing industry, visual inspection in manufacturing plants is used to ensure the quality of products and parts. Most of the current visual inspections are performed by workers. However, visual inspection process by workers occasionally causes human errors such as variation in pass/fail criteria for defective parts or overlooking defective parts due to individual differences. For those reasons, demand for development of visual inspection system by image processing has been increased [1]. A template matching inspection method based on image recognition is an automated method of visual inspection [2], [3]. In inspection by template matching, the shape and location of the inspection target must be fixed. That method is an effective method if inspection items are simple and will not change significantly in the future. However, it is not suitable for the visual inspection system because it requires large cost when there are complex decisions, multiple types of inspection items or flexible responses to market trends.

In recent years, many studies has been conducted on product inspection systems that apply image recognition based on artificial intelligence(AI) [4]. In fact, we have been conducting research on image recognizers using artificial intelligence in our research [5]. However, AI-based product inspection systems cannot explain the reasons for wrong decisions due to the problem of the AI being a black box [6], [7]. So, this research does not apply AI for visual inspection system.

This research aims to construct a visual inspection system that can detect defects whose position is not fixed and whose shape is unknown. In general, such visual inspections detect defects based on the reflection of linear light such as fluorescent lights. On the other hand, this study targets the products made of low-reflective materials which do not reflect lights; so that, our visual inspection system is not able to use reflection of lights. To overcome this difficulty, we propose to utilize a string shadow to detect defective area. The shadow of string has the property of changing shape based on distortion of the material when projected onto low-reflective materials. Our method uses this property to detect distortion of low-reflective materials based on the shadow shape of string. In this research, our method can flexibly detect by characterizing the defective area utilizing a string shadow and determination the defective area not by pattern matching but by the distance to the approximate linear line of a string shadow. From the experimental results, we succeed in detecting defects on material.

2. Method for defective detection

We introduce the method of defective detection utilizing a string shadow in this section.

2.1. *Characterization from a string shadow*

Out method for visual inspection is to light on a string that placed horizontally to the inspection target and to form a string shadow on it, then that judges defective or non-defective from form of a string shadow. Fig. 1(a)

Keiji Kamei, Tomorou Kawahara, Yoshiyuki Daimaru

shows the shadow of a non-defective material and (b) the shadow of a defective material.

For preprocessing, the shadow image from the camera is denoised by Gaussian filter, binarized, and then edge-smoothed again by Gaussian filter by OpenCV [8] as shown in Fig. 2.
Fig.1 String shadow. (a)non-defective. (b)defective.

Fig.2 Example of after preprocessing.

2.2. *Environment for inspection*

The string shadow is affected by positions for light, camera, string and material as follows.

1. The closer the distance between light and a string, the more the light diffuses and a shadow becomes more fading.
2. The closer the distance between a string and the material, the darker the shadow of a string.
3. When the distance between light and a string is about 45 cm, light is not diffused and shadow is clearly projected.
4. The smaller the angle between the camera and the material, larger the change in the shape of the shadow of the defective area.

From these features for a string shadow, the positional relationship is chosen to have the largest change in the shape of shadow of defective area, as shown in Fig. 3.

2.3. *Linear approximation of a string shadow and judgement based on sum of distance between line and shadow*

Fig. 4 shows that area of non-defective shadow has an almost constant gradient, whereas one part of gradient changes for the defective one. When the contour on the upper side of shadow is approximated by linear line,
Fig.3 Positional relationship.

defect detection is based on the sum of relative distances between shadow and approximated linear line.

Fig.4 Defective shadow after preprocessing.

When width of linear approximation is Δy, the examples of linear approximated line by start point y and end point $y + \Delta y$ are shown in Fig. 5. A wide black area is created between approximated linear line and shadow contour in defective case as Fig. 5(b).
Fig.5 Differences of shadow. (a)non-defective. (b)defective

When the approximated linear line is $f(y)$ and the shadow curve is $g(y)$, gradient a of the approximated linear line is Eq. (1). Thus, linear line, $f(y)$, approximated equation is Eq. (2).

$$a = \frac{g(y_0 + \Delta y) - g(y_0)}{\Delta y} \tag{1}$$

$$f(y) = y_0 + a(y - y_0) \tag{2}$$

where, y_0 is start point of linear line. The sum of relative distances between shadow and approximated linear line is defined as,

$$S = \int_y^{y+\Delta y} |f(y) - g(y)| dy \tag{3}$$

S in Eq. (3) in defective case is larger than non-defective case from Fig. 5. S is obtained by shifting the starting point, then the sum of S is used to determine non-defective and defective. Since this method makes relative

judgments rather than absolute judgments, it is expected to have a high degree of flexibility to suit a wide variety of shapes. On the other hand, a problem with this method is the possibility of successfully approximating the defect area as a linear line depending on the value of Δy. To solve this problem, starting point y for approximated linear line is shifted several times to vary the sum of the relative distances, then determination of non-defects and defects is based on comprehensive results. This will avoid inspection errors by considering approximations which are not coincidental successes of linear line approximations.

3. Experiments

We first examine the variation of shadow contour with and without defects, and then examine the difference in the sum of relative distances between approximated linear line and a shadow contour with and without defects.

3.1. *Sample of visual inspection*

Fig. 6 shows the non-defective and defective samples used to be inspected. The defective sample has two kinds of defectives with different concavities, i.e., dent and depression.
Fig.6 Samples. (a)non-defective. (b)defective

3.2. *Comparison of shadow contour*

Fig. 7 shows the variations in shadow contour coordinates with and without a dent defect. The figure shows that gradient varies linearly without dent, while gradient with dent varies significantly around y at 500 to 700, which is the defective area, in the case of dent defect.
Fig.7 Comparison results of shadow contour(dent)

The same variations are also observed in case of depression. From these results, it can be said that the shadow contours are characterized by a large gradient variation in the defective area.

The product to be inspected in this study does not have a horizontal surface when viewed from the side. In addition, because the height varies depending on the inspection location, the shape of shadow and the location where it is formed are continuously altered. A method of determining by the rate of change of gradient could be considered, but it is difficult to define determination sections because gradient varies depending on the inspection location and the shape of the product and size of defect.

3.3. *Defect detection based on the sum of relative distances between a string shadow and linear line approximation*

In this experiment, two non-defective shadow images are utilized for each defect, shown as Fig. 8(a), to also verify the sum of the relative distances of non-defective shadows, shown as red and green area in Fig. 8(b).
Fig.8 Example of viewpoint. (a)dent defective. (b)non-defective

The results of linear line approximation of dent defect and non-defect are shown in Fig. 9 with the starting point of approximation set to 0 and Δy set to 200. Fig. 10 shows the actual coordinates of a string shadow.
Fig.9 Liner line approx. for "Dent defect"

From figures, there is a large deviation between the approximated linear line and the actual coordinates for defect and non-defects with y-axis between 500 and 600. The same deviation is also happened in case of depression.

Keiji Kamei, Tomorou Kawahara, Yoshiyuki Daimaru

Table 1 shows the results of comparison for the sum of relative distances between a string shadow and linear line approximation in case of dent and depression defects.
Fig.10 Before liner line approx. for "Dent defect"

Table 1. Comparison of the sum of relative dist.

	Kind of defect	Non-defect1	Non-defect2	defect
Sum of relative dist.	dent	340	344	668
	depression	458	394	576

Table 1 shows that the sum of relative distance with dent is about 300 larger than without, and about 150 larger for depression. It can be said that the sum of relative distances is smaller because of the gradual change in shadow in case of depression defect. For this, it is shown that linear line approximation successfully for slowly varying defects and might fail to detect defects. To solve this, starting point y for approximated linear line is shifted, mentioned in Section 2.3. Let d be the distance of the start point y from the image origin and shift y 19 times in total by +10 in the range of $d = 0$ to 190, then obtain the sum of relative distances for 20 times. Table 2 shows the results of shifting of starting point.

Table 2. Results of shifting. ND1, ND2 and Df correspond to "Non-defective 1", "Non-defective 2" and "defective", respectively.

	dent			depression		
	ND1	ND2	Df	ND1	ND2	Df
Avg.	448.5	459.4	582.3	406.0	399.3	565.4
Max	653	696	881	662	546	828
Min	304	271	435	234	252	341

Table 2 shows that the mean, maximum, and minimum values differ by about 100 or more between the undistorted and the distorted samples. In particular, it can be said that defects in products can be detected by using the maximum value as a criterion for determination because the maximum value differs by about 200 depending on occurrence of defects. From these results, defect detection can be performed flexibly for defect detection problems that cannot be solved by template matching.

4. Discussions

Real-time processing is required in the production environment, and the camera frame rate is 30 fps, so processing must be completed within 33[ms] before the next image is received. The frame rate at 200[kpx] is 20[ms], on the other hand, at 900[kpx] of it is 55[ms]; consequently, a frame rate drop occurred. So, it can be expected that current PC can support up to about 500[kpx], otherwise stronger PC is needed.

5. Conclusions

In this study, defect images are characterized by the shadow of a string to develop a defect detection method for low-reflective materials, and defect features are detected not by pattern matching but by the sum of relative distances to an approximated linear line. From the experiment, it is effective to shift the starting position multiple times because the sum of relative distance varies greatly depending on the starting position of the approximated linear line. It can also be said that defect detection is possible by using the maximum value as a defect determination criterion. We aim to further improve the system by conducting experiments in actual environments and trying out various kinds of samples.

Abstract

As the shortage of agricultural population is becoming an issue, services that remotely monitor the agricultural environment using IoT are being offered in the market. However, small- and medium-scale private farmers are unable to purchase or rent IoT equipment and monitoring tools because they have to spend their budgets on maintenance and utilities in greenhouses to support environmental management, and the construction of data infrastructure has not been widely adopted. Therefore, in this experiment, we developed an agricultural IoT that can be provided to medium and small farmers, and a module that enables collection, accumulation, and visualization of time-series data acquired from sensors. The module provides an architecture that includes multiple sensing, networking, processing, and visualization applications to keep deployment and management costs low. To demonstrate its feasibility, the proposed IoT system was built, experimentally tested, and verified in a greenhouse in Yatsushiro, Kumamoto, Japan, by intermittently monitoring temperature, humidity, carbon dioxide concentration, solar radiation, and soil moisture content in the greenhouse for two years. The results obtained confirm that the proposed IoT remote monitoring module facilitates farmers to monitor the growing environment of their crops and enables them to improve their productivity by progressively increasing their technology level.

Keywords: IoT，Agricultural，Monitoring System, visualization

1. Introduction

Smart Agri and Agri Tech are attracting attention as new forms of agriculture that utilize advanced technologies such as robotics, ICT to enable labor-saving, high-quality production [1]. One of the technologies that support this Smart Agri is the spread of the Internet of Things (IoT), whereby various "things" are now connected to the internet IoT refers to a system whereby sensors are built into various "things", which are then connected to the internet, and a large amount of data acquired via the internet It is a mechanism whereby large amounts of data acquired via the internet are stored in the cloud. This accumulated large amount of data is known as 'big data' (BD), and although BD cannot create value simply by accumulating it, new value can be created by analyzing the accumulated data [2].

In agriculture, where declining productivity due to an ageing population and a lack of bearers is a problem, there are high hopes for this IoT as a way to improve productivity with fewer people. It is desired to acquire environmental information on farms, which is a factor that changes the quality and quantity of agricultural products, and to visualize this information. In addition, one of the challenges for future development is to analyze the acquired data and weather data and utilize them as time-series data for forecasting, thereby improving productivity and ensuring the production of high-quality and stable agricultural products [3]. Here, an example of a farmer growing banana and coffee in Yatsushiro, Kumamoto Prefecture, Japan, is presented. Banana and coffee are mainly grown in tropical regions. Japan belongs to the temperate zone, and farmers across the country are searching for new cultivation methods to enable the cultivation of tropical plants such as banana and coffee in temperate Japan. Farmers in Yatsushiro City, the site of this experiment, also grow bananas and coffee and maintain a tropical environment in vast plastic greenhouses. However, in Japan, which has four seasons, temperatures vary throughout the year and it is difficult to maintain a constant environment inside the greenhouses.

Moeko Tominaga, Yasunori Takemura, Junya Era, Wataru Kaishita, Eiji, Mizoe, Tomoyasu Furukawa

However, in Japan, which has four seasons, the temperature varies throughout the year and it is difficult to maintain a constant environment in the vast greenhouses, which affects the growth and production of the plants. For this reason, many companies are introducing agricultural IoT, collecting environmental data in greenhouses and providing visualization services. However, small- and medium-scale individual farmers have to spend their budgets on the maintenance of their greenhouses, utility costs and other costs to support environmental management, and are unable to purchase or rent IoT equipment and monitoring tools, which means that the construction of data infrastructures has not become widespread. Therefore, in this experiment, we developed an agricultural IoT device that can be provided to medium and small farmers, and built a system for collecting, storing and visualizing time-series data acquired from sensors.

2. Development concept

The concept was set up as follows.

- To collect on temperature, humidity, carbon, dioxide concentration, moisture content and solar radiation in order to investigate environmental information in greenhouse from all perspectives.
- Designed to continue to operate even under severe environmental conditions and to ensure that data acquisition is not interrupted.
- Programmed to be able to be used universally at other sites, and designed so that sensors can be connected using connectors.
- Collect agricultural IoT devices that meet the above conditions using inexpensive and highly accurate sensors.

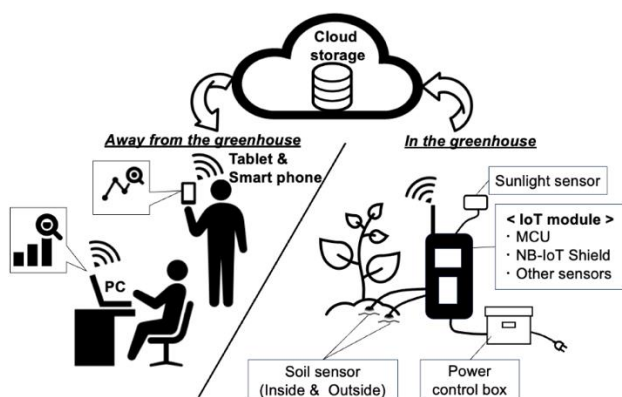
A system of IoT modules configured according to the concept is shown in Fig. 1. All sensor values are regularly collected by microcomputer and stored in storage in the cloud. The user can view the values of these sensors numerically and graphically at any time and from anywhere.


Fig. 1 System image of the IoT module

The developed IoT device is shown in Fig. 2 and the specifications are given in Table 1. As an Micro Controller Unit (MCU), the Arduino, which is also used in other smart farming systems [4], [5], was used. The developed IoT device was equipped with several types of sensors to collect data in order to investigate the environmental information inside the greenhouse from all perspectives.

In order to develop an IoT device that can continue to operate even in a harsh environment, a temperature and humidity sensor was also attached to the inside of the greenhouse, and a durability test was conducted to investigate at what temperature range the device would break down. The results showed that failures occurred at around 50 °C, so a fan was installed inside the chamber to prevent failures due to overheating of the IoT device. In addition, a Watch Dog Timer (WDT) was incorporated into the software to monitor whether the MCU program stopped or communication was interrupted, and if so, measures were taken to restart the program. By taking countermeasures in terms of hardware and software, we were able to develop an IoT device that could continue to operate even in a harsh environment.
Fig. 2 IoT devices developed (being implemented in a green house in Yashiro).

(Only some data on coffee was extracted)

3. System configuration diagram

The system configuration is shown in Fig. 3. The data acquired from each sensor connected to the MCU was A/D converted and the time-series data was stored in the data server via the LET module. The data server used SORACOM Harvest provided by SORACOM, and SORACOM Lagoon (Fig. 4) was used as the visualization tool.
Fig. 3 System configuration diagram

4. Field experiments and time series data obtained

The developed agricultural IoT equipment was actually installed in a plastic greenhouse in Yatsushiro to monitor the growing environment of banana and coffee as shown in Fig. 5. The monitoring period started intermittently in 2021 and lasted for two years until 2023. The data interval was 15 minutes. An example of the data collected is shown in Fig. 6. This is temperature data, where temperatures inside and outside the developed agricultural IoT module were collected for one month. As can be seen from Fig. 6, sensor values were successfully retrieved and stored in cloud storage at 15-minute intervals. The sensor values also show that the internal temperature tends to be 1-5 ℃ higher than the temperature outside the IoT module, but is kept almost the same due to heat dissipation.

However, as a problem, the phenomenon of system stoppages could appear. When the system is restarted, it returns to a state where data can be continuously retrieved again. The data in which this phenomenon appears is shown in Fig. 7. The period during which the sensor values are not updated is the period during which the system is stopped. This has not yet been resolved. As a countermeasure, the system was monitored and improved so that it can be restarted remotely in the event of a stoppage. After the improvements, the system stoppages have not been reproduced, but the program is being logged so that the cause of the reproduction can be clarified.

5. Conclusion

In this study, an IoT device for agriculture was developed and actual field observation experiments were conducted in greenhouses. As a result, a device with the following functions was developed.

- To continue to operate normally in greenhouses where the humidity is above 90% and the temperature exceeds 30°C.
- Data is uploaded to the cloud every 15 minutes and can be immediately visualized.
- The device can observe multiple parameters (temperature, humidity, barometric pressure, Sunlight, soil moisture and carbon dioxide concentration in the air).
- Robust against communication errors.

In the future, the durability of the system will be increased by improving the modules so that the system can run without stoppages for a long period of time.

Abstract

Currently, the decrease in the working population is a significant problem in agriculture in Japan. In addition, the prices of imported vegetables and fruits have been rising due to international trade problems such as the weak yen. This study has developed an environmental data storage system using IoT to assist the labor force and to understand the cultivation data of crops that have not been cultivated in Japan. Using this big data, we have constructed and evaluated a forecasting system. In this study, we focus on the domestic cultivation of bananas grown in the tropics as the subject to obtain data and make predictions. For learning, a system was constructed to infer the next day's temperature by time-series analysis, using as input data obtained from the IoT. In this paper, we report a comparison of two time series analysis algorithms.

Keywords: Time-series data analysis, ARIMA model, prophet model, IoT, agriculture

1. Introduction

For In recent years, the Internet of Things (IoT) has become increasingly popular, and various " devices" are now connected to the Internet. The IoT is a system in which sensors are embedded in various " products," connected to the Internet, and a large amount of data acquired via the Internet is stored in the cloud. This accumulated large amount of data is called "Big Data (BD)," and today there are tens of billions of IoT devices in the world, all of which continue to generate new data. BD cannot create value simply by accumulating it, but it can create new value by analyzing the accumulated data. In addition, with the development of computer technology, the computation time of AI (Artificial Intelligence) has been shortened, and many companies have developed home appliances and automobiles that incorporate AI, making the IoT and AI a familiar presence. As evidence of this, the number of IoT devices is on an increasing trend with respect to transition data, and is expected to exceed 32.33 billion units by 2022 [1] . In Japan, the government and companies are actively working toward the realization of Society 5.0, and it is expected that a society that uses information in a wide variety of ways will expand in the future [2].

For example, the utilization of IoT databases is expected in various fields. One example is in the field of agriculture, where the number of farmers is decreasing year by year due to the problem of declining productivity caused by the aging of the farming population and the lack of farmers to take on the workforce. Therefore, as a solution, it is expected to improve productivity with a small number of people, and a necessary method to acquire environmental information on farms, which is a factor that changes the quality and quantity of agricultural products [3]. As a solution to this problem, visualization and prediction functions of environmental information using IoT are expected. One of the challenges in future development is to analyze the acquired IoT data and weather data and utilize them as time-series data in forecasting algorithms in order to improve productivity and realize high-quality and stable crop production [4].

The purpose of this research is to build an AI using time-series data with IoT technology, and to generate and validate prediction data using time-series data. The experiment involves time-series prediction of environmental data in a plastic greenhouse in Yatsushiro City, Kumamoto Prefecture, where tropical crops are harvested. The time-series forecasting algorithms were compared using the ARIMA model [5] and Prophet [6], because of their ability to consider the effects of periodicity and external factors.

2. Methodology
2.1. ARIMA (Auto Regressive Integrated Moving Average) model

Yasunori Takemura, Naoya Nishida, Moeko Tominaga, Eiji Mizoe, Tomoyasu Furukawa

The ARIMA model [5], derived by Box & Jenkins, is a model consisting of three components: AR (Auto Regressive) model, MA (Moving Average) model, and summed components (integrated). Time series data may have non-stationary time series processes when a trend analysis is performed, which cannot be handled by the ARMA model. Therefore, non-stationary time series must be converted to stationary time series and then fit into the ARMA model. The ARIMA model, which adds a summation component to the ARMA model, is then applied to the non-stationary time series and aims to make them stationary by taking the "d" th-order difference. The general equation is shown in Equation (1) below.

$$y_t - y_{t-d} = c + e_t + \sum_{i=1}^{p} \emptyset_i y_{t-i+} + \sum_{j=1}^{q} \theta_j e_{t-j} \qquad (1)$$

In the equation, t denotes time, d, i and j denote the time at the regression point in time. e indicates the error height, y is the output, and c, ϕ and θ are constants. In recent years, it has been used as a forecasting system for COVID-19 [7] , and has also been used in research such as stock price forecasting [8].

2.2. Prophet model

Prophet is a library for time series analysis developed by Meta in 2017. The advantages of this model are that it can be built without statistical knowledge, it can be trained even with missing values, and it is easy to interpret the prediction results. Prophet is based on the Generalized Additive Model (GAM) [9], which is a model that uses a It predicts future values by modeling and combining four terms: the trend term (growth: $g_{(t)}$), the seasonality term (seasonality: $s_{(t)}$), the holidays effect term (holidays: $h_{(t)}$), and the error term $\varepsilon_{(t)}$). The model equation is shown in Equation (2) below.

$$y = g_{(t)} + s_{(t)} + h_{(t)} + \varepsilon_{(t)} \qquad (2)$$

3. Evaluation Methodology
3.1. Correlation coefficient

The correlation coefficient expresses the strength of the relationship and correlation between two items as a positive or negative value, and can be objectively analyzed in the range of 1 to -1. 1 is closer to a positive correlation and -1 to a negative correlation. Equation (3) below shows the formula for obtaining the correlation coefficient. In this research, we aim to use data obtained from IoT data and weather data as explanatory variables in the algorithm in order to increase the accuracy of data prediction, and to select data by examining the correlation coefficient with the output values.

$$r_{xy} = \frac{\sum_{i=1}^{n}(x_i - \bar{x})(y_i - \bar{y})}{\sqrt{\sum_{i=1}^{n}(x_i - \bar{x})^2}\sqrt{\sum_{i=1}^{n}(y_i - \bar{y})^2}} \qquad (3)$$

3.2. Akaike's Information Criterion (AIC) [10]

It is a statistic that evaluates the predictability of a statistical model using the residuals between observed and theoretical values, with a smaller value indicating a better fit. If the log likelihood of the model is L and the number of parameters in the model is p, the AIC is calculated by the following Equation (4). In this paper, the AIC is used as an evaluation criterion when selecting parameters for the ARIMA model. L is the maximum likelihood and p is the number of free parameters. In the present model, we adopted a low value of AIC to avoid a complex model in determining the AR and MA coefficients in the ARIMA model.

$$AIC = -2\ln(L) + 2p \qquad (4)$$

3.3. Coefficient of determination R^2

The coefficient of determination, also known as the contribution ratio, is a measure of the explanatory power of the predicted value of the target variable relative to the observed value of the target variable in a regression analysis. The coefficient of determination is generally expressed as R^2. R^2 takes values between 0 and 1, and the closer to 1, the more valid the regression equation is. When the actual data are (x_i, y_i), the data estimated from the regression equation are $(y_i, \hat{y_i})$, and the mean value obtained from the entire data is $(\bar{x}, \bar{y})$, the following Equation (5) is shown.

$$R^2 = 1 - \frac{\sum_{i=1}^{n}(y_i - \hat{y_i})^2}{\sum_{i=1}^{n}(y_i - \bar{y})^2} \qquad (5)$$

4. Data set and Experiment Environment
4.1. Experiment Environment

The field for this experiment was a farmer in Yatsushiro City, Kumamoto Prefecture, who grows bananas and coffee. Since Japan belongs to the temperate zone, farmers across the country are searching for new cultivation methods to make the cultivation of tropical plants such as bananas and coffee possible in temperate Japan. The farmers in Yatsushiro City, which is the focus of this experiment, also grow bananas and coffee in a vast plastic greenhouse, maintaining a tropical environment. However, in Japan, which has four distinct seasons, temperatures vary throughout the year, making it difficult to maintain a constant environment in the vast greenhouses, which affects the growth and production of the plants. For this reason, many companies are introducing agricultural IoT, collecting environmental

data in greenhouses and providing visualization services. However, small- and medium-scale private farmers have to spend their budgets on environmental management, such as maintenance and utility costs in greenhouses, and are unable to purchase or rent IoT equipment and monitoring tools, which has hindered the diffusion of data infrastructure construction. Therefore, in this experiment, we developed an agricultural IoT system that can be provided to small and medium farmers, and collected, stored, visualized, and analyzed time-series data acquired from sensors, with the goal of predicting environmental information for the next day based on time-series data.

4.2. *IoT Device and Data set*

Figure 1 shows the IoT device developed. The developed IoT devices were equipped with multiple types of sensors to collect data in order to investigate environmental information in greenhouses from various perspectives. In addition, we conducted a durability test to determine the temperature range at which the device malfunctions, aiming to develop an IoT device that can continue to operate even under harsh environmental conditions. The results showed that the IoT devices failed at temperatures around 50 degrees Celsius, so a fan was installed inside the chamber to prevent failures due to overheating of the IoT devices. In addition, a Watch Dog Timer (WDT) was incorporated into the software to monitor the microcontroller for program stoppages and communication interruptions, and to restart the program in the event of a stoppage. We developed IoT devices that can continue to operate even in harsh environments by implementing countermeasures on both the hardware and software sides.

From this device, temperature, humidity, air pressure, carbon dioxide, solar radiation, and soil moisture in the greenhouse can be obtained. In addition, we also obtained meteorological data supplied by the Japan Meteorological Agency as necessary data for forecasting, such as altar instantaneous wind speed, precipitation, sunshine duration, maximum wind speed, and average wind speed, and examined whether these data could be utilized as explanatory variables for the model.

a.   Device   b.   Setting Environment
Fig. 1. IoT Device

Table 1. The planning and control components.

Item	Correlation Coefficent
Temperature in plastic greenhouses 1 day ago	0.886252
Average temperature 1 day before [JMA].	0.578104
Lowest temperature 1 day ago [JMA].	0.567764
Highest temperature 1 day ago [JMA].	0.546740
Solar radiation 1 day ago	0.438165
Moisture content 1 day ago (outside)	0.365323
Maximum instantaneous wind speed 1 day ago [JMA].	0.109610
Precipitation 1 day ago [JMA].	0.086130
Sunshine hours 1 day ago [JMA].	0.077532
Moisture content 1 day ago (inside)	0.015999
Maximum wind speed 1 day ago [JMA].	-0.195937
Average wind speed 1 day ago [JMA].	-0.198114
Air pressure 1 day ago	-0.284419
Humidity 1 day before	-0.467905
Carbon dioxide concentration 1 day ago	-0.680186

The correlation coefficients between the output target, temperature in the plastic greenhouse, and the other data sets are shown in Table 1, and the explanatory variables needed to predict the temperature in the greenhouse were extracted from the threshold values. As a result, five items were extracted as positively correlated: the temperature in the greenhouse one day before, the average temperature one day before, the minimum temperature one day before, the maximum temperature one day before, and the amount of solar radiation one day before. Two items, carbon dioxide concentration one day before and humidity one day before, were selected as negatively correlated items, and the temperature in the greenhouse one day before had a high correlation coefficient with the objective variable to be predicted. Therefore, the high correlations were adopted as explanatory variables in the model. As a pre-processing step for time series forecasting, the data set is divided into two types of data sets: training data and validation data. In this experiment, in order to predict the temperature in the greenhouse on the next day, the validation data was set as the last three days, and the other data was used as the training data. The other data were used as training data. Data for training The training data are For the training data, we used 14464 data sets from January 18 to December 25, 2022. We used the temperature inside the greenhouses as input and the temperature, carbon dioxide level, average temperature, humidity, and solar radiation of the previous day with high correlation coefficient as

Yasunori Takemura, Naoya Nishida, Moeko Tominaga, Eiji Mizoe, Tomoyasu Furukawa

explanatory variables. In addition, 145 pieces of data from December 26 to 28 were utilized as test data for accuracy verification.

5. Experiment Result

Analysis of the ARIMA model chorreogram shows that the data has a period of one year, and the candidate parameters for AR(p) are in the range of 0 to 4, and the candidate parameters for MA(q) should be designed in the range of 0 to 2. Figure 2 and 3 show the prediction results when good parameters are set based on these results. Figure 2 shows the forecasting results without explanatory variables. The black dots indicate the values that are the correct answers, the orange line shows the predictions of the ARIMA model, and the blue line shows the Prophet predictions. The value of R^2 is 0.98 for the ARIMA model, and 0.83 for Prophet's model. The values of R2 for the test data are 0.32 for the ARIMA model and 0.74 for the Prophet model. This indicates that the Prophet model gives better predictions when there are no explanatory variables. Next, Figure 3 shows the results of the model with additional explanatory variables. The black dots indicate the values that are the correct answers, the orange line shows the predictions of the ARIMA model, and the blue line shows the Prophet predictions. The ARIMA model, the value of R^2 in the training data is 0.80, and for the Prophet model, the value is 0.85. The predicted values for the test data were 0.88 for the ARIMA model and 0.85 for the Prophet model. These results indicate that the accuracy improves with the addition of explanatory variables, and that the ARIMA model is more accurate when explanatory variables are added.
Fig. 2 The experiment data using ARIMA and Prophet model (No explanatory variables)
Fig. 3 The experiment data using ARIMA and Prophet model (No explanatory variables)

6. Conclusion

Then paper, we developed a model that acquires data in agriculture using IoT devices and utilizes the acquired data to make predictions. The ARIMA model and the Prophet model were used for development and comparison. In the experiment, we examined the correlation between the output temperature and the data acquired to use the explanatory variables, and compared the models with and without the variables with high correlation values added as explanatory variables. The results showed that the models with explanatory variables were more accurate and the ARIMA model had the best performance. Future issues include repeated experiments to improve accuracy and evaluation through long-term operation of the forecasting system.

Abstract

In the process of collecting drifted debris along a coastal area, it has been required to quantify the collection results. This study introduced a Software as a Service (SaaS) equipped with image processing capabilities for the detection and identification of debris in photographs. The SaaS was developed to facilitate the automated weighing of the collected debris. In the beach cleanup event in June 2023, 317 images capturing debris found during the coastal cleanup were gathered on a cloud server from 90 participants via this SaaS. These images were subsequently analyzed by object recognition AI executed on a cloud server, leading to the detection and identification of 954 instances of debris. This result represents the actual amount of debris collected during this cleanup event, and indicates that the achievements of the event were quantified via the SaaS.

Keywords: Coastal environment, Cloud edge, SaaS, AWS

1. Introduction

The impact of marine debris is a global issue [1]. The familiar scenery of the beach can be destroyed by a large amount of debris drifting to the coast after being carried from urban areas through rivers. In Japan, an island nation surrounded by the sea, this is a significant problem that needs to be addressed as soon as possible. In recent years, much research has been conducted on quantifying the amount of beach-drifted debris. Especially, methods based on high-resolution images acquired from UAVs or satellites have been developed [2], [3], [4]. In both proposed methods, deep learning has been actively utilized, and certain results have been achieved for a local region of the beach. These methods can quantify the physical situation of the debris spread on the beach compared to human-powered methods. However, these image processing-based methods have not been implemented in an actual field. It is estimated that people engaged in cleanup tasks may not consider utilizing such technologies to improve the effectiveness of cleanup.

Additionally, these latest technologies have not been widely disseminated to the public.

In this study, considering this situation, it is estimated that a system that can be used with already familiar devices is needed for non-engineers or general consumers participating in the quantifying work of debris. In other words, a method that can be completed with only a smartphone and its operation method is important to promote a quantitative understanding of waste. The performance of smartphones equipped with high-resolution cameras has been increasing year by year. Furthermore, the advancement of AI through cloud computing, which is a core technology in Digital Transformation (DX), has created a social situation where high-performance PCs are not needed for individuals. In this study, while utilizing image processing-based litter detection and identification methods similar to previous studies, an attempt has been made to widely establish the work of quantifying debris by developing a Software as a Service (SaaS) to provide users with functions related to image analysis and information collection on the cloud. Users are required to take a photo containing the debris found on the beach during the beach cleanup, and the identification process of the debris category and the quantification process for

Ayumu Tominaga, Ryohei Komori, Eiji Hayashi

each category are completed on the cloud. The SaaS implemented with such functions has been developed. In this paper, to socially implement the proposed method, the verification results are reported.

2. Proposed method

2.1. *Beach debris quantifying though cloud service*

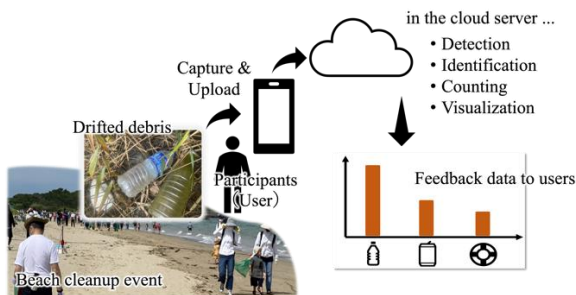
In this study, an application integrating AI and cloud services has been developed to facilitate the quantitative assessment of beach-drifted debris. Fig. 1 represents a use case of the application. Users of this application are participants in a beach cleanup event. Typically, they explore the beach, find debris, and pick it up. In the proposed method, users are expected to take a photo capturing the found debris. After finishing the cleanup work (or during the cleanup), these photos will be uploaded to cloud storage via the internet. Subsequently, the photos will be analyzed by AI upon upload. Finally, the information needed to quantify the debris, such as the type of debris and the quantity of each type, will be gathered as a database on the cloud. As for the expectation of this proposed method, the event that originally gathered labor to collect debris would transform into an initiative constructing a large-scale database focusing on the physical situation of the drifted debris. This database will be provided to the participants or organizers of the event, and it can be used for evaluating the results of the executed event or planning the schedule for the next event.


Fig. 1 Usecase of the application in the proposed method

2.2. *Design of the application*

To achieve the usecase as shown in Fig. 1, the application has been designed as follows:

- Users can upload images without depending on a specific location.
- The images will be uploaded to cloud storage and automatically analyzed by AI upon upload.
- AI detects all debris in the image, classifies them, and quantifies the number of each debris type. These

results are then gathered in cloud storage for easy access.
- Users can review the data analyzed by AI through the application.

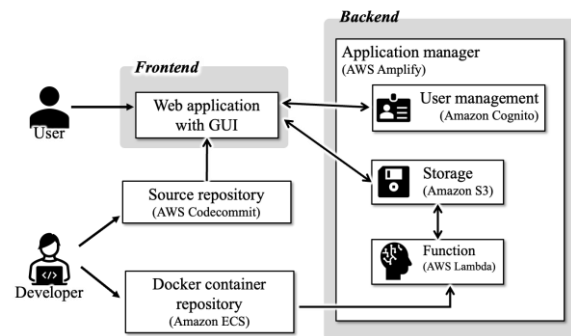
In this study, a web application with a graphical user interface (GUI) has been selected and developed to meet the previously specified requirements. Cloud storage and CPU resources on the cloud have been utilized to automate image processing. By leveraging cloud computing, a large amount of information about the debris can be collected through smartphones owned by individuals.


Fig. 2 The system structure and network resources

3. Developed web application

3.1. *Amazon Web Service (AWS)*

In developing the web application, Amazon Web Services (AWS) was chosen as the platform for constructing its network infrastructure. AWS, the cloud computing service provided by Amazon Web Services Inc., has been offering services, including network infrastructure. By integrating various services within AWS, the web application developer can rapidly create an application with extensibility and robustness.

3.2. *The system structure*

Fig. 2 shows the structure of the system (as the web application). As mentioned above, resources such as storage for data or image processing have been implemented by integrating services provided by AWS (e.g., AWS Amplify, S3, AWS Lambda, etc.). The system can be divided into two subsystems: a frontend and a backend. The frontend is software that can be executed on a web browser, essentially a web page including a GUI. The resources required to implement the functions of the application are referred to as the backend, and they exist on the cloud.

In this study, the frontend was designed as a web page with a file browser UI, allowing users to choose images and buttons to initiate the upload of the selected image. On the backend side, the implementation included (1) User identification and management functions, (2) The

storage region on the cloud, and (3) Virtual CPU executing inferencing process. Particularly, the details of the inference processing are explained in the next section in this paper.

Fig. 3 Captured debris by user

Fig. 4 Example of detection and identification debris by the SaaS: Right side was identified "Styrofoam". Left side was identified "Other plastics".

3.3. *Inference process based on DNN*

In this study, a DNN-based inference is used to detect captured debris in an uploaded image and classify its category. In this process, *mmdetection* [5] was used as the DNN framework, and *Mask-RCNN* [6] was employed as the neural network architecture for detection of debris. And, *TACO dataset* [7], it is large dataset for garbage was utilized as the annotated data. In this study, the dataset was classified by eleven categories as below:

- Plastic bottle
- Can
- Glass
- Metal
- Tabaco
- Rubber
- Rope & String
- Styrofoam
- Paper
- Other plastics
- Others

Fig. 3 shows an example of input image including the actual beach-drifted debris, and Fig. 4 shows example of inference result of Fig. 3 image.

4. Experiment in actual environment

The developed system has been implemented in an actual beach cleanup event and verified. The event, held in June 2023 at Hokuto-mizukumi Park (Munakata, Fukuoka, Japan), aimed to have participants use the system. In this cleanup activity, approximately 70 individuals from 30 families participated, spending one hour cleaning up the beach. It is estimated that 30 to 40 smartphones were used to utilize the system. The participants were instructed to upload images capturing the found debris after finished the cleanup activity. The total number of gathered images was 317, and AI's identification processing detected 954 beach-drifted debris. Fig. 5 represents the numbers for each category of debris, with the majority falling under "Other plastics," including plastic fragments and buoys used in fisheries. As shown in Fig. 5, plastics were detected significantly more than other categories. Fig. 6 shows examples of results where debris identified as "Other plastics.". From these results, it was confirmed that:

- There were instances of misidentifying shells or colored natural objects as plastics.
- Single plastic objects were occasionally detected as multiple plastic objects.

So it will suggest (1) participants could easily spot plastics on the beach, leading to intensive collection, and
Fig. 5 The result of number of each category of detected debris

Ayumu Tominaga, Ryohei Komori, Eiji Hayashi

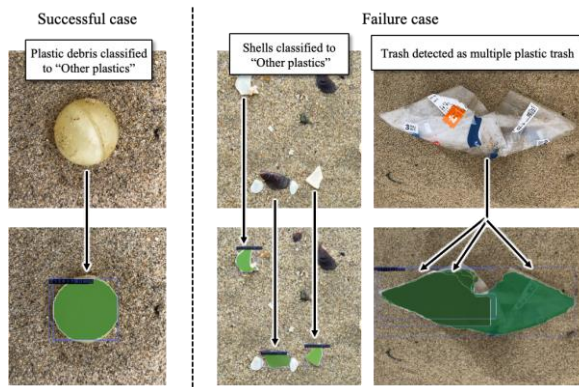
(2) to enhance object detection accuracy, reconstruction of the learning dataset for debris is necessary.


Fig. 6 Example of the input and detected "Other plastics"

5. Conclusion

In this study, a cloud service-based web application was developed to promote the quantification of beach-drifted debris. This web application, which can be used from a smartphone, aims to gather a large-scale beach debris dataset through beach cleanup events. One advantage of this proposal is that many people can easily participate in debris quantification work. In the case of experimental verification, the system successfully collected over 300 images capturing debris and detected over 900 debris with the participation of about 70 cleanup event participants. In the future, efforts will be made to enhance the usability of the application, making it less stressful for users. Additionally, long-term verification, spanning months or even years, will be conducted to address and improve the physical situation of beach-drifted debris.

Abstract

The advancement of digital transformation in manufacturing is expected to demand novel tasks for industrial machinery unlike before. When adding mechanisms or actuators to enhance machine functionality, concerns arise about potential system enlargement and increased complexity. The design concept of integrating multiple functions into mechanisms using a few actuators and components serves as one means to address these issues. We aim to elucidate the structural arrangement capable of achieving three functions, including normal motion, rapid motion, and variable stiffness, using two electric actuators. In this paper, we introduce a newly devised antagonistic wire-driven joint mechanism aimed at improving the variable stiffness function within the articulated mechanism we have developed, enabling three functionalities.

Keywords: Rapid motion, Variable stiffness, Link mechanism

1. Introduction

Digital transformation is being promoted through the use of robots and digital technologies, such as the Internet of Things and artificial intelligence, with the aim of increasing productivity and manpower saving. In response, robots will be required to perform tasks that have not been done before, and it will be necessary to promote research and development of robots that can perform movements and functions that have not yet been generalized. One area is soft robotics, which can perform rapid motion and variable stiffness. For example, in the food industry, in order to realize the automation of the serving operation of prepared food, it is necessary for the robot to grasp the hardness of the food and to pick and place it according to the hardness of the food so that the soft food does not fall apart. Mochizuki et al. are conducting research on non-contact acoustic impedance estimation using ultrasonic waves before picking to optimize the gripping rigidity in order to reduce damage caused by food picking operations using robot hands [1]. To achieve automation, this system needs to be supplemented with a hand that can change the stiffness of the fingertips. In addition, percussion testing is being researched to predict the firmness of tomatoes to determine their expiration date, to estimate the sugar content of fruit, and to determine whether canned goods are defective [2], [3]. To automate percussion testing, an appropriate hammering mechanism is required in addition to a sensing system.

Adding additional mechanisms and actuators to integrate multiple functions into a robot can increase system complexity and size. Therefore, a design concept that allows mechanisms to have multiple functions with fewer actuators and parts is one way to address these issues.

Katsuaki Suzuki, Yuya Nishida , Kazuo Ishii

Aiming to realize three functions with a small number of actuators, we developed a joint mechanism that realizes normal motion, rapid motion, and variable stiffness with two motors [4], [5]. Our research results have shown that these functions can be realized. However, in the variable stiffness function, an end-effector does not rotate unless the load torque applied to the end-effector exceeds the torque applied to the end-effector by the pre-compressed spring to increase stiffness. In this paper, we propose a new antagonistic wire-driven joint mechanism that can rotate the end-effector at the moment load torque is applied to the end-effector, even in a stiff state, in order to improve the functionality related to variable stiffness of joint mechanisms that can realize the three functions.

2. Antagonistic wire-driven joint mechanism

Fig. 1 shows the proposed mechanism. The proposed mechanism consists of the end-effector, a main joint, two wires, two springs, two linear guides, and two cam units. Assume that the positions of the linear guide and main joint are fixed in space. Additionally, the linear guide and slider are a prismatic pair. The internal structure of the cam unit consists of a slider, a passive pulley, an input pulley, a cam follower, a cam, a worm wheel, a worm, and a motor.The function of the cam unit is to extend and retract the wire and release the energy stored in the spring. Rotation of the motor causes the cam to rotate through the worm gear mechanism. Since the cam follower and the input pulley are connected, when the input pulley rotates, the cam follower performs an orbital motion. Therefore, the input pulley rotates driven by the rotation of the cam. For ease of understanding, we will now discuss the structure using the simplified proposed mechanism shown in Fig. 2.

The main difference between Fig. 1 and Fig. 2 is that the cam unit is represented by an electric actuator. As shown in Fig. 3, during normal motion, the end-effector rotates counterclockwise with actuator 1 in the active state and actuator 2 in the passive state. For rapid motion, as shown in Fig. 4, when the two actuators are active, the two sliders move toward the main joint and energy is stored in the two compression springs. Now, when actuator 1 is in the braking state and actuator 2 is in the passive state, the forces on the wires are out of balance and the two sliders are moving away from the main joint. Since actuator 1 is in the braking state, the compression spring force acting on the sliders acts on the end-effector

through the wires, and the end-effector performs a rapid motion. Next, consider the variable stiffness function. As shown in Fig. 5, first assume a state in which the two springs are compressed by ε_{sp} and the two actuators are braked. Then assume a state in which a load torque is
Fig. 1 Conceptual model
Fig. 2 Simple model
Fig. 3 Normal motion
Fig. 4 Rapid motion
Fig. 5 Variable-stiffness function

applied to the end effector and the end effector is rotated counterclockwise to θ_o. At this time, wire 2 is wrapped around the end effector and slider 2 makes a translational movement toward the main joint, increasing the

compressive force acting on spring 2. Therefore, the torque due to the compression force of spring 2 acts on the end-effector in the direction of resisting the load torque. On the other hand, since the wire 1 originally wound around the end-effector is unwound, the slider 1 makes a translational movement in the direction away from the main joint, and the compression force originally acting on the spring 1 decreases. In other words, the torque due to the compression force of spring 1 acts on the end effector in the direction to assist against the load torque. By using this load torque support mechanism, the end-effector can be rotated at the moment when a load torque is applied to the end-effector. In addition, by adjusting the value of ε_{sp}, the compression force of the spring can be changed, and thus the rotational rigidity of the joint can be varied. The relation between the load torque T_q and the internal force acting inside the mechanism is expressed as follows based on their geometric relation:

$$T_q = k_{sp}R_o\left(\frac{\delta_{sp1}}{sin\,\alpha_1} - \frac{\delta_{sp2}}{sin\,\alpha_2}\right) \qquad (1)$$

In Eq. (1), α_* is expressed as follows:

$$\alpha_* = tan^{-1}\frac{l_{sp*}l_{w*} + l_sR_o}{l_sl_{w*} - l_{sp*}R_o} \qquad (2)$$

The rotational stiffness K of the end-effector is expressed using the following equation by differentiating the load torque T_q exerted on the end-effector by the angle θ_o of the output link:

$$K = \frac{dT_q}{d\theta_o} = K_{b2} - K_{b1} \qquad (3)$$

In Eq. (3), K_{b*} is expressed as follows:

$$K_{b*} = \frac{R_o^2k_{sp}l_{w*}}{l_{sp*}\,sin\,\alpha_*} + \frac{\left[\frac{R_o^2k_{sp}\delta_{sp*}l_{w*}l_s}{l_{sp*}(l_{sp*}^2 + l_s^2)} - \frac{R_o^3k_{sp}\delta_{sp*}}{(R_o^2 + l_{w*}^2)}\right]}{sin\,\alpha_*\,tan\,\alpha_*} \qquad (4)$$

In Eq. (4), with $\varepsilon_{sp} = 0$, $K_{b1} = 0$ for counterclockwise rotation of the output link and $K_{b2} = 0$ for clockwise rotation.

3. Analysis of output characteristics

Using the equations derived in Chapter 2, we analyzed the output characteristics with respect to variable stiffness. Fig. 6 shows the profile of the load torque T_q and angle θ_o of the end-effector at initial spring displacements ε_{sp} of 0, 5, 10, and 15 mm (Eq. (1)). Further, Table 1 shows the values of each parameter used in the analysis. The analysis was performed assuming that a load torque was applied to the end-effector and the

angle θ_o was rotated from 0[deg] (initial posture) to +40[deg] and then from 0[deg] to -40[deg]. The analysis results confirm that the load torque increases as the angle θ_o increases. Furthermore, as the value of ε_{sp} increases, the load torque required to rotate the joint increases. Even when ε_{sp} was set, the load torque applied to the end-effector did not have to exceed the torque applied to the end-effector by the pre-compressed spring. On the other hand, it can be observed that the maximum displacement angle decreases as the value of ε_{sp} increases. This is because as ε_{sp} increases, the distance between the slider and the main joint becomes shorter and the range of motion of the slider becomes smaller. Fig. 7 shows the profile of the rotational stiffness K and angle θ_o of the end-effector when the initial spring displacement ε_{sp} is 0, 5, 10, and 15 mm (Eq. (3)). It can be observed that as ε_{sp} increases, the rotational stiffness of the main joint increases. It can also be observed that the value of each stiffness increases rapidly near the end point of the motion. This is because as the angle θ_o increases, the distance between the slider and the main joint becomes shorter, and the tension generated in the wire increases as α_* becomes smaller.
Fig. 6 Relationship between the rotational angle of end effector and load torque

Table 1. Design parameters

k_{sp}	Spring constant	500 N/m
R	Radius of end-effector	0.01m
l_s	Length of slider	0.02 m
l_{spn}	Natural length of spring	0.02 m
$max(\theta_o)$	Maximum movement range	$+40°$
$min(\theta_o)$	Minimum movement range	$-40°$
Fig. 7 Relationship between the rotational angle of
end effector and rotational stiffness

4. Conclusion

In this study, we describes the structure of the new mechanism and demonstrated a method for realizing normal motion, rapid motion, and variable stiffness. Additionally, we derived expressions for variable stiffness and analyzed. In the previously developed joint mechanism, the end-effector does not rotate unless the load torque exceeds the torque applied to the end-effector by the spring preloaded to increase the rigidity. As a result of the analysis, it was theoretically clarified that the newly proposed joint mechanism can solve this problem and rotate the end-effector at the moment the load torque is applied. Future issues include the search for a more optimal link ratio and the need to verify the effectiveness of the system by fabricating an actual machine and evaluating its performance.

Abstract

The number of robots exiting in human living spaces has increased, and interaction between humans and robots has become an important issue. The purpose of this study is to propose a future society where humans, animals, and robots coexist. We organize relay race, or ekiden in Japanese, where they compete together as runners. The competition rules have been established to ensure that each runner can compete fairly. This paper explains the competition rules and discuss the fairness of the rules

Keywords: Robotics competition, Ekiden, Human-Robot Interaction, Robot coexistence society

1. Introduction

Various robotics competitions [1], [2] have been held for social implementation with the development of robotics and artificial intelligence. In these competitions, robots mainly compete about functional performance. On the other hand, the content of robotics competitions changes to more challenging tasks aimed at coexistence between humans and robots [3].

Traditionally, robots have been introduced into industrial environments where safety has been ensured by cages. However, in recent years, the environment in which robots work has been changed to match the daily lives of humans. Research on human-agent interaction [4] and human-robot interaction [5] have aimed to the future society in which humans and robots coexist in harmony. On the other hand, in the universal situation of human society, there are many types of mobile objects: humans, animals, and vehicles. There are few examples of demonstration experiments or discussions about the role of robots in such environments.

We have held "Gakken Hills Interdisciplinary Ekiden" as the opportunity to think about the future society in which humans and robots coexist in harmony [6]. This ekiden is the relay race which humans, animals, and robots compete together on the same field. We held the 8th race on May 13, 2023. This paper describes the competition rules, introduces the characteristics and transition of participants from the 1st to the 8th races, and discusses the fairness of the rules.

2. Gakken Hills Interdisciplinary Ekiden

Takuya Fujinaga, Moeko Tominaga, Daigo Katayama, Kazuo Ishii

2.1. *Overview*

We organize this ekiden with the aim of making it a starting point for thinking about the future society in which humans and robots coexist and discussing the directions and challenges of such a society. The 1st race was held in 2014 and the 8th in 2023. Various runners have participated so far: humans regardless of age or gender, animals (mainly dogs) and robots with various movement and operation methods. To ensure fairness for the runners in this ekiden, where a wide variety of runners coexist, we have set our own competition rules. The competition rules have been adjusted every year based on law revision, developments in science and technology, and past competition results. In the following, the current competition rules are described.

2.2. *Rules for all runners*

Runners are divided into categories [P] (Person), [A] (Animal) and [R] (Robot). Category [P] is humans aged 18 years or older, [A] is dogs, cats, and other animals (excluding horses, cows, and other light vehicles) and [R] is robots and electric wheelchairs (excluding flying robots). One of the rules for the [R] sets the use of an electric motor as a prime mover, and electric wheelchairs are classified as the [R].

One team consists of four runners, and, in principle, the four runners are two males and two females. However, the [A] and [R] can be classified as either male or female. Note that within one team, the [A] and [R] can each have up to one runner participating. The race distance differs depending on the category: about 1.6km for the [P] and [A], and about 0.8km for the [R]. For details of the course, see the ekiden website [7].

This ekiden sets advantages so that humans, animals, and robots can compete fairly. The rank in the competition are determined based on the results of applying advantages to the race results. Details of the advantages are stated in 2.4.

2.3. *Rules for robots*

The rules for robot participation are as follows. We set these rules based on Japanese road traffic act.
- The max size is 120cm, 70cm, and 120cm in length, width, and height, respectively.
- An electric motor is used as a prime mover.
- Traveling speed is 6 km/h or less.

- No sharp protruding parts or devices that may cause harm to others.
- The robot has a function that enables it to be stopped quickly in an emergency.

The advantages are applied to different categories of runners in this ekiden, and robots have different advantages depending on their movement and operating methods. Runners in the [R] are classified into the following three classes.
- Direct operation class:
  requires human intervention (e.g. electric wheelchairs, electric kickboards)
- Remote operation class:
  no requires human intervention
- Automatic operation class:
  applicable to three or more of the following five items
  - Do not require a remote controller or other operating device (e.g. human following).
  - Do not require real-time operation by humans (e.g. driving using satellite positioning systems).
  - Make action selections based on environmental recognition (e.g. obstacle avoidance).
  - Have originality (e.g. does not use existing products as a base, or not wheel-based type).
  - Submit a technical poster

Note that in this ekiden, the human intervention is defined as pushing, carrying, or directly touching the robot to adjust its traveling direction by humans.

2.4. *Advantages*

The advantages are determined by the age of the [P], the participation of animals, the robot specifications. The results which are applied the advantages are used to determine the final competition results and the rank. Three types of advantages are defined: age advantage, animal advantage and robot advantage. For the age advantage, let N_p and Age_{total} be the number of participants in category [P] and their total age, respectively. If Eq. (1) is satisfied, Adv_p seconds (Eq. (2)) is subtracted from the race result.

$$Age_{total} > 25 \times N_p \qquad (1)$$

$$Adv_p = Age_{total} \times 2 \qquad (2)$$

For the animal advantage, let T_A be the race time in the [A]. The unit is seconds. The result R_A seconds which applying the animal advantage is calculated from Eq. (3). Note that the method of calculating R_A depends on the value of T_A.

$$R_A = \begin{cases} \dfrac{1}{2}T_A + 120 \ (T_A \le 600) \\ \dfrac{1}{10}T_A + 360 \ (600 < T_A \le 2400) \end{cases} \quad (3)$$

For the robot advantage, let R_A be the race time in the [R]. The unit is seconds. The result R_R seconds which applying the robot advantage is calculated using one of Eqs. (4) to (6). Eq. (4) is for the direct operation class ($R_{R(Direct)}$), Eq. (5) for the remote operation class ($R_{R(Remote)}$) and Eq. (6) for the automatic operation class $R_{R(Auto)}$). Note that T_R is between 480 seconds (8 minutes) and 2400 seconds (40 minutes).

$$R_{R(Direct)} = \frac{1}{10}T_R + 390 \quad (4)$$

$$R_{R(Remote)} = \frac{1}{10}T_R + 270 \quad (5)$$

$$R_{R(Auto)} = \frac{1}{10}T_R + 150 \quad (6)$$

The constant number of these equations for the advantages was determined based on the results of previous competitions results to ensure that all runners can compete fairly.

3. Results and discussion

Table 1 shows the transitions in the number of participants from the 1st to the 8th races. The number of runners per team was six from the 1st to the 5th races, and from the 6th race, it was four due to a change in the rules. Regarding the proportion in each race, the category [P] accounts for 70-90%, the [A] was just under 10%, and the [R] was just over 10%. The number of participants in the [A] so far has been 15, all of them dogs. All runners in the [P] and [A] completed the race. The number of participants in the [R] so far has been 45. For the traveling method of the [R], two of the 45 robots were multi-legged or bipedal walking types rather than wheel-based type. For the operating method, six out 45 robots were semi- or full-automatic. Examples of its

Table 1 Transitions in the number of participants

Times	Team	[P]	[A]	[R]
1	13	70	1	7
2	10	52	1	7
3	7	31	3	8
4	6	30	2	4
5	8	43	1	4
6	10	34	3	3
7	12	40	2	6
8	12	40	2	6

Table 2 Average and standard deviation (S.D.) of 8th race results in each category (m: minutes, s: seconds)

Category	Average	S.D.
[P]: male	8m21s	1m33s
[P]: female	10m19s	1m36s
[A]	7m04s	16s
[R]	6m50s	54s
Fig. 1: Average and standard deviation of each race result in each category

operation methods were as follows: human tracking using image processing, driving using waypoints, route tracking using the global navigation satellite system, simultaneous localization and mapping (SLAM) using a laser sensor and an inertial measurement unit. Runners who completed the race within the time limit was 35 robots. The multi-legged and bipedal walking types mentioned above were unable to complete the race. Of the six autonomous robots, two were able to complete the race within the time, one using waypoints and the other using SLAM.

Table 2 shows the average and standard deviation of the results for each category in the 8th race. The results of the [A] and [R] were equal to or higher than those of the [P]. Therefore, rules regarding advantages works, and runners could compete regardless of their characteristics. The details are on the ekiden website [7].

This paper discusses the validity of rules regarding advantages. Fig. 1 shows the average and standard deviation of the competition results for each category since the 6th race. The results for the [A] and [R] are the results of applying the advantages. Note that the race distance for the [R] has been changed since the 6th race, so only the results from then on are shown. The results of the [P] have little variation each race. On the other hand, the [A] was at a slow compared to the [P] in the 6th race, and furthermore, the standard deviation was large in the 7th race. The [R] is also at a slow compared to the [P] in the 6th race. However, in the 7th race, the

Takuya Fujinaga, Moeko Tominaga, Daigo Katayama, Kazuo Ishii

robot advantage was revised based on the previous race results of the [P], so the results of the 7th and 8th races of [R] and [P] are fair. Based on this result, the animal advantage was similarly revised for the 8th race. In the 8th race, the results of the [A] and [R] were equal to or better than those in the [P]. Therefore, these results show that for each runner to compete fairly, it is appropriate to set an advantage based on a certain standard.

4. Conclusions

We have held the ekiden for thinking about a future society in which humans and robots coexist in harmony. The 1st race was held in 2014, and the 8th in 2023. The rules have been revised for each race based on previous race results and law revision. With the spread of robots, laws regarding robots were established, and the rules for the 8th race were determined based on the laws. This paper showed validity of the rules from race results. We have continued to discuss how robots coexist with humans in future society through this ekiden.

Abstract

Underwater robots are utilized for underwater observation. Generally, the development of underwater robots demands a significant amount of funds, posing a high barrier for research, development, and education. The aim of this study is to reduce these barriers, facilitating broader implementation of research, development, and education in the field of underwater robotics. This paper describes the development policy and cost of a low-cost underwater robot and discusses considerations based on the results in the robotics competition.

Keywords: Underwater robot, Underwater drone, Remotely operated vehicle, Low-cost, Robotics competition

1. Introduction

Underwater robots are used as a means of underwater observation. Research and development of underwater robots has been studied since the 1960s [1]. Recently, underwater robots are called as underwater drones and become spread to society. When using underwater robots as tools for underwater geological and biological surveys etc., it is beneficial to use commercially available underwater robots. However, when underwater robots are the subject of research and development or education, the specifications required for the robot vary depending on the purpose. Therefore, it is necessary to develop the robot independently. Underwater robots come in a variety of sizes, from large to small, and research and development has been carried out depending on the purpose [2], [3]. There are also underwater robots developed for education [4].

Generally, the development of underwater robots demands a significant amount of funds, posing a high barrier for research, development, and education. Although some underwater robots have been developed for low-cost, the development cost still ranges from $4,000 to $15,000 [5], [6], [7]. Underwater robots differ from robots that move on land or in the air, and the following are the minimum requirements for their development: watertightness, pressure resistance, and adjusting buoyancy etc. There are also various types of tacit knowledge.

The aim of this study is to reduce barrier of the development cost, facilitating broader implementation of research, development, and education in the field of underwater robotics. This paper describes the development policy and cost of a low-cost underwater robot and discusses considerations based on the results of the robotics competition.

2. Method

2.1. *Development policy*

Underwater robots are mainly classified into five types: glider, cruise, hovering, biomimetic, and vehicle. The selection of each type is determined by the target work and research policy. The glider-type generally does not have propulsion devices and can adjust their own buoyancy and center of gravity, enabling long-term observation. The cruise-type has a long and slender structure, so it has high propulsion efficiency and can conduct wide-ranging surveys. The hovering-type can perform more complex movements than the above-

mentioned types by attaching multiple propulsors, making detailed observations possible. The biomimetic-type imitates the characteristics of fish and other animals, can be propelled by fish fins rather than propellers, and are superior to the above types in terms of energy efficiency and consideration for marine life. The vehicle-type can move on the seabed or on the hull of a ship and perform work on those surfaces, such as digging and cleaning. This study adopts the hovering-type for the purpose of detailed underwater observation. The underwater robot developed in this study is designed to operate underwater for about 30 minutes to 1 hour, targeting shallow part of the ocean with an observation depth of 10m or less.

The main components of the hovering-type underwater robot that performs underwater observation are as follows: computers, sensors, thrusters, energy sources. The computers control the underwater robot by controlling the propeller, acquiring sensor information, and selecting the actions. There are various types of sensors depending on the purpose of observation, such as cameras and acoustic devices. Underwater robots also require positioning and navigation equipment and sonar sensor to measure their own posture, position, speed, and surrounding environment. In some cases, sensors account for a large portion of the development cost. Electric thrusters are generally used as propulsion devices, and a high degree of freedom in movement performance is achieved by attaching multiple thrusters. The energy sources need to be selected appropriately to operate the above-mentioned components at the desired operating time. In addition to the above components, communication equipment, work equipment, ballast, etc. are added as necessary.

The low-cost underwater robot in this study also consists of computers, sensors, thrusters, and energy sources. The sensors are equipped with a camera, depth sensor, and inertial measurement unit (IMU). As an option, add underwater lights to conduct underwater observations. In order to control this robot from the ground and check the data acquired by the robot, the external computer on the ground and the internal computer on the underwater robot are connected with an optical fiber cable, and this robot is moored from the ground using this cable. Therefore, this robot becomes a remotely operated vehicle (ROV). However, the development policy is to make it easy to expand the

sensor so that it can be changed to an autonomous underwater vehicle (AUV).

The functional requirements for the low-cost underwater robot are described above. As non-functional requirements, this robot is considered portability and parts availability. For the portability, the design is based on the weight and ease of carrying by one person. To ensure the ease of obtaining the parts, use parts that can be easily purchased at online shopping or home centers. Note that some parts are manufactured using 3D printer and laser beam machining. Regarding the development cost, previous studies has proposed a cost of $4,000 to $15,000 for a low-cost underwater robot. In this study, the development cost is less than $2,000.

2.2. *Low-cost underwater robot*

The design drawing of the low-cos underwater robot is shown in Fig. 1, and the components are shown in Table 1. Although, there is a certain distance offset between each component to show the components in Fig. 1, each component is connected as shown in the actual appearance in Fig. 2. This robot mainly consists of the following.
- Frame (No. 1 and 2 in Fig. 1)
- Main box (No. 8) that stores the computers, depth sensor, IMU, etc.
- Battery box (No. 9) that stores the batteries and circuits
- Thrusters (No. 21 and 22)
- Camera unit (No. 4)
- Underwater lights (No. 5)
- Acrylic plates and joints to connect the above components (No. 16-19)

The energy from the battery box is supplied to the main box via cable gland. A total of six thrusters are installed, total of four ones in the front and rear for movement in the xy-plane, and two in the center for movement in the z-axis direction. The camera unit is independent from the main box, and the data is acquired by connecting its power and signal lines to the main box. Each box has holes for cable glands, and the number of holes can be increased or decreased as the number of sensors or thrusters changes, ensuring expandability. Additionally, when this robot adjusts its buoyancy, it fills the poly vinyl chloride (PVC) pipe of the frame with fresh water to maintain neutral buoyancy. A cap (No. 3) is provided to make it easy to put in and take out the water.

The specifications of this robot are shown in Table 2, and the system architecture is shown in Fig. 3. This robot is a size and weight that can be carried by one person. In terms of watertightness and pressure resistance, it can withstand water depths of 1.5m for 30 minutes. Testing at deeper water depths is a future task. To access the internal computer from the external computer, the ethernet connection is converted to an optic fiber connection inside the main box, and the signal is transmitted to the external computer through the optical fiber cable. The external computer is paired with the joystick device via Bluetooth, and the operator can remotely control the underwater robot by operating the joystick device. The internal computer is connected to each sensor and a micro controller unit (MCU). The MCU sends signals to the electronic speed controllers (ESCs), which controls the thruster speed, and to the underwater lights and indicator LEDs. The LEDs are installed to check the on/off status of the internal computer and the operating status of this robot. Fig. 4 shows the circuit architecture inside the battery and main boxes. The battery box has two power supplies: 11.1V for the thrusters and underwater lights, and 5V for the computer and optical media converter. Note that 5V is converted from 7.4V batteries. For the software, this robot distributes processing between the internal computer and MCU and the external computer (Fig. 5). The former acquires data from each sensor and controls the thrusters, underwater lights, and indicator LEDs, while the latter sends commands to the underwater robot and analyzes the acquired data. This robot realizes distributed processing using robot operating system (ROS).

The development cost for this robot is approximately $1,800 (250,000 yen). The proportions of parts by categories are as follows: 6.0% for the frame, 9.6% for cable-related parts, 30.4% for the main box including internal computer, MCU, and ESCs, etc., and 6.8% for the battery box including batteries, converters, and

(a) Front view   (b) Rear view

8	Main box	19	Joint for fixing the two boxes
9	Battery box	20	Thruster guards
10	Cable gland for a power line	21	Thrusters for clockwise propellers
11	Switches	22	Thrusters for counterclockwise propellers

relays, etc., 8.0% for thrusters, 13.6% for sensors, 17.6% for underwater lights, and 8.0% for other including mechanical and electronic parts and 3D printer materials. The frame is used PVC pipe. Products from *TAKACHI Electronics Enclosure* Co., Ltd. are used for the cable gland, main and battery boxes. The internal computer is Jetson Nano and the MCU is Arduino Micro. The type of battery is LiPo. The thruster is a brushless motor for drones, and the motor has a rotation speed of 3100rpm per unit voltage when no

load is applied. The ESC, camera, depth sensor, etc. are products from *BlueRobotics*. The IMU is used BNO055 produced by *BOSCH*.

3. Results and discussion

To evaluate the performance of this robot, it participated in an underwater robotics competition held on October 7, 2023 [8]. This robot entered in the AUV category, but its operation method was ROV. The field of this competition consists of the following areas: for slaloming between buoys, for passing through gates, for observing, for searching an acoustic source, for floating. This robot challenged areas other than the searching an acoustic source area. Fig. 6 shows the depth data and yaw angle data during this competition. This robot started to dive into the field (Fig. 6), moved on the bottom ((ii)), traveled the slaloming area ((iii)), passed the gate, and observed the target ((iv)). Then, this robot turned its direction of travel toward the starting point, that is, rotated its heading 180 degrees, and returned to the starting point. Finally, this robot attempted to float, but the fuse for the 11.1V blown, making it impossible to continue and the trial ended.

The results of this competition confirmed that this robot was able to move on the xy-plane at a speed of approximately 0.15m/s. Fig. 6 showed that the depth and posture of this robot could be measured using each sensor. In the observation area, the USB camera inside this robot was able to read the target panel with QR code and numbers printed on it. On the other hand, regarding the movement in the z-axis direction, the xy-plane of this robot has a larger square measure than other planes, so the underwater drag during floating or diving is also large. For this reason, the load on the thrusters was greater in the z-axis movement than in the xy-plane one, and the fuse worked as a safety measure.

Fig. 2 View of developed low-cost underwater robot

Table 2 Specifications

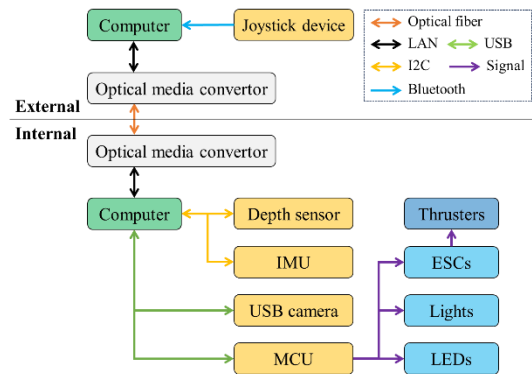
Dimensions	410 x 400 x 240mm (L x W x H)
Weight	7.0kg (8.0kg when the pipe is filled with water)
Batteries	11.1V, 2.2Ah x 2, 7.4V, 2.2Ah x 2
Computer	CPU: Quad-core ARM A57 @ 1.43GHz, Memory: 4GB
Sensors	USB camera, Depth sensor, IMU
Communications	Ethernet, Optical LAN


Fig. 3 System architecture for in/external of this robot
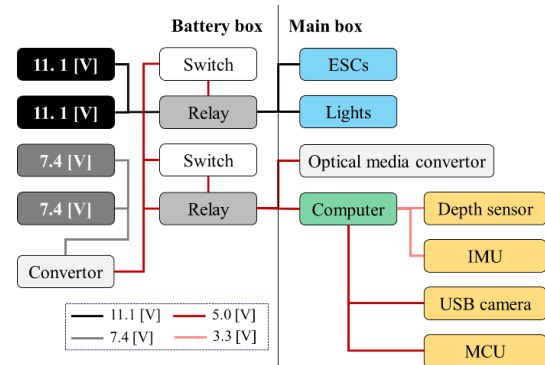

Fig. 4 Circuit architecture
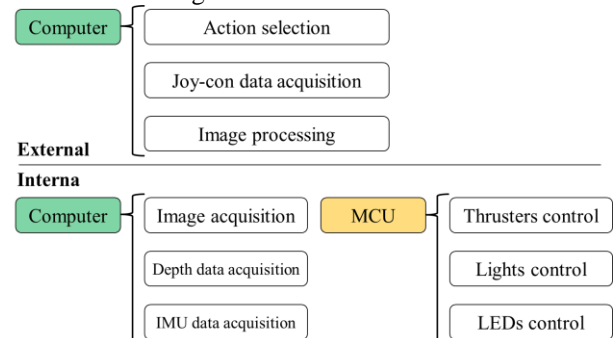

Fig. 5 Software architecture of in/external computer
Fig 6 Results of depth data and yaw angle

This robot used a glass tube type fuse, and the holder for it is made of resin. During test before this competition, the plastic holder melted due to the heat generated by the load caused by the rotation of the thrusters. Therefore, as a safety measure, a 5A fuse was used. However, when designing this robot, cables were selected with a permissible current of 15A. Based on these findings, future tasks for this robot include reconsidering the shape of this robot and redesigning the circuit inside the battery box so that it can move in the z-axis direction. Additionally, the purpose of this study is to develop a low-cost underwater robot platform and make it open access. Towards this end, future tasks also include conducting pressure tests, implementing depth and heading control, dead reckoning, and underwater object detection using each sensor.

4. Conclusion

This paper described the development policy and cost of a low-cost underwater robot. This robot was a hovering-type and ROV. The development cost was $1,800. This paper analyzed the sensor data and discussed the motion performance based on the results in the robotics competition. The next tasks are to improve motion performance in the vertical direction and make it an AUV using sensor data. The goal is to open source the requirements and tacit knowledge for the development of the low-cost underwater robot.

Abstract

The synergistic collaboration between UAVs and UGVs addresses the limitations of individual platforms, offering a versatile solution for reconnaissance tasks in diverse environments. The proposed system employs ROS as the underlying architecture to facilitate seamless communication and coordination among multiple UAVs and UGVs. We delve into the intricacies of developing a robust communication framework that enables real-time data exchange and decision-making, fostering a synchronized and adaptive operation. Furthermore, the article explores strategies for path planning and navigation, considering the unique mobility constraints of UAVs and UGVs. Optimal coverage is ensured through efficient exploration and coverage of the reconnaissance area, under by comparing raster-scan, expanding spiral and zig-zag area exploration approaches. The article concludes by discussing potential extensions, such as the integration of machine learning techniques for enhanced autonomy and the scalability of the system for larger-scale missions by presenting a ROS-based framework that maximizes the synergy between UAVs and UGVs.

Keywords: Heterogeneous unmanned systems, Cooperative Path Planning, Reconnaissance, UAV, UGV, ROS

1. Introduction

With the surge in utilization of unmanned systems for research and their applications, the need for cooperation among heterogenous systems has made to the spotlight. The cooperation among heterogeneous systems exploits the diversity of features in unmanned system to achieve such mission objectives which are near impossible for homogenous systems. Forming a cooperative reconnaissance strategy for multiple unmanned vehicles in unknown areas has proven to be reliable and improves the heading errors of the vehicles [1]. Effective reconnaissance in modern military applications possesses the key for a strategic advantage, and also helps to neutralize surprise attacks, ambushes and can prevent the damages through improvised explosive devices (IEDs) with proactive sensory modules [2]. This is why combining Unmanned Ground Vehicles

Anees ul Husnain, Norrima Mokthar, Takao Ito, Siti Sendari, Muhammad Farris Kyasudeen, Muhammad Badri M Noor, Heshalini Rajagopal

(UGVs) alongside UAVs to coordinate area reconnaissance combines the technical and tactical capabilities of both to achieve the same. However, there are certain challenges linked with combing these unmanned systems.

This work addresses one of such challenges that naturally appears when the UAVs and UGVs are required to perform a coordinated reconnaissance in an unknown area. The nature of terrain and obstacles can affect the conditions required to maintain the reconnaissance formation between the aerial and ground vehicles [3]. A set of conditions is established which comprises two key components: a). The unmanned vehicles, UAV and UGV, have to explore the territory in close proximity. b). Minimize the impact of terrain-based slowness of UGV on the UAV.

This work presents a novel technique and coordination architecture that ensures the conditions above and explores the area effectively.

2. Proposed Method

2.1. UAV / UGV Coordination Architecture

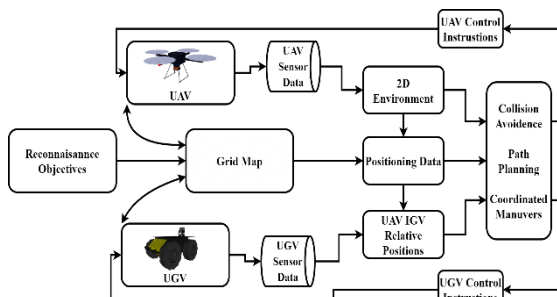
The requirements for reconnaissance formation are primarily derived from the differences in maneuverability between both of the vehicles and impact of terrain on movability of UGV. The relative positions of the heterogenous vehicles, reconnaissance objectives and the environment data (grid map) are combined to generate the planning data, as shown in Fig. 1. The planning data further combines with the relative positions of UAV and UGV, and the trajectory data from UAV is fed to the path planning unit. The path planning unit, considering the conditions mentioned in Section 1, generates instructions for both UAV & UGV for coordinated maneuvers alongside requirements like collision avoidance.


Fig. 1. UAV/UGV Coordination Architecture

2.2. Measure of Objectiveness in coordination

Self-assembly is a technique to attain cohesion in heterogenous robots which is perceived as robotic intelligence. The robots are required to assemble themselves that may not be possible through maneuverability [4]. There are three primary objectives under self-assembling the UAV and UGV to generate maneuver instructions and capitalize on interaction between them to work on complex tasks more efficiently.

(i)   Robustness: To reperform the task while maintaining the cohesion in proximity in case of any missing area to be explored.

(ii)   Versatility: To adjust and readjust the maneuvers because of uneven terrain and ground obstacles for the UGV.

(iii)   Cost reduction: To minimize the cost for the above. Here the cost is computed in terms of the time lapsed and number of turns a robot has to take. through design of large numbers of robots.

2.3. Attraction / Repulsion Mechanism in UAV / UGV

There are two primary tasks which are being performed at all the time: collision avoidance for the ground vehicle and flocking of UAV with respect to the ground vehicle. Collision avoidance in this work is basically a necessary condition for the UGV to maintain a minimum safe distance from its surroundings objects.

This work is inspired from a recent published work which engaged heterogenous robots in an 'invisible binding' by implementing an "Attraction / Repulsion" mechanism using Voronoi partitioning, based on Voronoi Diagrams for collision avoidance [5]. However, our approach exploits the idea of attraction-repulsion for heterogenous robots and generates path instructions in a zone-based coordinate system. Aggregation and dispersion are the two phenomena which are derived from the inter-robot's distance and their distribution in the area needed to be explored. This work mitigates this problem through establishing zones based on the distances and focuses on reconnaissance of the territory.

The proposed model consists of four constraints i.e. placement, repulsion, attraction, and orientation. The placement may take place either randomly or with some prior information from the area of reconnaissance. The model is based on a set of universal equations proposed by Ian Couzin cited by [6]. Referring to Eq. (1), Eq. (2)

and Eq. (3), where dr, do and da represent the radii of repulsion, operation and attraction zones with i and j representing coordinates. Fig. 2 presents an illustration for the three scenarios.

$$d_r(t + \tilde{L}) = -\sum_{j \neq i}^{M_r} \frac{rij(t)}{|rij(t)|} \quad (1)$$

$$d_o(t + \tilde{L}) = \sum_{j \neq i}^{M_o} \frac{Vj(t)}{|Vj(t)|} \quad (2)$$

$$d_a(t + \tilde{L}) = -\sum_{j \neq i}^{M_a} \frac{rij(t)}{|rij(t)|} \quad (3)$$
Fig. 2. Attraction Repulsion Mechanism with Placement and operational zone

2.4. Parallel Maneuver Generations for UAV / UGV

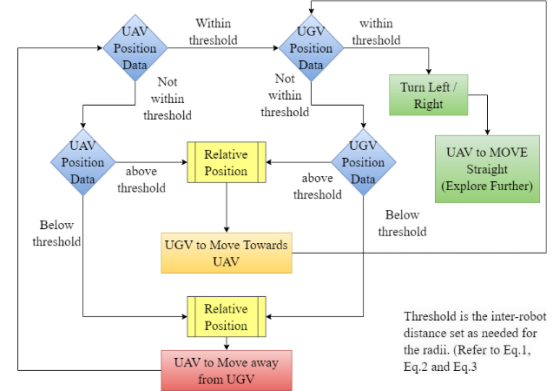
Here it is important to mention that either of the heterogeneous robots has to be set as the leader or follower. Moreover, the radii of the zones are adaptable according to the terrain and area under consideration. The maneuver generation takes sensor and positioning data from both unmanned vehicles and create relative positions of UAV and UGV, refer to the Fig. 1. This data generates maneuvering instructions in a 2D workspace, assuming a constant altitude of the UAV. Fig. 3 presents the maneuver generations of for both UAV and UGV. To better understand the flow of an instruction generation, consider the UAV and UGV in the placement zone.


Fig. 3. Parallel Maneuver Generation for UAV /UGV

3. Implementation

3.1. Simulation Setup

Robot Operating System (ROS) is an opensource platform that provides libraries for and tools for a diverse range of robotic applications. These libraries include the hardware abstraction, driver packages, data visualizers, inter-module communication packages and protocols [7]. Gazebo on the other hand simulates the robotic application in a simulated environment [8]. Both these projects are lead by a community called open robotics [9].

For this work, we consider HUSKY and HECTOR which are emulated versions of opensource UGV and UAV, respectively. The integration of Husky and Hector within ROS provides the foundation of collaborative autonomous systems, showcasing the potential coordination among heterogeneous robots. There are four key components for setting up this collaboration:
  (i)   Sensor data Integration
  (ii) Communication of sensor data, control instructions and status of UAV / UGV
  (iii) Motion Control and Mission Planning.
  (iv) Mapping and Navigation.

3.2. Experimentation

The experimental scenarios are established for a comprehensive evaluation of the collaboration and exploration capabilities of Hector and Husky. There are two primary considerations in mind before setting up experimental scenarios:
  (i)   To validate the ability of this collaboration system for exploration and mapping
  (ii) To evaluate the adaptiveness of the system against the challenges in the environment. (Under this work, the challenges refer to static obstacles and uneven terrain.)

Anees ul Husnain, Norrima Mokthar, Takao Ito, Siti Sendari, Muhammad Farris Kyasudeen, Muhammad Badri M Noor, Heshalini Rajagopal

3.3. Flow of Activities

(i) Initialize the ROS-Gazebo environment through ROS launch file. For uneven terrain, there is a stock environment available in Gazebo which has been deployed.

(ii) Deploy Hector UAV and Husky UGV equipped with LiDAR sensors.

(iii) Command Husky for Autonomous Exploration and Hector for aerial mapping.

(iv) Initiate the program for exchanging Lidar and positioning data between Husky and Hector and compute relative positions. The relative data and position histories are stored and explored regions are marked with the coordinates of the environment.

(v) Constraints initialization: This is the main program which generates the thresholds from the relative positions. This module also utilizes LiDAR data from Husky for its collision avoidance.

(vi) Creation of unified map that combines the explored area from both of the platforms.

(vii) Collection of performance parameters which are percentage of area explored, number of maneuvers required, and overall time taken.

(viii) Analysis of exploration data and suggestions for optimizations.

4. Results and Discussion

Since there isn't any notion of geo-referenced coordinates in Gazebo, therefore, the positioning data in the simulation, for both the platforms, is collected in Cartesian Coordinate space. Fig. 4 presents the screenshot of deployment of both platforms while coordinating repulsive motion.

Fig. 4. Hector and Husky Deployment in a stock environment in Gazebo

The synergic collaboration between the two autonomous platforms performed simultaneous mapping based on the combining the aerial and ground data. The UGV is instructed to follow a programmed exploration strategy which can be modified as needed, while the Hector UAV performs the mapping of the aerial mapping of the environment.

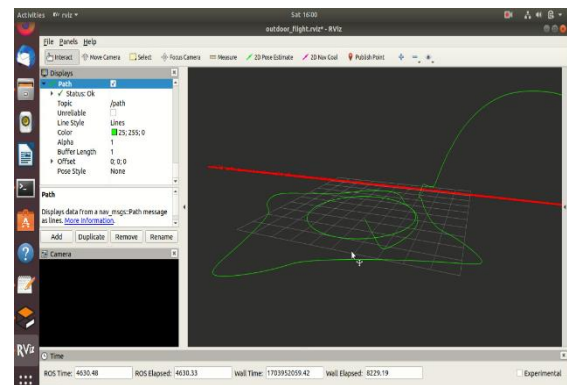
Fig. 5 presents the initialization of exploration through Husky in the pattern given to it. While Fig. 6 presents the aerial mapping of Hector of the environment shown in Fig. 4.


Fig. 5. Expanding Circular Exploration lead by Husky UGV, path trail in RVIZ visualizer
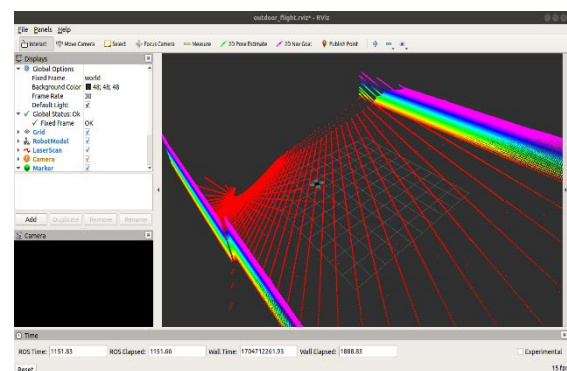

Fig. 6. Aerial Mapping being conducted through Hector UAV, LiDAR data being shown in RVIZ

5. Conclusion

The work demonstrated a successful integration of two heterogeneous autonomous unmanned systems in ROS-Gazebo environment, proving their potential to use them for reconnaissance applications in unknown workspaces. The key feature of this work was to propose an attraction-repulsion mechanism among the aerial and ground vehicles for a strategic and coordinated exploration. This work is at the early stages of experimentation and possess the potential for further enhancements which primarily include optimization of exploration algorithms and strategies. Moreover, this

work just incorporates two unmanned systems which can be expanded to exhibit a swarm intelligence behavior among UAVs or UGVs. We believe that the future of exploratory missions in unknown or hostile environments is very promising when it comes to unmanned systems.

6. Acknowledgements

This work is conducted under research group formed at University of Malaya, Kuala Lumpur in which the individuals from diverse universities and industries participate. The author gratefully acknowledges ACR Lab, Faculty of Engineering, University of Malaya and their members for providing assistance during assembling and testing.

Authors Introduction

Mr. Anees ul Husnain

Anees is currently pursuing his Doctoral in Electrical Engineering at University of Malaya, Malaysia. He holds a master's degree in computer engineering from UET Taxila, Pakistan. He is working on autonomous path generation of UAVs to monitor fugitive emissions.

Ir. Dr. Norrima Mokhtar

Norrima Mokhtar received the Bachelor of Engineering (B. Eng) degree in Electrical Engineering from University of Malaya in 2000. She was appointed as a lecturer to serve the Department of Electrical Engineering, University of Malaya immediately after graduating with her Master of Engineering. As part of her career development, she received SLAB/SLAI scholarship to attain her Ph.D. in 2012. She is now serving Department of Electrical Engineering, University of Malaya.

Dr. Takao Ito

He is Professor of Management of Technology (MoT) in Graduate School of Engineering at Hiroshima University. He is serving concurrently as Professor of Harbin Institute of Technology (Weihai) China. He has published numerous papers in refereed journals and proceedings, particularly in the area of management science, and computer science. He has published more than eight academic books including a book on Network Organizations and Information (Japanese Edition). His current research interests include automata theory, artificial intelligence, systems control, quantitative analysis of inter-firm relationships using graph theory, and engineering approach of organizational structures using complex systems theory.

Dr. Siti Sendari

She is a lecturer at Universitas Negeri Malang, Indonesia, specializing in intelligent systems, robotics, and evolutionary computation. She holds the position of Head of Laboratory in the Department of Electrical Engineering at the Faculty of Engineering. Her work focuses on intelligent systems and related areas, contributing to the academic community.

Ir. Muhammad Farris Kyasudeen

He is associated with Universiti Teknologi MARA (UiTM) in Malaysia. He is part of the Faculty of Electrical Engineering at UiTM's branch in Pulau Pinang, where he holds the position of Ir. Abstract

Facial expression recognition (FER) has been acknowledged as a significant modality that could bring facial expression into human-machine interaction and make the interaction more efficient. However, the ability of FER to operate in a fully automated and robust manner is still challenging. Illumination effects, for example, make the facial expression images always contaminated with different levels of ambient noise (such as brightness variation) in a cluttered background. Thus, this paper aims to investigate the illumination effects (brightness variations) on facial expression recognition using empirical mode decomposition reconstruction techniques. In this framework, firstly, the noisy facial expression images were simulated with the illumination effects using different brightness levels of 30%, 40%, 50%, 60%, and 70%. Then, the EMD will decompose the noisy facial expression images into a small set of intrinsic mode functions (IMF), namely IMF1, IMF2, IMF3, and residue. Based on property held by EMD, the signals are decomposed into several IMF components, each with a different time scale. Because the last several IMFs represent the majority of illumination effects, various reconstruction techniques for IMFs have been investigated at various brightness levels. Feature reduction techniques Principal component analysis (PCA) and linear discriminant analysis (LDA) have been employed to reduce the high-dimensional space of IMF features into low-dimensional IMF features. The reduced IMF reconstructions were then used as input to the k-nearest neighbour classifier to recognise the seven facial expressions. A series of experiments have been conducted on the JAFEE database using various reconstruction IMFs together with PCA plus LDA. Based on the results obtained, the reconstruction of IMF1 + IMF2 + IMF3 shows the highest accuracy in high illumination conditions, which is 99.06%.

Keywords: Illumination, Facial Expression Recognition, Empirical Mode Decomposition, PCA plus LDA.

1 Introduction

Facial expression is the most natural and important tool people have to show their emotional-state or deliver information. For decades, facial expression has been regarded as an important modality for conveying feelings and attitudes, and it has had an impact on physical communication. Specifically, facial expression is formed by contracting facial muscles [1]. Facial expression recognition (FER) is a function that humans and computers can perform by locating the face from its sources. Then, facial features will be analysed to classify the emotion [2]. A lot of information about human

behaviour can be effectively extracted from their facial expression. Facial expression recognition (FER) has been acknowledge as a significant modality that could bring facial expression into human machine interaction and makes the interaction more efficient. However, the ability of FER to operate in fully automated with robust is still challenging. Illumination effects for example, make the facial expression images always contaminated with different level of ambient noise (such as brightness variation) in clutter background. In previous work, limited study was conducted on illuminations effects for facial expression recognition. For example, [3] have combined the logarithm transform, discrete cosine

Hasimah Ali, M Hariharan, Wan Khairunizam Wan Ahmad, M Elshaikh

transform, and illumination compensation as a normalised DCT to eliminate illumination variation contained in the facial images of the JAFFE database. To recognise the facial expression, the extracted features from the pre-processed image were combined with a neural network classifier. However, analysis of the effects of illumination was not discussed. In [4], the authors utilized the independence component analysis (ICA) and locality-preserving projection to compare the effectiveness of those methods towards the illumination variations on the face recognition. They found ICA outperformed the results on YALEB database with 64 illuminations types. In [5], the authors utilized deep learning approach for emotion recognition under different pose and illumination variations. The Convolution Neural Network were constructed using 15 layers (three layers per emotion) that learn from facial expression database (CMU Multi-PIE) using input size of 32 x 32 in recognizing the five basic emotions. Although they achieved 96.55%, selecting optimum the input size considered to be computational cost. In [6] the authors utilized a deep stacked convolutional autoencoder in attempting reconstruct new input images with better illumination for facial expression recognition. The model used as pre-training in greedy layer-wise by learning the image representation and then map it to approximately reconstruction of input image. The network model learns to encode the input images and create a feature vector form relatively similar illumination, ignoring the level of luminance of the facial images. Even though the used of deep learning is emerging, however handcraft features of the image provides significant impact in understanding the behaviour of spatial details of the images. Therefore, in this study, we propose to investigate the illumination effect on facial expression recognition (FER) by using empirical mode decomposition (EMD) approach. In this framework, the original facial expression database will go through face detection in a manipulated illumination condition, and then various illumination coefficients will be analysed. The EMD will be used to decomposed the illuminated images (in our case brightness variations) into a set of intrinsic mode functions (IMFs). These IMFs will be used to further analyse the illumination effects containing in facial expression images. The significant IMFs will be reconstructed by removing the one contains illuminations. In order to reduce dimensionality of reconstructed IMF, PCA plus LDA will be adopted.

Finally, the reduced features of reconstructed IMFs will be classified using k-NN classifier to recognize the seven facial expression under the illumination effects.

2 Materials and Method

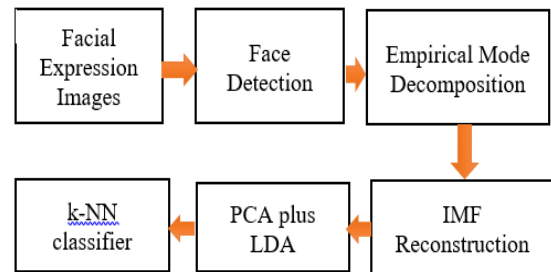
Fig. 1 shows the framework of the proposed system. It consists of five phases: facial expression image database, pre-processing, EMD-based feature extraction, IMF reconstruction, and classification. In this framework, firstly, the facial expression image was pre-processed to detect the local region of the face. Then, brightness variations were simulated on the detected face. By decomposing an image into a set of intrinsic mode functions via a sifting process on the simulated brightness of a facial expression database, the nonlinear technique, namely EMD, has been used as a feature extraction-method. To assess performance, an IMF reconstruction was performed on various IMFs. Later, feature reduction was applied to the reconstructed image to reduce its dimensionality before being subjected to the classifier. The detailed description of the process is highlighted as follows:


Fig. 1. Framework of the proposed method

2.1 *Facial Expression Database*

In this study, the Japanese Female Facial Expression (JAFFE) database has been used. It contains 213 grayscale facial expression images of ten subjects, all Japanese women, with seven facial expressions: neutral (30 images), angry (30 images), sad (30 images), happy (31 images), disgust (29 images), surprise (31 images), and fear (32 images).

2.2 Image Pre-Processing: Face Detection

Face detection is a technique used to detect and localize the face region from the unwanted background. The original size of JAFFE image is 256 x 256 pixel was cropped into 128 x 96 pixel that contains the face region. Fig. 2(a) and Fig. 2(b) show the example of the original and cropped image of seven facial expressions of a JAFFE subject, respectively.
Fig. 2. Seven facial expression of JAFFE's subject: (a) original and (b) cropped image

2.3 Brightness Variation

In this study, illumination variation with different levels of brightness was used to simulate illumination effects that mimic real-world applications. The illumination variations were simulated by varying the brightness effect by controlling the intensity of each individual pixel inside the image. The percentage illumination level used in this project is 30%, 40%, 50%, 60%, and 70%. A percentage greater or less than those specified will result in either increased brightness or decreased darkness.

2.4 Feature Extraction: Empirical Mode Decomposition

Empirical mode decomposition (EMD) is a method of decomposing a natural signal without leaving the time domain. EMD decomposes any nonlinear signal into a small set of finite intrinsic mode functions (IMFs). Although EMD is focused on analysing one-dimensional signals, it can also be extended to bi-dimensional empirical mode decomposition (BEMD) to analyse two-dimensional signals while still having similar concepts and procedures [7], [8]. The main advantage of EMD is that it can extract data about local trends in the input signal by calculating and quantizing oscillations. Such oscillations can be quantized by local details and matching a local trend. The fundamental ideas of EMD are the implementation of the incorporation method such as cubic splines, sifting phase to extract the intrinsic

mode function, and numerical convergence criteria to stop the sifting phase.

In the EMD technique, there are two steps that must be met to extract the intrinsic mode functions (IMFs). To begin, the number of extremes and zero crossings must be equal, or at most one. Second, the mean of its upper and lower envelopes must not be more or less than zero. Those two steps satisfy the physically compulsory process for defining a significant instantaneous frequency. The EMD technique's entire procedure is as follows: for input signal s(t):

1. Determine the local maxima and local minima of s(t). Let $d_0(t) = s(t)$.
2. Incorporate the local maxima and the local minima to develop the upper envelope eu(t) and lower envelope el(t), correspondingly, using cubic B splines.
3. Calculate the mean of envelope m(t): $m(t) = (e_u(t) + e_l(t))/2$.
4. Determine the details using $d_1(t)=d_0(t)-m(t)$ (sifting phase).
5. Repeat steps 1-4 on the residual signal until the details signal $d_k(t)$ is included in the IMF: $c_1(t)=d_k(t)$
6. Procedures 1–5 should be repeated on the residual $rn(t)=s(t).C_n(t)$ to obtain all of the signal's IMFs ($c_1(t), c_2(t),..., c_n(t)$).

When the residual signal is either unaltered, monotone, or a function with just one extrema, the procedure is terminated. The advantage of the EMD approach is that once these IMFs are acquired, they may easily switch back and forth from them to the original signal. Similarly, the original signal may be reconstructed by combining all of the IMFs together, which can be adjusted to account for slight variations owing to the implant discovered in the method. EMD can be expressed in mathematically as:

$$X(n) = \sum_{n=1}^{N} C_n(t) + R_N(t) \qquad (1)$$

According to the technique, lower-order IMFs record rapid oscillation modes, whereas higher order IMFs record low oscillation modes. In this research, two-dimensional empirical mode decomposition (BEMD) is used to reduce illuminated face pictures into a limited collection of intrinsic mode functions (BIMFs). The BIMFs are features recovered at various scales or spatial frequencies using phase sifting.

2.5 Dimensionality reduction: PCA plus LDA

In this work, the PCA plus LDA has been employed as dimensionality reduction on the extracted IMFs features

2.5.1 PCA

Although the intrinsic mode functions effectively represent the different frequencies of oscillation for different expressions (local trends) in the image, the mode function responses can be large. A 128 x 96 image, for example, decomposes with the EMD resulting mode function into a 128 x 96 = 12,288-dimensional vector. To reduce the dimensions of the feature vector, we applied PCA to our mode function. Let consider, if $A = \{a_1, a_2, a_3 \ldots a_N\}$ is a vector of N images.

i. First, calculate the mean (μ) of the matrix, and covariance matrix (S) as:

$$S = \frac{1}{n}\sum_{i=1}^{n}(a_i - \mu)(a_i - \mu)^T \qquad (2)$$

ii. Calculate both eigenvalues (λ_i) and eigenvectors (v_i) of S as:

$$Sv_i = \lambda_i v_i, \qquad (3)$$

where i=1, 2, 3…n.

iii. Lastly, sort the eigenvectors in descending order that associated to the largest eigenvalues. The new projected space is given b:

$$y = W^T a, \qquad (4)$$

which W is represent the transformation matrix [9].

2.5.2 LDA

One of the main problem in pattern recognition is the curse of dimensionality. LDA is one of the method used to solve the issue of dimensionality by reducing the features from higher-dimensional space to lower-dimensional space. The goal of LDA is to shape the class scatter by maximizing the between-class scatter and minimising the within-class scatter [9]. In this framework, firstly we need to compute the between-class variance S_B as:

$$S_B = \sum_{i=1}^{n} N_i(\mu_i - \mu)(\mu_i - \mu)^T \qquad (5)$$

Second, within-class scatter, S_w need to be computed by $S_W = \sum_c \sum (a_k - \mu_i)(a_k - \mu_i)^T$. Finally, the lower-dimensional feature projection, W_{lda} can be determined via:

$$W_{lda} = \arg\max \left| \frac{W^T S_B W}{W^T S_W W} \right| = [w_1, w_2, w_3 \ldots w_m] \qquad (6)$$

in which w_i ($i = 1, 2, \ldots m$) is the set of S_B and S_w generalized eigenvectors based on the largest generalized eigenvalues λ_i of $S_B w_i = \lambda_i S_W w_i$.

2.5.3 PCA plus LDA

To avoid singularity of the S_w, [10] proposed PCA plus LDA. This framework involves two stages. First, original feature vector having f-dimensional feature space is mapped onto t-dimensional intermediate feature space in which ($t < f$) via PCA. Then, project the intermediate (t-dimensional) to k-dimensional feature space via LDA resulting new projected space as:

$$z_i = W_{pca}^T W_{lda}^T x_i \qquad (7)$$

where i = {1, 2, 3..N} is the number of input images.

3 Results and Discussion

In order to evaluate the effectiveness of the proposed system, the JAFFE database, which is publicly available, has been used in this experiment. The facial images obtained from successful face detection and applied with different levels of illumination will undergo feature extraction using the EMD technique in order to extract the features called intrinsic mode functions (IMFs) through sifting procedures. IMFs are extracted from high-dimensional data. As a result, feature reduction using PCA and LDA was used before being fed as input to the k-NN classifier to classify all seven emotions: anger, disgust, fear, neutral, happiness, sadness, and surprise.

3.1 Brightness Variation on Facial Expression Images

The facial images from JAFFE database are simulated with different level of illumination which is 30%, 40%, 50%, 60% and 70%. This is done by adding and subtracting the intensity of each pixel inside of the facial images. Fig. 3 shows the simulated illumination of facial expression images.
Fig. 3. Simulated illumination effects of facial expression images at different brightness level

3.2 Performance of applied EMD on expression images

The two-dimensional breakdown of a picture using the sifting process results in an interpretable display. Each IMF carries information on a certain scale that is efficiently segregated. Fig. 4 depicts the EMD decomposition of facial expression image into IMF1, IMF2, IMF3, and residual. Note that, the IMF1 contains local information about the smallest scales in the image, whereas the residue contains information about greater scales [7]. Specifically, IMF1 corresponds to the lowest time scale associated with the information's quickest time fluctuation. As the decomposition process progresses, the time scale increases, and the mean frequency of the mode decreases. As observed in Fig. 4, the set of IMF reveals the influent structure from the smallest to the largest relative to the input images. The IMF1 shows the most distinct facial features, including the boundary lines around the face region such as the mouth, nose, and eyes, which are crucial for expression recognition.
Fig. 4. EMD decomposition that associated with 30% brightness level

3.3 Performance Analysis on Facial Expression Recognition using Reconstructed Intrinsic Mode Function

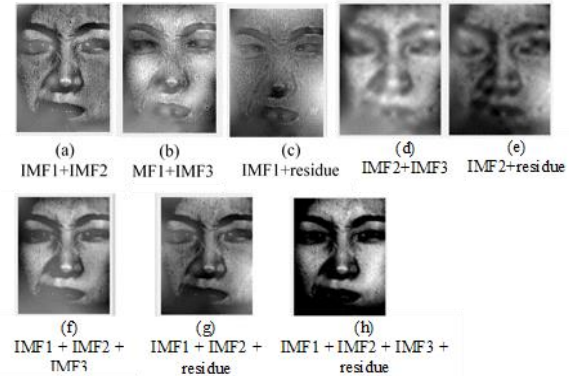
According to [11], the majority of the illumination effects is represented by the last several IMFs. To evaluate how EMD can be employed to reduce the illumination effects in the proposed system. Fig. 5 shows the different combinations of the reconstructed mode functions. It should be noted that Figure 5(h) is a reconstruction of all IMF and a residue, and thus serves as a reference image. As can be seen in Fig. 5, the illumination effect was highly dominant in (b), (c), and (d). Whereas, (e), (f), and (g), the illumination effect appeared at a low degree. Meanwhile, in (a), which is IMF1+IMF2, the effects were almost gone. This observation agrees with [11] in which the several last mode functions are affected by illumination.


Fig. 5. Reconstruction of different mode functions (30% brightness level): (a) IMF1+IMF2, (b) IMF1+IMF3 and (c) IMF1+residue, (d) IMF2+IMF3, (e) IMF2+residue, (f) IMF1 + IMF2 + IMF3, (g) IMF1 + IMF2 + residue and (h) IMF1 + IMF2 + IMF3+residue (reference)

3.4 Performance Analysis of Applied PCA plus LDA on reconstructed IMFs

In this work, three reconstruction modes of IMFs have been investigated: IMF1+IMF2, IMF1+IMF2+IMF3, and IMF1+IMF2+IMF3+residue. Due to the higher dimensionality of feature space, the frameworks of PCA plus LDA were applied. The rationale for using PCA plus LDA is that, the feature vector space was reduced from a high-dimensional to a low-dimensional space by utilising the PCA plus LDA framework as mentioned in Section 2.5. Fig. 6 shows the distribution of reduced features due to IMF1+IMF2+IMF3+residue, whereas Fig. 7 shows the distribution of reduced features due to IMF1+IMF2+IMF3 at a 30% brightness level. Note that classes 1, 2, 3, 4, 5, 6, and 7 are denoted as *angry* (red), *disgust* (orange), *fear* (green), *happy* (cyan), *neutral* (blue), *sad* (purple), and *surprised* (pink), respectively. It can be seen in Fig. 6 that there is a low degree of overlap between the emotions of fear, anger, disgust, and neutral. Fig. 7 shows that the class emotions are well differentiated from one another.

Hasimah Ali, M Hariharan, Wan Khairunizam Wan Ahmad, M Elshaikh
Fig. 6. Distribution of reduced features of **IMF1+IMF2+IMF3+residue** for seven facial expressions at 30% brightness level.
Fig. 7. Distribution of reduced features of **IMF1+IMF2+IMF3** for seven facial expressions at 30% brightness level.

3.5 Experimental Results

In this section, the reduced features using PCA plus LDA were applied to the reconstruction IMFs to recognize the seven facial expressions. The objective is to investigate the effectiveness of reconstruction IMFs in dealing with variations in illumination. Three different modes of IMF reconstruction were evaluated, namely IMF1+IMF2+IMF3+residue (used as reference), IMF1+IMF2+IMF3, and IMF1+IMF2 under different levels of illumination, which are 30%, 40%, 50%, 60%, and 70%. In this work, k-nearest neighbour was used as a classifier using a 10-fold cross validation strategy.

Fig. 8, Fig. 9, Fig. 10, Fig. 11, and Fig. 12 illustrate the recognition rate of IMF reconstruction of facial expression recognition at brightness levels of 30%, 40%, 50%, 60%, and 70%, respectively. As observed in Fig. 8, the reconstruction of IMF1+IMF2 shows the

highest recognition rate, which is 99.06% at a 30% brightness level. It seems that the combined IMF1+IMF2 is enough and would achieve similar recognition as in the reference. We agree that, the illumination effect may lie inside the IMF3 and residue. When the brightness level increased to 40% (Fig. 9), the combined IMF1+IMF2 again showed the highest recognition rate of 99.53%, which is slightly higher by 0.53% than the reference.

In Fig. 10, at a brightness level of 50%, the combined IMF1+IMF2+IMF3 shows the highest recognition of 99.53%, which is the same as the reference. Similar trends appear for brightness levels of 60% (Fig. 11) and 70% (Fig.12), where the combined IMF1+IMF2+IMF3 outperformed the results, which are 99.53% and 98.59%, respectively. This can be inferred from the fact that as the brightness level increases, the combined IMF without residue shows significant results. Thus, we agree that the majority of illumination effects may be represented by the last IMFs and residue.

Fig. 12. Accuracy of FER based on reconstructed IMF at 70% brightness level.

4   Conclusion

This paper used an empirical mode decomposition approach to present the effects of illumination on facial expression recognition. Firstly, pre-processing of the facial image has been done via face detection to extract the local region of the face. Then, the face image was simulated to mimic the illumination effects by varying the brightness level between 30%, 40%, 50%, and 70%. Then, the simulated facial images were decomposed using empirical mode decomposition into a finite set of intrinsic mode functions. This work (IMF1, IMF2, IMF3, and residue) has been extracted via a sifting process. According to the findings, illumination effects may have been observed in the last few IMFs. Three reconstruction modes were considered for illumination analysis, which are the combined IMF1+IMF2, IMF1+IMF2+IMF3, and IMF1+IMF2+IMF3+residue (as reference). Based on the results obtained, at low brightness levels (30% and 40%), the combined IMF1+IMF2 gives the highest recognition rate of FER. However, as the brightness level was further increased to 50%, 60%, and 70%, the combined IMF1+IMF2+IMF3 gave the highest recognition rate. Therefore, we can conclude that as the brightness level increases, the combined IMF without residue shows significant results, and we agree that the majority of illumination effects may be represented by the last IMF and residue. However, more research on a larger dataset using different machine learning techniques is required to improve the robustness of FER to illumination effects.

Abstract

In this letter, a highly stable soliton mode-locked Erbium-doped fiber laser (EDFL) is passively obtained using a molybdenum disulfide (MoS_2) thin film as a saturable absorber (SA). The MoS_2 thin film obtained via electrochemical deposition technique is integrated into an EDFL cavity to generate mode-locked pulses operating at 1.88 MHz with a pulse duration of 3.03 ps. Supercontinuum (SC) light is generated using the proposed soliton mode pulses operating at 1560.4 nm as they are injected into a 100 m long highly nonlinear photonic crystal fiber (HN-PCF) after it is amplified to the output power of 17.8 dBm. The SC light operates in a wavelength range starting from 1360 nm to more than 1750 nm with the intensity above -35 dBm. The proposed supercontinuum laser can be seen as a promising light source for metrology and sensing applications.

Keywords: Fiber laser, supercontinuum, molybdenum disulfide, soliton.

1. Introduction

Super-continuum (SC) light sources combine the broadband attributes of lamps with the high brightness and spatial coherence of lasers. They have attracted extensive attention in recent years owing to their numerous applications in optical coherent tomography [1], optical communication [2], metrology [3] and sensing [4]. Broadband SC lasers are normally generated through a mode locked laser, which is coupled into a highly nonlinearity fiber (HNLF). The nonlinear mechanisms leading to the generation of SC include stimulated Raman scattering (SRS), four-wave mixing (FWM), self-phase modulation (SPM), cross-phase modulation (XPM), and dispersive-wave generation (DWG) [5]. Since the Raman Effect is self-phase-matched and shifts light to longer wavelength by emission of optical phonons, the SC spreads to longer wavelengths very efficiently. The short wavelength edge arises from four-wave mixing, and often the short wavelength edge is limited by increasing group velocity dispersion in the fiber.

Many works have been performed to understand the phenomenon as well as to implement the intended practical devices. To achieve a wider continuum and higher output power, mode-locked laser system that provides picosecond pulse train with high peak power must be employed as a pump source. Such systems utilizing passive saturable absorber (SA) as a mode-locker have been widely reported over the last decade.

2. Methodology

2.1. *Fabrication of MoS² SA*

Within the framework of this experimental investigation, we propose a methodology that leverages the electro-deposition technique. More precisely, the experiment is designed to employ the electrodeposition process for cathodically depositing a molybdenum sulphoselenide film. This deposition procedure will be implemented on tin oxide-coated conducting glass substrates, as well as silicon and/or metal substrates [6]. The electro-deposition

Aeriyn D. Ahmad, Norrima Mokhtar, Hamzah Arof, Sulaiman Wadi Harun, Ahmad Haziq Aiman Rosol.

technique has undergone thorough investigation, particularly in the fabrication of metallic alloy thin films. As compared to alternative methods, electrodeposition stands out for its scalability and cost-effectiveness. This method is notably advantageous due to its non-vacuum nature and its operation at room temperature [7]. A cyclic voltammetry analysis and the electrodeposition of the thin film are conducted using a three-electrode configuration. The electrolysis cell comprises an ITO-coated conductive film designated as the working electrode (WE), where the deposition of the molybdenum disulfide (MoS2) thin film takes place [8]. In contrast, a graphite rod serves as the counter electrode (CE), and a saturated calomel electrode (SCE) with an Ag/AgCl reference system functions as the reference electrode [9].

2.2. *Cavity Characterization*

In this area, we carry out an experimental demonstration of a simplified optical fiber-based supercontinuum source operating a simple mode-locked fiber laser saturating Molybdenum Disulfide (MoS^2) as a saturable absorber (SA).

The suggested supercontinuum (SC) laser system is illustrated in Fig. 1, comprising three main keys: the MoS^2-based mode-locked Erbium-doped fiber laser (EDFL), an optical amplifier, and a 100-meter-long highly nonlinear photonic crystal fiber (HN-PCF). The mode-locked EDFL utilized a 2.4-meter-long Erbium-doped fiber (EDF) pumped with a 980 nm laser diode serving as the gain medium. The SA was tested by encapsulating the newly developed MoS^2 thin film, obtained through the electrochemical deposition technique. We achieved the growth of the MoS^2 thin film on a transparent conductive indium tin oxide (ITO) film by functionalizing MoS^2 nano-flakes in the presence of monochloroacetic acid. This thin film was integrated into the EDFL cavity to function as a mode-locker.

To enhance the cavity nonlinearity and align the dispersion with the nonlinearity, a 70-meter-long standard single-mode fiber (SMF) with a group velocity dispersion (GVD) of -21.7 ps2/km was incorporated into the cavity. An isolator was employed to maintain unidirectional laser oscillation within the cavity. An 80:20 coupler was utilized to extract 20% of the output laser while retaining 80% of the light within the cavity to sustain the oscillation. The GVD values for both EDF and wavelength division multiplexer (WDM) were approximately 27.6 ps^2/km and -48.5 ps^2/km, respectively. The total cavity length amounted to 83 meters, with an anomalous net cavity dispersion of -1.59 ps^2. The output from the mode-locked laser was

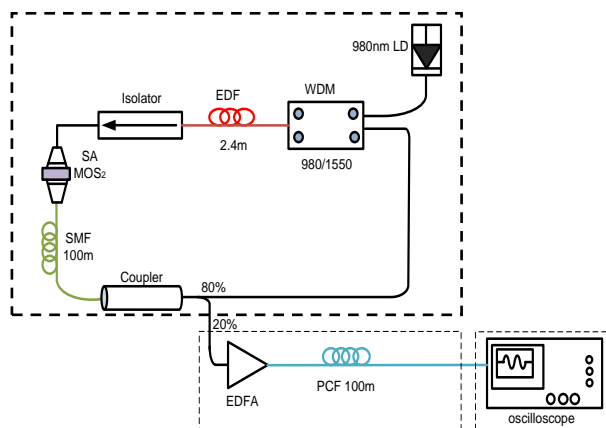
subsequently amplified and introduced into the HN-PCF for generating supercontinuum light.


Fig 1. The SC laser system consisting of three main components namely MoS$_2$ based mode-locked laser, optical amplifier, and a HN-PCF spool.

2.3. *Mode-Locking of MoS^2*

With anomalous net cavity dispersion, fundamental mode locking in the soliton regime is achieved from the EDFL at the pump power of 76.8 mW. By adjusting the pump power up to the maximum pump power of 123.7 mW, the mode-locking state is still preserved. The output spectrum of the output pulses measured by an optical spectrum analyzer (OSA) is depicted in Fig. 2. It centered at 1560.4 nm with a 3 dB spectral width of 2.2 nm. The Kelly sidebands are clearly seen to appear at both sides of spectrum symmetrically, indicating the EDFL operates in conventional soliton mode-locking state. Fig. 3 illustrates the typical pulse train, which has uniform intensity with the interval of two pulses of 536 ns. The pulse period corresponds to the repetition rate of 1.88 MHz, which agrees with the cavity length. The radio-frequency spectrum is measured to study the stability of soliton pulse as shown in Fig. 4. The signal-to-noise ratio (SNR) at the fundamental repetition rate of 1.88 MHz is measured to be higher than 60 dB, which indicates the pulsed laser operates at high stability. Fig. 5 shows the autocorrelation curve, which was obtained by an autocorrelator to measure pulse duration. The full width at half maximum (FWHM) is 4.70 ps, which indicates that the pulse duration is 3.03 ps considering the pulse shape is Sech^2.
Fig 2. Output Spectrum taken from OSA
Fig 3. Output measured from oscilloscope
Fig 4. Radio Frequency Output at 30MHz span
Fig 5. Autocorrelator

The average output power and pulse energy characteristics are shown in Fig. 6. As the pump power increases, both output power and pulse energy increase almost linearly. At the maximum pumping of 123.7 mW,

the output power and pulse energy are obtained at 0.79 mW and 0.42 nJ, respectively. To generate SC photons, the soliton laser is amplified by the optical amplifier and then launched into the HN-PCF. The amplifier boosts the signal up to the output power of 17.8 dBm so that it can initiate a spectral broadening in the so-called 'long pulse' regime. The HN-PCF used in the experiment has a zero dispersion at 1550 nm with á length of 100 m and nonlinearity coefficient of around $11W^{-1} km^{-1}$.
Fig. 6. The average output power and pulse energy at various launched pump power.

3. Results and Discussion

3.1. *Generation of Supercontinuum Light*

As the soliton picosecond pulses created through saturable absorption of MoS_2 are coupled into a HN-PCF, broadband SC photons are generated via various nonlinear mechanisms as shown in Fig. 7. We observe an SC light spanning from 1360 nm up to more than 1750 nm with output power of more than -35 dBm. As the amplified 1560.4 nm soliton pulse laser is injected into the PCF, the SC spreads to longer wavelengths very efficiently due to Raman effect, which is self-phase-matched to allow a shifting of light to longer wavelength by emission of optical phonons. The short wavelength edge arises from parametric four-wave mixing, which breaks up the higher-order solitons to produce frequencies at wavelengths shorter than the zero-dispersion wavelength.

The SC bandwidth can be further expanded by increasing the peak power of the injected pulses. This could be realized by improving the average power as well as compressing the pulse duration of the mode-locked laser. We expect a smaller pulse duration with the improvement of modulation depth and non-saturable loss of the MoS_2 SA. The use of an amplifier with higher saturated output power is also expected to further expand the bandwidth as well as improving the flatness and power of SC light.

Aeriyn D. Ahmad, Norrima Mokhtar, Hamzah Arof, Sulaiman Wadi Harun, Ahmad Haziq Aiman Rosol.
Fig. 7. SC generation due to the injection of the amplified soliton pulses into 100 m long HN-PCF.

From the broader bandwidth SC output, the potential application can be implemented are pulse generation, pulse amplification, pulse compression, metrology, spectroscopy, imaging, telecom and on-chip integration [10].

4. Conclusion

In conclusion, our research endeavors have yielded a successful demonstration of broad-spectrum supercontinuum (SC) light generation through the implementation of a newly developed mode-locked Erbium-doped fiber laser (EDFL) utilizing Molybdenum Disulfide (MoS^2) as a saturable absorber. The MoS2 thin film, synthesized via the electrochemical deposition technique, was seamlessly integrated into the EDFL cavity. This integration facilitated the generation of mode-locked soliton pulses operating at 1560.4 nm, characterized by a repetition rate of 1.88 MHz and a pulse duration of 3.03 picoseconds. The resultant pulses were subsequently amplified to an output power of 17.8 dBm and introduced into a 100-meter-long highly nonlinear photonic crystal fiber (HN-PCF) to induce SC light. The generated supercontinuum light spans a wavelength range from 1360 nm to beyond 1750 nm. This achievement holds significance in the context of advancing optical sources for applications in diverse fields such as telecommunications, metrology, and sensing.

Abstract

Arsenic(As) and selenium(Se) has become an increasingly serious water contamination worldwide, so the development of adsorbents to improve the adsorption performance of As and Se oxyanions is desired. In this study, NiZn adsorbents intercalated acetate, chloride, nitrate, and sulfate anions to interlayers of NiZn hydroxy double salts were prepared and their adsorption behavior of As and Se oxyanions was investigated. The Langmuir isotherm model, characteristic of monolayer adsorption, fit the experimental data well with $R^2 > 0.94$. The adsorption capacity(q_{max}) of Se(IV) was the other NiZn-AcO $\approx$ NiZn-Cl > NiZn-NO$_3$ > NiZn-SO$_4$ and that of Se(VI) was the order of NiZn-Cl > NiZn-AcO > NiZn-NO$_3$ > NiZn-SO$_4$. The q_{max} of as(V) on NiZn-Cl was about twice as large as that on NiZn-AcO, NiZn-NO$_3$ and NiZn-SO$_4$. NiZn-Cl was found to adsorb As(V) and Se(VI) oxyanions more efficient than NiZn-AcO.

Keywords: NiZn hydroxy double salts, arsenic, selenium, adsorption, Langmuir isotherm model

1. Introduction

Arsenic and selenium are known to be harmful to human body even at low concentration. The environmental standard values for arsenic [1] and selenium [2] in drinking water are set by the WHO guidelines as less than 0.01 mg/dm^3. Arsenic in nature has oxidation states of -3, 0, +3, and +5, and exists as inorganic and organic arsenic. Inorganic arsenic is known to more toxic than organic arsenic. Inorganic arsenic in natural water forms mainly oxyanions, arsenite (AsO_3^{3-}, As(III)) and arsenate (AsO_4^{3-}, As(V)). The acid dissociation constants of As(III) are pK_{a1}=9.23, pK_{a2}=12.13, and pK_{a3}=13.4, and there are four chemical forms, H_3AsO_3, $H_2AsO_3^-$, $HAsO_3^{2-}$, and AsO_3^{3-}[3]. The acid dissociation constants of As(V) are pK_{a1}=2.24, pK_{a2}=6.96, and pK_{a3}=11.5, and the chemical species are H_3AsO_4, $H_2AsO_4^-$, $HAsO_4^{2-}$, and AsO_4^{3-} [3]. Selenium solubilized and released into waste water exists in +4 and +6 oxidation states. Chemical species of selenium with these oxidation states are oxyanions selenite (SeO_3^{2-}, Se(IV)) and selenate (SeO_4^{2-}, Se(VI)) with high solubility and mobility in both aquatic and soil environment.. The acid dissociation constants of Se(IV) are pK_{a1}=2.62, pK_{a2}=8.23, and there are three chemical forms, H_2SeO_3, $HSeO_3^-$, and SeO_3^{2-} [4]. The acid dissociation constants of Se(VI) are pK_{a1}=1.7 and the chemical species are $HSeO_4^-$, and SeO_4^{2-} [4].

Hydroxyl double salts HDSs, one of inorganic anion-exchanger with a general formula $[M_A^{II}_{(1-x)}M_B^{II}_{2x}(OH)_2(Y^{z-})]_{2x/z}.nH_2O$. Specifically, the NiZn double basic salt with acetate anion (NiZn-AcO) Ni_{1-} $_xZn_{2x}(OH)_2(OCOCH_3)_{2x}.nH_2O$ has a structure in which 1/4 of Ni^{2+} in brucite-like layer of $Ni(OH)_2$ is removed from the brucite-like layer and two Zn^{2+} are located outside the layers, just above and below the Ni^{2+} vacancy [5], [6]. The layers have positive charges in excess, which are balanced by intercalation of acetate anion. The acetate anions bind directly to the tetrahedral sites along with three OH$^-$ groups from the layer to satisfy the coordination number of Zn^{2+}. The acetate anions are exchanged with guest ions in aqueous solution. Most of research on HDS is in the field of catalysis [7] and, to my knowledge, there are few applications in the aqueous environment. We reported that NiZn-AcO is an effective adsorbent for arsenic removal than MgAl Layered double hydroxide [8]. Kozai *et al.* showed that NiZn hydroxyl double salts is more effective than LDH for selenium removal using selective coefficients [9], but adsorption isotherms and adsorbent evaluation after adsorption selenium were not studied.

In this study, NiZn adsorbents with chloride, nitrate and sulfate anions in the interlayer of NiZn were prepared to improve for arsenic and selenium removal performance and their adsorption behavior for arsenic and selenium was evaluated.

2. Experimental

Kaoru Ohe, Ryosuke Tabuchi, Tatsuya Oshima

2.1. *Preparation of NiZn adsorbents*

NiZn-AcO, NiZn hydroxide double salt intercalating acetate anion (AcO) was first prepared by modifying the synthetic method reported by Rojas *et al*. [5]. NiZn-Cl adsorbent was prepared by an ion-exchange method. One gram of NiZn-AcO was added to 50 cm^3 of 1 M NaCl solution and stirred at 333 K for 24h. The supernatant was then wasted and fresh 1 M NaCl solution was added and stirred. This procedure was repeated three times. NiZn-NO$_3$ and NiZn-SO$_4$ were prepared in the same procedure as NiZn-Cl using 1 M Na NO$_3$ and 1 M Na$_2$SO$_4$, respectively. The resulting adsorbents were washed several times with deionized water, dried in a vacuum drying oven and characterized by XRD, FT-IR, and CHN elemental analysis.

2.2. *Adsorption test of arsenic and selenium*

All adsorption test was carried out by batch method at 303 K. 1.0×10^{-4} M metal solution was adjusted to a given pH using HCl solution or an aqueous NaOH solution in the pH-dependent adsorption test. In the adsorption isotherm experiments, metal concentrations were prepared at 2.0×10^{-4} - 4.0×10^{-3} M and adjusted to the prescribed pH with the aqueous NaOH solution. Ten mg of NiZn adsorbent and 15 cm^3 of metal solution was added to a sample tube and shaken in at 303 K, 120 rpm for 24 h. pH of the filtrate was measured. The metal concentrations of the solutions before and after adsorption equilibrium were measured using atomic absorption spectrophotometer and ICP emission spectrometer. The amount of adsorption(q) and the adsorption percentage ($A\%$) were calculated according to the following equations, respectively:

$$q = (C_{int} - C_{eq})\ v/w \qquad (1)$$
$$A = (C_{int} - C_{eq})\ /\ C_{int} \qquad (2)$$

where C_{int} and C_{eq} are initial and equilibrium concentration, respectively [mM], v is the volume of solution , w is the weight of adsorbent [g], q is the amount of arsenic or selenium adsorbed , A is the adsorption percentage [%]

Langmuir equation and its variant equation are given in Eq.(3) and (4), respectively.

$$q = K_L q_{max}\ C_{eq}\ /\ (1 + K_L C_{eq}) \qquad (3)$$
$$C_{eq}\ /\ q = C_{eq}\ /\ q_{max} + 1\ /\ K_L\ q_{max} \qquad (4)$$

where q_{max} is the maximum adsorption capacity [mmol/g] and K_L is the adsorption equilibrium constant [dm^3/mmol]

3. Results and Discussion

3.1. *Characterization of NiZn adsorbents*

NiZn adsorbents prepared were identified by XRD and FT-IR analysis. XRD diffraction pattern of NiZn-AcO is shown in Fig. 1. The diffraction peaks of 001, 002 and 003 are at $2\theta = 6.8$, 13.6, 20.6, respectively, in agreement with the literature values [5]. The interlayer distance of
Fig. 1 XRD patterns of NiZn-AcO, NiZn-Cl, NIZn-NO$_3$ and NiZn-SO$_4$..

NiZn-AcO was determined to be 8.40 Å by subtracting the thickness of the basic layer, Ni(OH)$_2$, of 4.60 Å. Similarly, peaks derived from layered compounds were observed in the diffraction patterns of NiZn-Cl, NiZn-NO$_3$, and NiZn-SO$_4$, with d$_{001}$ values of 8.09 Å, 9.14 Å, and 9.14 Å, respectively, as shown in Fig. 1 [10].

Chemical formula of NiZn adsorbents was determined using atomic absorption analysis (Ni/Zn mole ratio), CNH elemental analysis (amount of acetate) and TG/DTA (amount of adsorption water) [11]. Table 1 shows the chemical formulas of the NiZn adsorbent, in which acetate anion in NiZn-AcO is ion-exchanged with Cl$^-$, NO$_3^-$ and SO$_4^{2-}$. The anion exchange capacity of NiZn-AcO is 2.45 meq/g. The amount of Cl$^-$, NO$_3^-$ and SO$_4^{2-}$exchanged were in the order of Cl$^-$ (2.22 meq/g) > SO$_4^{2-}$ (2.09 meq/g) > NO$_3^-$ (1.57 meq/g).

Table 1. Chemical formula of NiZn adsorbents

NiZn adsorbents	Chemical formula
AcO	Ni$_{0.67}$Zn$_{0.34}$(OH)$_2$(CH$_3$COO)$_{0.34}$ 0.65H$_2$O
Cl	Ni$_{0.67}$Zn$_{0.34}$(OH)$_2$(CH$_3$COO)$_{0.03}$(Cl)$_{0.31}$ nH$_2$O
NO$_3$	Ni$_{0.67}$Zn$_{0.34}$(OH)$_2$(CH$_3$COO)$_{0.12}$ (NO$_3$)$_{0.22}$ nH$_2$O
SO$_4$	Ni$_{0.67}$Zn$_{0.34}$(OH)$_2$(CH$_3$COO)$_{0.05}$ (SO$_4$)$_{0.15}$ nH$_2$O

3.2. *Adsorption isotherms of arsenic and selenium*

To evaluate the adsorption performance of NiZn adsorbents for As and Se oxyanions, adsorption isotherms of e and As oxyanions at 303 K were conducted. Langmuir isotherm model, characteristic of monolayer adsorption, since the amount increases with increasing concentration and approaches a constant value at high concentrations. The Experimental data for the adsorption of Se and As oxyanions using NiZn adsorbents fit Langmuir plot well with R^2 >0.94 (Fig. 2). The maximum adsorption capacity (q_{max}) and adsorption equilibrium constant (K_L) for Se(IV), Se(VI) and As(V) were

calculated from the Langmuir equation (Eq. (3) and (4)) and are shown in Table 2.
Fig. 2 Langmuir plots of Se(VI) on NiZn-AcO, -Cl, -NO$_3$ and -SO$_4$...

Table 2. Parameters of the Langmuir adsorption isotherms for Se(IV), Se(VI) and As(V)at 303 K.

Adsorbates	Adsorbents	pH$_{eq}$	q_{max} [mmol/g]	K_L [dm^3/mmol]	R^2
Se(IV)	NiZn-AcO	8.54±0.33	1.48	7.10	0.94
	NiZn-Cl	7.88±0.39	1.44	9.98	0.994
	NiZn-NO$_3$	7.67±0.59	1.54	7.47	0.971
	NiZn-SO$_4$	7.35±0.39	0.909	4.09	0.965
Se(VI)	NiZn-AcO	6.85±0.15	0.979	14.2	0.989
	NiZn-Cl	6.72±0.54	1.19	4.31	0.988
	NiZn-NO$_3$	6.60±0.42	0.983	12.8	0.997
	NiZn-SO$_4$	6.77±0.21	0.718	0.531	0.99
As(V)	NiZn-AcO	10.3±0.32	0.446	287	0.998
	NiZn-Cl	9.67±0.43	0.947	14.3	0.997
	NiZn-NO$_3$	10.0±0.36	0.524	77.6	0.999
	NiZn-SO$_4$	9.59±0.49	0.564	11.1	0.988

The maximum adsorption capacity (q_{max}) of Se(IV), Se(VI), and As(V) by NiZn-Cl, -NiZnNO$_3$, and SO$_4$ was almost the same or increased compared to that of NiZn-AcO, except for NiZn-SO$_4$. Since the dissolved species of Se(VI) or As(V) have a significant effect on qmax, the saturated adsorbed amount of Se(VI) or As(V) was converted to an equivalent unit by considering the mole fractions of the main dissolved species at each pH, which were obtained from the acid dissociation constants. As shown in Table 2, Se(VI) species are SeO$_4^{2-}$ from pH, the qmax of NiZn-AcO and NiZn-Cl are calculated to be 1.96 meq/g and 2.38 meq/g, respectively. Acetate in NiZn-AcO and NiZn-Cl The Se(VI) exchange percentage was estimated to be 80.0% and 107% by comparing the amount of acetate anion and Cl- (meq/g) in NiZn-AcO and NiZn-Cl, respectively, as shown in section 3.1.

When Se(IV) was examined similarly, the exchange rate of Se(IV) by NiZn-Cl (82.7%) was slightly lower than that of NiZn-AcO (96.7%) From the pH given in Table 2, the qmax of NiZn-AcO and NiZn-Cl were calculated to be 0.918 meq/g and 1.91 meq/g, respectively, considering the mole fraction of As(V) chemical species, and the

exchange percentage of As(V) was estimated to be 37.5% and 85.9%. These results indicate that NiZn-Cl can adsorb Se(VI) and As(V) more effectively than NiZn-AcO.

3.3. *Effect of contact time of Se(VI) adsorption*

The effect of contact time on Se(VI) adsorption by NiZn-AcO and NiZn-Cl is shown in Fig. 3. The time to reach equilibrium for Se(VI) adsorptions was 5 min which was extremely rapid. During the first 5 min 95.2% of Se(VI) was adsorbed on NiZn-AcO, whereas NiZn-Cl adsorbed 92.7% of Se(VI). These fast adsorption process has been considered ion exchange reactions involving, which is similar to ion exchange in LDHs [12].
Fig. 3 Time course of Se(VI) adsorption on NiZn-AcO and NiZn-Cl...

3.4. *XRD results of NiZn adsorbent after Se(IV) and Se(VI) adsorption*

The basic brookite layer thickness does not change much during the process of anion exchange, but the interlayer distance varies with the placement and size of the intercalated anions. When inorganic anions are replaced by organic anions in the LDH interlayer, the LDH layer space increases significantly [12]. In the present study, the (003) diffraction peaks observed in
Fig. 4 XRD patterns of NiZn-AcO adsorbed (a) Se(IV) and (b) Se(VI)...and NiZn-Cl adsorbed (c) Se(IV) and (d) Se(VI)..

Kaoru Ohe, Ryosuke Tabuchi, Tatsuya Oshima

NiZn-AcO and NiZn-Cl have the d_{003} values of 13.0 and 8.09 Å, respectively (Fig. 1), and these peaks shifted after the adsorption of Se(IV) or Se(VI) (Fig. 4). and NiZn-Cl host layer thickness is 4.6 Å, the NiZn-AcO interlayer distance decreased significantly from 8.4 Å to 4.63 Å (Se(IV)), 4.52 Å (Se(VI)), and the NiZn-Cl interlayer distance increased from 4.49 to 4.53 Å (Se(IV), Se(VI)). Se(IV), Se(VI)). The interlayer distances after selenium adsorption were almost equal, suggesting that the interlayer acetate anions and Cl⁻ were replaced by Se(IV) or Se(VI).

4. Conclusions

NiZn adsorbents NiZn-Cl, NiZn-NO$_3$, and NiZn-SO$_4$ were prepared by ion exchange method using NiZn-AcO obtained by hydrothermal synthesis. Experimental investigating the adsorption of arsenic and selenium oxyanions from aqueous solutions using the NiZn adsorbents indicated that the arsenic and selenium oxyanions could be adsorbed on NiZn-AcO, NiZn-Cl, NiZn-NO$_3$, and NiZn-SO$_4$. Se(IV), Se(VI) and As(V) were found to be adsorbed on NiZn adsorbent by Langmuir isotherm model. The adsorption isotherm for As(V) shows that NiZn-Cl has twice higher adsorption capacity than NiZn-AcO. The adsorption of Se(IV) by NiZn-NO$_3$ was slightly increased compared to NiZn-AcO. The exchange of acetate anion in the NiZn interlayer with chloride ions improved the adsorption performance of As(V) and Se(VI).

Abstract

Large-scale analyses, using numerical models with over 10 trillion elements, are required for the analysis of a large space such as a concert hall with higher-frequency bands. Large spaces are often limited to low-frequency analysis. In this study, the number of elements is reduced by wave acoustic analysis using higher-order elements. Based on the results using higher-order elements, it is shown that it is possible to analyze a real environment model such as a live music club and a concert hall.

Keywords: large-scale simulation, acoustical sound field, higher-order element

1. Introduction

Estimation of the sound field is important for improving the quality of acoustic spaces such as concert halls and live music clubs [1]. Scale model experiments and the computer simulations are used for estimation of the sound field. Scale model experiments are used in many fields [2], however, creating models requires a lot of time and is expensive. On the other hand, computer simulation creates a model and sound in a virtual space. Therefore, in the computer simulation, it is easy to change the conditions of the analysis as well as to change materials and shapes. However, a large-scale analysis, using a numerical model with over 10 trillion elements, is required for the analysis of a large space with high frequency. n a large-scale finite element steady-state acoustic analysis, the iterative domain decom-position method [3] is proposed and applied as a parallelization technique. It is shown that the large-scale analysis becomes possible by the iterative domain decomposition method [4]. In this study, higher-order elements are introduced into a parallel finite ele-ment steady-state acoustic analysis method and greatly reduce the number of elements. Higher-order elements are not actively used because the matrix expands. In particular, there are some examples of higher-order elements, e.g., higher than the 3rd order ele-ment [5], however, there are few examples of acoustic analysis. As far as we know, there is no example showing the superiority of reducing the number of necessary elements by applying higher-order elements, especially in large-scale acoustic calculations using the domain decomposition method.

2. Finite element

2.1. Higher-order elements

To reduce the number of elements, 2nd and 3rd order elements are introduced. With higher-order elements, the number of nodes increases because the nodes are placed on the sides and faces of the element. Fig. 1 shows the nodal arrangement of the tetrahedras with 1st, 2nd, and 3rd order elements. Table 1 shows the shape function of each element [6].

2.2. Helmholtz equation

In the 3-dimensional sound field, the wave equation for velocity potential is expressed by the following equation:

$$\frac{\partial^2 \phi}{\partial x^2} + \frac{\partial^2 \phi}{\partial y^2} + \frac{\partial^2 \phi}{\partial z^2} - \frac{1}{c^2}\frac{\partial^2 \phi}{\partial t^2} = q \tag{1}$$

where ϕ is the velocity potential, c is the speed of sound, and q is the distribution function.

To consider the steady-state, the velocity potential is expressed by Eq. (2). Using Eq. (1) and Eq. (2), the Helmholtz equation is obtained:

$$\phi = \Phi e^{-j\omega t} \tag{2}$$

$$\frac{\partial^2 \Phi}{\partial x^2} + \frac{\partial^2 \Phi}{\partial y^2} + \frac{\partial^2 \Phi}{\partial z^2} + \frac{\omega^2}{c^2}\Phi = q \tag{3}$$

where ω is the angular frequency.

The velocity potential of Eq. (3) and calculate the sound pressure using the following equation are obtained:

$$p = j\omega\rho\Phi \tag{4}$$

where j is the imaginary number, and ρ is the medium density.

2.3. Finite element formulation

To derive a weak form, the Galerkin method is applied to Eq. (3). By applying the finite element approximation and discretization, the following equation is obtained:

$$-k^2[M]\{\Phi\} + j\omega\rho[C]\{\Phi\} + [K]\{\Phi\} = \{q\} \tag{5}$$

where $[\,\cdot\,]$ is a matrix, $\{\,\cdot\,\}$ is a vector. In Eq. (5), the matrices $[M]$, $[C]$ and $[K]$ can be calculated using Eq. (6.1,2,3):

$$[M]_e = \iiint_{\Omega_e} \{N\}\{N\}^T d\Omega_e \tag{6.1}$$

$$[K]_e = \iiint_{\Omega_e} \nabla\{N\}\nabla\{N\}^T d\Omega_e \tag{6.2}$$

$$[C]_e = -\frac{1}{Z_n}\iint_{\Gamma_e} \{N\}\{N\}^T d\Gamma_e \tag{6.3}$$

where N is the shape function, $[M]_e$ and $[K]_e$ are the volume integrals, and $[C]_e$ is a surface integral to the sound-absorbing boundary surface. Z_n is a specific acoustic impedance.

2.4. Calculaion of element matrix

Let us consider the calculation $\{N\}\{N\}^T$ in Eqs. (6.1) and (6.3). This calculation uses an integration formula of the 3 or 2-dimensional finite element method. These integration formulas are shown in the following equations [7].

$$\iiint_{\Omega_e} L_1^k L_2^l L_3^m L_4^n dxdydz$$
$$= 6V_e \frac{k!\,l!\,m!\,n!}{(k+l+m+n+3)!} \tag{7}$$

$$\iint_{\Gamma_e} L_1^k L_2^l L_3^m dxdy = 2A_e \frac{k!\,l!\,m!}{(k+l+m+2)!} \tag{8}$$

On the other hand, the calculation of $\nabla\{N\}\nabla\{N\}^T$ in Eq. (6.2) shown in the following equation.

$$\frac{\partial f}{\partial x} = \frac{1}{6V_e}\left(b_1 \frac{\partial f}{\partial L_1} + b_2 \frac{\partial f}{\partial L_2} + b_3 \frac{\partial f}{\partial L_3} + b_4 \frac{\partial f}{\partial L_4}\right)$$

$$\frac{\partial f}{\partial y} = \frac{1}{6V_e}\left(c_1 \frac{\partial f}{\partial L_1} + c_2 \frac{\partial f}{\partial L_2} + c_3 \frac{\partial f}{\partial L_3} + c_4 \frac{\partial f}{\partial L_4}\right) \tag{9}$$

$$\frac{\partial f}{\partial z} = \frac{1}{6V_e}\left(d_1 \frac{\partial f}{\partial L_1} + d_2 \frac{\partial f}{\partial L_2} + d_3 \frac{\partial f}{\partial L_3} + d_4 \frac{\partial f}{\partial L_4}\right)$$

We convert the finite element equations of (5) to a matrix form as follows:

$$Ku = f. \tag{10}$$

2.5. Hierarchical domain decomposition method

The original analysis domain is first divided into parts, which are further decomposed into smaller domains called subdomains. This is called the hierarchical domain decomposition method (HDDM) [8], [9].

3. Numerical experiment

3.1. Verification by benchmark problem

Fig.2 shows that test model for simulation. The model is AHLV100 that is known as a reference model in code_Aster. This is also described in the ADVENTURE_sound manual as a sample. This simulation was done to confirm the use of transient analysis in ADVENTURE_Sound. To evaluate the accuracy of the acoustic analysis code, an acoustic benchmark problem is used. The analysis uses the test model AHLV100 of Code_Aster [10], which is known as a representative benchmark problem among acoustic problems (Fig. 4).

This model is an acoustic tube that has a length of 1 [m], a height of 0.1 [m] and a width of 0.2 [m]. It has a vibration boundary at the left end and a sound absorption boundary at the right end. The other faces are given rigid boundaries. The specific acoustic impedance Z_n=445.9 [kg/m^3 · s] is given as a sound absorption boundary condition.

The accuracy is calculated from the average error of four points on the sound absorption boundary. The formula for calculating the theoretical solution is as follows:

$$p(x,y,z) = \rho c V_n exp(-ikx) \tag{11}$$

where ρ is the medium, c is the speed of sound, and V_n is the particle velocity.
Fig. 2. Acoustic benchmark problem AHLV100

3.2. Performance evaluation

The performance of higher-order elements is evaluated based on the number of elements, accuracy rate, and memory usage. The performance evaluation conditions are: 4.0 [kHz] for frequency, air for medium, and 343 [m/s] for sound velocity. The analysis uses a PC cluster composed of 5 PCs (40 cores) equipped with a multicore CPU (Intel Core i7-9700K, 3.6GHz 8core, 32GB of memory).

Numerical results for the error rate, plotted against the number of elements, are shown in Fig. 3. Results for the memory, plotted against the number of elements, are shown in Fig. 4.
Fig. 3. Error rate plotted against the number of elements
Fig. 4. Memory usage plotted against the number of elements

The accuracy increases dramatically when a higher-order element is applied. In particular, the accuracy changes more rapidly as the order increases.

3.3. Analyses using real environment models

To confirm the effectiveness of higher-order elements, the sound field of the real environment model is analyzed. The model used for analysis is concert hall model that is shown in Fig. 5.
(a) Concert hall 3D CAD model
(b) Concert hall model dimensions
Fig. 5. Concert hall model

The concert hall model is constructed based on real spaces [11].

The concert hall model is 11.5 [m] wide, 7 [m] high, and 23.5 [m] deep. The sound source is set as a pair of speakers at either end of the stage. Oakwood flooring, a wooden stage, and a glass wool wall at the back of the hall are used as sound-absorbing boundary conditions. The sound field is analyzed by applying a 400 [Hz] sound to these models.

The results of these analyses are shown in Table 2. The visualization results are shown in Fig. 6, and the convergence histories of the iterative method (COCG) are shown in Fig. 7. The concert hall analysis using the 1st and the 2nd order elements are excluded from the evaluation because the number of elements exceeds 100 million. The data I/O library currently applied is 32 bit. This library cannot use data sizes that exceed 100 million elements. A 64-bit I/O library is currently under development.

Table 2. Numerical results of the concert hall model

Element type	Number of elements	Number of nodes	Elapsed Time [sec]	Memory requirement [MB/core]
1st order	823,285,162			
2nd order	102,910,645			
3rd order	878,624	4,051,235	53.97	391.97

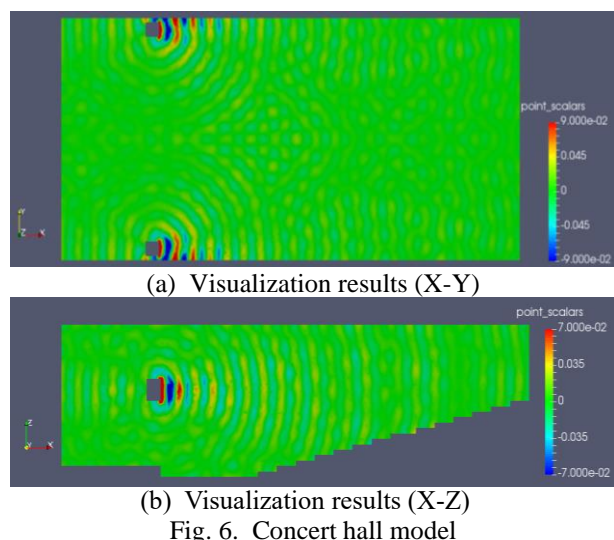
(b) Visualization results (X-Z)
Fig. 6. Concert hall model

Fig. 7. Converegence history of the COCG


4. Conclusion

This paper described a large-scale acoustic analysis method using a domain decomposition method and the introduction of higher-order elements. The performance of proposed method was evaluated with higher-order elements using of AHLV100. The error rate, number of elements, and memory usage were the considered as evaluation criterions. It was shown that the calculation efficiency improved in higher-order elements. In particular, in the 3rd order element, the calculation efficiency was vastly improved. Furthermore, the accuracy of higher-order elements was verified. The 2nd order element and the 3rd order element were compared in terms of the number of elements and calculation time. Additionally, real environment model was analyzed, namely, a small concert hall model. It was shown that the real environment models could be successfully analyzed by using higher-order elements.

Abstract

Identifying acoustic effects of sound waves emitted by a sound source on the listener is important for understanding the localization of sound as perceived by the listener. In this presentation, we will analyze the effect of the presence of a chair on the psychoacoustic effect using a practical model simulating a psychoacoustic experiment consisting of a loudspeaker, a listener, and a chair. Non-steady state analysis is required to analyze changes in acoustic effects over time. To analyze the interference of sound waves in the vicinity of the listener, a short Gaussian pulse-like solitary wave is set up on the loudspeaker's vibrating surface. Since sound waves in the audible band are used for these simulations, a mesh size of less than 25 mm is used. The laboratory is 3m of depth and width, and 2.5m of height, which means that the computational whole target consists of over 15 million elements. This simulation requires a large number of calculations, so a parallel computing method with ADVENTURE_Sound that is an open-source software for sound simulation, is used to run the simulation. From the simulation results of the non-stationary analysis and consider the effect of the presence of the chair on the sound image localization.

Keywords: large-scale simulation, acoustical sound field, non-steady state analysis

1. Introduction

In the experimental environments, there are objects to disturb sound wave propagation: wall, floor, ceil and chair, etc. Since the effects of these objects change the sound waves reaching the listener's ears, the accuracy of sound image localization may also change. Our goal is to clarify the effect of these environments on the sound image localization characteristics. To evaluate the time-related effects of objects around the listener on the sound waves reaching the listener's ears, this paper examines a non-steady state sound field simulation is performed.

2. Adventure Sound
2.1. Brief introduction

ADVENTURE_Sound is an open-source software for sound simulation. This allows us to simulate parallel finite element analysis software for the sound fields in huge space. Analyses are performed by solving the large-scale linear system with parallel computing based on the Mandel's domain decomposition method (DDM) [1].

2.2. Simulation procedures with ADVENTURE_Sound

The procedure to use ADVENTURE_Sound is as follows; 1) generate the mesh data, 2) add boundary conditions (BCs), 3) subdivide the mesh data into subdomains, 4) simulate the sound field distributions, 5) convert to the results to vtk data for visualization. On the fourth procedure, it needs to calculate Helmholtz equation in the time domain. For this, Newmark β method is adopted to the equation. As the boundary conditions, input wave function and first and second derivatives of that function.

3. Preliminary test to simulate non-steady state analysis

3.1. Test model

Fig.1 shows that test model for simulation. The model is AHLV100 that is known as a reference model in code_Aster. This is also described in the ADVENTURE_sound manual as a sample. This simulation was done to confirm the use of transient analysis in ADVENTURE_Sound.

Akihiro Kudo, Makoto Sakamoto, Amane Takei
Fig. 1. Test model

3.2. Specs of the parallel computer

Our parallel computer is called as TOMAHAWK.
Table 1 shows that the detailed specs of the parallel computer.

Table 1. Specs of parallel computer

CPU	Intel Xeon E5-2650L,1.8GHz with 16 cores L2 20480[KB]
Main memory/node[GB]	32
Number of nodes	8
Total cores	128
OS	CentOS 6.2
Compiler	gcc-4.4.7 mipch-3.2

3.3. Simulation conditions

Table 2 shows that analysis conditions.

Table 2. Analysis conditions for the test model

Mesh size[m]	0.012
Number of elements	140, 604
Absorption boundary [kg/m^{2}s]	445.9
Medium(air) r_0[kg/m^3]	1.3
Speed of sound c_0[m/s]	343
Time resolution Δt [μs]	1.0
Duration time to simulate[μs]	4000
Velocity potential $\{\Phi\}_t$ Full width at half maximum[ms] Cut-off frequency f_c[Hz]	Gaussian pulse 0.264 646

For boundary conditions as input wave, the single wave is useful to analysis the transient sound field, because sound reflections are observed clearly. In this study, a gaussian pulse as velocity potential is adopted as follows,

$$\{\Phi\}_t = e^{-\{\alpha(t-t_0)\}^2} \ ... \qquad (1)$$

In the Eq. (1), decay parameter α is set to 3141, delay parameter t_0 is set to 0.001[s].
An input wave for boundary conditions is shown in Fig. 2.
Fig. 2. An input wave for boundary conditions

3.4. Simulation results

Fig.3 shows that the simulation results at some time points. In this figure, bright red color indicates that high intensity of the vector potential that is proportional to the sound pressure.
Fig. 3. Simulation results at some time points

3.5. Discussions

From this figure, a single waveform with continuous and positive intensity was observed and the waveform moves from left side to right. Because the sound wave takes 2900μs to reach the right side and length of AHLV100 is 1m, estimated sound speed is 345m/s. This estimate is consistent with the theoretical value. The simulation results show that the use of ADVENTURE_Sound in non-steady state acoustical analysis is appropriate.

4. Simulation of acoustical experimental environment

4.1. Simulation model

Fig. 4 is the dimensions on the side view of simulation model. Table 3 and 4 are dimensions of target and analysis conditions for acoustical experimental environment, respectively.
In this simulation model, there are one loudspeaker and snowman pair that simulates an acoustical experimental arrangement. The snowman simulates a listener's head and torso [2]. In addition, this model also includes a chair to hold the listener in position. These are practical and typical acoustical experimental environment. By

analyzing the sound waves at a position corresponding to the ear of the Snowman model, it is possible to evaluate the effect of sound reflections from the chair as an obstacle on the sound image localization.

Fig. 4. Dimensions on the side view of simulation model

Table 3. Dimensions of the target

Room, width [m] ×depth[m]×height [m]	3×3×2.5
Room volume [m^3]	22.5
Loudspeaker, width [m] ×depth [m] ×height [m]	0.1×0.12×0.12
Diameter of the listener head, torso [m]	0.177, 0.3 [2]
Distance from loudspeaker to listener [m]	1.5
Backrest, width [m] ×depth [m] ×height [m]	0.5×0.1×0.65
Seat, width [m] ×depth [m] ×height [m]	0.5×0.5×0.1

Table 4. Analysis conditions for the acoustical experimental environment

Mesh size [m]	0.025
Number of elements	14,497,814
Room wall, floor, ceiling [kg/m^{2}s]	445.9
Loudspeaker, snowman, chair [kg/m^{2}s]	4.56× 10^9
Medium(air) r_0 [kg/m^3]	1.3
Speed of sound c_0 [m/s]	343
Time resolution Δt [µs]	1.0
Duration time to simulate [µs]	8000
Velocity potential $\{\Phi\}_t$	Gaussian pulse
Full width at half maximum [ms]	0.264
Cut-off frequency f_c [Hz]	646

4.2. Simulation results

Fig. 5 is the simulation results on the xy-plane at y=1.5m. Since gaussian pulse is given to the surface of the loudspeaker, the sound waves are spread over. As sound wave travels from the loudspeaker, the sound directivity can be observed on x-axis.

Fig. 6 is the simulation results on the xy-plane at z=1.0m. The distance from the loudspeaker to the listener is 1.5m, so it takes 4.4ms for the sound wave to reach the listener.

From these results, the sound wave reaches to the listener at approx. 5ms and the time for gaussian pulse to show its maximum value is 1ms, because it takes for approx. 4ms, the simulation corresponds to the theoretical value.

Fig. 5. Simulation results on the xz-plane at y=1.5m

Fig. 6. Simulation results on the xy-plane at z=1.0m

4.3. Discussions

Fig. 7 is the snapshots on the xz-plane at y=1.5m.
From 6.7ms to 7.3ms, an increased sound pressure was observed bottom of the listener's torso due to the sound waves reflecting off the seat of the chair.
The sound wave reaches the listener at approx. 5.2ms and the sound wave reflected by the chair returns to the listener at approx. 6.4ms, so this duration time is 1.2ms. This might affect the spaciousness of sound image although not directional accuracy of the sound image localization, because this time interval exceeds the

Akihiro Kudo, Makoto Sakamoto, Amane Takei

maximum time difference 0.6ms that humans use to localize a sound image [3].

Fig. 7. Snapshots on the xz-plane at y=1.5m

5. Conclusion

Purpose of this paper is to clarify the effect of these environments on the human auditory characteristics, especially sound image localization ability. The simulation target is loudspeaker and snowman model with chair, was adopted as a typical acoustical experimental environment. The simulation results showed that 1) An increased sound pressure was observed bottom of the listener's torso due to the sound waves reflecting off the seat of the chair, 2) The time taken for sound wave reaching the listener to reflect off the chair and return to the listener, was 1.2ms.

Since the time required for sound image localization is up to 0.6ms and the sound wave delay caused by chair reflection is shorter than this time, the reflection on chair may affect the spread of the sound image more than the directional accuracy of sound image localization.

Abstract

DeepInsight method, which interprets non-image data as image data, has garnered significant attention; however, a universal approach for this method has yet to be standardized. Our objective was to formulate a comprehensive method for DeepInsight, encompassing three key steps: strategic variable placement, effective feature extraction, and optimal model construction. Consequently, we successfully developed a model capable of predicting the Nikkei Stock Average with an accuracy of approximately 60%, marking a significant stride towards establishing the versatility of the DeepInsight method.

Keywords: DeepInsight method, t-SNE, Convolutional Neural Network, Morphological analysis.

1. Introduction

1.1 Research background

Machine learning faces challenges when dealing with high-dimensional data, known as the curse of dimensionality [1]. This issue arises because as the number of dimensions increases, the potential combinations of data grow exponentially, leading to computational challenges and inadequate learning results. To address this, two approaches can be employed:

1) Dimensionality Reduction: One strategy is to reduce dimensionality while preserving information. t-SNE [2] is a common technique that expresses data distances as conditional probabilities, keeping similar high dimensional data close in lower dimensions.

2) Feature Combination Restrictions: Another approach involves limiting combinations of features. Deep Learning [3] achieves this by dividing the problem into smaller regions, but it is most effective with data exhibiting strong pixel correlations, such as images. DeepInsight method [4], has emerged to extend deep learning to non-image data, although a standardized procedure for its application is yet to be established.

With the rise of social media, text mining utilizing platforms like SNS has gained prominence. Predicting stock prices has seen success by leveraging emotions expressed on SNS. Researchers are exploring deep learning analysis of news articles to build more accurate models, especially as sentiment analysis on platforms like

Toyoaki Tomimoka, Satoshi Ikeda, Makoto Sakamoto, Takao Ito

SNS has proven effective. The broader adoption of these techniques holds promise for improving predictions and insights across various domains.

1.2   Research purpose

The aim of this research is to transform the three stages involving proper variable placement, feature extraction, and model construction into a versatile DeepInsight method. By utilizing the proposed method, we aim to accurately predict tomorrow's stock price movements and validate the effectiveness of the approach.

2．Research method

2.1   Summary of t-SNE

The t-SNE is a dimension reduction algorithm designed to reduce high-dimensional data to two or three dimensions. The algorithm represents the proximity between points x_i and x_j on a high dimension as a joint probability distribution p_{ij}:

$$p_{ij} = \frac{p_{j|i} + p_{i|j}}{2n} \ (i \neq j), \ \ p_{ii} = 0.$$

Here $p_{j|i} = \dfrac{\exp\left(\dfrac{-\left\|x_i - x_j\right\|^2}{2\sigma_i^2}\right)}{\sum_{k \neq i} \exp\left(\dfrac{-\left\|x_i - x_k\right\|^2}{2\sigma_i^2}\right)}$ for $i \neq j$.

And the proximity between points y_i and y_j in a low dimension as a joint probability distribution q_{ij}:

$$q_{ij} = \frac{\left(1 + \left\|y_i - y_j\right\|^2\right)^{-1}}{\sum_{k \neq i}\left(1 + \left\|y_i - y_j\right\|^2\right)^{-1}} \ (i \neq j).$$

The objective is to match the distance relationships between data points in high dimensions with those in low dimensions after dimension reduction. This is achieved by setting set $p_{i|j} = q_{i|j}$, and the Kullback-Leibler (KL) divergence is employed to measure the distance between $p_{i|j}$ and $q_{i|j}$ with the goal of minimizing the loss function:

$$C = \sum_i KL(P_i \| Q_i) = \sum_i \sum_j p_{ij} \log \frac{p_{ij}}{q_{ij}}$$

Finally, stochastic gradient descent is used to minimize the loss function. The gradient is given by

$$\frac{\delta C}{\delta y_i} = 4\sum_j (p_{ji} - q_{ji})(y_i - y_j)\left(1 + \left\|y_i - y_j\right\|^2\right)^{-1}$$

Using this gradient, is gradually updated using the renewal formula:

$$Y^{(t)} = Y^{(t-1)} + \eta\frac{\delta C}{\delta Y} + \alpha\left(Y^{(t-1)} - Y^{(t-2)}\right).$$

Here, t denotes the iteration, η is the learning rate, and α is the momentum term.

2.2   Learning Image Data with t-SNE using CNN

A Convolutional Neural Network (CNN) comprises fully connected, convolution, and pooling layers. In the fully connected layer, units are interconnected, with weights depicted in Fig. 2.1. Inputs and outputs to each unit are one-dimensional vectors, and the output unit's value is determined by multiplying input values by connection weights and adding bias.
Fig. 2.1 Fully Connected layer weights

In the Convolutional layer, the outcomes of convolution operations for each filter are generated and serve as one unit in the subsequent layer. To derive the output, akin to the Fully Connected layer, compute the inner product for each filter, incorporate the bias, and apply the activation function. The Pooling layer condenses information to convert the input data into a more manageable format. Fig. 2.2 illustrates Max-pooling, wherein the maximum value is selected from color-coded small areas.
Fig. 2.2 Max-pooling

2.3   Morphological analysis
Fig. 2.3 Example of Morphological analysis

Morphological analysis dissects sentences into morphemes, assigning parts of speech. Using a wordbook, the least-cost method selects optimal words based on part-of-speech

connection and word appearance. This process is applied to news articles to count occurrences of words essential for stock price prediction, as illustrated in Fig. 2.3.

3. Experiment

3.1 Create input data

In the experiment, two datasets were used:
1) Daily stock prices of the 225 stocks constituting the Nikkei Stock Average.
2) Word count in news articles.

For 2), news articles related to stocks from the Kabutan website [5] during the period from 2020 to 2021 were used. Morphological analysis was applied to the news articles to count the occurrences of words considered effective in predicting stock prices (e.g., "weak yen"). A specialized dictionary (with 563 registered words) tailored for stock price prediction was employed for word counting. The data for stock prices and word counts in news articles were consolidated into a single CSV datasheet (Table 3.1).

Table3.1 CSV datasheet

	10/1	10/2	・・	10/10
company1	a1	b1	・・	j1
company2	a2	b2	・・	j2
・・	・・	・・	・・	・・
company225	a225	b225	・・	j225
word1	A1	B1	・・	J1
word2	A2	B2	・・	J2
・・	・・	・・	・・	・・

The first row of Table 3.1 represents the dates for which data was obtained. In this study, one sheet was created for a continuous 10-day period. Lowercase letters (a1, a2, etc.) represent daily stock prices for individual companies, while uppercase letters (A1, A2, etc.) represent the word count for each date. A total of 222 sheets of data were created for the entire data collection period. Using t-SNE, the data from each of the 225 sheets were transformed into image data composed of 783 points (225 for stock prices + 563 for words), as illustrated in Fig. 3.1. These images will be used as training and testing data for the Convolutional Neural Network (CNN).
Fig. 3.1 An example of t-SNE transformation on CSV data

Each generated image is labeled with 0, 1, or 2. Here, 0 signifies that the next day's Nikkei Stock Average will remain unchanged (range from -100 yen to +100 yen), 1 indicates an increase (range from more than +100 yen), and 2 indicates a decrease (range from less than -100 yen).

3.2 Data processing

Firstly, split all the data into training and test sets. Allocate 80% of the total data to the training set and 20% to the test set to ensure unbiased data representation. Subsequently, normalize the input image data. Given that color values are typically expressed as {0, 1, ..., 255}, normalizing the data to the range [0, 1] can be achieved by dividing each value by 255. Finally, apply a one-hot vector transformation to the label data of the input images, converting them into a binary class matrix.

3.3 Evaluation method

Display the accuracy rates for each training and test dataset to assess the progress of learning and whether DeepInsight method is effective for prediction.

3.4 Experimental results

The number of training data is 175, and the number of test data is 45. Among the 45 test data, the percentage of '0' was 16%, the percentage of '1' was 53%, and the percentage of '2' was 31%, indicating that the percentage of '0' was relatively small, with '1' accounting for more than half.

Fig. 3.2 Experimental result

In Fig. 3.2, where the horizontal axis represents the epoch (number of executions) and the vertical axis represents accuracy (correct answer rate), the accuracy rate of the training data reached nearly 100% at 25 epochs. The test data achieved its highest accuracy rate of 59.6% at 27 epochs, but further increasing the number of epochs did not lead to a higher accuracy rate. Additionally, at epoch 10,

Toyoaki Tomimoka, Satoshi Ikeda, Makoto Sakamoto, Takao Ito

the accuracy rates of the training data and test data were similar, but thereafter, a significant difference emerged.

Examining the conditional probabilities in Table 3.2, out of 45 test data items, 53% (24 items) were predicted as '1', and among those, 58% (14 items) were correctly predicted as '1'. In contrast, 31% (14 items) were predicted as '2', and among those, 50% were correctly predicted as '2'.

Table3.2　Conditional probability

	0	1	2
0(16%)	14%(1)	71%(5)	14%(1)
1(53%)	16%(4)	58%(14)	25%(6)
2(31%)	14%(2)	36%(5)	50%(7)

4.Consideration

Our experiment aimed to turn the three steps of appropriate variable placement, feature extraction, and appropriate model construction into a general-purpose DeepInsight method. Appropriate variable placement was achieved by using t-SNE to convert effective prediction words obtained through morphological analysis of stock price statistical data and news articles into image data. Feature extraction utilized CNN, an effective method for image recognition in machine learning. Despite struggling with suppressing overfitting, we achieved a maximum accuracy of approximately 60%. Assuming the model was used for actual trading, this resulted in an approximately 11% increase in profits over one month, surpassing the average annual interest rate for stock investments (3-10%).

These results indicate that the "appropriate variable placement," "feature extraction," and "appropriate model construction" approach is effective in DeepInsight. Future challenges include increasing the types of label data and improving overall accuracy.

Abstract

There are 25 species of bioluminescent fungi that have been confirmed in Japan, and 12 species have been confirmed in Miyazaki Prefecture. Those fungi are very small. Therefore, it is difficult to observe the structure of fungi exhibited in museums with the naked eye. The purpose of this research is to display 3DCG models of mushrooms using AR (Augmented Reality) technology in order to facilitate observation of these small mushrooms exhibited in museums. Two hundred visitors to the museum were asked to use the application and complete a survey. In order to measure the ease of observation of different app functions and mobile devices used in the survey, we divided the respondents into four groups.

Keywords: AR, Exhibition Support, Museum, bioluminescent fungi

1. Introduction

Augmented reality is a technology that superimposes digital information on the real world. In recent years, AR technology can be used not only on head mount display, but also on mobile devices such as smartphones. This study will examine the use of AR technology to support observation in museums. There are 25 species of bioluminescent fungi that have been confirmed in Japan, and 12 species have been confirmed in Miyazaki Prefecture. Those fungi are very small. Therefore, it is difficult to observe the structure of fungi exhibited in museums with the naked eye. The purpose of this research is to display 3DCG models of fungi using AR (Augmented Reality) technology in order to facilitate observation of these small fungi exhibited in museums.

2. AR Application Development
2.1. Development Environment

An AR application was created for use with smartphones and Tablets. The development environment is shown (Table 1). Blender is a comprehensive 3DCG software. It was used to create a 3DCG model of fungi [3], [4]. Unity was used to develop applications for mobile terminals [1], [2].

Table 1. Development Environment

OS	Windows 10 Pro
Software	Blender 2.93
	Unity 2020.3.22f1
	Visual Studio 2019
Smart phone	Galaxy S8
Tablet	Yoga Tab 11

2.2. Target fungi

The bioluminescent fungi, *Favolaschia peziziformis* [Fig. 1], *Cruentomycena orientalis* [Fig. 2] and *Favolus manipularis* [Fig. 3], were the subjects of this study.

2.3. 3DCG of fungi

The CG model was created based on the images provided.

Fig. 1 *Favolaschia peziziformis*

Kakeru Takemura, Ota Hamasuna, Fumito Hamakawa, Satoshi Ikeda, Kaoru Ohe, Amane Takei, Makoto Sakamoto, Shuichi Kurogi
Fig. 2 *Cruentomycena orientalis*

Fig. 3 *Favolus manipularis*

2.4. AR application

An image that serves as a marker is loaded, and an AR 3DCG model of a mushroom is displayed on top of it. When the marker disappears from the screen, the displayed 3DCG model also disappears, and when the same or another marker is scanned, the 3DCG model is displayed again. This application was used as the basic application. In addition to the basic application, another application was prepared with a function that tilts the mushrooms in the same direction when the user moves his/her finger while touching the AR-displayed mushrooms on the screen. A demonstration of the application in use is shown below.

3. Evaluation experiment

3.1. Experimental environment

The evaluation experiment was conducted at the Miyazaki Prefectural Museum. A special exhibition was being held and a place for observation using the application was set up next to the mushroom exhibit. Visitors were asked to cooperate in the evaluation experiment.

3.2. Experimental procedure

The experiment should take no more than 5 minutes. After the observation using the app was over, the participants were asked to fill out a questionnaire. The experiment was divided into four groups using smartphones and tablets, basic apps and apps with additional features. A total of 200 people, 50 in each group, were surveyed. How the experimental procedure is shown.

i. Explain that specimens of glowing mushrooms are on display.
ii. Explain to users how to use the application.
iii. Users use the app to make observations.
iv. Users are free to finish their observations.

Show how the Questionnaire items [Table 2].

Table 2. Questionnaire items

1. Observation was fun.
2. I interested in fungi.
3. New discoveries were made.
4. I understand the structure.
5. It was easy to observe.
6. AR experience was good.
7. Operation was easy.
8. I want to use it in other exhibits.
9. I got the emotion of observing native fungi.
10. I wanted to touch the fungi.
11. Did you notice the hole?
12. Did you notice the rounded bottom?
13. Did you notice the reddish color?
14. Did you notice how the back of the fungus's umbrella is shaped like folds?
15. Did you notice the reticulated underside of the fungus umbrella?

3.3. Questionnaire Results

The questionnaire included questions to answer about the experience of observing the mushrooms using the application and whether or not they noticed any characteristics of the fungi. The questionnaire was based on the MES [5]. Ten questions on a 5-point scale were asked, five questions asking if the mushrooms were observed for their characteristics, and one open-ended question. The results of the questionnaire are shown below [Table 3], [Table 4].

Table 3. Experiences observed using the app (average)

item	Basic apps	Additional apps	Smartphone	Tablet
1	4.9	4.92	4.92	4.9
2	4.57	4.58	4.54	4.61
3	4.72	4.71	4.67	4.76
4	4.51	4.47	4.94	4.48
5	4.76	4.78	4.82	4.72
6	4.91	4.87	4.91	4.88
7	4.75	4.63	4.77	4.61
8	4.8	4.68	4.73	4.74
9	4.44	4.49	4.53	4.4
10	4.45	4.45	4.39	4.51

Table 4. About the characteristics of fungi

item		11	12	13	14	15
Basic apps	Noticed	88 %	68 %	89 %	58 %	66 %
	Didn't notice.	12 %	32 %	11 %	42 %	34 %

Additional apps	Noticed	87%	82%	92%	80%	85%
	Didn't notice.	13%	18%	8%	20%	15%
Smartphone	Noticed	84%	69%	85%	63%	71%
	Didn't notice.	16%	31%	15%	37%	29%
Tablet	Noticed	91%	80%	96%	75%	80%
	Didn't notice.	9%	20%	4%	25%	20%

Since all items were 3 or higher in the experience observed using the app, it can be said that the app is an aid to observation. In comparing the results between the basic app and the app with additional functions, there was a clear difference between Q7 and Q8. The respondents' opinion that simple functions were easier to operate and use was based on the belief that they wanted ease of use rather than in-depth observation. For the question about mushroom characteristics, differences were found at 12, 14, and 15. Apps with additional features for areas that cannot be observed without looking directly at the mushroom from the side, such as the back of the mushroom, were a good result. Comparisons will be made between the use of smartphones and tablets. Differences were found in Q4, 5, 7, 9, and 10. Smartphones can be handled with one hand, making it easier to operate and observe from various angles, which is thought to have led to better understanding of mushrooms. Tablets were found to provide a sense of immersion due to their large screens. In the questions about mushroom characteristics, there was a 10% difference in Q12, 13, and Q14, with tablet users being able to observe mushrooms in more detail.

4. Conclusion

We were able to confirm that AR technology supports observation in museums. The apps with additional functions were found to allow more detailed observation of the mushrooms. As for the difference between the different devices, it was also found that the tablet device allowed for more detailed observation of the mushrooms. However, the basic function apps were better in terms of ease of use, while smartphones were rated higher in terms of ease of observation. Therefore, it is better to use a smartphone when carrying a mobile device for observation when used in a museum. In this way, it is important to use different app functions and mobile devices depending on the situation in which they are used. In this study, we supported the observation of small objects, but in the future we would like to consider supporting the observation of very large objects that are difficult to observe.

abstract

Miyazaki Prefecture is blessed with the rich nature of the Kyushu Mountains, where many mushrooms have grown wild since ancient times, and the production of dried shiitake mushrooms ranks second in Japan after Oita Prefecture. SUGIMOTO Co., Ltd., which will be cooperating with us this time, is a long-established company established in 1970, and at times it is necessary to sort over 1 ton. However, since selection is still done manually, it is very difficult for employees to do the selection. The goal of this research is to determine the quality of shiitake mushrooms using deep learning and video image processing.

Keywords: image classification, video processing, CNN, OpenCV

1. Introduction

SUGIMOTO Co., Ltd. collects dried shiitake mushrooms directly from approximately 600 producers in Takachiho. Shiitake mushrooms are at their peak in spring and autumn, and at peak times, more than 1 ton of shiitake mushrooms can be brought in a day [1]. However, shiitake mushrooms are still sorted manually, and sorting this much requires a lot of effort. The goal of this research is to use deep learning and video processing to determine the quality of donko, a high-quality dried shiitake mushroom.

2. Development environment

In creating this program, we developed it in the following environment (Table 1). In the experiment, a stand was fixed to a conveyor belt, and the smartphone camera was attached to the end of the stand with the camera facing down.

Table 1 Development environment

OS	Windows10
language	Python
camera	moto g30
software	iVCam
software	OpenCV
	PIL
	NumPy
	Pandas

3. Method

3.1. Target of selection

The following two targets are selected. The one on the left (Fig. 1) is a good shiitake mushroom, and the one on the right (Fig. 2) is a bad one.

Fig. 1 Good item   Fig. 2 Bad item

The following four main examples of bad items are listed below. Fig. 3 shows a state where the pileus of a shiitake mushroom part is broken. Fig. 4 shows a state in which the pileus of a shiitake mushroom is greatly deformed. Fig. 5 shows a state where there are holes caused by insect damage. Fig. 6 shows the pileus of a shiitake mushroom part being rubbed.

Fig. 3 Cracked   Fig. 4 Deformed

Fig. 5 Hole   Fig. 6 Rubbed

Ota Hamasuna, Kakeru Takemura, Kodai Hasebe, Fumito Hamakawa, Bidesh Biswas Biki, Satoshi Ikeda, Kaoru Ohe, Amane Takei, Makoto Sakamoto, Kazuhide Sugimoto,
The example of a bad item mentioned this time is the front side with a pileus of a shiitake mushroom on top. Although there are characteristics of bad items on the back side as well, this experiment focused on the front side. The reason why we focused on the front side is that it takes a huge amount of time to collect samples from the front and back sides, and the camera can only capture either the front or back side due to the sorting process on the conveyor belt.

3.2. CNN

In the experiment, CNN was used as an algorithm to determine whether an image was a good item or a bad item. Explain about CNN. CNN (Convolution Neural Network) is a network often used in image recognition research. This CNN is characterized by being constructed by stacking layers with several unique functions, such as convolutional layers and pooling layers [1]. Currently, it is attracting increasing attention as it is being used in a variety of fields. The image in Fig. 7 shows the flow of handwritten digit classification using CNN. First, handwritten digits are given as an input image, the features of the image are extracted by convolution, and the extracted features are aggregated in a pooling layer. Finally, the fully connected layer transforms the output into a one-dimensional form and outputs each selection result as a probability.
Fig. 7 Classification of handwritten digits [2]

3.3. Video image processing

In this research, we extract still images of shiitake mushrooms from moving images and select them using a model learned by CNN. The video image used in the experiment was taken from directly above the conveyor belt, and the shiitake mushrooms were flowing from left to right. Fig. 8 shows an image of the program being executed.
A still image extracted from a moving image is displayed at the top left of the screen. Extract three still images of the shiitake mushroom using OpenCV. The extraction location is when the shiitake mushrooms flow to the left, center, or right side of the screen. The three images are selected by the model, and the one with a majority of selection results is the final result. At the bottom center of the screen, a "○" is displayed if the item is good, and an "×" is displayed if the item is bad. If the test is in progress, "・・・" is displayed. The number of good

items and bad items is displayed at the top right of the screen. The count is performed when the final result is obtained.

Fig. 8 Program running

4. Experiment content

An evaluation experiment was conducted to verify the usefulness of the developed sorting system. They sort out 17 good and 23 bad mushrooms, and tally up whether the final result matches the shiitake mushrooms that were flushed. The number of matches is defined as the number of correct answers, and the accuracy is defined as follows. Since the final result is updated sequentially until the flow is finished, the last displayed final result is taken as the detection result. The number of cards trained on the CNN was 668 for good and 759 for bad, split 8:2 between training and testing.

$$accuracy = \frac{Number\ of\ correct\ answers}{Number\ of\ shiitake\ mushrooms\ shed} \times 100(\%)$$

5. Experimental result

As a result, the accuracy was low, with 41.1 % of good items and 91.3 % of bad items. Most of the shiitake mushrooms thrown away by the model were sorted out as bad shown in Table 2.

Table 2 Program execution results

	Good item	bad item
number of flows	17	23
The number of correct answers	7	21
accuracy	41.1%	91.3%

The figure below (Fig. 9) shows the selection results of the CNN model in the still image state. Although the accuracy of sorting out bad items as bad items was high, the accuracy in sorting out good items as good items was poor.
Fig. 9 Results of still image selection using CNN

6. Conclusion

This research is still in its infancy, and the experimental results were very poor. First, there is the problem that it is difficult to distinguish between good items at the CNN learning stage. It was difficult for me to sort by just looking at still images. When actually sorting, not only the front side but also the back side is important. Since this study was an experiment on only the front side, information on the back side was missing, and we believe that the accuracy is reduced. As a result, the accuracy of moving images deteriorated even more than the accuracy of still images. The reasons for the lower accuracy in the video images are that in the case of the video images, the shiitake mushrooms swayed on the conveyor belt, making it impossible to obtain accurate images, and that the images to be trained by the CNN and the video images on the conveyor belt had different lighting and size of the shiitake mushrooms within the frame. Future issues include the following.

- Increasing the number of images for learning
- Collect images of the back side of shiitake mushrooms
- Organizing the environment in which still images are collected and the environment in which video images are taken
- Reconstruction of CNN model

Acknowledgment

I would like to thank my supervisor, Professor Masato Sakamoto, for his guidance in preparing this thesis. We would like to thank Kazuhide Sugimoto of Sugimoto Shoten Co., Ltd. for providing information on shiitake mushrooms for this study.

Prof. Satoshi Ikeda

He received PhD degree from Hiroshima University. He is an associate professor in the Faculty of Engineering, University of Miyazaki. His research interest includes graph theory, probabilistic geometry, fractal geometry and measure theory.

Prof. Kaoru Ohe

She received her Ph.D. degrees from University of Miyazaki, Japan, in 2014. Currently she is an Associate Professor of the Center for Science and Engineering Education, Faculty of Engineering. Her research is separation engineering especially adsorption hazardous heavy metals and oxyanions

Prof. Amane Takei

He is working as Associate Professor for Department of Electrical and systems Engineering, University of Miyazaki, Japan. His research interest includes high performance computing for computational electromagnetism, iterative methods for the solution of sparse linear systems, domain decomposition methods for large-scale problems. Prof. Takei is a member of IEEE, an expert advisor of IEICE, a delegate of IEEJ, a director of JSST.

Prof. Makoto Sakamoto

He is presently a professor in the Faculty of Engineering, University of Miyazaki. His first interests lay in hydrodynamics and time series analysis, especially the directional wave spectrum. He is a theoretical computer scientist, and his current main research interests are automata theory, languages and computation. He is also interested in digital geometry, digital image processing, etc.

Mr. Kazuhide Sugimoto

He was Born in Takachiho town, Miyazaki Prefecture. After working in sales in the food service and apparel industries, he joined SUGIMOTO Co., Ltd., a wholesaler of dried shiitake mushrooms produced in Takachiho town, in 2011 after the Great East Japan Earthquake. In response to the current harsh situation, such as aging contract farmers and sluggish demand for dried shiitake mushrooms, he decided to protect the producers by promoting new business development, which he had experienced in sales. New items developed using shiitake mushrooms from Takachiho Township have become a standard item at supermarkets and department stores outside the prefecture. In March 2020, he was appointed as Representative Director, and in 2021, he was selected as a Small and Medium Enterprise Supporter and GFP Ambassador.

Predicting High Volatility Cryptocurrency Prices using Deep Learning

Abstract

Even if you want to make a profit from cryptocurrency, you are worried that you will lose money, and it is difficult to afford it. There are a vast number of papers that study such unpredictable price fluctuations of cryptocurrency. Currently, it is mainstream to use learning deep to predict the price of cryptocurrency. The goal of this research is to predict the price of cryptocurrency over the long-term using deep learning. The algorithms used are LSTM, GRU, and Bi-LSTM. The targeted cryptocurrencies are Bitcoin, Ethereum, Litecoin, and Cardano. Finally, we will compare it with previous research and verify the performance of our model.

Keywords: Price prediction, Cryptocurrency, LSTM, GRU, Bi-LSTM

1. Introduction

Cryptocurrency is still not very familiar to Japan and may feel like a distant entity, but it is actually something that will affect our lives in the near future. The main uses of Bitcoin are investment and speculative management. Cryptocurrency, which started out as a niche product used by small online groups, has now become mainstream, attracting the attention of both financial professionals and the general public. With a market capitalization reaching billions of dollars, this market has also become a new arena for speculators [1]. Cryptocurrency assets lack intrinsic value, regulatory oversight, lack of fixed-term investment funds, thin order books, short-term investment methods, and collective psychology, causing cryptocurrencies to be highly volatile [2]. Therefore, it is effective to perform technical trading on products with high volatility, and if you trade well, you can generate large profits [3]. Therefore, it is useful to predict the price movements of cryptocurrency using DNN (deep neural network). The goal of this research is to use DNNs such as LSTM, GRU, and Bi-LSTM to predict cryptocurrency such as BTC, ETH, LTC, and ADA with higher accuracy than previous research.

2. Method
2.1. *Cryptocurrency*

Cryptocurrency is a currency that is exchanged only as electronic data, does not have the power of compulsory currency imposed by the state like legal currency, and is primarily used for transactions over the Internet. Since the advent of Bitcoin, which began operations in 2009, derivative cryptocurrency called altcoins have been created one after another, and with the appearance of cryptocurrency exchanges that exchange legal currency and cryptocurrency, holding cryptocurrency has become easier. It spread rapidly [4]. There are various types of cryptocurrencies such as BTC, ETH, LTC, NEM, Ethereum Classic, LISK, etc., and the number is still increasing. The targets to be predicted in this research are

Tsutomu Ito, Kodai Hasebe, Fumito Hamakawa, Bidesh Biswas Biki, Satoshi Ikeda, Amane Takei, Makoto Sakamoto, Md Riajuliislam, Sabrina Bari Shital, Takao Ito

BTC (Bitcoin), ETH (Ethereum), LTC (Litecoin), and ADA (Cardano).

2.2. Algorithm

We will explain the three algorithms used in this research to predict cryptocurrency: LSTM, GRU, and Bi-LSTM. First, I will explain LSTM (Long Short-Term Memory). Although RNN (Recurrent Neural Network), which is a neural network that remembers past states, is suitable for analyzing time-series data, it has not been able to properly process long-term data [5]. LSTM overcomes this weakness and can maintain long context relationships. Data is controlled by three gates centered on the memory cells. The three gates are called forget gate, input gate, and output gate, and each uses a sigmoid function to determine whether or not to pass data. Fig. 1 shows the contents of LSTM.
Fig.1. The structure of LSTM [6].

GRU (Gated Recurrent Unit) is said to have similar performance to LSTM, and requires less calculation than LSTM, allowing for faster learning. LSTM is a cell that makes it possible to learn long-term features, which was impossible with RNN, but it has the problem of high computational cost. High calculation costs are not desirable, not only in machine learning. The solution is to eliminate memory cells and reduce the number of gates to reduce computational costs. In LSTM, two states, the storage cell, and the output value, are passed on to the next cell, but GRU combines these states into one. In addition,

LSTM requires one gate controller for input gate, forget gate, and output gate, but in GRU, forget gate and input gate are operated by one controller. Fig. 2 shows the contents of the GRU.
Fig.2. The structure of GRU [6].

The structure of Bi-LSTM (Bidirectional LSTM) ~~has a structure that has~~ with a forward LSTM and a reverse LSTM is shown in Fig. 3. LSTM only flows in the forward direction, but when Bi-LSTM predicts data, for example, given x_n a signal to be predicted, prediction is performed $x_{END} \sim x_{n+1}$ using the Forward Layer in $x_0 \sim x_{n-1}$ the forward direction and the Backward Layer in the reverse direction. It has the characteristic of doing. This allows it to handle more data than LSTM when the same amount of data is used for learning. However, since it handles a large amount of data, it takes longer to process than LSTM [7].
Fig.3. The structure of Bi-LSTM [8].

3. Experiment Content

The conditions for conducting the experiment are described below.

- Three algorithms were used in the experiment: LSTM, GRU, and Bi-LSTM.
- The four cryptocurrencies targeted for prediction are BTC, ETH, LTC, and ADA.
- There are two evaluation indicators: RMSE and MAPE.

3.1. *Development environment*

The model was trained and executed using Google Colab, which allows experiments to be performed for free. The number of CPU cores is 2, the number of threads is 4, the RAM is 12.7GB, and the disk is 225.8GB. The deep learning models LSTM, GRU, and Bi-LSTM used in the experiment were implemented in Python version 3.10.12. We used python libraries such as Sklearn and Keras, which are used for deep learning, and numpy and pandas, which are used for numerical calculations and analysis.

3.2. *Data*

The dataset was collected from Yahoo Finance (https://finance.yahoo.com/). We collected the prices of four types of cryptocurrencies on a daily basis: Bitcoin (BTC), Ethereum (ETH), Litecoin (LTC), and Cardano (ADA). The training data consists of January 1, 2018 to June 8, 2022 (80% of the data), and the test data consists of June 9, 2022 to November 30, 2023 (20% of the data). ~~be done. Split the~~ The data proportion of 80:20 for training and testing is designed in this research. The

detailed information of data specifications is listed in Table 1.

Table 1. Data specifications.

Attribute	Explanation	Type
Date	Date of transaction	Date
Open	First traded price	Continuous
High	Highest traded price	Continuous
Low	Lowest traded price	Continuous
Close	Last traded price	Continuous
Adj Close	The closing price before the split is the adjusted price after the split.	Continuous
Volume	Quantity of trades completed during the period	Continuous

3.3. *Evaluation index*

Root-Mean-Square Error (RMSE) and Mean-Absolute-Percentage error (MAPE) are used to evaluate the algorithm in this study. The smaller the RMSE and MAPE values, the better the prediction model performance. In Eq. (1) and Eq. (2), n is the number of elements, y_i is the correct value, and $\hat{y}_i$ is the predicted value.

$$RMSE = \sqrt{\frac{1}{n}\sum_{i=1}^{n}(y_i - \hat{y}_i)^2} \qquad (1)$$

$$MAPE = \frac{1}{n}\sum_{i=1}^{n}\left|\frac{y_i - \hat{y}_i}{y_i}\right| \qquad (2)$$

4. Experimental result

Table 2 shows the results predicted according to the conditions in Chapter 3. Evaluation values are rounded down to the fifth decimal place. Bold letters in the evaluation value indicate the lowest value (the highest value in terms of accuracy). The results showed that the accuracy of Bi-LSTM was better than other algorithms for all cryptocurrencies.

Table 2. Performance results of this research model.

Currencies	Methods	RMSE	MAPE
BTC	LSTM	807.7135	0.0332
	GRU	873.7594	0.0362
	Bi-LSTM	**770.3047**	**0.0314**
ETH	LSTM	21.0737	0.0123
	GRU	33.0912	0.0192
	Bi-LSTM	**15.1817**	**0.0092**
LTC	LSTM	1.5991	0.0188
	GRU	1.7605	0.0207
	Bi-LSTM	**1.1928**	**0.0130**
ADA	LSTM	0.0203	0.0578
	GRU	0.0236	0.0695
	Bi-LSTM	**0.0172**	**0.0526**

5. Comparative verification

In the comparative verification, we compare the performance of the model for predicting the price of cryptocurrency in this study with other models in previous studies [9], [10]. Here, we will verify whether the model proposed in this study is effective. When making comparisons, we will verify that the period of experimentation is consistent with previous research. Table 3 is a comparison between this research model and the previous study [9] model, and Table 4 is a comparison between this study and the previous study [10]. The accuracy of Bi-LSTM in this study was good in all comparisons, indicating that the model in this study is effective.

Table 3 Comparison of this study and previous study [9] .

Currency	Studies	Methods	RMSE	MAPE
BTC	Our model	LSTM	1184.7059	0.0426
		GRU	1094.3126	0.0422

		GRU	5.453	0.078
		Bi-LSTM	**1.988**	**0.020**
	[10]	LSTM	9.668	0.064
		GRU	8.122	0.046
		Bi-LSTM	8.025	0.041

6. Conclusion

In this study, we used three algorithms, LSTM, GRU, and Bi-LSTM, to predict the prices of four cryptocurrency: BTC, ETH, LTC, and ADA. The model was evaluated using the evaluation indicators RMSE and MAPE. The research results showed that Bi-LSTM made the most accurate predictions for all cryptocurrency, followed by LSTM and GRU. Finally, we conducted a comparative verification with previous studies and showed that this study is more effective than previous studies. Future works could include applying reinforcement learning to previous studies [11] and predicting price fluctuations based on the number of tweets [12].

Abstract

In recent years, three-dimensional computer graphics (3DCG) technology has been developed. In addition, much research has been done on weathering representations such as rust and moss for realistic representation. However, when outputting simulation results on an image, a large number of images are required to display different simulation results in a three-dimensional space. In this paper, a simulation method using vertex information of a 3D model and simple images is proposed. In this method, when the number of vertices is sufficient, the simulation result output does not use images, thus reducing the data increase. This figure is one of the experimental results.

Keywords: Computer graphics, Vertices, Rust, Weathering, Visual simulation

1. Introduction

In recent years, three-dimensional computer graphics (3DCG) have been used in films, games, VR-based education, and medicine. In this context, there is a need to make 3DCG look more realistic. However, it is not subject to interferences such as environment or time and therefore does not degrade as in reality. This is why research into weathering expressions for CG is being conducted to this day.

This study proposes a method to implement weathering representations such as rust and moss using vertex information and UVs, instead of outputting simulation results as images for textures. The simulation results were also applied to a 3DCG model in practice.

2. Research Background

To date, a plethora of research has been done on weathering representations related to computer graphics. However, most of them require the simulation results to be output as images for textures. However, when simulations are performed on multiple models, images are required for the number of models, resulting in a large amount of data. With the aim of being flexible enough to deal with existing models and real-time representations, a simulation method using vertex information and UVs of 3DCG models was developed in this study.

In this study, the UV map used for the material representation of the original 3DCG model is called the base UV map, and the UV map for simulation is called the simulation UV map.

Tsutomu Ito, Fumito Hamakawa, Kodai Hasebe, Satoshi Ikeda, Amane Takei, Makoto Sakamoto, Takao Ito

3. Development Environment

The development environment is shown in Table 1, with C# used as the programming language for Unity and Python for Blender.

Table 1. Development Environment.

OS	Windows10
Software	Blender 3.6
	Unity 2022.3.14fl
	Visual Studio 2019
	Adobe Illustrator 2023

4. Simulation Method

4.1. *Adjacency list*

In this study, simulations are performed using vertex information in 3DCG. Vertex adjacency information was obtained, and an adjacency list was created to represent the phenomenon of rust and moss propagating locally in weathering simulations. The method for creating the neighborhood list used vertex information constituting polygons and edges, although the method of searching for neighborhood information differs from software to software. The adjacency list of vertexes v_i at index number i is Fig. 1.

vertex	adjacent to
v_0	v_1, v_2
v_1	v_0, v_2
v_2	v_0, v_1
Fig. 1. Adjacency list at vertex.

4.2. *Initial condition setting*

The susceptibility to rust and moss varies with the environment, such as humidity and sunlight, but also with the material of the object, just as there is a difference in the probability of rust between metal and plastic. Few previous studies have considered the material of the object and conducted simulations, and most of them assume that the entire object is made of the same material. In this study, the user can control the erosion probability of the initial state like a mask image by painting directly using the base UV map.

4.3. *Dynamic environment acquisition*

Most of the previous studies assume a situation where the object is in the same environment and in the same shape at every step. However, some objects may change dynamically, such as changing orientation over time or increasing obstacles. Therefore, in this study, by incorporating vertex information into the local transition rules, real-time changes such as changes in orientation and up/down can be managed.

4.4. *UV-based erosion representation*

Determine UV coordinates from the degree of rust and moss erosion at the vertices using the adjacency list. The color of the eroded object is also determined by the user entering a gradient image. In addition, as multiple UV maps are used, they can be used in conjunction with the base colors of existing 3DCG models as shown in Fig. 2 and Fig. 3.
Fig. 2. Base color.　　Fig. 3. Initial condition.

5. Experimental Results

This paper describes some of the experimental results, mainly related to rust formation. The transition conditions for rust generation are as follows, based on previous studies [1], [2], [3].

- Rust progression from 0 to the maximum rust value R_{MAX} determined by the user.
- Rust progression is assigned to each vertex.
- Vertex v as the initial rust occurrence has a low probability of rust progression R_v increases by 1.
- Vertex adjacent to a vertex with progression greater than 1 has its R_v increased by 1 by a function that takes gravity and probability into account.
- Vertexes above a certain level of progression are peeled off.
- UV placement of vertex v at index number i in step t is determined by $R_{v_i}^t / R_{MAX}$

In this experiment, simulated UVs are applied to the mask textures in Fig. 4 and the color textures in Fig. 5. The mask texture is a grayscale image and can be used to express textures such as the metallic feel and roughness of the surface of the 3DCG model by inputting the simulation results into software shaders. Besides, it can

also be used to control the range of application of noise textures to represent uneven and rusty surfaces or the base color of an existing 3DCG model. Color textures represent color scales. In addition, alpha values can be set, and the expression of peeling and holes above a certain value is implemented.

Fig. 4. Mask texture.　　Fig. 5. Color texture.

5.1. *Base experimental*

In this experiment, simulations were performed on a cube that was tilted. The results, shown in Fig. 6 and Fig. 7, show rust propagating according to gravity. In addition, the strongly eroded areas have holes and peeling. The rust-free area in Fig. 6 has no surface irregularity due to the noise texture in Fig. 7, indicating that the mask texture controls the texture of the 3DCG model.
Fig. 6. Ex1 Mask result.　　Fig. 7. Ex1 Color result.
5.2. *Verification of randomness*

In this experiment, the same 3DCG model, the same transition rules, and the same textures as in 5.1 were used in the simulation. The results in Fig. 8 and Fig. 9 differ from those in 5.1, indicating that the same image and the same model can output different patterns of results depending on the probability.
Fig. 8. Ex2 Mask result.　　Fig. 9. Ex2 Color result.
5.3. *Shape change*

In this experiment, only the tilt of the object was changed from 5.1 to the simulation. 5.1 shows that rust

propagates in the left front direction because the object is tilted in the left front direction. However, in this experiment, the rust propagated in the right-most direction as the object was tilted in the right-most direction as illustrated in Fig. 10 and Fig. 11.
Fig. 10. Mask result in　　Fig. 11. Color result in
different shapes.　　　　　different shapes.

5.4. *Initial condition*

In this experiment, the objects and initial conditions were changed and simulated. The initial state is shown in Fig. 3. Fig. 12 and Fig. 13 show that rust only occurs in the most rust-prone white area in the initial state, and no rust occurs in the most rust-prone black area.

Fig. 12. Mask result in　　Fig. 13. Color result in
another object.　　　　　another object.

6. Consideration

From 5.1 and 5.2, it was shown that rust propagates in the direction of gravity depending on probability as in previous studies, and that the location of rust and the direction of rust propagation change depending on probability. This indicates that the same mask texture and color texture can output different patterns of results for the same object of the same shape existing at the same time. This means that the simulation results do not need to be output to an image, which may reduce the amount of data when multiple patterns of weathering representation are desired for the same object. In addition, since the simulation results are the erosion degree for each vertex, they can be saved by outputting them to a CSV file or other format.

From 5.3, it was shown that the simulation results can be output in response to tilt even when the object shape is changed. This is because the vertex information is

Tsutomu Ito, Fumito Hamakawa, Kodai Hasebe, Satoshi Ikeda, Amane Takei, Makoto Sakamoto, Takao Ito

referenced in the transition rule, and it can respond to changes in the tilt and size of the object during simulation. In addition to vertex position information, vertex distance and the number of neighbors can also be referenced. However, if the neighbor information changes, such as when a vertex is deleted or added, it is necessary to reacquire the neighbor information.

From 5.4, it is shown that it is possible to limit the impact of the simulation by setting initial conditions. This allows the base UV map and simple painting to control the strength of the influence of different metals and materials, without the In this study, only rust was mentioned, but by changing the texture and transition rules for each, the propagation of moss can be represented as shown in Fig. 14.

Fig. 14. Simulation results assuming moss in another object.

7. Conclusion

In this study, we performed weathering simulations using vertex adjacency and UV information. As in the

previous study, expressions such as rust and moss propagation could be made without outputting them to the texture. However, the number of vertices needs to be increased for more realistic expressions and detailed patterns. Therefore, if real-time changes are to be observed, it is necessary to optimize the number of vertices and to limit the number of objects to be simulated at the same time.

For future works, it is necessary to pursue the improvement of transition rules and the fields in which this vertex technology can be utilized.

Authors Introduction

Prof. Tsutomu Ito

He is Associate Professor of the Department of Business Administration at National Institute of Technology, Ube College, Japan. His current research interests include internet of things (IoT), mechanical engineering, artificial intelligence (AI), automata theory, quantitative analysis of Japanese Keiretsu. Dr. Ito earned his doctor degree of Engineering from Hiroshima University, Japan in 2018.

Mr. Fumito Hamakawa

He is a master student at Department of Computer Science and System Engineering, University of Miyazaki. His current research interests are computer graphics, cellular automaton simulation, and so on.

Mr. Kodai Hasebe
He is a master student at Department of Computer Science and System Engineering, University of Miyazaki. His current research interests are image processing, machine learning, and so on.

Prof. Satoshi Ikeda

He received PhD degree from Hiroshima University. He is an associate professor in the Faculty of Engineering, University of Miyazaki. His research interest includes graph theory, probabilistic algorithm, fractal geometry and measure theory.

Prof. Amane Takei

He is working as Associate Professor for Department of Electrical and systems Engineering, University of Miyazaki, Japan. His research interest includes high performance computing for computational electromagnetism, iterative methods for the solution of sparse linear systems, domain decomposition methods for large-scale problems. Prof. Takei is a member of IEEE, an expert advisor of IEICE, a delegate of the Kyushu branch of IEEJ a director of JSST.

Prof. Makoto Sakamoto

He is presently a professor in the Faculty of Engineering, University of Miyazaki. His first interests lay in hydrodynamics and time series analysis, especially the directional wave spectrum. He is a theoretical computer scientist, and his current main research interests are automata theory, languages, and computation. He is also interested in digital geometry, digital image processing, computer vision, computer graphics, virtual reality, etc.

Prof. Takao Ito

He is Professor of Management of Technology (MOT) in Graduate School of Engineering at Hiroshima University. His current research interests include automata theory, artificial intelligence, systems control, quantitative analysis of interfirm relationships using graph theory, and engineering approach of organizational structures using complex systems theory.

Investigating the Engineering Interventions in the Conservation of Malaysia Heritage Structures: A Review on Preserving Historical Edifices Through Advanced Civil Engineering Techniques.

Abstract

This review delves into the realm of Malaysia's heritage conservation, spotlighting the transformative impact of advanced civil engineering techniques. Through the integration of Fiber-Reinforced Polymers (FRP) and nanotechnology, historical edifices are fortified, seamlessly blending modern engineering with architectural elegance. Non-destructive testing (NDT) methods, including ground-penetrating radar and Finite Element Analysis (FEA), empower conservationists with deep insights into structural intricacies, guiding targeted interventions. In the digital sphere, 3D laser scanning captures intricate details, while Virtual Reality (VR) simulations facilitate immersive exploration and informed decision-making. Beyond preservation, these technologies foster public engagement, ensuring a collective understanding of Malaysia's cultural heritage. This harmonious fusion of tradition and cutting-edge engineering ensures the enduring legacy of Malaysia's architectural treasures.

Keywords: Heritage conservation, Non-destructive testing (NDT), Finite Element Analysis (FEA), 3D laser scanning, Virtual Reality (VR)

1. Introduction

Heritage structures stand as invaluable remnants of our cultural legacy, embodying the architectural achievements and historical significance of bygone eras [1]. However, the preservation of these structures poses intricate challenges that demand innovative engineering solutions [2], [14]. As urban landscapes evolve and modernization accelerates, the need to safeguard these historical edifices has never been more pressing [3]. This review embarks on a comprehensive exploration of the engineering interventions essential in the conservation of heritage structures, delving into the intricate amalgamation of tradition and technology [4], [6]. Through a meticulous analysis of advanced civil engineering techniques, this study aims to shed light on the nuanced methods employed to preserve the structural integrity, cultural heritage, and aesthetic essence of these buildings. By examining the successes, challenges, and lessons learned from previous conservation projects, this research endeavors to offer valuable insights into the sustainable preservation of our architectural heritage, ensuring that these treasures endure for generations to come. In this pursuit, study will navigate the intersection of history, culture, and engineering prowess, striving to strike an intricate balance between preservation imperatives and contemporary demands [5].

2. Preserving Historical Edifices in Malaysia

Conducting a thorough exploration of Malaysia's rich historical and cultural heritage is vital. This involves studying the evolution of architectural styles and understanding the cultural significance of historical edifices within Malaysian society [6], [23]. The architectural diversity in Malaysia, influenced by Malay, Chinese, Indian, and colonial elements, forms a critical backdrop for conservation efforts [7]. Malaysia's architectural heritage is a tapestry woven from centuries of cultural interactions and influences. The evolution of

architectural styles in Malaysia reflects the rich history of the nation, characterized by the convergence of Malay, Chinese, Indian, and colonial elements. Traditional Malay architecture, exemplified by intricate wooden carvings and steeply pitched roofs, showcases indigenous craftsmanship [8], [19]. The Chinese influence is evident in the intricate details of temples and clan houses, emphasizing symmetry and ornate decorations [9]. Indian architectural traditions, characterized by vibrant colors and sculpted facades, have left an indelible mark on religious structures across the country [10], [26]. Additionally, the colonial era introduced a blend of European styles, seen in buildings with ornate facades, arched windows, and grand pillars, reflecting the British, Dutch, and Portuguese colonial influences [11].

Understanding the unique architectural amalgamation is crucial in preserving historical edifices. Each cultural influence represents a chapter in Malaysia's history, encapsulating the nation's multicultural identity. Preservation efforts must delicately balance these diverse elements, ensuring that the architectural heritage reflects the harmonious coexistence of cultures within Malaysian society [12]. The selection process involves collaboration with local heritage organizations and experts. It's crucial to choose diverse edifices, considering regional representation and architectural styles. Identifying overlooked structures that are significant to local communities ensures a holistic approach to preservation [13].

3. Advanced Civil Engineering Techniques in Conservations Work

The preservation of historical edifices necessitates the integration of advanced civil engineering techniques, marking a paradigm shift in heritage conservation practices. Traditional methods, while valuable, often face limitations in addressing the complex challenges posed by aging structures and evolving environmental conditions. Advanced civil engineering techniques encompass a spectrum of innovative approaches, from cutting-edge materials science to sophisticated computational modeling and non-destructive testing methods. These techniques play a pivotal role in the structural assessment, restoration, and long-term sustainability of historical buildings, ensuring the preservation of cultural heritage for future generations.

3.1 Advanced Structural Assessment

Non-Destructive Testing (NDT) is a techniques like ground-penetrating radar (GPR) and ultrasonic testing enable engineers to assess internal structures without damaging the building fabric [14]. Ground-penetrating radar (GPR) operates on the principle of emitting high-frequency radio waves into the structure. These waves penetrate the materials and reflect back when encountering boundaries between different materials or voids. By analyzing the time taken for the signals to return and their strength, engineers can create detailed subsurface images without invasive measures.

Finite Element Analysis (FEA) is another civil engineering computational methods such as FEA provide detailed insights into stress distributions and structural vulnerabilities, aiding in targeted interventions [2], [15]. FEA tools enable engineers to visualize the impact of interventions on the structure's aesthetics. Conservationists can assess how alterations might affect the visual aspects of the edifice, ensuring that preservation efforts align with historical significance and architectural beauty. FEA can validate restoration efforts. By comparing the digital model of the restored structure with historical data, conservationists can ensure that the restoration accurately reflects the original design, maintaining the structure's historical authenticity [16]. Incorporating Finite Element Analysis into heritage conservation efforts empowers engineers and conservationists with detailed, data-driven insights. It enables targeted, efficient interventions while preserving the historical and aesthetic essence of these invaluable structures.

3.2 Innovative Materials and Techniques

Fiber-Reinforced Polymers (FRP) composites offer lightweight and high-strength solutions for structural reinforcement, preserving the original aesthetics [17]. Fiber-Reinforced Polymers (FRP) are composite materials made of a polymer matrix reinforced with fibers such as glass, carbon, or aramid. These materials offer exceptional strength-to-weight ratios and durability, making them ideal for structural reinforcement applications. FRP composites are used to reinforce historical structures without significantly altering their original appearance. For instance, FRP strips can be bonded to beams and columns, providing additional strength without compromising the aesthetic integrity [18]. In earthquake-prone regions, FRP materials are employed to enhance the seismic resilience of historical buildings. They can be strategically placed to reinforce vulnerable areas, ensuring the structure's stability during seismic events [19].

Nanotechnology Applications Nanomaterials, such as self-healing coatings, enhance the durability and resilience of historical structures against environmental

factors [20]. Nanotechnology involves the manipulation of materials at the nanoscale, where their properties exhibit unique characteristics. In heritage conservation, nanomaterials are utilized for their ability to enhance the durability, resilience, and protective qualities of historical structures. Nanomaterials, such as microcapsules containing healing agents, are embedded in coatings applied to building surfaces. When the structure experiences minor cracks due to environmental stresses, these capsules rupture, releasing the healing agents and effectively repairing the damage [21]. Hydrophobic nano coatings repel water and prevent moisture infiltration, safeguarding historical structures from water-related deterioration. These coatings can be applied to various surfaces, including stone, wood, and metal, preserving the integrity of the building materials [22].

The integration of FRP composites and nanotechnology applications represents a forward-thinking approach in heritage conservation, combining structural reinforcement with advanced protective coatings. These techniques not only strengthen historical structures but also contribute to their long-term resilience against various environmental challenges, ensuring the preservation of cultural heritage assets.

3.3 Preservation through Digital Technologies

3D Laser Scanning: High-resolution 3D scans aid in documenting intricate architectural details, facilitating accurate restoration [23]. 3D laser scanning involves using lasers to create highly detailed, three-dimensional representations of physical objects, including historical buildings. Laser scanners emit laser beams that bounce off surfaces and return to the scanner. By measuring the time, it takes for the laser to return, the scanner can create precise 3D models. 3D laser scanning captures intricate architectural details, including ornate carvings, moldings, and textures, with unparalleled accuracy. This documentation serves as a digital record of the structure, aiding in historical analysis and preservation efforts [24]. Laser scanning provides precise measurements, allowing conservationists to assess dimensions, angles, and spatial relationships within the building. These measurements are crucial for restoration work, ensuring that new elements align perfectly with the original design [25]. 3D models generated through scanning enable virtual preservation. Conservationists can digitally archive buildings, allowing future generations to explore and study historical structures in virtual environments [26].

Virtual Reality (VR) Simulations: VR technologies allow conservationists to visualize proposed changes and assess their impact on the historical context [1]. Virtual Reality (VR) simulations immerse users in computer-generated environments. Conservationists use VR technologies to create virtual replicas of historical structures, enabling interactive exploration and analysis. Conservationists use VR simulations to visualize proposed alterations or restoration efforts. This immersive experience allows stakeholders to assess the visual impact of changes before implementation, ensuring that modifications align with the historical context below. VR simulations enhance public engagement by allowing virtual tours of historical sites. This interactive experience fosters public interest, awareness, and appreciation for cultural heritage, promoting advocacy for conservation efforts [28]. VR simulations serve as educational tools, enabling students, architects, and conservationists to virtually explore historical buildings.

The integration of advanced civil engineering techniques in heritage conservation signifies a progressive approach toward preserving our architectural legacy. By leveraging cutting-edge methods and materials, conservationists can ensure the structural integrity, authenticity, and longevity of historical edifices, contributing significantly to the safeguarding of cultural heritage for generations to come. This evolving field continues to redefine the boundaries of conservation practices, marking a new era in the intersection of engineering innovation and cultural preservation.

4. Conclusion

This comprehensive exploration into the conservation of Malaysia's rich heritage structures illuminates the pivotal role played by advanced civil engineering techniques in preserving these historical gems. Fiber-Reinforced Polymers (FRP) emerge as lightweight, yet robust solutions, seamlessly merging modern engineering with historical aesthetics. Collaborating with nanotechnology, self-healing coatings and hydrophobic nano coatings fortify structures against environmental ravages, ensuring their endurance for posterity.

Non-destructive testing (NDT) methods like ground-penetrating radar (GPR) and ultrasonic testing, coupled with Finite Element Analysis (FEA), provide profound insights into the structural intricacies of historical edifices. These techniques empower conservationists with precise stress distributions, vulnerability identifications, and predictive capabilities, guiding meticulous interventions that preserve both the architectural integrity and historical

Muhammad Azizi Azizan, Nurfadzillah Ishak, Hazry Desa

resonance.

In the digital realm, 3D laser scanning meticulously captures architectural nuances, laying the foundation for precise restoration. Virtual Reality (VR) simulations then breathe life into historical spaces, enabling immersive exploration and informed decision-making. Beyond conservation, these technologies foster public engagement, ensuring a collective understanding and appreciation of Malaysia's cultural heritage.

As custodians of Malaysia's architectural legacy, conservationists stand at the nexus of tradition and technology. Armed with these advanced tools, they meticulously balance preservation imperatives and contemporary demands. Through this synergy, Malaysia's heritage structures not only withstand the tests of time but also continue to inspire, educate, and enrich future generations, ensuring the vibrant preservation of the nation's cultural heritage.

Abstract

Encapsulates a comprehensive investigation into the symbiotic relationship between Unmanned Aerial Vehicles (UAVs) and data mining, as encapsulated in the discourse titled "Drones and Data." This exploration delves into the multifaceted applications and transformative impact of UAV technology within the data mining landscape. The examination begins by elucidating the pivotal role of UAVs, highlighting their mobility, accessibility, and capability to collect data from challenging or remote environments. As technology evolves, UAVs have emerged as versatile platforms that redefine the data is collected and analysed across diverse sectors. The narrative unfolds through distinct dimensions, encompassing precision agriculture, environmental monitoring, infrastructure inspection, mining and exploration, disaster response, and urban planning. The technological transitions facilitated by UAVs, emphasizing the integration of machine learning algorithms, cloud-based data processing, and the collaborative synergy between stakeholders. These advancements position UAVs as transformative tools that not only enhance the efficiency of information acquisition but also open avenues for innovative solutions and insights. Therefore, this study a glimpse into the intricate web of applications and technological advancements at the intersection of UAVs and data mining. It serves as a scholarly guide, navigating the reader through the evolving landscape of "Drones and Data," UAVs play a central role in unlocking unprecedented insights and efficiencies, reshaping the future of data mining.

Keywords: Acceptance, Readiness; Unmanned Aerial Vehicle; Data Mining

1. Introduction

In recent years, the integration of Unmanned Aerial Vehicles (UAVs) in data mining applications has witnessed a remarkable surge, reshaping the landscape of information acquisition and analysis. UAVs, commonly known as drones, have become pivotal tools in various industries, offering unique advantages that propel the field of data mining into new frontiers [1]. As technology continues to advance, UAVs have emerged as versatile platforms capable of transforming how we collect and analyze data. Their applications span a wide spectrum, from environmental monitoring and agriculture to infrastructure inspection and disaster management. In the realm of data mining, UAVs play a crucial role in augmenting our ability to gather information with unprecedented efficiency and accuracy [2].

2. Unmanned Advantages of UAVs in Data Mining
2.1. *Mobility*

UAVs provide unparalleled mobility, enabling access to areas that are challenging or impossible for traditional data collection methods. Whether navigating dense forests, inspecting infrastructure, or monitoring vast agricultural landscapes, UAVs offer a dynamic and flexible approach to data acquisition [3].

2.2. *Accessibility*

The ability of UAVs to access hard-to-reach or remote locations is a game-changer in data mining. They overcome geographical constraints and offer a cost-effective alternative to manned missions, allowing for more frequent and widespread data collection [4].

2.3. *Data Collection in Challenging Environments*
UAVs excel in collecting data from environments that pose logistical or safety challenges. From rugged

terrains to disaster-stricken areas, UAVs can swiftly and efficiently capture valuable information, contributing to a more comprehensive understanding of diverse landscapes [5].

2.4. *High-Resolution Imaging*

Equipped with advanced imaging technologies, UAVs capture high-resolution aerial imagery, facilitating detailed spatial analysis. This capability is particularly beneficial in applications such as land-use mapping, environmental modelling, and infrastructure planning [6].

2.5. *Real-time Monitoring*

UAVs enable real-time data acquisition and monitoring, allowing for quick decision-making in dynamic situations. This responsiveness is crucial in applications like disaster response, where timely information can save lives and mitigate the impact of emergencies [7].

The synergy between UAVs and data mining opens up new avenues for exploration and discovery. This introduction sets the stage for a comprehensive examination of how UAVs are reshaping the field, emphasizing their mobility, accessibility, and prowess in collecting data from challenging or remote environments. As a delve deeper into the subsequent sections, study will unravel the multifaceted applications and the transformative impact of UAVs in the realm of data mining [8].

3. UAV Readiness Index (URI) for Data Mining: Navigating the Technological Landscape

The integration of Unmanned Aerial Vehicles (UAVs) into data mining practices is contingent on the acceptance and readiness of stakeholders within diverse industries. This section introduces a UAV Acceptance and Readiness Index, exploring the factors influencing the adoption of UAV technology for data mining and the preparedness of various sectors to embrace these advancements.

Table 1. Regulatory Environment

Regulatory Environment	
Acceptance	Readiness
The willingness of regulatory bodies to adapt and establish clear guidelines for UAV usage in data mining applications [9].	The development of regulatory frameworks that balance innovation with safety, fostering a conducive environment for UAV adoption [9].

Table 2. Technological Infrastructure

Technological Infrastructure	
Acceptance	Readiness
Embracing UAV technology requires a robust technological infrastructure capable of supporting data-intensive processes [10].	Investment in the necessary hardware, software, and communication systems to accommodate the seamless integration of UAVs into data mining workflows [11].

Table 3. Stakeholder Awareness and Education

Stakeholder Awareness and Education	
Acceptance	Readiness
Recognition and understanding of the benefits of UAVs in data mining among stakeholders, including industry professionals, policymakers, and the public [12].	Educational initiatives aimed at raising awareness about UAV capabilities, data security, and the potential impact on various sectors [13].

Table 4. Cost Considerations

Cost Considerations	
Acceptance	Readiness
Recognition of the cost-effectiveness of UAV technology compared to traditional data collection methods [14].	Financial preparedness to invest in UAV infrastructure, training, and maintenance, considering the long-term benefits and efficiency gains [15].

Table 5. Data Security and Privacy

Data Security and Privacy	
Acceptance	Readiness
Acknowledgment of the importance of data security and privacy in UAV-enabled data mining applications [16].	Implementation of robust security measures, encryption protocols, and adherence to privacy regulations to address concerns associated with data collection from aerial platforms [17].

Table 6. Industry Collaboration and Standards

Industry Collaboration and Standards	
Acceptance	Readiness
Willingness of industries to collaborate and share best practices for UAV integration into data mining workflows [18].	Development and adherence to industry standards that streamline UAV adoption, ensuring interoperability and consistency across applications [19].

Table 7. Training and Skill Development

Training and Skill Development	
Acceptance	Readiness
Recognition of the need for specialized training programs to equip professionals with the skills required for UAV-assisted data mining [20].	Implementation of training initiatives to build a workforce capable of operating, maintaining, and extracting valuable insights from UAV-collected data [21].

Table 8. Public Perception and Acceptance

Public Perception and Acceptance	
Acceptance	Readiness
Public perception and acceptance of UAV technology, considering factors such as noise, visual impact, and potential disruptions [22].	Public awareness campaigns to foster understanding and acceptance of UAVs, addressing concerns and showcasing the societal benefits of UAV-enabled data mining [23].

The UAV Acceptance and Readiness Index provides a comprehensive framework for assessing the feasibility of integrating UAV technology into data mining practices. As navigate through the subsequent sections, each factor in this index will be explored in detail, shedding light on the evolving landscape of acceptance and readiness for UAV-enabled data mining across various sectors.

4. Methods

A quantitative approach was employed in this research. A self-administered questionnaire with close-ended questions using a five-point Likert scale ranging. The final questionnaire has been through the preliminary tests which consist of validity and reliability analysis. Content validity is applied by inviting a group of five experts to be selected to pre-test and to review the set of questionnaires. They consist of two academicians working in universities as lecturers and researchers in the area of construction and town planning and three practitioners or project managers who have experience in managing development projects.

Meanwhile, the internal consistency of data reliability in this research was verified by using the Cronbach's Alpha coefficients through the pilot survey, where 30 usable responses from the pilot survey. It was found that the questionnaire coefficient of Cronbach's alpha was more than 0.7 which was deemed as reliable for quantitative data collection. In order to distribute the final survey, a simple random sampling was applied in this research as the population sample is known. In this research, the targeted population is 70 organizations from government agencies and development firms in Kuala Lumpur. Kuala Lumpur has a high number of developments of township and is considered as a positively data mining active location in Malaysia. A total of 56 required samples were successfully obtained and usable for analysis. Data collected were analysed using IBM SPSS Statistical Software which descriptive analysis has been employed in order to achieve the research objective.

5. Results and Discussion
5.1. *The level of the acceptance and readiness of Unmanned Aerial Vehicle implementation in data mining procedures*

Table 9 shows the means and standard deviation based on each variable which is for capabilities factor of Unmanned Aerial Vehicle technology. The variables consist of Regulatory Environment (mean=4.60, sd.=0.34), Technological Infrastructure (mean=4.47, sd.=0.44), Stakeholder Awareness and Education (mean=4.43, sd.=0.44), Cost Considerations (mean=4.41, sd.=0.47) and Data Security and Privacy (mean=4.38, sd.=0.52). Furthermore, for the readiness elements of implementation Unmanned Aerial Vehicle technology are Industry Collaboration and Standards (mean=3.56, sd.=0.44), Training and Skill Development (mean=3.24, sd.=1.38), Public Perception and Acceptance (mean=3.06, sd.=0.95). The mean value score interpretation of the variables used in this study were be interpreted.

Table 9. Descriptive Analysis

Variables	Mean	Std. Deviation	Mean Value Score Interpretation
Acceptance Factors			
Regulatory Environment	4.60	0.34	High
Technological Infrastructure	4.47	0.44	High

Stakeholder Awareness and Education	4.43	0.44	High
Cost Considerations	4.41	0.47	High
Data Security and Privacy	4.38	0.52	High
Readiness Elements			
Industry Collaboration and Standards	3.24	1.38	Moderate
Training and Skill Development	3.06	0.95	Moderate
Public Perception and Acceptance	3.12	1.37	Moderate

Note: The mean value categorized into three levels: low = 1.00 to 2.66; moderate = 2.67 to 3.33; and high = 3.34 to 5.00.

Based on the result illustrated in the Table 9, it can be concluded that in navigating the UAV Acceptance and Readiness Index for Data Mining, our exploration has unveiled critical dimensions shaping the trajectory of UAV technology adoption within the data mining landscape. The confluence of regulatory adaptability, technological infrastructure, stakeholder education, cost considerations, industry collaboration, and public perception forms a complex web influencing the acceptance and readiness for UAVs. The journey through this index demonstrates a forward momentum, wherein regulatory bodies are increasingly adapting to UAV applications, fostering an environment conducive to innovation while ensuring safety and compliance. Technological infrastructure investments have paved the way for seamless UAV integration, with robust hardware, software, and communication systems supporting data-intensive processes. Stakeholder awareness and education emerge as pillars of knowledge empowerment, fostering a deeper understanding of UAV benefits among professionals, policymakers, and the public. Educational initiatives play a crucial role in dispelling concerns, promoting transparency, and positioning UAVs as transformative tools in data mining.

6. Conclusions

As summarised, the UAV Acceptance and Readiness Index for Data Mining represents a holistic transition toward embracing UAVs as integral components of data mining workflows. As stakeholders align their strategies with the dimensions outlined in this index, the landscape of data mining is poised for transformative change [24].

The journey doesn't end here but propels us forward, navigating the future where UAVs play a central role in unlocking unprecedented insights and efficiencies in the world of data mining.

Abstract

This paper introduces the concept of a variable arm for a quadrotor which is able to perform the manoeuvrability of the quadrotor by changing the arm length's. The variation in arm's length affects the bending moment generated by the thrust force, resulting in the tilting and movement of the quadrotor. The primary goal of this project is to develop a quadrotor with an adjustable arm length to control its manoeuvrability effectively, thus minimizing the need for additional thrust force during flight control. The study focuses on designing a quadrotor with the capability to extend or retract its arms. The proposed concept relies on altering the bending moment through the variable arm to control the quadrotor's manoeuvrability. A quadrotor equipped with a variable arm was successfully designed and tested, with its performance evaluated in executing agile maneuvers. The experiment demonstrated that the variable arm induced body rotation in the quadrotor, effectively regulating its manoeuvrability and the study validates the potential of the variable arm approach for controlling quadrotor movement.

Keywords: N Retract, Control, Agile maneuvers, Body rotation, Performance evaluation, Validation.

1. Introduction

The quadrotor's working principle can be elucidated through Newton's Third Law of Motion, which states that every action has an equal and opposite reaction [1]. When the quadrotor's motor rotates the propeller, it generates a downward force on the air, a phenomenon explained by Bernoulli's Principle [2]. In a standard quadrotor, different motor speeds in the four motors allow for thrust generation, enabling precise control of the quadrotor's movements [3]. As the size and weight increase, greater thrust must be produced to lift the quadrotor effectively [4]. Typically, achieving this entails designing the quadrotor with higher-speed motors or larger propellers to generate the necessary thrust to counter the quadrotor's weight [5]. Consequently, this results in higher current consumption and increased power usage, leading to reduced flight endurance [6]. In this context, designing the quadrotor using conventional methods can be both costly and inefficient [7]. This project proposes a variable arm approach to control the quadrotor, utilizing different arm lengths to regulate its manoeuvrability [8].

The research on variable arm-controlled quadrotors draws on a foundation of related work in the fields of sensor networks, IoT applications, and intelligent systems. Kousik et al. leveraged a hybrid Convolution Recurrent Neural Network for improved salient object detection [9], showcasing advancements in intelligent systems. Singanamalla et al. addressed reliability and energy efficiency in emergency transmission within wireless sensor networks [10], contributing to the broader context of networked systems. Alzubi et al. conducted a survey on specific IoT applications, providing insights into the diverse applications of IoT across various domains [11]. Furthermore, Kallam et al. explored low-energy aware communication processes in IoT through a green computing approach [12], aligning with the focus on energy efficiency in the development of the variable arm-controlled quadrotor. Suresh et al. proposed an energy-efficient mechanism for leveraging IoT [13], setting the stage for considerations related to energy efficiency in unmanned aerial systems. Mekala et al. presented a computational intelligent sensor-rank consolidation approach for the industrial Internet of Things (IIoT) [14], providing valuable insights into intelligent systems applied to industrial contexts. Additionally, Reddy et al. focused on smart assistance for elderly individuals in emergency situations using IoT [15], showcasing the potential applications of intelligent systems in healthcare scenarios. Collectively, these works contribute to the foundation of knowledge necessary for understanding and advancing the development of innovative systems, such as the variable arm-controlled quadrotor presented in the current paper.

2. Materials and Methods

The quadrotor, depicted in Fig. 1, is designed in the form of a variable arm quadrotor, comprising 10 essential components. These components include the Arduino Mega, serving as the microcontroller, an ESC controller responsible for regulating the RPM of the brushless DC motor, the MDD3A driver for controlling the electric actuator's movement, and an MPU 6050 sensor located at the quadrotor's center to detect its acceleration and rotation. Additionally, there are two sets of variable arms and fixed arms, a LiPo Battery for power supply, an A2212 2200KV brushless DC motor, and a base frame. Specifically, the variable arm is engineered as an electric actuator with a linear guide and designed to securely hold the brushless DC motor.
Fig. 1. Variable arm quadrotor.

3. Conceptual Modelling

The standard quadrotor achieves manoeuvrability by adjusting its speed to generate varying thrusts. The quadrotor's design follows a plus configuration, which offers simplicity in both calculation and analysis compared to the cross configuration. Hence, the calculations are conducted with two propellers while assuming the other two propellers remain constant. In Fig. 2, a free-body diagram illustrates both the normal quadrotor and the variable arm quadrotor, showcasing the relationship between angle, acceleration, and the difference in thrust production with various arm lengths. Fig. 2(a) displays the normal quadrotor, controlled by different thrust forces, while Fig. 2(b) demonstrates the variable arm quadrotor, which relies on adjusting the arm length for control.

$$W = L\cos(Angle) + R\cos(Angle) = 3L_y + R_y \quad (1)$$

$$F = ma \quad (2)$$

Based on Fig. 2, the quadrotor weighs 1.94 kg, and each arm requires a thrust force of 4.76 N to maintain equilibrium. By assuming that only one thrust is changed while the other three remain constant, Eq. (1) can be utilized to determine the force R required for the quadrotor to attain a specific angle. The acceleration generated by Eq. (2) is depicted in Fig. 3(a) while Fig.

3(b) illustrates the vertical force produced by both constant thrust (L_y) and the changed thrust (R_y).
(a)
(b)

Fig. 2. Free body diagram for (a) normal quadrotor and (b) variable arm quadrotor.
(a)
(b)

Fig. 3. (a) The acceleration and (b) changes of vertical force.

When the angle increases, the constant thrust generates less vertical force. Therefore, to achieve equilibrium for the quadrotor, the changed thrust should be increased to enhance the vertical force produced.

Additionally, this will result in a bending moment, as shown in Fig. 4(a), where the constant length of 200 mm is used in Eq. (3).

$$M = FL \qquad (3)$$

Based on the bending moment in Fig. 4(a), the concept of a variable arm is introduced, as demonstrated in Fig. 2(b). In this configuration, the quadrotor can be adjusted in angle by modifying the variable arm. When keeping the thrust constant, altering the length of the thrust from the quadrotor's center affects the bending moment, as indicated by Eq. (3).

By maintaining L1 and constant thrust S, the bending moment on the quadrotor can be made equivalent to that in Fig. 4(a) by adjusting the length of L2, as shown in Fig. 4(b). Consequently, increasing the length will lead to a higher bending moment.

(a)

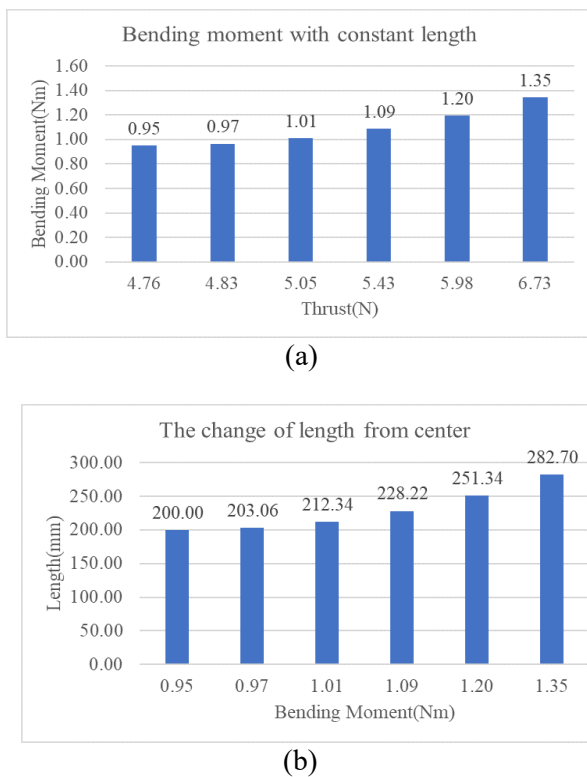
(b)


Fig. 4. Bending moment with (a) different thrust and (b) different length.

4. Result and Discussion

Based on the previous conceptual modeling, a prototype was developed to observe and gather data regarding the quadrotor's movement with varying arm lengths. The quadrotor is secured by a gripper and positioned in a way that allows testing for rotation and acceleration. To measure these parameters, an MPU6050 sensor is utilized, providing data along the X, Y, and Z axes.

The quadrotor's design consists of 2 variable arms and 2 fixed arms. Consequently, altering the length of the variable arm causes the quadrotor to rotate along one axis and move along another. Specifically, the quadrotor rotates on the Y axis to move along the X axis.

Additionally, data from other axes are used to assess the stability and functionality of the variable arm.
Fig. 5. Input signal and movement of the variable arm.

To control the extension or retraction of the variable arm, a signal is sent from the Arduino Mega microcontroller to the MDD3A driver. Fig. 5 illustrates the input signal for extending the variable arm. The positive values indicate forward movement, while negative values indicate backward movement. The electric actuator's extension speed is set at 8 mm/s with a 30 mm stroke length. By incorporating program delay time, the extension length of the variable arm can be precisely controlled.

For data collection, the variable arm is extended to different lengths (8 mm, 16 mm, 24 mm, and 30 mm) and held for a few seconds at each length to gather relevant information. The entire extension cycle takes approximately 88 seconds.

4.1. With Constant Thrust Force

Fig. 6 and Fig. 7 demonstrate that as the arm length increases, the rotation and acceleration of the quadrotor also increase. However, it is evident that the relationship between extension length and these variables is not linear. To address this, a simplified graph for Fig. 6(b) and Fig. 7(b) was created, selecting the second highest positive value or lowest negative value to minimize the influence of noise from Fig. 6(a) and Fig. 7(a).
(a)
(b)

Fig. 6. (a) Acceleration on X axis for dataset 1 (Ax1) & dataset 2 (Ax2) and (b) simplify data for acceleration on X axis for dataset 1 (Ax1) & dataset 2 (Ax2).
(a)
(b)

Fig. 7. (a) Rotation on Y axis for dataset 1 (Ry1) & dataset 2 (Ry2) and (b) simplify data for rotation on Y axis for dataset 1 (Ry1) & dataset 2 (Ry2).

(a)

(b)

Fig. 8. (a) Acceleration on Y axis for dataset 1 (Ay1) & dataset 2 (Ay2) and (b) rotation on X axis for dataset 1 (Rx1) & dataset 2 (Rx2).
(a)
(b)

Fig. 9. (a) Acceleration on Z axis for dataset 1 (Az1) & dataset 2 (Az2) and (b) rotation for Z axis for dataset1 (Rz1) & dataset 2 (Rz2).

On the other hand, Fig. 8 and Fig. 9 display readings for Ax, Az, Rx, and Rz, but with considerable noise. Observing the graphs, most of the data for Ax, Az, Rx, and Rz falls within a range of values from 3 to -3, 5 to 15, 0.2 to -0.2, and 0.15 to -0.15, respectively. However, there is a significant amount of data that exceeds these ranges, indicating an unstable condition for the quadrotor. This instability could be attributed to various factors such as environmental conditions like surrounding air flows, unstable signals from the microcontroller, inconsistent power supply, and the accuracy and sensitivity of the sensor being used.

4.2. With Variable Thrust Force

The variable thrust force incorporates a straightforward program for regulating the RPM of brushless DC motors, utilizing the range established from earlier findings. During quadrotor operation, the craft is tilted at an angle to facilitate movement, and thus, the Rx, Rz, and Az ranges are utilized, with Ax being disregarded. Az comes into play to ensure the quadrotor remains in an equilibrium state and maintains its position.

Consequently, this approach has the potential to reduce noise and enhance the quadrotor's overall stability.
(a)
(b)

Fig. 10. (a) Acceleration on X axis for dataset 3 (Ax3) & dataset 4 (Ax4) and (b) simplify data for acceleration on X axis for dataset 3 (Ax3) & dataset 4 (Ax4).
(a)
(b)

Fig. 11. (a) Rotation of Y axis for dataset 3 (Ry3) & dataset 4 (Ry4) and (b) simplify data for rotation on Y axis for dataset 3 (Ry3) & dataset 4 (Ry4).

In Fig. 10 and Fig. 11, as the variable arm length increases, both rotation and acceleration also experience a corresponding increase. To create a simplified representation, we referred to the movement depicted in Fig. 5 and extracted the second-highest positive value or lowest negative value for Fig 10(b) and Fig. 11(b). This approach helps mitigate any potential noise influence from Fig. 10(a) and Fig. 11(a) on the graphs.
(a)

(b)

Fig. 14. Frequency signal to brushless dc motor for (a) dataset 3 and (b) dataset 4.

In Fig. 12 and Fig. 13, the presented results still exhibit some degree of noise. However, upon comparison with the outcomes from the previous section, it becomes evident that the quadrotor demonstrates enhanced stability and balance. Fig. 14 illustrates that the frequency signal sent to the motor undergoes alterations in a random pattern, without showing any discernible relationship to changes in the variable arm.

5. Conclusion

In this project, a quadrotor with a variable arm length was constructed. The variable arm is used to control the manoeuvrability of the quadrotor. Data were collected in four sets, consisting of two with constant thrust force and two with variable thrust force. The analysis of the constant thrust force data indicated that the quadrotor exhibited instability, likely resulting from factors such as surrounding airflow, an unstable signal from the microcontroller, and fluctuations in the power supply. To address these issues, a variable thrust force was implemented to minimize noise and stabilize the quadrotor. The results displayed a clear linear relationship between the variable arm length and the rotation and acceleration of the quadrotor. As the arm length increased, both the rotation and acceleration of the quadrotor also increased. Additionally, the findings revealed that extending the variable arm eliminated the need for extra thrust force, enabling the motor to fully utilize its capacity in carrying the payload. The graphs further indicated some noise variation, potentially caused by vibrations in the brushless DC motor. In conclusion, a

concept utilizing an electric actuator and linear guide for the variable arm was introduced, proving suitable for enhancing the manoeuvrability of the quadrotor by adjusting the arm length.

Abstract

This paper introduces a smart water meter that utilizes the capabilities of the Internet of Things (IoT) to automate the collection of meter readings. The primary goal of this project is to create an IoT-based device for reading water meters, while simultaneously developing a compatible mobile application. Instead of relying on manual meter reading, which requires human effort, this project proposes the use of an IoT-enabled water meter to collect the data automatically. The device employs a camera and Convolutional Neural Network (CNN) for image processing, making it easy to detect the meter reading accurately. The IoT system architecture involves the use of an ESP32 CAM for data collection, a laptop as a gateway, and the Message Queuing Telemetry Transport (MQTT) protocol for data transfer. The collected data is stored in Firebase's real-time database, and the mobile application is designed to monitor and analyze the data. A functional prototype of the device is constructed and tested in a housing area. The collected data is then monitored through the developed mobile application. Lastly, the data is analyzed to assess the suitability of the proposed method, and recommendations for future improvements are provided.

Keywords: IoT, Neural Network, Smart Water Management, Message Queuing system.

1. Introduction

Water consumption is currently in high demand and has been increasing due to population growth. Insufficient water management capacity, unstructured management, and the adverse effects of urbanization contribute to water shortages [1], [2], [3]. Particularly in residential areas, households consume a significant amount of water daily [4], [5]. This excessive consumption, exceeding the available water supply, raises concerns about future water shortages. Lack of public awareness, a significant percentage of non-revenue water, inefficient water demand management, and low water tariffs are generally recognized as the main causes of excessive water usage [6]. Excessive water consumption is also attributed to water losses. To address this issue, the water balance needs to be calculated, distinguishing between revenue water and non-revenue water. Unbilled permitted use and water losses are further categorized into apparent losses, which include customer meter errors and unauthorized use, and true losses, such as leaks in mains, service connections, and storage tanks [7].

Traditionally, water meters have been used for invoicing water consumption, and manual meter reading is the prevailing method. However, this approach requires a significant workforce and is prone to errors that can harm water companies. Moreover, manual meter reading often necessitates entering indoor premises, adding to the challenges faced by users and hindering daily operations [8]. Mechanical water meters, while reliable and affordable, do not allow for automatic or real-time monitoring of water usage. Consequently, water management companies have relied solely on them, despite the labor-intensive, time-consuming, and error-

prone nature of the process [8]. The market is gradually shifting towards smart meter reading methods, which eliminate the need for manual reading. This transition began in industrialized Western countries, with the United States leading the adoption of smart meter reading technology in the 1980s [9].

The automated collection and analysis of meter data are facilitated by smart water metering (SWM) systems, which incorporate various technologies. Customers can access their water usage data through online platforms such as websites or mobile applications, allowing them to manage their daily water usage more efficiently. Smart metering improves operations by reducing costs associated with operation and maintenance, per capita usage, waste, and leaks. Key benefits include monitoring water flow, distribution, and consumption, improving access to clean and safe water, enabling frequent or real-time access to water consumption information and billing, reducing the need for manual meter reading, enhancing leak and fraud detection, and improving data collection accuracy [10].

2. Methodology

2.1. Hardware Requirement

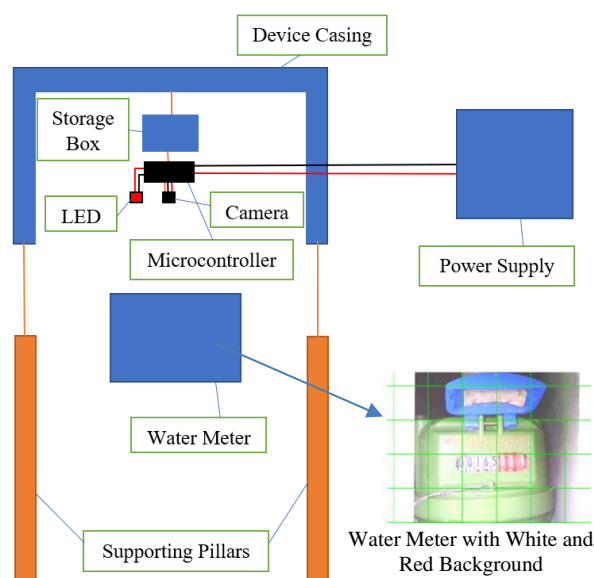
The primary microcontroller employed in this project is the ESP32 Cam, which runs the main program. The program code is uploaded to the microcontroller using a programming software platform. Additionally, an SD card is utilized to expand the memory capacity, enabling the installation of the program, and recording of collected data. The camera module, a crucial component, is connected to the microcontroller and serves the purpose of monitoring the water meter by capturing images of the meter reading as shown in Fig. 1.


Fig. 1. The construction of a smart water meter featuring a display with white and red backgrounds.

2.2. Image Processing

The image processing algorithm used in this project has been modified from an open-source codebase originally created by Jomjol [11]. When an image is captured, it is sent to a web server for processing. On the server, the image alignment is adjusted to a specific orientation to facilitate smooth text recognition. Image segmentation can also be fine-tuned within a certain range to accurately detect numbers within the image. Additionally, artificial intelligence has been integrated into the image processing algorithm. By employing a Convolutional Neural Network (CNN) and training it with various types of water meter images, the accuracy of number recognition has significantly improved. The introduction of AI has enabled the microcontroller to perform data computation at the edge, rather than relying on cloud computing. This approach minimizes delays in obtaining data. Instead of waiting for data to be processed in the cloud, the microcontroller can analyze the information locally, resulting in real-time or near-real-time data processing.

2.3. Data Transfer

The image processing software developed by Jomjol utilizes MQTT to transfer data. The configuration for MQTT can be pre-set within the web server [11]. In this project, the microcontroller remains powered on for 24 hours, and data is collected at 30-minute intervals. To facilitate data transfer using the MQTT protocol, an MQTT broker must be installed on a device to host the server. In this case, the Aedes broker was chosen due to its easy installation process. Additionally, the Aedes broker is compatible with Node-Red, a programming tool used for sending data to Firebase. With some coding, the microcontroller can function as an MQTT publisher, responsible for publishing data on a specific topic. The Aedes broker then manages the published message and alerts subscribers who have subscribed to the same topic. In this scenario, the published message refers to the processed data, while the laptop acts as a subscriber, having Node-Red installed to receive the data. As a result, the microcontroller can establish communication with the laptop for data transfer. Leveraging the capabilities of Node-Red, the data can be further transmitted and stored in the real-time database of Firebase.

2.4. Cloud

For data transfer via MQTT, a connectivity platform is required, and in this case, a laptop is utilized as the gateway. The laptop acts as an intermediary, receiving data from the microcontroller and sending it to the cloud. Facilitating this communication is Node-Red, which has been installed on the laptop. All the data transmitted by the microcontroller is written into the Firebase real-time database. This includes the initial water meter reading as well as the most recent reading, along with timestamps indicating when the data was captured. The presence of data stored in the Firebase real-time database is considered a successful transfer of data from the microcontroller to the cloud at this stage. This mechanism

aligns with the cloud and network aspects in the architecture of IoT.

2.5. Application

The final component of the IoT architecture involves application and data analysis. In terms of application, users can access the water meter data through a dedicated app from anywhere, as long as they are connected to a Wi-Fi network. Achieving this functionality involves synchronizing the database with the developed mobile application. Additionally, the app has the capability to generate a bill based on the collected data.

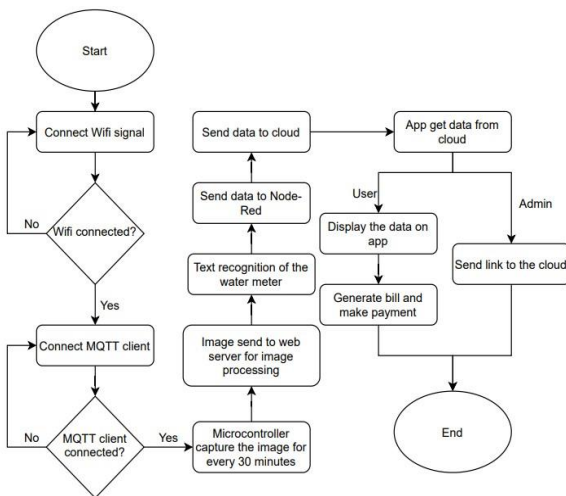
2.6. Flowchart


Fig. 2. Smart water meter system flowchart.

This paper proposes a method for obtaining water meter readings through a smart water meter system. To initiate the system, the microcontroller is powered on using a 5V DC power supply, enabling it to connect to a Wi-Fi network. Once a stable Wi-Fi connection is established, the program is designed to connect to the MQTT broker as a client. Once all connections are established, the microcontroller is ready to commence its operations.

The camera captures the first photo of the water meter immediately upon activation, with the triggering interval set to every 30 minutes. The captured image is then uploaded to a web server for further processing, aimed at extracting the data from the image. The text recognition process concludes by sending the detected value to the database via a tool called Node-Red.

The mobile application serves as a means for consumers to retrieve and monitor data from the cloud. It allows them to access the water meter readings and view them on their mobile devices. Additionally, administrators can utilize the app to monitor the readings and even send payment links to the cloud. Fig. 2 shows the flowcharts of the developed smart water meter system.

2.7. Circuit Connection
Fig. 3. Schematic diagram.

Fig. 3 illustrates the schematic diagram of the Smart Water Meter, showcasing the essential components of the electronic circuit setup for this project. The ESP32 Cam is a highly functional microcontroller board that integrates a powerful ESP32 chip, along with built-in Wi-Fi and Bluetooth capabilities. It serves as the primary component of the setup. Additionally, the hardware includes a camera module, enabling the device to stream video and capture high-resolution images. Furthermore, the microcontroller and an SD card are utilized to store the programmed code, offering versatile and expandable storage options. To enhance the lighting conditions for image capture, an additional LED is incorporated to illuminate the surroundings.

Regarding the power supply, this project utilizes a DC power source. To ensure compatibility with the hardware components, a 5V converter is employed. Acting as a crucial intermediary, the converter transforms the incoming AC power into a reliable 5V DC supply, which powers the main component of the project. This configuration guarantees a consistent and dependable power source, facilitating the smooth operation of the hardware and efficient execution of the programmed tasks.

3. Results and Discussions

3.1. Hardware Setup

A custom casing as shown in Fig. 4 has been designed specifically for the ESP32 Cam to serve as storage. This casing is positioned above the water meter and securely fixed in place using supporting pillars. This ensures that the captured images remain clear and avoid any blurring or distortion.
Fig. 4. Device casing - front view.

(a)

(b)

Fig. 5. (a) Water usage page and (b) water bill page.

3.2. Mobile Application

A mobile application has been developed with various functionalities, including the ability to scan the Smart Water Meter to establish a connection with the app. It enables users to monitor their water consumption and generates bills based on their usage. The usage page provides insights into the user's water consumption, while the billing page generates the corresponding water bill. The app retrieves data directly from the connected smart water meter, ensuring accurate and up-to-date information.

With this mobile application, users can easily track their latest water usage and view the associated bill to understand the amount they need to pay. This functionality promotes increased awareness of current water consumption, leading to potential cost savings. By being more mindful of their water usage, users can effectively manage their consumption and make informed decisions to optimize their expenses. Fig. 5 illustrates the display of information in the developed app, specifically showcasing water usage details and the current usage bill. This information can be accessed within the app and has the capability to be printed for reference or documentation purposes.

3.3. Data Analysis

Thorough analysis and discussion are conducted on the collected data, considering the output results. This data is obtained using the smart water meter device to retrieve the meter reading. All the collected data is extracted into an excel file to generate a graph for visualization as shown in Fig. 6. The blue line represents the value obtained after image processing, while the orange line represents the actual reading recorded from the captured image of the water meter.

Fig. 6 reveals the presence of spikes in the graph, indicating instances where the image processing detected false numbers from the water meter images. The primary cause of this issue is likely attributed to variations in the lighting conditions during image capture. The most common error occurs when detecting the last 3-digit number on the meter. Within the collected data, a cluster of errors is observed in the middle portion. This is attributed to a specific number repeatedly reading inaccurately, leading to the appearance of multiple spikes. However, as the dial turns to a different number, the errors diminish, resulting in fewer spikes toward the end of the data.

Another factor contributing to the occurrence of spikes is the presence of different background colors for the digits, specifically the red color shown in Fig. 1. The AI model used for the project was trained on images with a white background, which impacts the accuracy of the model and prevents it from reaching the desired level of performance.
Fig. 6. Comparison of manual water meter actual reading between reading detected by the camera using image processing technique.

3.4. Data Accuracy

The spike in Fig. 6 may happen due to the different background color of the digits which is red color. The accuracy is only 3.33% for the device detecting all 8-digit numbers on the water meter. By reducing the last digit number with the red background, the accuracy has increased significantly to 53.33%. It is proved that the AI model can detect all the digits with white background as the accuracy for the first 5 digits is 100% accurate. The AI model is not trained with red background digit numbers, hence the accuracy for detecting the meter reading is not that high. Therefore, this explains the accuracy result in Fig. 7 that this AI model used has a low accuracy for detecting the meter digit number with red background.
Fig. 7. White and red background effects on water scale meter accuracy.

4. Conclusion

Based on the aforementioned results, the system operates smoothly without encountering any critical errors, despite the detected data not being highly accurate. The accuracy of the data primarily depends on the AI model utilized for image processing. This discrepancy arises because the AI model was trained on a different type of water meter, distinct from the one employed in this project. Without proper training, the model's accuracy may be compromised. Nonetheless, the overall performance of the AI model is commendable, as it accurately identifies digits with a white background, exhibiting significantly higher accuracy than those with a red background. Thus, it can be concluded that a properly trained dataset greatly enhances accuracy. Utilizing the collected data enables us to ascertain the daily water usage for each household. By leveraging this data, predictions can be made to determine the water consumption in different areas, alerting the water supply company accordingly. This valuable information empowers the company to identify areas requiring additional water supply, ensuring residents do not face water shortages. Over time, as more data is gathered, the predictive capabilities of the system improve, resulting in more accurate forecasts. In summary, this IoT-based metering device resolves the issue of manpower required for water meter data collection while also offering long-term cost savings.

5. Future Recommendation

For the future implementation of this smart water meter system, there is a need to enhance the design of the device casing. The design should prioritize reliability and adhere to sound design principles. Additionally, the issue of sunlight penetration during the daytime must be addressed by reimagining the casing product. Furthermore, to address the common problem faced by all electronic devices, a comprehensive plan for sustainable energy usage in the power supply is necessary. Additionally, to improve the accuracy of the system, alternative algorithms can be explored and employed in conjunction with the AI model. Lastly, the mobile application can be enriched with additional features to enhance user experience. For example, incorporating a water leak detection feature would enable users to receive alerts regarding the condition of their pipes. Moreover, the billing system can be enhanced by expanding the range of payment methods, allowing for convenient online payments and improving user-friendliness.

Abstract

This research employs object detection and instance segmentation algorithms to distinguish between objects and backgrounds and to interpret the detected objects. The YOLOV8 (You Only Look Once) framework and COCO dataset are utilized for detecting and interpreting the objects. Additionally, the accuracy of detection, segmentation, and interpretation is tested by placing objects at various distances from the camera. The algorithm's performance was evaluated, and the results were documented. In the experiments, a sample of 11 objects was tested, and 8 of them were successfully detected at distances of 45cm, 75cm, 105cm, and 135cm. For instance, segmentation, segmentation maps appeared clean when detecting a single object but faced challenges when multiple objects overlapped.

Keywords: Image Processing YoloV8, COCO, Segmentation, Object detection.

1. Introduction

Traditional methods in object detection rely on hand-crafted features and rules to identify and categorize objects, whereas machine learning-based approaches involve algorithms trained on extensive labeled image datasets. Notably, machine learning-based methods offer the advantage of handling complex and diverse environments by learning and adapting to new data [1]. However, they can be computationally demanding and require substantial labeled data for training. In the past few years, there have been notable strides in object detection algorithms, especially with the rise of deep learning-centered methods that have demonstrated cutting-edge capabilities on a variety of benchmarks. These methods utilize neural networks to learn features and classify objects, successfully finding applications in various domains [2], [3]. Nevertheless, prevailing monitoring systems might exhibit limited adaptability in computer vision, leading to difficulties in accurately detecting and classifying objects or features within visually intricate settings, including those characterized by low illumination, high contrast, or complex backgrounds [4]. Furthermore, current monitoring setups often heavily rely on human operators to analyze images and spot potential issues [5]. This manual procedure can be time-intensive and prone to errors, as human operators might encounter challenges in consistently and precisely interpreting images or detecting subtle anomalies [4]. To confront these challenges, this project introduces an object detection and self-interpreting application designed to augment monitoring systems.

2. Related Work

The research landscape in computer vision and deep learning has witnessed significant advancements in recent years, particularly in the domain of object detection and segmentation. Notably, Kousik et al. proposed a hybrid Convolution Recurrent Neural Network for improved salient object detection [9]. Additionally, Mekala et al. introduced a Deep Reinforcement Learning (DRL) based 4-r Computation Model for Object Detection on Roadside Units (RSU) using LiDAR on the Internet of Things (IoT) context [10]. Deep learning and image processing techniques for cancer diagnosis were effectively employed by Prassanna et al. [11], while Ghantasala et al. focused on texture recognition and image smoothing for microcalcification

Law Jack Lee, Hazry Desa, Muhammad Azizi Azizan, Abadal-Salam T. Hussain, Muhammad Hassan Tanveer

and mass detection in abnormal regions [12]. In the context of the Internet of Medical Things, Manimurugan et al. utilized a deep belief neural network for effective attack detection in smart environments [13]. Furthermore, Natarajan et al. applied fully convolutional deep neural architecture for the segmentation of nuclei in histopathology images [14]. Lastly, Selvaraj et al. proposed an optimal virtual machine selection approach using swarm intelligence for anomaly detection [15]. These diverse works collectively contribute to the broader understanding and application of advanced techniques in the realm of computer vision and deep learning.

3. Methodology

Overall Object Detection and Instance Segmentation Segmentation is a specific type of image analysis that focuses on identifying individual instances of objects and outlining their boundaries [6]. Two essential computer vision tasks, semantic segmentation, and object detection are closely related to instance segmentation [7]. Semantic segmentation seeks to correctly assign the appropriate object category to every individual pixel present within an image. However, it fails to differentiate among separate instances of identical object classes. For instance, if there are three dogs in an image, semantic segmentation will only identify pixels belonging to one of these three dogs.

Conversely, object detection involves predicting both the object's bounding box and its corresponding class for every instance of an object present in the image. However, it does not provide per-pixel identification for each object instance. Hence, object instance segmentation is notably more challenging than semantic segmentation and object detection because it seeks to both identify and label each object instance on a per-pixel basis [7].

To create a dataset, for example, one can collect images of cats and dogs, organizing them into two folders: "cats" and "dogs." Each folder should contain a similar number of images. In each folder, a total 80% of the images are allocated as training images, and the remaining 20% are used as test images. Annotations are required for the training images, involving manually drawing bounding boxes and segmenting the dogs or cats from the background. These annotations produce coordinates that are recorded in a blank text file, essential for the machine's ability to locate objects during image training and testing. Fig. 1 displays an example of object detection, with a bounding box around the Region of Interest (ROI), labelled with its name, and segmented with a coloured mask layer within the ROI, utilizing the COCO dataset [8].

Fig. 1. Object detection and instance segmentation.

4. Results and Discussion

4.1 Object Detection and Self-Interpreting Application Within Different Distance.

To test the ability of detection and interpreting application, the experiment was carried out in room. 11 objects were selected, and each object was placed in 45cm, 75cm, 105cm and 135cm apart from the webcam. The results were recorded in Table 1 below. A tick indicates that the detection was successful, and a cross indicates that the detection was unsuccessful.
(a)

(b)

Fig. 2. (a) Scissor at 45 cm distance and (b) scissor at 75 cm distance from the camera.

(a)

(b)
Fig. 3. (a) Scissor at 105 cm distance and (b) scissor at 135 cm distance from the camera.

failed to do so at 75cm, 195cm, and 135cm distances. Such limitations arise from the detection and segmentation networks, as overlapping objects pose challenges in separation and precise localization. The output image may look acceptable, but it merely represents the network's best estimation of object locations. When multiple objects overlap, the model may struggle, resulting in inaccurate bounding boxes or masks, which can sometimes lead to incorrect labels.

(a)

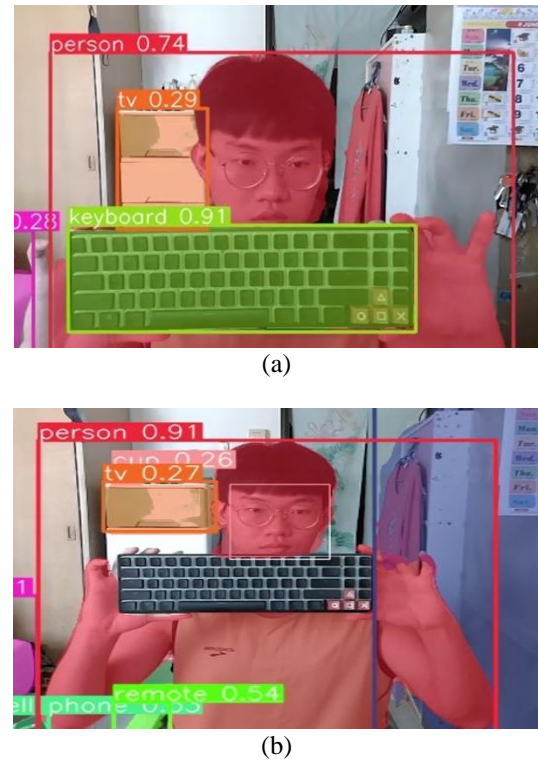
(b)


Fig. 4. (a) 45 cm distance (b) 75 cm distance away from the camera.

Fig. 2 and Fig. 3 present examples of various distances captured by the webcam. The figures show a pair of scissors, accurately detected, and identified by the system. Most large objects, such as a person, cell phone, keyboard, and bowl, were successfully detected and identified. However, at distances of 105 cm and 135 cm, the objects like the mouse, fork, and spoon were not recognized. This lack of recognition was primarily due to object occlusion. When the fork and spoon were held at 105 cm, the student's fingers obstructed part of the objects, making it challenging for the Yolo model to detect them. Furthermore, the webcam's resolution also impacted the Yolo model's detection rate. Although the webcam supported 1080p Full HD video quality, the output was compressed to 640px x 640px for smoother video operation. It is essential to note that this experiment was conducted on a CPU-only machine, resulting in significantly lower performance compared to using a GPU-supported machine.

Instance Segmentation Within Different Distances. The results obtained from the YOLOV8 model for instance segmentation were observed and collected. When a single object was detected at distances of 45cm, 75cm, 105cm, and 135cm, the segmentation maps of a person appeared to be clean, as evident from Fig. 2 and Fig. 3. However, in cases where multiple objects overlapped, the model encountered difficulties in accurate segmentation. Fig. 4 and Fig. 5 demonstrate the inconsistent segmentation of a keyboard at different distances. While the keyboard could be segmented successfully at 45cm when accompanied by a human, it

5. Conclusion

The experiment involving object detection and a self-interpreting system was carried out successfully, employing the YOLOV8 framework and the COCO dataset to collect the results. Out of the 11 objects that underwent testing, 8 of them were effectively identified at different distances: specifically, 45cm, 75cm, 105cm, and 135cm. This led to the algorithm used in the experiment achieving an accuracy rate of 72% in terms of object detection and interpretation. However, there were instances where 4 objects failed to be detected accurately at distances of 105cm and 135cm. This was attributed to the lower image quality at these distances. Notably, the segmentation maps displayed clean results when a single object was detected, but inconsistency in segmentation maps arose when multiple objects overlapped, mainly due to the limitations of the detection and segmentation network. In conclusion, while the experiment demonstrated promising results with a 72% accuracy in object detection and interpretation, challenges persisted in cases of poor image quality and overlapping objects, affecting the segmentation performance.

Abstract

The motion planning algorithm of the robot arm plays an important role in the working process of the robot arm, especially in the complex environment, an efficient algorithm is more conducive to the robot arm to complete the corresponding planning task. Aiming at the problems such as low exploration efficiency and poor planning path in the current motion planning task of robotic arm, we propose a distance constraint mechanism. Based on RRT^* and $Informed-RRT^*$, the algorithm uses halton sequence to generate random points and introduces the current lowest cost path length. To avoid useless nodes extension. The simulation results show that the algorithm with distance constraint mechanism can improve the exploration efficiency and planning quality to some extent.

Key words: mechanical arm, Motion planning, Distance constraint, Improved RRT^* algorithm, halton sequence

1. Introduction

The robot arm has changed from the original rough industrial production equipment to today's multi-disciplinary industrial automation equipment, entering all corners of society, showing the powerful role of the robot arm. At the same time, higher requirements are also put forward for the motion planning of the robotic arm. Therefore, the study of the motion planning of the robotic arm has important engineering value [1], [2].

At present, there are four main types of path planning methods for robotic arms: graph search-based algorithm, artificial potential field method, random sampling method and deep reinforcement learning method [3]. The algorithm based on graph search needs to be discretized in the whole planning space, so it is not suitable for the space with higher latitude. The artificial potential field method is easy to make the manipulator fall into the local minimum under the influence of the influence field, and the efficiency is greatly reduced. Methods based on deep reinforcement learning also have problems of poor process interpretability and stability [4].

The method based on random sampling is one of the most common methods for path planning of manipulators. Its core idea is to replace the complex actual planning space by the simple planning space obtained by sampling, so as to reduce the space complexity. the method based on random sampling is efficient and suitable for high-dimensional space. Lavalle [5] proposed a classical RRT algorithm, which has strong exploration ability and

probability completeness, but cannot guarantee the optimal solution and a large number of unnecessary waypoint searches. Frazzoli [6] proposed RRT^* on the basis of RRT, which is an algorithm with asymptotic optimality. Compared with RRT, it adds two processes of re-selecting parent nodes and rewiring, Therefore, an optimal or suboptimal path can be found. Gammell [7] improved on the basis of RRT^* and proposed the $Informed-RRT^*$ algorithm. The principle is that after finding the first feasible solution, the subsequent sampling range is limited to a high-dimensional ellipsoid determined by the cost of the feasible solution. The convergence speed of RRT^* is improved.

To sum up, in order to solve the problem of low efficiency and too many redundant nodes in the RRT^* computing planning. In this paper, a distance constraint mechanism is introduced to improve RRT^* and $Informed-RRT^*$, which can greatly reduce the search and expansion of unnecessary waypoints and plan a high-quality path.

2. Methodology
2.1. Random tree growth distance constraint mechanism

RRT^* algorithm has asymptotic optimality, but the random number growth in the sampling process has a strong blindness, thus reducing the efficiency of the algorithm. $Informed-RRT^*$ Although the sampling points can be limited to an ellipse, the expansion of random trees within the ellipse is still blind. Therefore, this paper proposes a distance constraint mechanism, which introduces the current lowest cost path length. When the

random tree is extended, the minimum actual cost to reach the new node is calculated plus the Euclidean distance from the new node to the end point. If the estimated distance is greater than the current lowest cost path length, the new node will not be extended, which increases the search efficiency of the algorithm to a certain extent. A condition that determines whether a new node can be expanded:

$$g_T(x_{new}) + \hat{h}(x_{new}) < c_{best} \qquad (1)$$

Where $g_T(x)$ represents the minimum actual cost from the starting point to the new node, $\hat{h}(x)$ represents the Euclidean distance from the new node to the end point, and c_{best} is the current lowest cost path length.

Similarly, the current lowest cost path length is also introduced in the process of rewiring in random trees. When a new node is selected as the parent node at a certain point in the neighborhood, if the minimum actual cost to reach the point plus the Euclidean distance from the point to the end point is greater than the current lowest cost path length, the parent node of the node will not be replaced. A condition that determines whether a node in the neighborhood can replace the parent node:

$$g_T(x_{new}) + ||x_{new} - x_{near}|| + \hat{h}(x_{near}) < c_{best} \qquad (2)$$

Where $||x_{new} - x_{near}||$ indicates the Euclidean distance between x_{new} and x_{near}.

2.2. Random sampling point optimization strategy

RRT^* and $Informed - RRT^*$ algorithms have the problem of poor uniformity in the random sampling of points in space, so the space cannot be explored more fully. A random point sampling method based on halton sequence is proposed for reference to halton sequence. Random sampling method (Fig.1) and halton sequence-based sampling method (Fig.2) are shown in the figure below.
Fig.1 Random sampling method
Fig.2 Sampling method based on halton sequence

It can be observed that the sampling points in the upper left part of Fig. 1 are sparse, while the middle part is dense. In Fig. 2, the distribution of sampling points is more uniform, thus improving the ability to explore the space.

3. Algorithm simulation analysis

In order to verify the validity of the distance constraint mechanism, the RRT^*, $Informed - RRT^*$ and the improved $DC - RRT^*$ and $DC - Informed - RRT^*$ are simulated and analyzed experimentally in a three-dimensional environment.

In MATLAB, simulation experiments in simple and complex obstacle avoidance environments are set respectively. The simulation environment was set to the three-dimensional space of $[0.2 \times 0.12 \times 0.2]$, the search starting point was $[-0.09\ 0.37\ 0.1]$, the target point was $[0.09\ 0.43\ 0.1]$, the exploration step was 0.01, and the number of iterations was set to 100 to reduce the randomness of the algorithm. The experimental results are shown in the figure and table below.

a. RRT^* algorithm tracing

b. $DC - RRT^*$ algorithm tracing

c. $Informed - RRT^*$ algorithm tracing

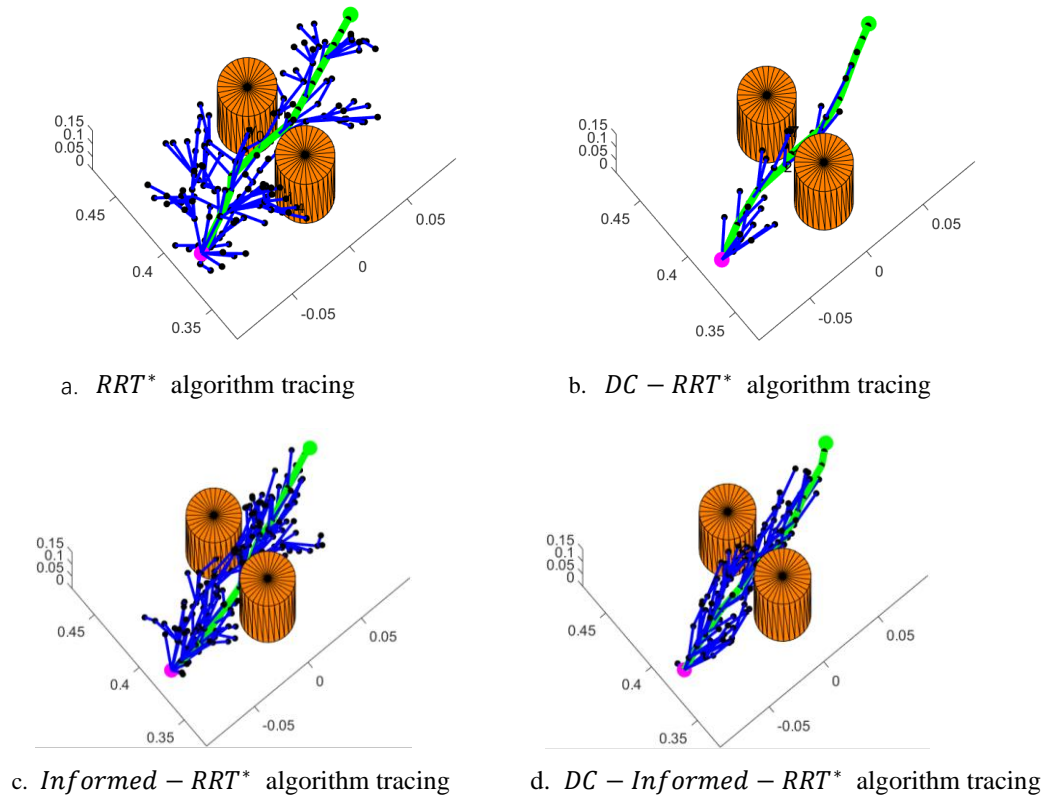
d. $DC - Informed - RRT^*$ algorithm tracing


Fig.3 Algorithm tracing in 3D simple scenes

Table 1.   Performance comparison of algorithms in 3D simple scenes.

algorithm	average path length /m	average running time /s	Node usage /%
RRT^*	0.2042	6.67	6.62%
$DC - RRT^*$	0.1934	5.41	10.96%
$Informed - RRT^*$	0.1930	8.42	6.38%
$DC - Informed - RRT^*$	0.1906	5.72	12.31%

As shown in Fig. 3, The blue line represents the extended branch, and the green line represents the final path. RRT^* produces many useless branches. $Informed - RRT^*$ also has some useless branches, but fewer than RRT^*. The final path of the two is tortuous and the path length is long. After the introduction of distance constraint mechanism, the useless branches of $DC - RRT^*$ and $DC - Informed - RRT^*$ are significantly reduced, the final path is smoother and the path length is shorter. Combined

with the data in Table 1, the average path of $DC - RRT^*$ is reduced by 5.29% from 0.2042m to 0.1934m compared with RRT^*. The average running time decreased by 18.90% from 6.67s to 5.41s; The node utilization rate is increased from 6.62% to 10.96%, and the average path of $DC - Informed - RRT^*$ and $Informed - RRT^*$ is reduced from 0.1930m to 0.1906m by 1.24%. The average running time decreased by 32.07% from 8.42s to 5.72s; Node usage increased from 6.38% to 12.31%.

Tianbin Meng, Jiwu Wang

a. RRT^* algorithm tracing

b. $DC - RRT^*$ algorithm tracing

c. $Informed - RRT^*$ algorithm tracing

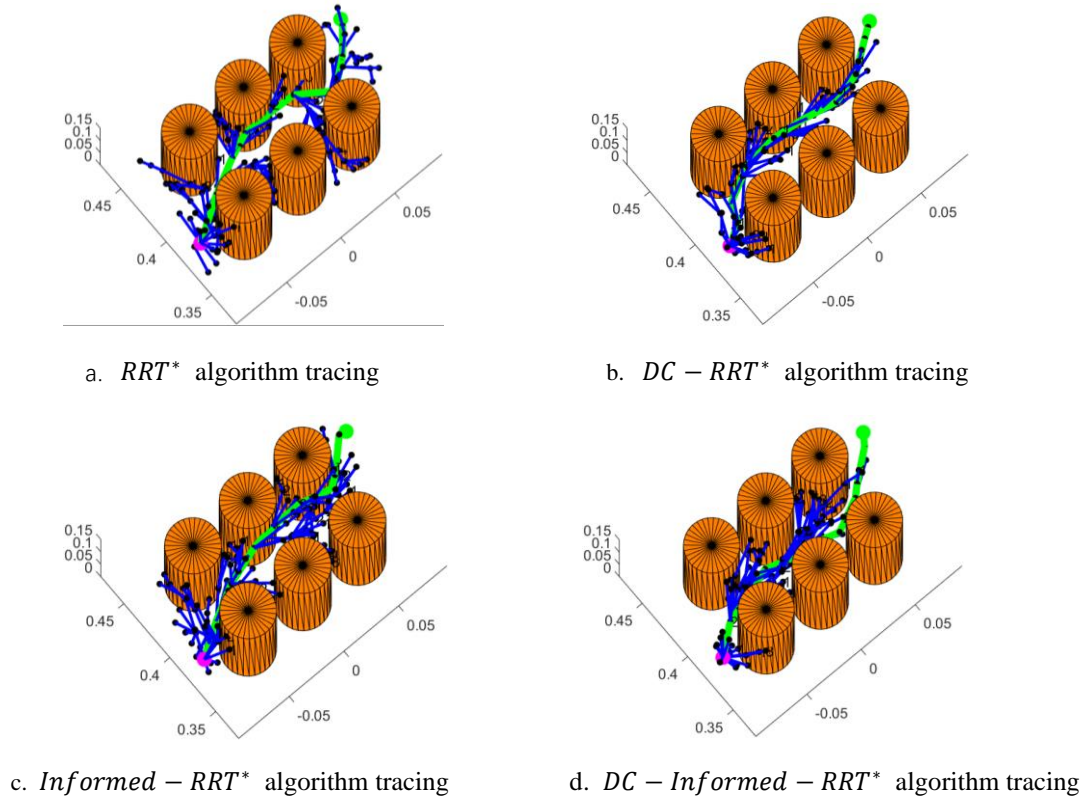
d. $DC - Informed - RRT^*$ algorithm tracing


Fig.4 Algorithm tracing in 3D complex scenes

Table 2.   Performance comparison of algorithms in 3D complex scenes.

algorithm	average path length /m	average running time /s	Node usage /%
RRT^*	0.2191	17.16	7.63%
$DC - RRT^*$	0.2056	18.42	14.75%
$Informed - RRT^*$	0.2003	20.41	7.01%
$DC - Informed - RRT^*$	0.1965	21.95	16.66%

Fig. 4 shows the planning results of the algorithm in a complex environment. Combined with the data in Table 2, the average path of $DC - RRT^*$ decreases by 6.16% from 0.2191m to 0.2056m compared with RRT^*. The average running time is 17.16s and 18.42s respectively, the node utilization rate is increased from 7.63% to 14.75%, and the average path of $DC - Informed - RRT^*$ is reduced from 0.2003m to 0.1965m, a decrease of 1.89%. The average running time was 20.41s and 21.95s respectively, and the node utilization rate increased from 7.01% to 16.66%.

According to the analysis, since the introduction of distance constraint mechanism reduces the expansion of nodes that are useless for optimizing the path, the node utilization rate is higher, and the node distribution is more concentrated near the final path, then the node is more likely to optimize the cost of the current path. Secondly, although the introduction of distance constraint mechanism reduces the expansion of useless nodes, the nodes are more concentrated. In a simple obstacle avoidance environment, the time to reduce the expansion of useless nodes is greater than the time to increase the process of parent node re-selection and rewiring, so the average running time is reduced. In complex obstacle avoidance environments, parent node reselecting and rewiring processes increase the time more than the time to reduce the expansion of useless nodes, so the average running time increases. The distance constraint mechanism proposed in this paper enables the algorithm to select and optimize the path with higher efficiency during operation, which makes the node utilization rate increase and the final path length decrease. Especially in the simple obstacle avoidance environment, the search efficiency of the algorithm is improved to a large extent.

4. Conclusion

In this paper, a motion planning algorithm based on RRT^* and $Informed - RRT^*$ with distance constraint mechanism is proposed to improve the problems of low exploration efficiency and poor planning path in the current motion planning tasks of robotic arms under different complexity scenarios. It mainly reduces the expansion of useless nodes when the random tree grows, so that the algorithm can select and optimize the path with

higher efficiency when running. Combined with halton sequence sampling method, the space exploration ability of the algorithm is improved. The simulation results show that $DC - RRT^*$ and $DC - Informed - RRT^*$ can reduce the path length, improve the node utilization rate, and improve the search efficiency of the algorithm to a large extent, especially in simple environment.

Abstract

The Rapidly Exploring Random Tree Star (RRT∗) is recognized as a better path planning algorithm, but its path quality and path planning speed still have room for improvement. In this paper, an improved RRT* algorithm(CSM-RRT*) based on constrained sampling mechanism is proposed .The entire planning process is divided into two steps: fast exploration and optimization of the initial path.   Subsequently, a dynamic sampling region consists of removed redundant nodes and collision nodes is formed around initial path By prioritizing exploration within this dynamic region, computational resources can be saved and the asymptotic optimal path can be quickly converged from the initial path. Eventually, simulation results presented in various obstacle environments confirm the efficiency of CSM-RRT*.

Keywords: Path planning, RRT*, Constrained sampling mechanism, Dynamic sampling region

1. Introduction

Rapidly-exploring Random Tree(RRT) is a sampling- based algorithm. Many scholars have conducted research on it. To further improve the speed of the RRT, a double-tree algorithm RRT-Connect [1] makes the target tree and the start tree grow alternately. To improve the path quality, RRT* [2] conducts the process of parent node selection and Rewire for the samples. As the number of nodes increases, the path gradually optimizes, but this process will consume a lot of time.In order to plan the best possible path within the same time, Informed RRT* [3] adopts an elliptical heuristic domain sampling method and continuously shrinks the elliptical region.In order to reach an optimum or near optimum solution at a much faster rate, Smart-RRT* [4] accelerate the rate of convergence. In addition, P-RRT* [5] incorporates the artificial potential field in RRT* to provide transcendental information for the path.Quick-RRT* [6] enlarges the set of possible parent vertices, which generates a better initial solution and converges to the optimal faster than RRT*.PQ-RRT* [7] combines the P-RRT* with the Quick-RRT* to generate better initial solutions.

Further research on path quality and planning speed of the RRT* has specific significance for solving the problem in complex constraints. Based on constrained sampling mechanism ,this paper proposes an improved RRT*algorithm, CSM-RRT*.By comparing with other algorithms,   effectiveness of the proposed algorithm is verified.

2. CSM-RRT*

This section introduces the strategies of the CSM-RRT*, including the following aspects: ChooseParent, Rewire and constrained sampling mechanism.

2.1. *Constrained sampling mechanism*

2.1.1. *Node saved strategy*

The regional exclusion mechanism(Fig.1) was proposed, in which random sampling points were eliminated in a circular area of the node to ensure the sparsity of the entire tree and improves the exploration efficiency.
Fig.1 regional exclusion mechanism.

X_{start} represents the initial node, X_{goal} represents the target, $X_{excluded}$ represents the nodes abandoned by the regional exclusion mechanism, and the circular dashed line represents the size of the exclusion region.

However, the x_{rand} was eliminated rather than x_{new}. Additionally, this method only focuses on the sparsity of the entire tree, without considering the sparsity of individual node. To address this issue, regional exclusion mechanism and node saved strategy are combined and applied to the path planning of the manipulator, ensuring the sparsity of both the entire tree and individual sub-node. The results proved to have good effect.

As shown in Fig.2, after adopting the region exclusion mechanism, the parent node O can extend 6 nodes if the exclusion radius r is equal to step size, and the distance between each node is equal to the step size. However, in general, the distance of each node is greater than the step size, when a parent node extends 4 nodes. For a node, we can record the number of expansions and collisions. And the constraint condition is set to 5 times. When the sum of the number of extensions and collisions reaches 5 times, it means that the node has been expanded, or there are a lot of obstacles around it, and it is difficult to continue to expand. In this case, we can save itself to ensure that the next sampling node will not appear in the vicinity again. At the same time, the redundant nodes of the regional exclusion mechanism will also be saved separately for path optimization.

(a)Node extension range   (b) collision detection failed node

Fig.2 Node saved strategy

2.1.2 Dynamic sampling region

As shown in Fig.3, after the initial path planning is completed, each node in the path has an exclusion region, which contains a large number of redundant nodes and collision points. For path optimization, the main goal of path optimization is to obtain an optimal or asymptotic optimal path.In general, an optimal path can only be obtained when the path is close enough to the obstacle.Therefore, redundant and collision nodes close to the initial path should be employed to concentrate on meaningful areas, while discarding nodes with higher path costs.Starting from the node closest to the endpoint, the nodes with the lowest path cost in the dynamic sampling domain are selected to continuously improve path quality. The initial path quickly converges to the optimal path through cyclic iteration.
Fig.3 Dynamic sampling region

With further optimization of the path, dynamic region will change and contain many nodes. Nodes in dynamic regions can be included multiple times, resulting in increased runtime. To accelerate exploration, hash table is used. In other words, even if a node is included in the exclusion region many times, its distance to the starting point only needs to be detected once, and the result is saved and used directly later to avoid repeated distance detection.

2.2. *ChooseParent and Rewire*

RRT* sets X_{near} within a certain radius range of the new node and as candidate parent nodes and candidate child nodes during ChooseParent and Rewire.The process is shown in Fig.4.
(a)chooseParent   (b)Rewire

Fig.4 Process of ChooseParent and Rewire.

3. Simulation results and Analysis

In order to ensure the reasonability of the statistical results, 50 sets of valid data are gotten for each algorithm when comparing each indicator. The experimental environment is shown in Fig.5.

(a)   (b)
Fig.5 Simulation environment (a)Simple environment (b)Cluttered environment. The entities are obstacles

The results are compared in four directions: initial path planning time T_{init}, the suboptimal path planning time $T_{5\%}$, the initial path cost C_{init} and the suboptimal path cost C_{cost}.

3.1. *Compare of algorithm convergence speeds*

The convergence speed of the algorithm is compared by T_{init} and $T_{5\%}$.

3.1.1 Simple environment

Fig.6 shows the path planning results of the three algorithms in the simple environment, and Table 1 shows the average value of T_{init} and $T_{5\%}$.

(a)   (b)   (c)
Fig.6 Path planning results in the simple environment (a) RRT*; (b)Informed-RRT*;(c) CMS-RRT*

As shown in Table 1, in terms of $T_{5\%}$,the CMS-RRT * algorithm respectively saved 2.3 seconds and 1 seconds compared to RRT * and Informed-RRT*. The initial path planning speed is 2.5 times faster than the RRT* algorithm. Considering the impact of time saved by the initial path, the CSM-RRT * algorithm did not show significant performance in path optimization in simple environments.

Table1.Average of T_{init} and $T_{5\%}$ of the two algorithms in the simple environment

Algorithm	RRT*	Informed-RRT*	CSM-RRT*
Average(T_{init}/s)	2.93	1.72	0.84
Average($T_{5\%}$/s)	5.46	3.23	1.56

3.1.2 Cluttered environment

Fig.7 shows the path planning results of the three algorithms in the cluttered environment,and Table 2 shows the average value of T_{init} and $T_{5\%}$.

(a)   (b)   (c)
Fig.7 Path planning results in the cluttered environment (a) RRT*; (b)Informed-RRT*; (c) CSM-RRT*

As shown in Fig.7 and Table 2, it can be seen that as the map becomes more complex, the initial path search efficiency of the CSM-RRT * algorithm is not as significant as in a simple environment.However, its path optimization performance is still much better than other algorithms, with an optimization speed increased by 2~5 times.The CSM-RRT* algorithm only samples around the initial path, rather than the entire environment, avoiding path optimization in invalid areas and ensuring fast convergence to the asymptotic optimal path.

Table2.Average of T_{init} and $T_{5\%}$ of the two algorithms in the cluttered environment

Algorithm	RRT*	Informed-RRT*	CSM-RRT*
Average(T_{init}/s)	4.64	2.76	1.58
Average($T_{5\%}$/s)	12.93	5.02	2.58

3.2. *Compare of path quality*

The path quality of the algorithm is compared by C_{init}, C_{cost} .At the same time, in order to avoid similar simulation results, the number of algorithm iterations is set to 2000 for the convenience of viewing algorithm differences.

3.2.1 Simple environment

It can be seen from Table 3 that the path quality of CSM-RRT * is not the beset among all initial paths.This is mainly because the region exclusion mechanism and node preservation strategy in the CSM-RRT * algorithm focus more on fast exploration of the initial path.

However, the final path cost of CSM-RRT * algorithm remains minimal, proving that CSM-RRT * is superior to other algorithms.

Table3.Average of C_{init} and C_{cost} of the two algorithms in the simple environment

Algorithm	RRT*	Informed-RRT*	CSM-RRT*
Average(C_{init})	712.06	707.58	716.84
Average(C_{cost})	703.85	697.59	692.21

3.2.2 Cluttered environment

In order to verify the stability of the algorithm, 50 repeated experiments were conducted on algorithms, and the final path cost simulation results(Fig.8) of the three algorithms in cluttered environments were obtained.
Fig.8 Path cost results in the cluttered environment

As shown in Fig. 8, the final path cost of the CSM-RRT * algorithm is much lower than those of the other algorithms, and the fluctuation between each path result is very small, indicating stable optimization ability. The performance indicates that with a limited iterations, the CSM-RRT* algorithm can quickly converge to the optimal path from initial path every time.

4. Conclusion

This paper proposes an improved RRT* algorithm, CSM-RRT*, which has some advantages in planning speed of initial path, convergence speed and path quality. The main idea of the CSM-RRT* algorithm is to remove and record the redundant nodes and collision points, control the direction of path growth and optimize paths in dynamic sampling region. Compare RRT* and Informed-RRT*,it is verified that the CSM-RRT* algorithm has good applicability to both simple and cluttered environments.

Abstract

Object detection is widely used in various production and life, such as mask detection and recognition during the epidemic, face recognition with masks. Object detection algorithm based on deep learning has always been an important research content and implementation method in the field of object detection. Due to the large number of lead seals and fuses, their locations are not fixed, the lead seals and fuses have difficulties such as few sample datasets, complex target background and easy to be blocked, and strong reflective interference, and the conventional image processing methods are difficult to solve the problem of effective object recognition. In this study, by expanding the datasets, using different data enhancement methods, and training in the improved algorithm, the detection accuracy, detection speed, and adaptability were effectively improved.

Keywords: YOLOv5; Deep learning; Object detection; Few-shot learning

1. Introduction

Visual inspection, as a key application in related fields, provides fundamental support for achieving automation and is a key link in promoting the development of industrial automation [1]. Feature based visual detection methods have been widely used in industrial inspection, but this traditional detection method relies too much on manually designed feature extractors based on experience, and when faced with changes in target morphology and interference, the detection accuracy will significantly decrease. With the development of machine vision and artificial intelligence technologies, deep learning has become a new paradigm for object detection tasks in the industrial field [2].

However, deep learning relies on a large amount of labeled sample data during the training phase, which has drawbacks in real application scenarios. In factories, it is often difficult to obtain sufficient sample data due to issues such as a single model [3]. In such cases, the limited number of labeled samples can lead to severe overfitting of deep learning models and a decrease in recognition accuracy. Moreover, with sufficient datasets, labeling data can be time-consuming and labor-intensive, leading to issues of omission and mislabeling during labeling.

In this study, we used different image processing methods to further expand the original dataset and perform other data augmentations. At the same time, the automatic annotation of the dataset is completed through code to ensure the accuracy of the annotation, and it is trained in the improved YOLOv5 network to improve detection accuracy.

2. Methodology
2.1. Yolov5 algorithm

The core idea of YOLOv5 algorithm is to treat the object detection task as a regression problem and segment the feature map into L×L sized cells, M bounding boxes are set for each cell to surround the target. Each cell is responsible for detecting targets that fall within its area. In one operation, the bounding boxes, localization confidence, and probability of each category of targets contained in all cells are predicted. Then, the detected bounding boxes are filtered using NMS (Non Maximum Suppression) method to obtain the position, category, and confidence of the target to be tested.

The implementation of YOLOv5 algorithm can be summarized as the following steps:

(1) Preprocessing. The input image is first preprocessed, including scaling, cropping, and normalization operations, to convert it into a format suitable for network input.

(2) Feature extraction. The input image is fed into the backbone network and the feature is extracted through the backbone network.

(3) Feature pyramid network. YOLOv5 utilizes Feature Pyramid Networks (FPN) [4] to fuse feature maps of different scales, capture targets of different sizes, and improve detection accuracy.

(4) Predictive header. YOLOv5 uses a prediction head to predict each cell, obtaining bounding boxes (including the position and size of the target), confidence (probability of target existence), and class probabilities.

(5) Decoding prediction. Decode and convert the output of the prediction head into actual image coordinates, including adjusting the predicted bounding box to the original image size, and calculating the category and confidence score of each target.

(6) Non maximum suppression. Use NMS algorithm to remove redundant detection boxes with high overlap, and finally retain the most likely object detection result.

(7) Post processing. Perform post-processing on the detection results processed by NMS, including visualizing and saving the results.

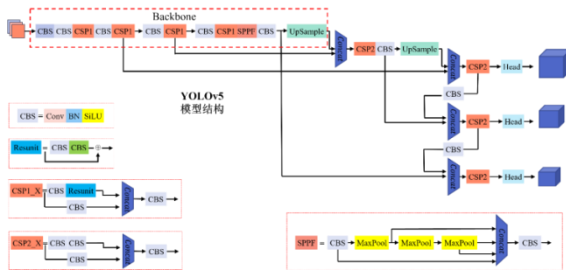
The YOLOv5-7.0 network model structure is shown in Fig. 1, which mainly includes Conv, CSPDarkNet, and SPPF modules.


Fig.1 YOLOv5-7.0 model structure

2.2. SENetAttention

In order to obtain attention in the channel dimension, the input characteristic graph is convoluted to obtain the dimension H × W × C, and then compress the input characteristic graph through global average pooling. This step converts the characteristic graph of each channel into the scalar of $1 \times 1 \times C$, thus forming a channel description vector, which captures the global spatial information of each channel and corresponds to the initial weight of each channel. This step is to compress (squeeze),as shown in equations (1) [5]:

$$Z_c = F_{sq}(x_c) = \frac{1}{H \times W} \sum_{i=1}^{H} \sum_{j=1}^{W} x_c(i,j) \qquad (1)$$

Where, *H* and *W* represent the height and width of the feature map, and x_c represents the input at each channel.

Then the second step is the excitation operation, which uses the small network of the Fully Connected (FC) layer to learn the relationship between channels. This network usually contains two full connected layers. The first full connected layer is responsible for mapping the channel description vector to a low dimensional space, with a

ReLU activation function in the middle, and the second full connected layer maps it back to the original number of channels, This process can be regarded as a bottleneck structure, which aims to extract the dependencies between channels. The mathematical expression of this process is shown in Formula (2):

$$s = F_{ex}(z,W) = \sigma(g(z,W)) = \sigma(W_2\sigma(W_1z)) \qquad (2)$$

Where, σ Represents the ReLU function, W_1 represents the parameters of the dimension reduction layer, W_2 represents the parameters of the dimension increase layer, and *z* is the output result from the previous compression step.

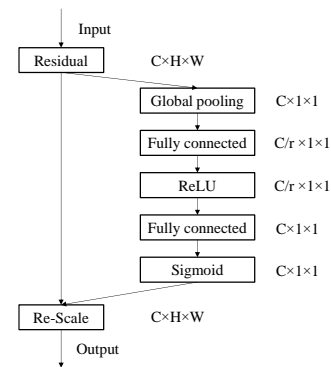
The last step is Re-scale, which multiplies the previously learned channel weight vector with the original feature map to achieve the function of adaptively adjusting the feature response of each channel and improve the performance of the network model. The network architecture of its algorithm module is shown in Fig. 2.


Fig.2 The diagram of the squeeze-and-excitation block

Adding the SENet attention module to the last layer of the Backbone network can effectively reduce the false detection rate and missing detection rate of lead seals and fuses, and improve the detection accuracy.

3. Data processing

3.1. image processing

For the image acquisition work of the product object, considering the complex surface structure of the product and the obvious reflective effect of the metal material and paint surface, the shooting effect is easily affected by the lighting conditions. According to this feature, the product is placed in a variety of lighting conditions, and different types of camera equipment are used to collect images. At the same time, local images and unmarked background images are taken in each lighting environment, in order to maximize the diversity of target images.Sample is shown in Fig. 3.

a) Low brightness environment   b) Normal lighting environment   c) High brightness environment
Fig.3 Shooting in various lighting conditions

ImgAug is a powerful and flexible image enhancement library based on Python language, which is mainly used in the field of deep learning and computer vision. It supports a variety of image processing libraries such as OpenCV. By calling ImgAug's API, the image can be transformed in various aspects such as geometry, color, contrast, etc., so as to expand the original image data set and improve the generalization ability and robustness of the model. With the help of its official API document, the corresponding Python code is written, and the image is transformed as follows. The process can be shown in Fig. 4.
Fig.4 Image enhancement process

Write python code to execute the above image enhancement operation, and realize the automatic annotation function of new images while realizing various transformations of images. By reading the XML annotation file corresponding to the original image, the position and coordinate information of all the annotation boxes are extracted, and according to the random enhancement process of each new image, the code automatically calculates and adjusts the information of the annotation box, thus generating a new XML file that is completely aligned with the target position in the new image. This method avoids the tedious work of manual marking and saves a lot of human resources. By automatically updating the annotation information, the enhanced image is consistent with the original annotation, thus improving the accuracy and reliability of the model. The new sample image of the original image after image enhancement is shown in Fig. 5.

a) Original image   b) New samples 1

c) New samples 2   d) New samples 3
Fig.5 New samples after image augmentation

Through the above image enhancement method, each initial image is expanded to 6 new images, and finally 441 images are obtained as the final data set.

4. Experiment and Comparison

After completing the dataset production and modifying the YOLOv5 model, conduct training and compare the training results of the unimproved model. At the same time, verify the accuracy of the same image.

Baseline is the yolov5 model without adding SE attention mechanism, and the training is carried out using the non-expanded dataset. The dataset is as shown in the figure. SENet is the yolov5 model with adding SE attention mechanism, and the training is carried out using the non-expanded dataset. SENet+dataset is the yolov5 model with adding SE attention mechanism, and the training is carried out using the expanded dataset. The unexpanded dataset has 63 pictures, and the expanded dataset has 441 pictures, as shown in the following Fig. 6.

a) Baseline   b) Expand the dataset
Fig.6 Image expansion

The key data of the training results are shown in Table 1. Among them, mAP (mean Average Precision) refers to the average precision, which comprehensively considers precision and recall to measure the performance of the model on detecting targets.

Yuxuan Gao, Jiwu Wang, Zixin Li

Table1. Comparison of data under different training conditions

	mAP (%)	precision (%)	time (ms)
Baseline	81.4	81.4	9.9
SENet	87.5	89.5	9.3
SENet+ dataset	96.3	96.9	12.3

From the table, it can be seen that compared to the baseline reference benchmark, the use of SENet attention mechanism in mAP has improved by 6.1%, and the combination of SENet and expanded dataset has improved by 8.2%; In terms of accuracy, compared to Baseline, the use of SENet attention mechanism improved by 7.9%, and the combination of SENet and expanded dataset improved by 7.4%.

The above data results demonstrate the advantages of SENet+augmented dataset. The best weight files trained using Baseline, SENet, and SENet+augmented dataset are tested on the images in the test set. The image detection results are shown in Fig. 7.

a) Baseline   b) SENet

c) NSENet+ Expand the dataset
Fig.7 Comparison of detection under different training conditions

From the figure, it can be seen that the effect is significantly improved after adding the SENet module network. However, due to the limited amount of data, there are still issues of false positives and missed alarms. After expanding the dataset, it can be clearly observed that not only is the accuracy further improved, but also false positives are reduced. In summary, the addition of SENet attention mechanism and the scalability of the dataset are helpful for model training and improving detection accuracy.

5. Conclusion

In this study, by improving the YOLOv5 model and expanding the dataset, the training accuracy is improved. The experimental results show that this method can meet the measurement accuracy requirements. Compared with the unimproved method, the method proposed in this paper improves detection accuracy and accuracy. This method can provide good support for deep learning based object detection research. However, due to the increased computational complexity of the algorithm, the running time is longer. In order to meet the real-time requirements of object detection, the speed of the algorithm needs to be further improved.

Abstract

In the production of castings, gas pores are a prevalent defect, particularly in components where air-tightness is crucial, such as cylinder blocks and heads. These defects primarily arise from the intrusion of gases into the casting during the combustion of resin in the sand core. Due to the complexity of the sand core's gas evolution and venting process, predicting gas pores using numerical simulation poses significant computational and time challenges. This paper introduces a rapid prediction method for gas pores based on the characteristic time of the sand core. By setting the heat transfer boundaries, initial conditions, and termination criteria for computation, the thermal conductivity of the sand core is adjusted. The termination computation time is used as the characteristic time of the sand core. This time is then compared with a critical characteristic time to predict the distribution of gas pores. As the analysis of more sand cores is incorporated, the precision of the critical characteristic time improves, leading to more accurate predictions of gas pores in castings.

Keywords: Gas pore; Numerical simulation; Iron casting; Sand core; Resin

1. Introduction

Gas pores are common and typical defects in cast iron and aluminum alloy castings, with entrapped gas pores being a major type of pore defect. In complex castings such as engine blocks and cylinder heads, numerous intricately shaped sand cores are employed. During the filling and solidification of molten metal, the sand cores are subjected to heating, causing the organic binder within them to decompose or burn at high temperatures, generating gas [1], [2]. If the gas cannot be expelled from the core and instead infiltrates the molten metal, it results in entrapped gas pores [3]. The factors influencing the occurrence of entrapped gas pores are numerous, making

Xiaolong Wang, Qihua Wu, Jiwu Wang, Jinwu Kang, Na Li, Yucheng Sun

it challenging to eliminate. This issue significantly impacts product quality, sometimes leading to the rejection of castings or the discovery of pore defects after machining. The complex formation mechanism of entrapped gas pores makes it difficult to predict using numerical simulation methods accurately [4], [5], [6].

This paper adopts a strategy for identifying hazardous sand cores and their critical points. Based on the principles of similarity in heat transfer within the sand core and the transport of gas within it, a virtual heat transfer method for sand cores is employed. The paper proposes a characteristic time indicator for predicting the occurrence of casting porosity induced by sand cores. This indicator is used to assess the critical points and severity of risks associated with sand cores, enabling the determination of whether casting porosity will be induced and predicting the location of gas pore formation. The characteristic time values are stored in a database for validation against actual test results. Furthermore, these values serve as a reference for predicting porosity in new sand cores.

2. Methods

2.1. *Heat transfer analysis and modified thermal property parameters*

Gases produced from the high-temperature decomposition of binders are expelled through exhaust channels. However, due to the intricate geometries of sand cores and variations in the distances from different points to the core head, some points, especially those farthest from the core head, may pose challenges in gas evacuation. This difficulty increases the probability of porosity formation. The term "distance" here is not spatial but pertains to the movement of gas within the sand core, exhibiting a certain similarity principle with heat transfer within the sand core. To identify the point farthest from the sand core, i.e., the most challenging gas evacuation point, a virtual heat transfer method is employed. The numerical simulation for virtual heat transfer focuses solely on the specific sand core in question, with other sand cores, moldings, and castings excluded from the simulation. These excluded components are, however, crucial for automatically determining the core head. This determination is achieved by identifying areas where the sand core does not contact the casting, signifying the presence of the core head.

Heat transfer analysis is the foundation of the resin burning, gas release and flow, the melt solidification, and the formation of gas pores. The heat transfer inside the casting, mold, and sand core during the casting process is expressed by the Fourier equation,

$$\rho c \frac{\partial T}{\partial t} = \frac{\partial}{\partial x}\left(k \frac{\partial T}{\partial x}\right) + \frac{\partial}{\partial y}\left(k \frac{\partial T}{\partial y}\right) + \frac{\partial}{\partial z}\left(k \frac{\partial T}{\partial z}\right) + q \quad (1)$$

where ρ is the density, c is the specific heat capacity, T is the temperature, t is the time, k is the thermal conductivity, and q is the latent heat term as the melt solidifies.

The nominal thermal conductivity of the sand core is adjusted based on the permeability of the sand core, and the adjustment formula is as follows:

$$\lambda_1 = \frac{K}{100}\lambda_0 \quad (2)$$

where λ_0 is the real thermal conductivity of the sand core (W/(m·K)), λ_1 is the nominal thermal conductivity of the sand core (W/(m·K)), K is the permeability of the sand core.

The nominal specific heat of the sand core is adjusted based on the gas generation of the sand core, and the adjustment formula is as follows:

$$c_1 = \frac{G}{20}c_0 \quad (3)$$

where c_0 is the real specific heat of the sand core (J/(kg·K)), c_1 is the nominal specific heat of the sand core (J/(kg·K)), G is the gas generation of the sand core.

2.2. *Determination of dangerous gas penetration points in sand cores*

During the simulation process, six distinct boundary interfaces are evident, as depicted in Fig. 1: metal-sand core, metal-air, metal-sand mold, sand core-sand mold, sand mold-air, and sand core-air. The aforementioned coating is applied to both the surface of the sand core and within the sand mold cavity. Consequently, the interfaces involving metal-sand core, metal-sand mold, and sand mold-sand core are influenced by the presence of this coating. Its inclusion results in heightened thermal and penetration resistance at these boundaries. Moreover, owing to the coating's exceptionally low gas permeability, certain segments exhibit zero gas permeability at room temperature, signifying an incapacity to permit gas passage.
Fig. 1 Boundary setting conditions.

Establishing the boundary conditions for the sand core involves setting the surface temperature of the core head to a constant 1500℃. The remaining exterior surfaces of the sand core are considered adiabatic. The initial temperature of the sand core's elements is set at 25℃. The virtual heat transfer computation is programmed to automatically terminate when the volume of the unheated portion of the sand core reaches 100 mm³ , as illustrated in Fig. 2. This moment is recorded as the characteristic time of the sand core.

(a) Before heat transfer

(b) After heat transfer
Fig. 2 Virtual heat transfer of sand core identifies the most challenging gas exhaust point.

When the characteristic time of the sand core exceeds the critical time for gas pore initiation, it is determined that the sand core induces gas pores in the casting. Conversely, when the characteristic time of the sand core is less than the critical time for gas pore initiation, it is determined that the sand core does not induce gas pores in the casting. The topmost units in the unheated portion of the sand core are selected, and these units are identified as the critical points for gas pore initiation in the casting. These critical points represent the locations in the sand core most susceptible to inducing gas pores in the casting.

Save the characteristic time of the sand core to the sand core characteristic time database, and adjust the critical characteristic time based on the actual occurrence of gas pores for each sand core.

3. Pore prediction results

3.1. *Parameters*

Predictions of pores were performed on a single cylinder head. The casting consists of the intake manifold, exhaust manifold, upper water jacket, lower water jacket, and chassis core.

Due to the relatively simple geometry of the intake and exhaust manifold cores, only the cores themselves were considered in the determination of dangerous areas during the assessment of the intake and exhaust cores. For virtual heat transfer computations, the thermal property parameters of the cores were set with a density of 1.6×10^3 kg/m³, a nominal specific heat of 1×10^3 J/(kg·K), and a nominal thermal conductivity of 0.5 W/(m·K).

3.2. *Gas pore*

The virtual heat transfer simulation was conducted for the casting and sand cores, and the computation was terminated upon meeting the specified conditions. The characteristic time for the sand cores was determined to be 2.1 s. The critical units of each sand core, as illustrated in Fig. 3, align with the experimental results, where the critical characteristic time for gas pore generation in the sand cores was identified as 1 second. Consequently, the casting exhibits gas pores, and the locations of these pores are depicted in Fig. 4.

(a) Intake and exhaust manifold cores

(b) Upper and lower water jacket cores

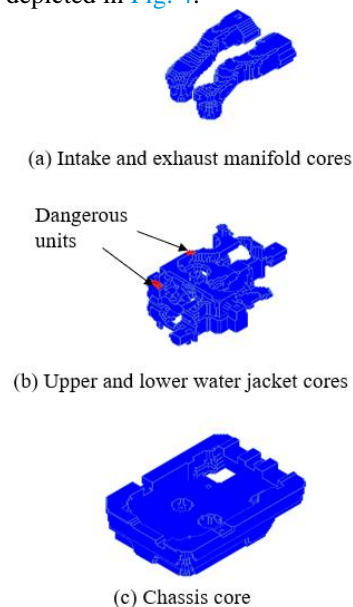
(c) Chassis core


Fig. 3 Dangerous units in each sand Core

Xiaolong Wang, Qihua Wu, Jiwu Wang, Jinwu Kang, Na Li, Yucheng Sun
Fig. 4 Casting pore results

Comparison with castings produced in the actual factory workshop reveals a consistent distribution of gas pores, validating the effectiveness of the proposed method.

4. Conclusion

This paper proposes a gas pore prediction method based on the characteristic time of sand cores, enabling the forecasting of pores in castings. It addresses the challenges associated with the complex gas generation and exhaust processes in sand cores, difficulties in predicting them through numerical simulation techniques, and the significant costs and time associated with such simulations. This method provides guidance for practical casting production. As the analysis of sand cores increases, the critical characteristic time becomes more precise, leading to more accurate gas pore predictions.

Abstract

In the foundry industry, accurate prediction of the temperature field of castings during solidification is crucial to ensure high product quality and improve productivity. This study provides an in-depth investigation of the Unet deep learning model used for temperature field prediction during solidification, focusing on the impact of key training parameters such as optimiser selection, batch size, number of iterations, and loss function selection on the prediction performance of the Unet model. The results of the study demonstrate the analysis of selecting and tuning these parameters to improve the accuracy and reliability of model predictions. The results of this study not only provide new ideas for the practice of deep learning applications in the foundry industry, but also help to improve the accuracy and efficiency of the production proces.

Keywords: casting, deep learning, temperature field prediction, parameter optimization.

1. Introduction

In recent years, deep learning has expanded in field prediction, simplifying traditional numerical simulations [1], [2] while maintaining accuracy. Specifically, in casting solidification, data-based methods predict temperature fields [3] effectively. However, incorrect network structures or training parameters can cause underfitting or overfitting, leading to errors. Thus, optimizing these parameters is vital for enhancing accuracy, reducing costs, and speeding up design iterations for precise temperature field prediction in casting processes.

2. Model Introduction

Selecting an appropriate network model structure is crucial for high-precision prediction of the temperature field during the solidification process of castings. The U-Net [4], [5] network demonstrates exceptional performance in the field of image segmentation, particularly in achieving precise segmentation with smaller datasets.
Fig.1. Unet network model [6]

In the prediction of temperature field during casting solidification, due to the time-consuming computation of

the finite difference method, it is difficult to generate a large amount of training data, and the encoder-decoder network architecture is able to efficiently extract the semantic features of the image and retain the positional information, which is suitable for prediction tasks with small datasets. The Unet network model is shown in Fig. 1.

In this study, we employ a network model (Fig. 1) with the classic U-Net structure to predict the temperature field during the solidification process of castings. The model takes the mold images of sand castings as input, and the output is the temperature field image after a certain time step. Both input and output are single-channel images.

3. Optimization Methods

In the realm of deep learning network architectures, the addition or alteration of various modules can significantly impact the final predictive performance. To

achieve optimal neural network prediction capabilities, this study delves into several key factors affecting model training, including the choice of optimizer, batch size, number of iterations, and the selection of loss functions. The following sections will present a detailed comparative analysis of these crucial elements, aiming to elucidate how to optimize deep learning network structures for higher accuracy in predictions. This translation is intended for application in academic papers.

3.1. *The Impact of Different Optimizers on the Prediction Accuracy of the Temperature Field*

In this set of comparative experiments, the batch size was set to 32, and the number of epochs was fixed at 200. Mean Absolute Error(MAE) was chosen as the loss function. To analyze the impact of different optimizers, three distinct optimizers were selected for comparison: Adam, Nadam and SGD. The learning rate for each was adjusted using a cosine annealing learning rate strategy. The experimental results are presented in Table 1.

Table 1. Comparison of results of different optimizers

Serial Number	Optimizer	Accuracy	Pearson Correlation Coefficient	Loss	Val-Loss	Training Time
1	Adam	0.9156	0.9989	0.0096	0.0230	66727.5657
2	SGD	0.8198	0.7685	0.1977	0.1769	68961.8629
3	Nadam	0.9118	0.9989	0.0099	0.0236	65335.4521
Fig.2. Error Plots of Predicted versus Actual Values Using Three Optimizers

According to the data presented in Table 1, the model demonstrates higher accuracy and correlation when employing the Adam optimizer, with the smallest loss value observed. To further analyze and compare these results, samples at a specific moment (t=10 minutes) were

randomly selected for visual analysis. Fig.2 demonstrates the distribution of errors between the temperature fields predicted by the model and the actual temperature fields, under three different optimizers: Adam, Nadam, and SGD.

3.2. *The Impact of Different Batch Sizes on Prediction Accuracy*

In this set of comparative experiments, building upon the results of the previous set, Adam was selected as the optimizer, with the number of epochs set to 200 and MAE employed as the loss function. To investigate the impact of batch size on model performance, three different batch sizes (16, 32, and 64) were established for comparative analysis. The experimental results are shown in Table 2.

Table 2. Comparison of results for different batch sizes (batch size)

Serial Number	Optimizer	Accuracy	Pearson Correlation Coefficient	Loss	Val-Loss	Training Time
1	16	0.9014	0.9889	0.0181	0.0217	68537.3182
2	32	0.9118	0.9989	0.0096	0.0230	66727.5657
3	64	0.8089	0.9979	0.0214	0.0286	66357.1713

Based on the data analysis from Table 2, it is observed that setting the batch size to 32 results in higher model accuracy and correlation, with the smallest loss value and shorter training time. Samples at the same moment (t=10 minutes) were selected for visual analysis.
Fig.3. Error Plots of Predicted versus Actual Values for Three Batch Sizes

Fig. 3 illustrates the distribution of errors between the predictedand actual values of the model under three different batch sizes (16, 32, and 64). The model exhibits relatively smaller prediction errors when the batch size is set to 32.

3.3. *The Impact of Different Iteration Counts on Prediction Accuracy*

In this set of comparative experiments, building upon the results of the first two sets, Adam was chosen as the optimizer, with the batch size set to 32 and Mean Absolute

Error (MAE) used as the loss function. To explore the impact of different numbers of epochs on model performance, three distinct numbers of epochs (50, 200, and 500) were established for comparative analysis. The experimental results are shown in Table 3.

According to the experimental data in Table 3, the model exhibits the highest accuracy and correlation, with the smallest loss value and relatively short training time, when the number of epochs is set to 200. With an increase in the number of epochs, the computational cost correspondingly rises. Therefore, when selecting the optimal parameters for the model, it is crucial to consider both prediction accuracy and computational cost as key factors in determining the most suitable parameter settings. Fig. 4 displays error distribution of the temperature field at different numbers of epochs (50, 200, 500), providing a more intuitive assessment of model performance.
Fig.4. Error Plots of Predicted versus Actual Values for Three Different Epoch Counts

Table 3. Comparison of results for different number of iterations (epoch)

Serial Number	Epoch	Accuracy	Pearson Correlation Coefficient	Loss	Val-Loss	Training Time
1	50	0.7264	0.8963	0.0302	0.0361	17488.4049
2	200	0.9118	0.9989	0.0096	0.0230	66727.5657
3	500	0.9083	0.9988	5.3330e-04	0.0040	157621.8659

3.4. *The Impact of Different Loss Functions on Prediction Accuracy*

In this set of comparative experiments, based on the results of the previous three sets, we selected the Adam optimizer with the number of epochs set to 200 (epoch = 200). Three different loss functions were chosen for comparative analysis: Mean Squared Error (MSE), Mean Absolute Error (MAE), and their combination (MSE + MAE). The experimental results are presented in Table 4.
Fig.5. Error Plots of Predicted versus Actual Values for Three Different Loss Functions

Based on the experimental data presented in Table 4, the highest accuracy and correlation, along with the smallest

Table 4. Comparison of results of different loss functions

Serial Number	Loss Function	Accuracy	Pearson Correlation Coefficient	Loss	Val-Loss	Training Time
1	MSE	0.9293	0.9990	4.9873e-04	0.0038	64514.8804
2	MAE	0.9118	0.9989	0.0096	0.0230	66727.5657
3	MAE+MSE	0.9083	0.9988	5.3330e-04	0.0040	67621.8659

Yahui Yang, Jiwu Wang, Jinwu Kang

loss value and relativly short training time, are observed when Mean Squared Error (MSE) is used as the loss function. Thus, choosing MSE as the loss function is the optimal parameter choice for the model. Fig. 5 illustrates the visualization of the error distribution of the temperature field predictions when different loss functions (MSE, MAE, and MSE+MAE) are employed.

3.5. *Experimental Results*

In the four comparative experiments conducted, we determined that the Adam optimizer is the optimal choice, surpassing Nadam and SGD in accuracy, correlation, and loss minimization. The model exhibits its best performance with a batch size of 32, effectively balancing efficiency and accuracy. Setting the number of epochs to 200 achieves a balance between computational cost and precision. Among the loss functions compared, Mean Squared Error (MSE) significantly excelled in predictive accuracy and minimizing loss.

4. Conclusion

In this study, we employed a data-driven Unet neural network model for temperature field prediction, optimizing its structure and training parameters (optimizer, batch size, epochs, loss function). The model, trained on 128x128 pixel image data, showed optimal performance with the Adam optimizer, a batch size of 32, 200 epochs, and Mean Squared Error (MSE) as the loss function, achieving an accuracy of 0.9293 and a correlation of 0.9990. These findings offer new insights and valuable references for the application of deep learning in the casting industry.

Abstract

Mobile phones and laptop computers require electrical power to recharge when the battery is down. As a result, it would be very useful if a portable charging station derived from renewable energy harvesting could be built, so that individuals could recharge their phones and laptops whenever needed. The objective of this project is to design and develop a green energy mobile and laptop charging station that uses wind and solar energy and evaluate the performance of the designed station under different working conditions. The efficiency of the power generated to charge the station is achieving 95.6% for solar charging, which is considered a high efficiency for a renewable energy charging station. Based on the analysis of the charging station results, it has been proven that it can provide sufficient power and is safe for use as a portable mobile laptop charging station.
Keywords: Energy conversion, Portable power supply, Universal mobile laptop charging

1. Introduction

Electricity is a vital part of modern life and for a country's economic growth and development. Over the next two decades, average power consumption is predicted to nearly double, with overall electricity demand expected to rise by 2.3 percent per year on average from 13,290 billion kWh in 2001 to 23,072 billion kWh in 2025 [1]. In Malaysia, home electric power consumption has grown substantially over the past years, resulting in high demand for energy to satisfy increasing social and economic activities.

Fossil fuels are the most famous resources used. However, these fuels are creating huge carbon emissions to the atmosphere which has negatively impacted the environment. As the demand for electric power rises, additional power generation is required to meet the demand. Due to the depletion of conventional resources, renewable energy resources are the most suitable resources for generating electric power with little environmental effect. Renewable or non-conventional energy are tidal energy, wind energy, hydropower, biomass, geothermal energy, and solar energy [2]. It also

Ammar A.M. Al-Talib, Ang Aun Jie, Idayu M.Tahir, Sarah Atifah Saruchi, Cik Suhana Bt. Hasan, Amar Rizwan, Rodney Tan

contributes to the achievement of Sustainable Development Goal 7 (SDG7), which calls for universal access to sustainable and renewable energy by 2030.

This project's goal is to create a portable dual-source charging station that can charge mobile phones and laptops using both solar and wind energy. A hybrid power system is a system that combines two or more renewable energy sources to provide continuous energy generation to fulfil load needs. Researchers have discovered that a combined solar and wind hybrid system is the most reliable and efficient, as well as being ecologically friendly and affordable in cost [3]. Several recent research [4], [5], [6] have combined two non-conventional sources to create a dual-mode portable mobile charger. Wind and solar hybrid systems for mobile chargers with minimal operating costs have been designed in this research. Additional components are necessary for laptop charging, which necessitates the use of an AC power source. When constructing a portable charging station for mobile and laptop devices, certain specifications and data are critical.

2. System overview

Major components of the system include power inverter, battery bank, system and battery controller, photovoltaic modules, wind turbines, and, in some cases, the prescribed electrical demands. Fig. 1 from MEDA [7] illustrates the system's basic working principle. The acquired energy from the wind turbine and PV array will be transformed into electrical DC power and stored in the battery bank. For the system under research, a monocrystalline solar panel and a vertical axis wind turbine are recommended. As compared to polycrystalline and thin-film solar panels, monocrystalline solar panels offer the highest efficiency of 15–20 percent [8]. According to the research [9], vertical axis wind turbines are more efficient to build and use in Malaysia's tropical and windy weather. A charge controller for wind and solar power is required to maintain your batteries properly supplied and avoid overcharging. For DC loads, the electric power stored in the battery bank may be utilized directly, however for AC loads, an inverter is required to connect to the battery bank. A power inverter is an electrical device that converts direct current (DC) from a battery bank to alternating current (AC). Finally, the system can be used to charge mobile phones and laptops.

2.1. *Fabricated prototype*

The prototype has been successfully built using
Fig. 1 A block diagram of Hybrid Solar-wind Energy system [7]

Fig. 2 Full components of prototype

Table 1 List of prototype components

No.	Component	Specifications
1	Power Inverter	200W
2	Dokio Solar charge controller	30A
3	PWM Solar Charge controller	10A
4	Battery Indicator Voltmeter	N/A
5	Dokio Solar Panel connector	N/A
6	SLA Battery	12V, 7.2Ah
7	Plastic Ammo Box	N/A
8	4-in-1 output panel	Voltmeter, switch, USB ports, 12V cigarette port

polystyrene boxes, a plastic ammo box, and cardboard. The components of the prototype are labelled in Fig. 2 and listed in Table 1. Fig. 3 shows the complete fabrication of the prototype.

The portable charging station consists of a Dokio solar charge controller, a PWM solar charge controller, a battery indicator voltmeter, a 12V, 7.2Ah GP SLA Battery, a 200W power inverter, and a 4-in-1 output panel as shown in Fig. 4. All the components in the circuit are linked in parallel with the 12V 7.2AH SLA Battery,

Fig. 3 The completed prototype

Fig. 4 The charging mobile phone and laptop with using the charging station

ensuring that the station can function even if one of the components fails. A switch, voltmeter, USB ports, and a 12V cigarette port are all included in the 4-in-1 output panel. The charging station can be turned on and the mobile phones can start charging through the USB port, while a power inverter must be connected to the 12V cigarette port to convert power into AC power for laptop charging.

3. Result and Discussion

The system has been tested to evaluate the performance of the designed station. The equipment used in the experiments was an 80 W Mono-solar panel, a 100 W wind turbine, and a 1000 W halogen lamp to generate electrical power. Several experiments have been conducted and the data were recorded and analyzed to evaluate the performance of the designed station under different working conditions. A multi-meter has been used to measure the current and voltage output from the solar panel and wind turbine, and then the energy output over the state of the battery of the experiments have been measured by the charge controller. The experiments have

Table 2. Data collected for four different experiments conducted

Experiment	Trial	Average Voltage Generated (V)	Average Current Generated (A)	Charging Duration (Hour:minute)	Solar Irradiances (W/m²)	Light Intensity (W/m²)	Speed of Wind (m/s)

4	1	12.64	0.750	14:51	-	474.61	3.6

Ammar A.M. Al-Talib, Ang Aun Jie, Idayu M.Tahir, Sarah Atifah Saruchi, Cik Suhana Bt. Hasan, Amar Rizwan, Rodney Tan

been conducted to fully charge the 12V 7.2Ah Sealed, Lead Acid Rechargeable Battery for each trial of experiments.

Experiments 1 and 2 are solar power charging for the designed station, with experiment 1 using sunlight to generate electrical power outdoor under the sun, whether experiment 2 is by utilizing a halogen lamp as the source of light to simulate the solar energy. The wind power charging for the station is evaluated with a power fan in experiment 3 to simulate the wind energy because of the low wind speed available outdoors. Experiment 4 is a hybrid solar and wind power charging system for the station, with a halogen lamp and a power fan used indoors to get more consistent and precise results. Table 2 shows the data collected for the four different experiments conducted.
Fig. 5 Overall average current generated and solar irradiance for experiment 1
Fig. 6 Overall average solar irradiance received for experiment 1.
Fig. 7 Overall average current generated for experiment 2.
Fig. 8 Overall average light intensity received for experiment 2.
Fig. 9 Overall average current generated with three different speeds for experiment 3.

The average overall electrical current generated and overall average solar irradiances received for experiment 1 are plotted and illustrated in Fig. 5 and Fig. 6 based on the data obtained. In Fig. 7 and Fig. 8, the overall average current generated and overall average light intensity received for experiment 2 are plotted and shown. Fig. 9 illustrates the relationship between current generated and wind speed.

According to Fig. 5 and Fig. 6, it is shown that the higher the solar irradiances come the higher the current generation output result. The results reveal that even the lowest solar irradiation of 679.46 W/m2 can generate an average of 12.67 volt and 0.873 amperes.

Fig. 7 and Fig. 8 are showing that as the light intensity increase, the current generated and output power increase.

As the solar panel receives more light intensity from the halogen lamp, the current generated is increasing as well as the power output. Although the light source to the solar panel is stable, the current and power generation is respectively low which is not utilizing the sunlight that contains higher solar irradiances. As a result, it also corresponds to the research done by [10], whereby the current rises steadily with an increase in solar irradiances or light intensity.

 Fig. 9 shows that when the wind speed increase, the current generated will also increase. However, it can still be observed that the current is increasing with the speed of wind increase which gets a maximum of 0.3A with a 3.6 m/s wind speed. As a result, it can be concluded that the greater the wind speed, the greater the magnitude of the current.

From Table 2, it is shown that an average of 0.75A is generated with an average light intensity of 474.61 W/m^2 and a constant speed wind of 3.6m/s. The results have been taken when both solar and wind harvesting systems are working together to charge the station. The duration to fully charge the station is around 14.85 hours which is faster than experiments 2 and 3.

The duration to fully charge the battery is also dependent on the renewable power supply. The higher the power supply to charge the station, the shorter the duration of the battery to be fully charged. The fastest battery of 7.2 Ah capacity could be fully charged in around 68 minutes with a charging current of 1.45 A. To protect the battery, the battery is recharging at 12 V which is around 50 % to avoid irreversible damage occurring. The fully charged battery can fully charge an iPhone 11 with a battery capacity of 11.9 Wh for 5.5 cycles and an Asus gaming laptop with a battery capacity of 48 Wh for 1.8 cycles.

3.1. *Result comparison*

The average experimental results from experiment 1 through experiment 4 are plotted and illustrated in Figure 10. The average result is calculated by averaging the measurements based on the state of charge of the battery, which acts as a comparison point. This is because the charge controller will supply power following the battery's status, which means that the power delivered will gradually grow following the status of the battery to prevent the battery from being damaged.

According to Fig. 10, experiment 1 is the most efficient

	Experiment 1	Experiment 2	Experiment 3	Experiment 4
Average Voltage (V)	12.95	12.56	11.33	12.64
Average Current (A)	1.06	0.42	0.275	0.75
Average Duration to Fully Charge (hours)	2.2	20.62	22.8	14.85
Theoretical Duration to Fully Charge (hours)	9.51	24	36.65	13.44
Fig. 10 Average experimental result from experiment 1 to experiment 4.

way, taking just 2.2 hours to fully charge the station with an average voltage of 12.95V and a current of 1.06A. It took around 7.31 hours less time than the expected result based on calculation. Even though the readings fluctuated during the experiment, it was still the most efficient method for solar charging when compared to experiment 2 which utilized a halogen lamp as the light source.

From Fig. 10, experiment 2 took an average of 20.62 hours to completely charge the station battery, which is around 18.4 hours longer than experiment 1. With an average of 12.56 V and 0.42A, the power generated was likewise significantly lower than experiment 1. It took around 3.38 hours less time than the expected result based on calculation. As a result, the most effective approach for successfully charging the station batteries for the solar harvesting system is charging with a solar panel directly under the sun, which will maximize the power generated among other methods.

Ammar A.M. Al-Talib, Ang Aun Jie, Idayu M.Tahir, Sarah Atifah Saruchi, Cik Suhana Bt. Hasan, Amar Rizwan, Rodney Tan

Due to the low wind speed available in Malaysia, experiment 3 aims to see how much power can be generated at various wind speeds. It only can generate an average of 11.33V and 0.275A, which only charged station batteries to 60% in an average of 22.8 hours. This is because the charge controller utilized for the wind harvesting system is a solar charge controller, resulting in the charge controller power output being unstable and low. Furthermore, the solar charge controller is only designed for solar power systems with electrical characteristics that differ from those of wind power, resulting in low power received to charge the station. As a result, by adopting an appropriate wind charge controller, the wind power charging system may be more effective.

Experiment 4 feeds the station using both solar and wind harvesting technologies. It aims to see if operating the combined harvesting system at the same time as charging the station is more efficient than working independently. According to Figure. 10, the result showed an average of 12.64V and 0.75A, and it took an average of 14.8 hours to fully charge the station. However, the required duration to completely charge took 1.41 hours longer than the theoretical calculation. This outcome might be impacted by the fact that an inappropriate charge controller is used for a combined solar and wind harvesting system that prolongs the duration to be fully charged. As a result, it can be proven that the combined solar and wind harvesting system has a better performance than a system that only harvested wind or solar.

4. Conclusion

In summary, the design of a mobile dual source charging station, by using wind energy and solar energy, has been fabricated with several materials such as polystyrene boxes, cardboard, and plastic ammo toolbox. The performance of the designed station under different working conditions was investigated and evaluated using handphone and laptop as load. Based on the comparison, the designed station has the best performance when both solar and wind harvesting systems are working at the same time. Therefore, this study is promising to develop a clean energy portable charging station that is environmentally friendly and able to act as a charging station when there is no power supply available.

Abstract

The objective of this project is to build an auto indoor hydroponics plant growing chamber that has an auto monitoring and controlling system. A ESP32 based hydroponics electrical system is built with the attachment of hardware components such as temperature and humidity sensor, light intensity sensor, water level sensor, and water flow rate sensor. The software development of the system is through Arduino IoT Cloud platform, which has an overall suitability in terms of features, cost, and user intuitiveness for starters. Results have shown that ESP32 can ensure stable power supply. After testing and validation, all of the electrical components are stored in a power enclosure box to prevent contact with liquid. In short, the developed auto indoor hydroponics plant growth chamber has effectively demonstrated the ability in easing the plant cultivation procedure for agricultural community.

Keywords: Auto Indoor Hydroponics, ESP32, Controlling and Monitoring Hydroponics

1. Introduction

The global population is expected to reach 9.8 billion in 2050 [1]. Meanwhile, scientists anticipate that a growing population will result in a decline in the amount of available land. The scarcity of land in the future is predicted to become a bottleneck in all industries, but especially in agriculture [2]. Not to mention, a lack of available land will make traditional farming difficult and increase the likelihood of a food crisis due to rising food demand but low yield rates [3].

All the aforementioned issues have made it difficult to provide adequate and nutritious food, particularly in urban areas. Therefore, new methods of producing enough food must be developed in order to sustainably feed the world's expanding population. New and modern farming techniques marked a significant technological advance for humanity. The substitution of liquid as the new growing medium for traditional growing medium can be the different approach for consistent crop production, preservation of rapidly depleting land and food availability. On that being in case, the rapid growth of hydroponic system is getting attention and increasing

Ammar A. M. Al-Talib, Tew Hwa Hui, Sarah 'Atifah Saruchi, Noor Idayu Mohd Tahir, Nor Fazilah Binti Abdullah

widespread all over the world. It is accounted to have a world growth of 18.8% from 2017 to 2023 [4]. Hydroponics is derived from Greek word means Hydro "water" and Pons "labour". It is a method to grow various plants in water containing fertilizer without any soil by using different inert mediums such as sand, gravel, rockwool that act as a mechanical support [5]. The growth of hydroponics plants must be in a controlled environment and often affected by different parameters such as electrical conductivity in nutrients, nutrients circulation rate, PH, light intensity air and water temperature. Hence, the plant can have growth in an optimal condition with frequent monitoring for better yield rate of the plants [2].

Therefore, this project aims to develop an auto indoor hydroponic system prototype with "auto" monitoring and controlling features with IoT capabilities.

2. Literature Review

In this section, understanding and evaluating the monitoring and controlling systems from past research studies can be well understood.

2.1. Water and Nutrient Flow Path Monitoring and Controlling System

Water flow path and control takes a critical role in hydroponics system as the growth condition of plant was highly determined by the nutrients absorbed.

Fig.1. refers to the system used by M. E. H. Chowdhury et al., 2021 [6]. It contains two circulation paths: nutrient solution circulation and clean water supply.

The pump on the clean water source will only operate when the nutrient container does not meet the height of the water level with the aid of the water level sensor. The placement of the water level sensor was determined with the water height formula used; the water level sensor of the system will be placed 22.4cm vertically on the inner container to ensure enough 37L water in the tank.

An additional water flow sensor has been provided on the nutrient container. The water flow sensor was capable of measuring volume circulation per day and water. The system will notify when there is no water flow sensing.
Fig. 1. Water, Nutrient and pH Monitor and Control System

2.2. Temperature and Humidity Monitoring and Controlling System

Temperature and Humidity around the plants is crucial as it may affect the growth of plants in different temperature environments.

Fig. 2. refers to the system used by S. Seni et al, 2020. [7]. It is an indoor hydroponics project in Malaysia that grow Pak Choy. There were two environmental sensors and two exhaust fans on each planting level on the system to ensure proper air circulation and detection. It's also observed that the reading of sensors values on different levels will be slightly different.

The temperature of the project is set within the allowable operating range of Pak Choy by implementing environment sensors and exhaust fans. The exhaust fans will be operating when exceed the allowable operating range. The project also identified that the temperatures will periodically rise in the afternoon that will cause continuous operation of exhaust fans in the afternoon.

Fig. 2. Temperature and Humidity Controlling System

2.3. *Light Monitoring and Controlling System*

Referring to another study about effects of Artificial Night LED Lighting by L. S. Wei et al, 2019, [8]. The proposed hydroponics system in Malaysia cultured the plant with a 18/6 (light/dark) photo period. Based on Table 1 below, it shows that the plant was cultured with 8hours of artificial lighting and 16 hours with natural lighting that continuously operate until plant maturity day.

Table 1. Light Duration Used in the Study

Natural Light without LEDs Support	Night-time without LEDs Support	Night-time with LEDs support
8am to 6pm	6pm to 12am	12am to 8am

2.4. *IoT Monitoring System*

Fig. 3. shows the overall system setup for the monitoring process. The proposed system is an Arduino Mega based hydroponic system with MQTT protocol to communicate between Arduino Mega and Node MCU for data processing. This system proposed precise monitoring of the nutrient solution's properties, such as electrical conductivity (EC), pH, and temperature, to ensure that the plants receive optimal levels of nutrients.The sensors result will then convert to JSON format and sent to cloud platform for monitoring. Overall, the proposed system is an important step forward in the field of hydroponics farming. It allows for precise and automated monitoring of nutrient solution levels reducing the need for manual labor of the farming process.
Fig. 3. IoT Monitoring Hydroponics System

3. Methodology and Setup

In this section, the monitoring and controlling systems from past research will be presented.

3.1. *Mechanical Design and Setup*

Fig. 4. shows the proposed hydroponics mechanical design with multiple main components. The hydroponic structure is arranged in a horizontal shape which has an overall dimension of around 1.25m x 0.79m x 1.2m (W x L x H) with 2 layers of planting platforms that can cover a total of 72 plants with 38 plants each layer. The system has additionally equipped with two ball valves that can help in controlling the water circulation and water level to void overflow piping [9]. The system has been installed in a chamber for easily controlled environments. The hydroponics system has mainly been using UPVC pipe as the structural material of the design for easily accessible, fabrication and assembly friendly as well as cost effective. Eventually, the chamber is also smaller in size as compared to a 160cm human being.
Fig. 4. Hydroponics Design with Main Components

3.2. *Electrical System Infrastructure*

Fig. 5. shows the proposed electrical schematic designed with Proteus. The proposed design has utilized ESP32 as the mainboard and different sensors such as the DHT11 for temperature and humidity sensing, the YF-S201 for water flow rate sensing, a water level sensor for nutrient level sensing, as well as light sensor module for light intensity sensing. Relays and actuating devices have been used to control the system automatically. In general, the total cost of components required to set up the system is about RM185.60

3.3. Software System Flow

Ventilation Flow Chart

Fig. 6. shows the hydroponics system monitoring and control flow chart. The main controller, an ESP32, will retrieve data from the sensor, DHT11. The ventilation fan will turn on when the temperature have reached the threshold set, vice versa. Meanwhile, the main microcontroller will then publish that data to the Arduino cloud to allow real-time monitoring for the user.
Fig. 6. Auto Ventilation Flow Chart

Grow Light Flow Chart

Fig. 7. shows the hydroponics system monitoring and control flow chart. The main controller, an ESP32, will retrieve data from the NTP servers and LDRs sensors. The LED strips will turn on when the time has reached the threshold set, vice versa. Meanwhile, the main microcontroller will then publish that data to the Arduino cloud to allow real-time monitoring for the user.
Fig. 7. Auto Grow Light Flow Chart

Nutrient Level and Water Flow Rate Flow Chart

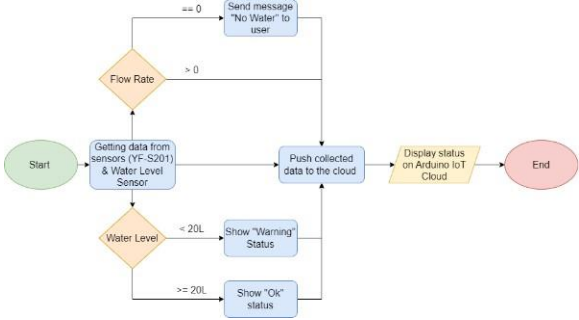
Fig. 8. shows the hydroponics system monitoring and controlling flow chart. The main controller, an ESP32, will retrieve data from the water flow and water level sensors. The monitoring system will notify the user when the water level and water flow has reached the threshold set. Meanwhile, the main microcontroller will then publish that data to the Arduino cloud to allow real-time monitoring for the user.


Fig. 8. Auto Grow Light Flow Chart

4. Results and Discussion

4.1. Testing, Analysis and Validation

Table 2 below shows the comparison of measured voltage and actual voltage of power supply pin on the microcontroller. The percentage error of most pins is within an acceptable range. However, the percentage error for the 3V pins is 10.33%, indicating that there is an issue with the expansion board. This might be due to the voltage drops across the pcb trace of the used expansion board. Nonetheless, since the measured voltages are 3.31V, it is possible that there is wrong labelling on the

board. The 3V pins will be used as a 3.3V power supply to the system.

Table 2. Measured Voltage and Actual Voltage

Input	Pin Symbol	Measured Voltage (V)	Actual Voltage (V)	Percentage Error (%)
5V 2A	VIN	4.98	5.00	0.40
	5V (1)	4.92	5.00	1.60
	5V (2)	4.91	5.00	1.80
	3.3V	3.31	3.33	0.60
	3V (1)	3.31	3.00	10.33
	3V (2)	3.31	3.00	10.33

Temperature And Humidity Testing and Analysis

Table 3 and Table 4, Are showing the comparison of temperature and humidity of used sensor and measurement tools. The results are retrieved every 5 minutes until 30 minutes. Based on the results, it is observed that the temperature measurements have an average percentage difference of 1%. Nevertheless, humidity measurements have an average percentage of 3.53%. Both measurements are relatively acceptable.

Table 3. Measured and Actual Temperature

Input	No	Temperature (°C)		% Difference
		DHT 11 Sensor	Measuring Tool	
23°C	Initial Data	23.50	23.20	1.29
	Data at 5 Minutes	23.40	23.20	0.86
	Data at 10 Minutes	23.40	23.20	0.86
	Data at 15 Minutes	23.30	23.10	0.87
	Data at 20 Minutes	23.30	23.00	1.30
	Data at 30 Minutes	23.20	23.00	0.87
Average Error Percentage Difference (%)				1.00

Table 4. Measured and Actual Humidity

Input	No	Relative Humidity (%)		% Difference
		DHT 11 Sensor	Measuring Tool	
23°C	Initial Data	60	58	3.45
	Data at 5 Minutes	59	57	3.51
	Data at 10 Minutes	59	57	3.51
	Data at 15 Minutes	58	56	3.57
	Data at 20 Minutes	58	56	3.57
	Data at 30 Minutes	58	56	3.57
Average Error Percentage Difference (%)				3.53

Table 5 and Fig. 9 are for the Water Level Testing and Analysis. It shows the ADC reading of the water level sensor corresponding with the height of the measuring tools. The ADC input channels of ESP32 have a 12-bit resolution, this means that analog readings of 0 to 4095 shall be obtained. However, the measured value is only ranging from 0 to 2019 only, this might be due to the corrosion of the water level sensor. The testing results helped in benchmarking the operating range of the water level sensor. Therefore, the water level sensor can be used in this system for water level measurements.

Table 5. Comparison of Level Sensor and Ruler

No	Water Level Sensor (12-bit ADC Reading)	Measuring Tools (cm)
1	0	0
2	976	1
3	1454	2
4	1703	3
5	2019	4

Ammar A. M. Al-Talib, Tew Hwa Hui, Sarah 'Atifah Saruchi, Noor Idayu Mohd Tahir, Nor Fazilah Binti Abdullah
Fig. 9. Actual Water Height Correspond to 12-bit ADC

For the water flow rate sensor testing and analysis, a mathematical equation is used to calculate the flow rate of the system is as follows, [6].

$$Flow\ Rate\ (L/min) = \frac{Sensor\ Frequency\ (Hz)}{7.5}$$

Based on Fig. 10, the obtained data suggests a linear relationship between the valve angle of rotation and the water flow rate, this proves that the water flow rate increases with increasing the valve angle. The R^2 value of 0.9635 indicates that the data points are well-fitted to the linear regression line, indicating that the valve angle and water flow rate have a significant correlation.
Fig. 10. Relationship of Valve Angle and Water Flow Rate

For the Light Intensity Testing, and based on the measurement conducted by comparing the light intensity sensor and lux meter in Table 5, it's identifying that the room lights itself is not enough to supply enough light intensity on the hydroponics system. The percentage difference of sensors and lux meter has less than 18% at different room conditions. It indicates that the light intensity sensor can be implemented in this prototype. Nevertheless, it's important to place the hydroponics system near a room that has exposure to sunlight for enough brightness for plants to conduct photosynthesis.

Table 5. Light Intensity Sensor and Lux Meter

Room Condition	Light Intensity Sensor (lux)		Lux Meter (lux)		% Difference	
	Top	Bottom	Top	Bottom	Top	Bottom
Sunlight	128.0	94.0	151.30	105.40	15.40%	10.82%
Room Lights	41.0	17.0	50.0	19.30	18.00%	11.92%
Without Lights	0	0	0	0	0%	0%

For the Relay Testing, Table 6 shows the results of controlling ventilation fan with relay, it is noticed that the ventilation fan will be turned on every afternoon. The fan will be turned off during mornings and nights. This is due to the reason that the ventilation fan will be turned on when reaching the state point.

Table 6. DHT11 and State of Fan

Threshold	Time (a.m. / p.m.)	Temperature of DHT 11 Sensor (℃)	State of Ventilation Fan (ON / OFF)
29.50℃	Morning 9 a.m.	25.40	OFF
	Afternoon 3 p.m.	30.30	ON
	Night 11 p.m.	27.80	OFF

Table 7 shows that the threshold was set, where the LED strips will be only turned on during 12 a.m. to 8 a.m. The LED strips will only turn on when it's midnight.

Table 7. Results of Time and State of LED

Threshold	Time (a.m. / p.m.)	State of LED Strips (ON / OFF)
12a.m. to 8a.m.	Morning 6 a.m.	ON
	Afternoon 12 p.m.	OFF
	Mid-night 1 a.m.	ON

4.2. Hardware Assembly and Implementation

Fig. 11. shows the detail of the placement of the electrical components. All the electronics components are placed in an enclosure to prevent direct contact with the water and easy for maintenance. The temperature sensor is located on the top layer of the hydroponics system. Meanwhile, there is also a light intensity sensor that is placed nearby. The second light intensity sensor is placed on the second layer. Next, the water flow rate and water level sensor are placed along the flow of circulation and inside the nutrient container. The ventilation fan is placed on the front of the chamber due to the reason that it can provide the lowest wire connection distance.

Fig. 11. Placement of Electrical Components

Final Implementation

Fig. 12. shows the final assembly of the hydroponics system. The assembly of the hydroponics system started with the structure, continued with circulation channels, chamber and finally electrical and electronics system.

Fig. 12. Mechanical Final Assembly

4.3. Software and Interface Implementation

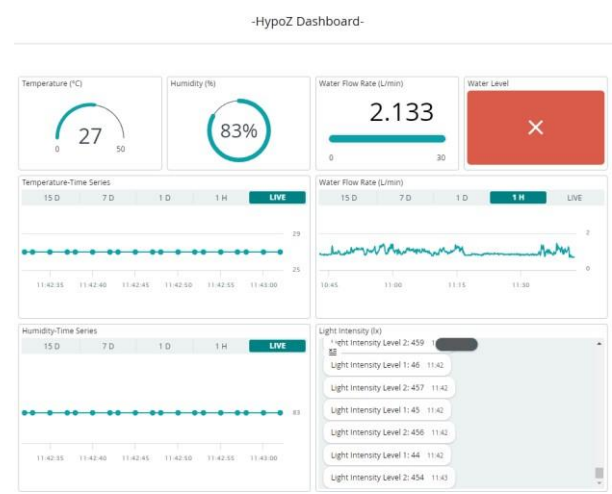
Fig. 13. and Fig. 14. shows the Arduino IoT cloud dashboard and mobile app that measures the temperature, humidity, water flow rate, water level and light intensity on top and bottom layer. There is only one page of the dashboard and app interface of the system for user friendliness. The top part of the interface shows the measurement values and status of sensors in real time. Meanwhile, the bottom part of the interface shows the measurement values retrieved over time.


Fig. 13. Web Interface of Arduino IoT Cloud System

Fig. 14. App Interface of Arduino IoT Cloud System

4.4. Hydroponic System Comparison

Table 8 shows two different similar commercial solutions as compared to the proposed system which are all solutions to indoor agriculture. It can be seen obviously that the proposed system offers more features with a monitoring and controlling system. Yet, remaining significantly cheaper and affordable to anybody to venture into agriculture.

Besides that, the proposed system has a medium power consumption as compared to the Grow IT premium kit. This indicates that the system has consumed less energy and power.

In general, the proposed system provides a cheaper and more features alternative for indoor farming, which is also suitable for growers that just started to venture into agriculture.

Table 8. Comparison of Hydroponics System

Similar Work or Commercial Solution	HypoZ	City Vertical Farm L	GrowIT Premium Kit
Plant Capacity	72	48	70
Volume	1.19 m^3	1.48 m^3	1.31 m^3
IoT Solution	Yes	None	None
Light Monitoring	Yes	None	None
Temperature Monitoring (M) and Control (C)	M and C	None	None
pH Monitoring (M) and Control (C)	None	None	None
Power Consumption	58.665 W	18 W	120 W
Price Information	RM 700.07	RM 2899.00	RM 2999.00
Vendor	Self Developed	CityFarm	GrowEatWell

5. Conclusion

The designed and tested prototype has shown successful results in achieving the objectives of this project. There is still room for improvements. It is recommended that the hydroponics structure can be attached with additional features such as air- conditioning and humidity controlling devices to effectively control the growing environment of the plants. Besides, features like pH and EC monitoring and controlling devices can be equipped, this may help to adjust accurately nutrient solutions up taken by the plants.

Abstract

This study explores the use of a solar driven water pump. PV technology replaces conventional electricity and diesel pumps by using solar energy to power DC or AC water pumps. The main objective of this study is to design and construct a solar-powered agriculture water pumping system and to evaluate its performance. The solar agriculture water pumping system used in this project consists of a 40-watt monocrystalline solar cell with an efficiency conversion of between 23% – 24%. This can supply power to a 16.8 W DC Flow Submersible Pump. It could lift the water up to 5m and a flow range of 700 Liter/Hour. The system also includes a PWM 30A Solar Charge Controller to regulate the input power to a 12V, 7.2A Sealed Rechargeable Battery. Finally, a 20m long watering kit with nozzles irrigation system is connected to a 12V DC Submersible Pump to water the plants.

Keywords: Solar panel, water pumped, renewable energy, irrigation system, SPVWPS.

1. Introduction

Electricity is an essential element of nature and a widely utilized form of energy that is vital for various human activities, such as lighting and work. With the ever-increasing global population, energy consumption has surged significantly in recent times. From 2005 to 2014, global energy consumption increased by 18%, and it is expected to grow by 35% by 2035 [1]. Renewable energy sources, including biofuel, waste, hydro, solar, wind, geothermal, and thermal, Comprise merely 13% of global energy consumption. Fossil fuels, such as natural gas, coal, and oil, make up 81%, while nuclear power contributes only 5.7% [2]. Sustainable energy, such as water, sunlight, and wind, is a solution that has no harmful impact on the environment and contributes to achieving sustainable energy goals [3]. The sun is the most significant power source on Earth, providing more energy in one hour than all nations produce in a year. It delivers over 15,000 EJ of energy to the planet every day, which is more than 104 times the daily energy used by human activities [4]. However, only 0.1% of the sun's energy is consumed for electricity [5]. Alexandre-Edmond Becquerel observed the PV effect for the first time in 1839 [6]. The initial contemporary silicon solar

Ammar A. M. Al-Talib, Noor Idayu Mohd Tahir, Ain Atiqa Mustapha, Amar Ridzuan Abd Hamid, , Sarah 'Atifah Saruchi, Yazan Shebli Ibrahim

cell was invented by Russel Ohl in 1946 [7]. Despite technological advancements, solar power installation costs five times more than coal, gas, or nuclear sources for electricity generation [8]. Agriculture is one of the important sectors in emerging nations. According to a World Bank estimate, rural agriculture areas employ nearly 86 percent of the global population (World Bank,2008). High water consumption coincides with periods of high solar irradiation. As a result, PV water pumping can help to alleviate the water shortage problem [9]. Climate change and population growth cause droughts and agricultural losses, prompting farmers to adopt solar-powered irrigation systems as an alternative energy source [10]. The world is facing a crisis in water and energy, both of which are critical for agricultural productivity. To cater to the needs of an expanding populace, a sustainable solution is necessary. The employment of solar photovoltaic water pumping systems is a feasible and economical substitute, especially in distant and undeveloped regions of developing nations. With continual innovation, these systems have gained widespread use in the industrial, residential, and agricultural sectors [11]. Solar Powered Photovoltaic Water Pumping Systems (SPVWPS) offers an alternative to traditional water pumping systems that rely on non-renewable sources like diesel, coal, and gas for electricity. Diesel systems require a lot of fuel, cause noise pollution, and result in environmental problems such as acid rain and greenhouse emissions [12]. Replacing diesel pumps with solar PV pumps costs 2-4 times as much. SPVWPS have eco-friendly operations and low maintenance costs [13]. Solar water pumping systems are in the nascent phase of development and require addressing several obstacles, including intermittent performance, steep upfront expenses, low efficiency of 15%-16%, and weather conditions that affect sun availability. Sun availability is not constant, and it varies from day to day, making it difficult to rely solely on solar power [14]. The performance of SPVWPS relies on factors such as the number of solar panels used, the type of controllers employed, and the energy storage system utilized. The pump, PV array adjustment, and ambient conditions also impact system efficiency. The maximum conversion efficiency of solar panels is 18%, and controllers like MPP tracking and charge controllers can increase efficiency and battery life. As SPVWPS only generates electricity during daylight, energy storage systems are used [15].

2. Methodology and Experimental Setup

The experimental setup comprises a 40-watt monocrystalline solar panel that generates a 12V DC output and 1.5A current. This panel is linked to a 30A PWM solar charge controller featuring an LCD controller and dual USB, which regulates the charging of 12V sealed lead-acid batteries with a 7.2AH capacity connected to the system. In addition, the charge controller

is connected to a 12V DC submersible pump for water flow. This pump has a power range of 16.8W to 26.4W, a Nylon PA66 shell is placed in a 20L water tank. It can deliver a flow range of 700 to 800L/H and is programmed to operate at specific times via a timer. The pump is connected to a 20m water pipe and is part of a watering kit that includes spray nozzles, and tee connectors, designed for plant irrigations. Fig. 1 depicts the overall prototype.

Fig. 1 Solar agriculture water pumping system prototype

2.1. Design of solar agriculture water pumping system

The design of the system is presented in Fig. 2 SolidWorks has been employed to produce a detailed representation of the design. The external frame of the system is constructed using wood. Additionally, two sheets of plywood, each measuring 40cm by 45cm, are used as supporting pieces. One of these pieces accommodates the solar panels, while the other houses the battery, charge controller, and timer. A submersible pump located inside the water tank and the tank itself are other essential components of the system.
Fig. 2 Different views of the prototype

The overall connection is illustrated as a block diagram in Fig. 3. To acquire an accurate experimental result and compare it to the theoretical outcome.
Fig. 3 Overall connection of the prototype.

3. Results and Discussion

In this section, Table 1 presents the average results for the three different solar panel orientation angles, with two different direct solar radiation of 854.3 W/m2 and 542.7 W/m2. Table 2 presents the average results of charging duration, solar panel voltage input, solar panel current input, and solar irradiations when the solar panel of three different tilt angles was placed directly under the sun. Additionally, Fig. 3 is displaying the average results of voltage drops, the discharge rate of water under two different conditions of discharge (nozzles connected to hoses of different lengths and free discharge), and the time required for the battery to be fully discharged. The readings shown in Table 3 are taken with a constant water volume of one litre per minute.

Table 1. The average readings throughout different tilt angles at Indoor two constant solar flux values.

Angle (°)	Direct solar radiation of 854.3 W/m^2				Direct solar radiation of 542.7 W/m^2			
	Charging Duration (Hour)	Solar Panel Voltage Input (V)	Solar Panel Current Input (A)	Light Intensity (W/m^2)	Charging Duration (Hour)	Solar Panel Voltage Input (V)	Solar Panel Current Input (A)	Light Intensity (W/m^2)
16	10	12.64	0.72	693.2	20	12.28	0.36	367.7
25	11.8	12.36	0.61	585.7	27.7	12.17	0.26	340.9

Table 2 .The average outdoor readings through different tilts angle of solar panel

Angle	Charging Duration (Hour)	Solar Panel Voltage Input (V)	Solar Panel Current Input (A)	Solar Irradiances (W/m^2)
16°	5.76	12.68	1.25	961.67
25°	6.79	12.64	1.06	896.3
45°	7.58	12.44	0.95	783.5

Table 3. Overall average results for hoses of different lengths

Tube length	Voltage output (V)	The discharge rate of water using a nozzles (L/min)	The discharge rate of water without a nozzle (L/min)	battery fully discharge (hours)
5m	13	0.866	1.44	3.5
10m	12.98	0.636	1.10	3.28
15m	12.94	0.566	0.75	3.03
20m	12.9	0.458	0.625	2.47

3.1. *Light Intensity*

Fig. 4 illustrates the light intensity recorded by the solar panel at different tilt angles. As the tilt angle increases, the amount of light received by the panel decreases significantly, particularly when the light source is positioned further away from the solar panel. This reduced light exposure results in a diminished input of voltage and current, ultimately leading to a lower power output generated by the solar panel.
Fig. 4 Light intensity vs different tilt angles at two different indoor direct solar radiations

3.2. *Solar Irradiations*

Fig. 5 illustrates the solar panel's received solar irradiance at various tilt angles when placed directly under the sun.
Fig. 5 Solar irradiance received at various tilt angles

Furthermore, it is observed that the solar panel receives the most radiation when placed at a smaller tilts angle, which leads to the generation of more power this can be seen in Fig. 6. Hence, it can be concluded that the tilts angle of the solar panel has a significant impact on the amount of radiation received and the subsequent power generated.
Fig. 6 Time required to charge battery against the state of charge at direct solar radiation of 854.3 W/m2

3.3. *Time required to charge the battery.*

In Fig. 6, the charging duration of the battery for three different tilts angles is shown as up to 10 hours when the height difference between the solar panel and the 1000-watt halogen bulb is 50 cm. Similarly, Fig. 7 illustrates the charging duration of the battery for the same tilt angles, but up to 20 hours and when the height difference is 70 cm. Furthermore, in Fig. 8, the duration to charge the battery for six hours is exhibited when it is situated directly under sunlight.
Fig 1. Time required to charge battery against the state of charge at direct solar radiation of 542.7 W/m^2
Fig 8. Time required to charge battery against the state of charge under outdoor sun light

Fig. 6 and Fig. 7 illustrate that the differences in the time required to charge the battery can be attributed to the amount of current generated by the solar panel, which is related to the amount of radiation received by the solar panel.

3.4. *The discharge rate of water*

Fig. 9 illustrates the collective findings of the water discharge experiment conducted with hoses of varying lengths and nozzle openings. The experiment involved the flow of one litre of water per minute from a 20L water tank. The presented results are based on the different percentages of nozzle openings tested.
Fig 9. Discharge rate of water against nozzles of different percentage opening

According to Fig. 9, the highest water discharge rate achieved is approximately 0.95 L/min, which occurred when a 5m long hose is connected to the nozzle while maintaining a 100% opening. Conversely, the slowest water discharge rate of 0.4 L/min is observed when the hose is 20m long, and the nozzle opening percentage is 20%, unlike the hoses of 10m and 15m lengths. It is worth noting that friction between the water and the hose's inner surface, as well as changes in elevation or flow direction, contribute to losses in water pressure, known as head loss, during water pumping through a hose. Consequently, it can be inferred that hoses with smaller nozzle opening percentages offer more resistance to water flow, which leads to reduced water pressure and discharge rates.

3.5. *Maximum height water can reach*

Fig.10 presents the findings obtained by using hoses of different lengths which are 0.5m, 1m, 1.5m, 2.0m, 2.5m, and 3m to determine the maximum height that water can reach using a 12v DC submersible pump.
Fig. 2 The discharge rate of water against hoses of different heights

The graph shows that the pump can lift water to a maximum height of 3m with a discharge rate of approximately 0.321 l/min, while the minimum height of 0.5m has the fastest discharge rate of water at around 1.95 l/min. This indicates that the pump's lifting ability decreases as the height of the hose increases, resulting in a decrease in the water discharge rate. This is due to the longer hoses creating more resistance and reducing the flow rate.

4. Conclusion

The designed prototype for a solar irrigation system has been fabricated and tested. The study indicates that more solar radiation will result in higher charging power, which is useful for running the solar irrigation system. Additionally, the system is capable of pumping water up to 20 meters by fully utilizing solar energy.

To maximize the efficiency of the system, it has been found that the solar panel should be tilted at an appropriate angle for each location, which enables the collection of more solar energy and facilitates faster battery charging. Moreover, the system is capable of pumping water up to a height of 3 meters.

To maintain long battery life, it has been found that shorter irrigation pipes are more suitable. Furthermore, the study revealed that the solar collector efficiency is 80%. Overall, the designed solar irrigation system has demonstrated its capability in achieving its intended objectives, and the findings of the study have provided valuable insights for future system improvements.

Abstract

Treadmills are one of the most popular training equipment in the gym and at home. The working principle of treadmills is by moving the belt with the human knee bending, which creates mechanical energy to turn the belt. A gear or pulley and belt system connects to the generator along the axel line of the rolling bars. The power generated by the DC generator is stored in a battery pack and could be used to charge phones or other equipment. It has been found that treadmills can provide an efficiency of 95% when the DC motor is used and 92% when the AC motor is used. The main objective of this study is to design and fabricate a powder-generating manual treadmill and to analyze the performance of the system under different operation conditions.

Keywords: Manual Treadmills, Gym Renewable Energy

1. Introduction

In 2015, the United Nations General Assembly established the Sustainable Development Goals (SDGs), which consist of 17 objectives to be accomplished by 2030. SDG 7 aims to provide affordable, reliable, sustainable, and modern energy for all [1] This goal is especially relevant during the COVID-19 pandemic, as measures such as movement control orders (MCO) have significantly increased residential energy consumption while commercial and business energy consumption has

decreased [2]. Impact of the MCO on electricity consumption has shown a sharp increase in residential electricity consumption [3]. To address this issue, the treadmill, which has become a popular fitness equipment for both home and gym use, can be modified to generate electricity. Originally the treadmill consumed energy to operate [4]. The treadmill consists of a wide belt driven by a variable-speed motor. However, by connecting it to a generator or an inverter, the kinetic energy generated by a person walking or running on the belt can be converted into electrical energy. This energy can then be used to power various devices or fed back into the power grid,

Ammar A. M. Al-Talib, Sarah 'Atifah Saruchi, Cik Suhana Hassan, Nor Fazilah Abdullah, Ain Atiqa Mustapha, Ahmad Jelban

making the treadmill a potential solution to the increased energy consumption during the pandemic [5].

2. Methodology and Experimental Setup

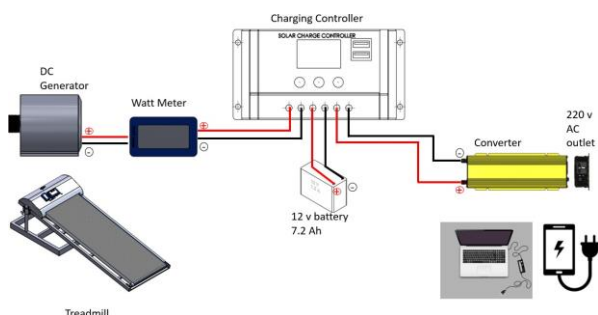
As shown in Fig. 1, this experiment is set up with a 36 V DC generator that is driven by a pulley linked by a belt, with the main motion generated by the user walking or running on the treadmill belt [6]. The generator is connected to a charging control that regulates the voltage and current supplied to a 12 V, 7.2 Ah battery. The battery then supplies a 200 W inverter, which converts DC to AC power that can be used to charge devices such as phones and laptops. A Watt meter is connected between the generator and the charging controller to measure the current and voltage produced by the generator.


Fig. 1 Connection Illustration of The Setup

2.1. Design and Modifications

As the treadmill was already made, modifications are required to convert the regular treadmill to manual one that is able to generate electricity. The modifications can be summarized as an assembly of a jack to have an incline, support for the side, generator base, motor pulley and treadmill roller. Fig. 2 shows the treadmill before modifications.

Fig. 2 Treadmill Before the Modifications

Fig. 3 shows the modified treadmill at its charging status.

Fig. 3 Charging Laptop from The Treadmill Battery

3. Results and Discussion

In this section, Table 1 shows the average results of 3 different people who tested the prototype. The results are the readings from the watt meter for the voltage and current while the average speed is from the speedometer after 5 minutes of walking on the treadmill. As stated, before the treadmill is not motorized, therefore the speed is not constant, and the only way to maintain a constant speed is dependent on the person himself. However, the adjustment of pace was constant to maintain a relatively constant speed.

Table 1. Average Speed for The Three Testers

	Person 1	Person2	Person 3
Speed (km/hr)	2.24	3.12	5.05
Current (A)	0.56	0.86	1.19
Voltage (v)	12.18	12.53	13.24
Power (W)	6.81	10.63	15.43

3.1. Discussion

Fig. 4 shows the average result for the three-persons. The results are combined in one graph, in terms of speed (km/hr), current (A), Voltage, and power (W).
Fig. 4. Average Results for The Three Persons

From Fig. 4, it can be noticed that the higher the speed the higher the voltage and current, and accordingly the power generated. The data represents the average speed that has been achieved by each user. The voltage and current generated by the lowest speed of 2.24 km/h are 12.18 v and 0.56A respectively. This speed can be achieved by anyone as it is within the normal walking speed. Speed 2 of 3.2 km/h induced a voltage of 12.53 v and a current of 0.86 A. The results are the average of the 3 trials by each person. And lastly, speed 3 which is the average of the highest speed that can be achieved at 5.05 km/h induced a voltage of 13.24 v and current of 1.19 A. Taking into consideration that the maximum current to charge the battery as recommended by the manufacturer is 0.1 to 0.25 of the battery capacity. The current achieved falls within these values. Based on the results, it is evident that there is a direct relationship between the speed, voltage, current, and power output of the manual Treadmill. When the speed of the person increases, the voltage and current generated also increase, resulting in higher power output.

3.2. Theoretical Current

From the generator specifications the RPM rating is 3400, while the current is 9.5 A for the 36 v. the generator efficiency is stated to be 78%. Eq. (1) is used to calculate the current produced by 1 RPM.

$$Current = \frac{I}{RPM} \tag{1}$$

The treadmill belt is connected to the roller pulley with a ratio of 1:20 which is measured experimentally. The ratio between the roller pulley and the generator pulley can be calculated using Eq. (2) to Eq. (5):

$$\frac{D_r}{D_m} = \frac{95}{35} = 2.7 \tag{2}$$

$$Roller\ Pulley\ RPM = \frac{speed(m/s)}{\pi D} \tag{3}$$

$$For\ Motor\ RPM = Roller\ Pulley\ RPM \times 2.7 \tag{4}$$

$$For\ Current\ generated\ current = current\ (\frac{A}{RPM}) \times Motor\ RPM \tag{5}$$

From Eq. (1) for each rotation of the generator, a current of 0.0029 A will be produced. The motor efficiency is 78% as stated by the manufacturer, which will be considered when calculating the current. The average speed in Table 2 will be considered for these calculations.

Table 2. Average Speed Current Calculation

	Speed 1	Speed 2	Speed 3
Speed (km/hr)	2.24	3.12	5.05
Speed (m/s)	37.28	52.0	84.11
Roller (RPM)	125.0	174.14	282.0
Motor (RPM)	337.41	470.16	761.31
Current (A)	0.91	1.27	2.06
Current with 78% efficiency	0.71	0.99	1.61

Eq. (6) is used to calculate the efficiency for actual current and theoretical current.

$$current\ efficiency =$$
$$= (1 - \frac{theoretical\ current - actual\ current}{theoretical\ current}) \times 100 \tag{6}$$

Table 3. Actual Current and Theoretical Current Efficiency

Actual Current (A)	0.56	0.87	1.19
Current with efficiency	0.71	0.99	1.61
Efficiency	78.88%	87.88%	73.91%

From Table 3, it can be noticed that the produced current is less than the theoretical current and that is due to the losses due to friction during the experiments.

4. Conclusion

In conclusion, the prototype of the manual treadmill is able to operate and generate electricity of different values depending on the walking/ running speed of the user as it is directly connected. The results have shown that the faster the walking on the treadmill, the higher the current generated which is required to charge a battery for later use. The average 3 speeds are 2.24 km/h, 3.12 km/h, and

Ammar A. M. Al-Talib, Sarah 'Atifah Saruchi, Cik Suhana Hassan, Nor Fazilah Abdullah, Ain Atiqa Mustapha, Ahmad Jelban

5.05 km/h which have generated a current of 0.56A, 0.86A, and 1.19 A respectively. While the voltage for the 3 speeds is 12.18 v 12.53 v and 13.24 v. For the application of the manual treadmill, 3 devices with different battery capacities have been tested. The devices are a smartphone, a smartwatch, and a laptop, with batteries capacities of 4200 mAh, 455 mAh, and 56 Wh respectively. After testing using USB and a normal charger it has been found that the 7.2 Ah battery can charge the smartform 4.8 times, the smartwatch 44.6 times, and the laptop 1.5 times. However, it is important to note that the manual treadmill is designed to be an affordable and accessible option for exercise beside being successful in generating electrical power. The findings of this research align with target 13.2 of the SDG's, which emphasizes the integration of climate change measures into policies and planning.

Abstract

This research explores the integration of smart technologies in traditional car jacks, aiming to enhance efficiency and user safety. By incorporating sensors and automation, the smart car jack introduced in this study not only streamlines the lifting process but also provides real-time data on load distribution and stability. ethodologically, the study involves the design, prototyping, and testing of the smart car jack, assessing its performance in various scenarios. Results demonstrate a significant reduction in lifting time and improved safety measures, positioning the smart car jack as a viable innovation in the automotive industry. The implications of this technology extend to increased convenience for users and a potential reduction in roadside accidents. This research contributes to the ongoing evolution of automotive tools and underscores the benefits of merging smart technologies with traditional equipment.

Keywords: Internet of Things; Car Jack, Smart, ESP32

1. Introduction

This paper addresses the challenges of roadside emergencies, such as flat tires, and the limitations of conventional scissor car jacks that require physical effort and can lead to backache problems. To tackle these issues, the paper presents a modified car jack design that is safe, easy to operate, and reduces physical effort for lifting and lowering vehicles during automobile repair, especially for roadside situations. The study explores the integration of Internet of Things (IoT) technology in automotive tools, particularly in the development of smart car jacks. The aim is to revolutionize the traditional car lifting process, making it smarter, safer, and more efficient. By incorporating IoT, the proposed smart car jack offers convenience and enhanced control over vehicle maintenance tasks [1].This paper introduces a novel smart car jack design that leverages IoT technology to improve the efficiency and safety of roadside repairs, alleviating the burden on car owners during emergencies. The focus is on developing a user-friendly and cost-effective solution that can significantly reduce the physical effort required for car maintenance tasks [2].

2. Methodology and Experimental Setup

A. Software and microcontroller

In this project, software holds a pivotal position in designing and developing a smart car jack with Internet of Things (IoT) capabilities. To achieve the project's objectives, the software utilized includes the Blynk platform and the Arduino Integrated Development Environment (IDE) [3]. Blynk serves as a mobile platform, enabling remote control of various hardware modules like Arduino and ESP32 over the internet. With Blynk, developers gain access to an array of features, empowering them to control hardware components, store, and display data, visualize

Noor Idayu Mohd Tahir, Ammar A.M. Al-Talib, Zeiad Mahmoud Ebeid Abdelghaffar, Cik Suhana Hassan

information, and more. It simplifies the process of connecting input/output components with hardware devices and facilitates seamless data transfer between them. The Blynk server, functioning as a cloud-based backend service, establishes communication between the smartphone application and the hardware, making it highly convenient for developers to manage and control their IoT systems efficiently [4]. In this project, the ESP32 is utilized as the primary microcontroller. The ESP32 is a powerful and versatile microcontroller that operates using the Arduino IDE, an open-source software platform for writing and uploading code to Arduino boards.

The ESP32, integrated with the Blynk platform, allows for enhanced remote control and monitoring of the smart car jack's hardware components.
Fig. 1. Prototype Design

To establish the connection between the ESP32 and the Blynk platform, the Blynk library was installed in the Arduino IDE [5].This library provides an interface for seamless communication between the ESP32 and the Blynk cloud server and mobile application. Once the library is installed, developers can utilize the Blynk API to program the ESP32, enabling control and real-time monitoring of the smart car jack's various hardware functionalities [6].

B. Prototype Design

This section presents the final design for the smart car jack project, as depicted in Fig. 1. The design features a scissor jack prototype mounted on a movable base, allowing for increased mobility. The prototype is equipped with mecanum wheels driven by a DC gear motor, transforming it into a smart car jack. To control the lifting mechanism, a steel rod is connected to a stepper motor, which receives instructions from the microcontroller, ESP32. The components of the design, except for the steel rod, are 3D printed using robust PLA+ (Polylactic Acid) material, renowned for its improved mechanical properties like enhanced

toughness and impact resistance compared to standard PLA. This ensures the smart car jack's stability and durability during the car lifting process. The final design incorporates a movable scissor jack prototype with mecanum wheels, operated by a stepper motor controlled by the ESP32 microcontroller. The use of PLA+ material for 3D printing ensures the structure's strength and ability to withstand the pressure exerted during the lifting operation.
Fig. 2. System wiring diagram.

C. Coding and Programming

The code implemented in this project outlines the core functionalities and control logic of the Arduino sketch for the IoT-enabled car jack. It begins by including essential libraries for Wi-Fi communication, Blynk (the IoT platform), and Stepper motor control. The Blynk template ID, obtained from the Blynk website, along with the name and authentication token, is defined to establish communication with the Blynk app. Wi-Fi credentials are set to connect the ESP32 board to the network. In the setup function, the code connects to Wi-Fi, initializes Blynk, and sets up the motor control pins, ensuring the motors start in a stationary state. The loop function continually checks for incoming commands from the Blynk app through virtual pins. Corresponding functions are executed to control the car jack's movements or perform other desired actions. Additional functions are defined for precise motor control, including forward, backward, left, and right movements. The Stepper1 function governs the stepper motor's rotation based on specified parameters for direction and the number of rotations required [7]. This pseudocode provides a concise overview of how the IoT-enabled car jack interacts with the Blynk app, processes input commands, and controls the motors to achieve specific movements.

D. Connections

Fig. 2 illustrates the interconnected setup of the Smart Car Jack Prototype, comprising two power supplies, three motor drivers, one stepper motor, four DC gear

motors, and the ESP32 microcontroller. The motor drivers are connected to the power supply and the respective motors, with specific pins interfacing them to the ESP32 for control signals.

Regarding the stepper motor, pin connections were established using pins 25, 26, 21, and 19 as IN1, IN2, IN3, and IN4 for its motor driver. These specific pins allow precise control and coordination of the stepper motor, significantly contributing to the overall functionality and performance of the Smart Car Jack Prototype.

3. Results and discussion

Tests to analyse the performance of the smart car jack: A. Prototype efficiency on different ground surfaces. Table 1 shows the car jack performance while moving on different surfaces, The prototype demonstrated varying speeds on different surfaces. It achieved the highest average speed of 0.41 m/s on asphalt, performed moderately on grass with an average speed of 0.23 m/s, but encountered challenges on sand, getting stuck in all trials and unable to complete the one-meter test. Surface conditions significantly affected its mobility and effectiveness [8].

Table 1. Test Results

Surface	Time taken (s)	Average speed (m/s)
Asphalt	2.46	0.41
Grass	4.32	0.23
Sand	Failed to finish	-

B. Analysing the performance of the car jack with no load.

The data of the car jack with no load has been tabulated in Table 2 and illustrated in Fig. 3 which shows that the car jack's consistent and efficient performance in both jacking up and jacking down processes without any load. The mechanism is well-calibrated and operates smoothly, ensuring reliable and convenient operations for users during routine tasks [9].

Table 2. Test Results

Trial Number	Time taken (s)	
	Jack Up	Jack Down
1	14.23	13.34
2	13.58	12.56
3	13.45	13.13
Fig. 3. The performance of the car jack with no load

C. Analysing the performance of the car jack with different loads.

The results reveal that the jacking up time increases with the load on the jack, indicating a direct relationship between them. Conversely, the jacking down time decreases as the weight applied to the prototype increases, showing an inverse relationship. These results provide valuable insights for optimizing the prototype's performance under varying load conditions, as illustrated in Table 3.

Table 3. Test Results

Weight (N)	Time taken (s)	
	Jack Up	Jack Down
150	23.58	11.54
200	27.34	10.28
250	31.27	9.56

D. Determining the maximum height of the prototype.

This test findings determine the prototype's maximum safe height as 30 cm, beyond which the stability and safety of the car lifting process could be compromised. Establishing this critical height limit provides valuable guidance for users to safely operate the smart car jack, ensuring both user and load safety during lifting operations. Table 4 shows the stability of the car jack with different heights.

Table 4. Test Results

Height (cm)	Observations
15	Completely Stable
25	Stable
30	Stable
35	Risky
40	Not Stable

Noor Idayu Mohd Tahir, Ammar A.M. Al-Talib, Zeiad Mahmoud Ebeid Abdelghaffar, Cik Suhana Hassan

E. Comparison between the jacking up speed of manual scissor car jack and the proposed prototype

The smart car jack prototype reaches its maximum height significantly faster than the manual scissor car jack, thanks to the use of a stepper motor that ensures precise and consistent movements. The elimination of human factors during operation contributes to enhanced efficiency and reliability, making the smart car jack an appealing choice for users seeking faster and more reliable lifting operations, as shown in Table 5.

Table 5. Test Results

Trial Number	Result to accomplish the task jack up and down (s)	
	Manual Scissor Jack	Proposed prototype
1	31.27	12.51
2	27.28	13.13
3	25.46	13.47

4. Conclusion

This study aimed to develop a smart scissor car jack with IoT capabilities, incorporating mecanum wheels and a stepper motor, controlled through the Blynk application. The prototype demonstrated remarkable performance, lifting a 200 N toy car to 30 cm in just 13.13 seconds, outperforming manual alternatives. The success of this project highlights the potential of IoT-integrated automotive tools in enhancing efficiency, safety, and convenience in vehicle maintenance. Future recommendations include improving mobility with larger wheels, implementing intelligent positioning systems, and enhancing safety mechanisms through IoT sensors. These enhancements will transform the smart car jack into an advanced and user-friendly automotive solution for various terrains and vehicles.

Abstract

Global warming remains one of the most detrimental by-products of industrialization. Fossil fuels contribute to the majority of greenhouse gases emitted but remain a popular option for the generation of energy. An easy fix for this conundrum is to utilize other forms of fuel for energy generation which burns cleaner and renewable as opposed to fossil fuels. The aforementioned solution would be to use biomethane generated from waste products which burn cleaner and comes from a renewable source. In this paper, an IoT based biogas monitoring system for biogas reactors is proposed. An ESP-32 microcontroller system is deployed and tested to detect the presence of gas production. A dashboard plotting the data obtained from sensors is designed to help user monitor parameters. Data obtained is automatically uploaded to a Google Spreadsheet for data.

Keywords: Sensors; Biogas monitoring; Microcontroller; IoT

1. Introduction

Fossil fuels have been lambasted for being one of the main contributors of global warming. The burning of fossil fuels releases harmful chemicals into the atmosphere such as carbon dioxide and nitrogen oxides into the atmosphere. Carbon dioxide contributes to the greenhouse effect in which the heat from the sun is trapped in the atmosphere. Since the mid-19th century, the United States alone were responsible for a whopping 29% of carbon dioxide emissions by humans or 328,000,000 metric tons of carbon dioxide [1]. With the increase in temperature comes the melting of the glaciers which results in an increase in sea levels. The world population continues to grow every year, and with that the demand for energy also continues to grow. In big countries such as China, it was estimated that the population in 2021 was 1.43 billion and 543.98 million in 1950 [2]. The increase in population also contributes to the increase in urbanization of a country. With the increase in urbanization comes the increase in energy demand as well. China's energy consumption in 2003

Ian Hoh Wen Yang, Ammar A.M. Al-Talib, Noor Idayu Mohd Tahir, Ayu Haslija Binti Abu Bakar, Nur Muhammad Afifi bin Zainal

reached 1678 million tonnes coal equivalent (or MTCE) where coal consumption took up 67% of the total consumption, oil taking up 23% and hydroelectricity and natural gas being 7% and 3%, respectively [3]. This shows that the burning of fossil fuels remains one of the preferred fuels for energy generation.

With the continuous use of fossil fuels, comes the detriment of the environment and eventual depletion of this fuel source as fossil fuels are not renewable. A promising solution for this is to use biogas as an alternative to fossil fuels. The decomposition of waste products such as animal manure and food wastes through anaerobic digestion of different microorganisms creates biogas as one of the end products of the decomposition process [4]. All that is required by the average household to create their own biogas is an affordable way to monitor the biogas production.

IoT helps connect previously unconnected and dumb physical devices while simultaneously giving them the intelligence to act on a command or situation. It is likely that the integration of IoT technology and other industries can change the mode of economic development, achieve green growth and low-carbon economy [5]. IoT technology has been widely used in environment protection, industry monitoring, food tracing source, logistic trading and other fields [6]. In this paper, a system that utilizes IoT to monitor components in a biogas reactor will be presented.

2. Methodology and Experimental Setup

2.1. *Materials*

Biogas samples were obtained by mixing animal manure and food waste in a blender and then adding inoculum to the solution. Desiccant beads were included in the biogas chamber to remove moisture.

2.2. *Apparatus and Equipment*

The microcontroller used for the data acquisition device is an ESP-32. An MQ-4 semiconductor sensor was used for the detection of methane. An MQ-135 sensor was used to detect the presence of carbon dioxide in the air while a DHT-11 sensor is used for detecting the presence of temperature and humidity. A soldering set was used to create a circuit board for the data acquisition device. IFTTT protocol was used to constantly update a Google Sheets file with the data obtained from the sensors.

2.3. *Prototype Setup*

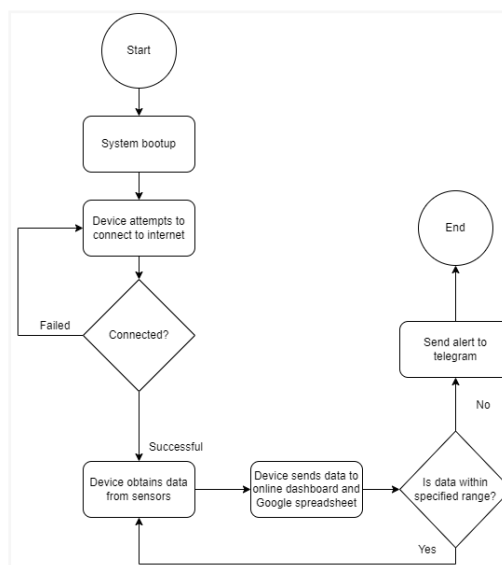
The basic idea of the system is to monitor the biogas generated in the biogas reactor and update the remote database. The microcontroller collects data from the sensors and then sends it to the Blynk mobile application and Google spreadsheets via IFTTT. Fig. 1 shows the overall architecture of the system proposed while Fig. 2 shows the system flowchart. The reactor contains a mixture of inoculum, food waste and rabbit dung. Biogas produced in the reactor travels from the reactor to a mason jar containing the sensors of the data acquisition device.
Fig. 1 Overall System Architecture


Fig. 2 System Flowchart

The data acquisition device is placed together with the biogas reactor. The device measures the methane gas as well as carbon dioxide produced by the biogas reactor and then uploads the data to Blynk's database and a Google spreadsheet via IFTTT. The data can then be viewed on Blynk's dashboard. The data acquisition

device requires an active internet connection to send data. A Telegram bot was created to receive alerts from the device if the data is out of the specified range.

2.3.1 Preheating Process

The MQ-4 and MQ-135 sensors require initial preheating before the sensors provide stable readings. The datasheet advises that the sensors be given a 24-hour period to preheat. The sensors were found to provide stable readings after 12-hours from the start of power on. The subsequent use of the sensors requires roughly 10-minutes of preheating.

2.3.2 Sensor Calibration Process

The MQ-4 and MQ-135 sensors require calibration. After the sensors were preheated and readings stabilized, data from a reference sensor was used to assist in the calibration process. Both readings were compared and the difference in data was compensated for in the code written for the ESP-32 microcontroller.

2.3.3 Data Acquisition Device fabrication

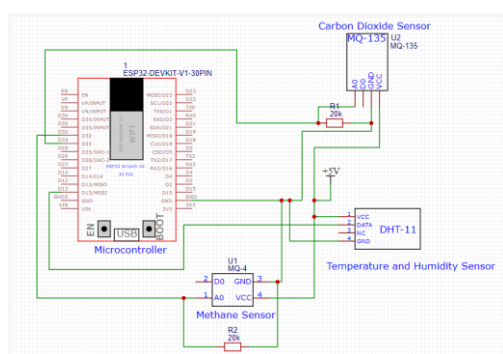
The data acquisition device consists of an MQ-4 sensor to detect methane, MQ-135 sensor to detect carbon dioxide, and DHT-11 to detect temperature including humidity. The microcontroller used for the device is an ESP-32. Fig. 3 shows the circuit diagram of the device.


Fig. 3 Data Acquisition Device Circuit Diagram

2.3.4 Blynk Dashboard and IFTTT

A dashboard was designed to show the data obtained by the device. The dashboard displays the data in the form of a graph and the value at an instance on a gauge. The data is provided in PPM (Parts Per Million) over time. Fig. 4 shows the dashboard as viewed on a computer and Fig. 5 shows the dashboard on the mobile application.
Fig. 4 The dashboard on the computer

Fig. 5 The dashboard on the mobile application

2.3.5 Telegram Alert Function

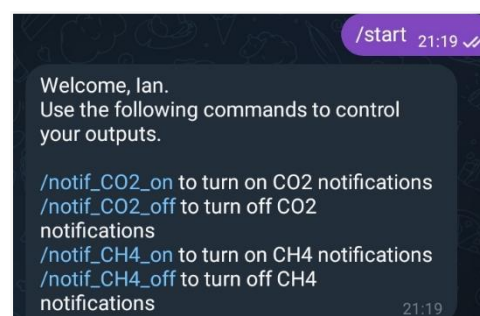
A Telegram message bot was created to receive alerts from the device in an event where a specific condition has been met (Fig. 6). An example of this would be when the methane or carbon dioxide levels drop below a certain level or when methane is detected. When the methane or carbon dioxide levels drop from a high concentration to a lower concentration, it may signify that a leak is present in the chamber and allows the user to perform data-driven decision making.


Fig. 6 Telegram Alert Function

2.3.6 Test Setup

The first prototype was built and tested as shown in Fig. 7. From the labels in Fig. 7, one represents the reference sensor, two represents the biogas reactor containing food waste and animal manure, three represents the sensors in a mason jar, and four represents the microcontroller.

Ian Hoh Wen Yang, Ammar A.M. Al-Talib, Noor Idayu Mohd Tahir, Ayu Haslija Binti Abu Bakar, Nur Muhammad Afifi bin Zainal

Fig. 7 Prototype test setup

3. Result and Discussion

3.1. *Data Acquisition Device*

In determining the sensor's accuracy, the sensor readings of the MQ-4 and MQ-135 were compared to a secondary set of data obtained in clean air and in biogas. The DHT-11 sensor data was compared with another measuring device that measures temperature and humidity.

Fig. 8 shows results of the MQ-4 sensor in clean air. The sensor readings fluctuate slightly when compared to the secondary set of data due to noise. Fig. 9 shows the results of the MQ-135 sensor in clean air. The data shows a similar trend when compared to the secondary set of data in clean air. Fig. 10 and Fig. 11 shows the comparison between the data obtained by the DHT-11 sensor and the reference measuring device. It was found that the temperature data from the DHT-11 sensor deviated about two degrees Celsius while the humidity data was found to deviate about three percent. As the data of the MQ-4 and MQ-135 fluctuates drastically, a tabulation of data was created for comparison (Table 1).
Fig. 8 Methane comparison graph
Fig. 9 Carbon dioxide comparison graph
Fig. 10 Temperature comparison graph
Fig. 11 Humidity comparison graph

Table 1 Sensor Data in Clean Air

| No. | Sensor Data | | | |
	MQ-4	MQ-135	Reference (methane)	Reference (carbon dioxide)

30	*3*	*440*	*0*	*461*
31	*4*	*465*	*0*	*463*

Fig. 12 shows the results of the MQ-4 sensor in biogas. It was observed that the MQ-4 sensor provided near similar readings compared to the reference sensor until near the end where a leak was likely the cause of the large deviation. Fig. 13 shows the MQ-135 sensor in biogas. The percentage of error was calculated using Eq. (1).

$$Percent\ error = \frac{Act-Meas}{Act} \times 100\% \qquad (1)$$

Where;

Act= Actual reading
Meas= Measured reading

It was discovered that the MQ-4 sensor had an error of less than 6% and was deemed accurate. It was discovered that in higher carbon dioxide concentration, the MQ-135 becomes less sensitive and thus has a 41% error. However, the MQ-135 did detect the presence of carbon

dioxide and is deemed acceptable. The data for Fig. 12 and Fig. 13 were tabulated in Table 2. The readings from the DHT-11 were affected by the heat generated by the MQ-4 and MQ-135. Due to the reference sensor being placed in a separate compartment, the data of the DHT-11 and reference sensor was different and was thus omitted.

*To save space methane and carbon dioxide has been abbreviated to CH₄ and CO₂ respectively.

3.2. Power Consumption

The current draw of the sensors including the ESP-32 were pulled from the data sheet. The power consumption was calculated using Eq. (2).

$$Power = \ Current \times Voltage \qquad (2)$$

Table 3 shows that the estimated power consumption of the device totals up to 2.702W. Although the power was calculated using the maximum rated current draw from the component's respective datasheet, the actual power consumption of the device could potentially be higher due to energy loss in the form of heat.

Table 3 Power Consumption

Component	*Current draw (mA)*	*Power (W)*
MQ-4	*150*	*0.75*
MQ-135	*150*	*0.75*
DHT-11	*0.3*	*0.0015*
ESP-32	*240*	*1.2*
Total	*540.3*	*2.7015*

3.3. Project Cost Analysis

The project cost analysis breakdown is shown in Table 4. Some of the components of the project such as the wires and soldering iron were not taken into account for as the cost is negligible due to only using a small amount.

Table 4 Cost Breakdown

Part name	*Individual Price (MYR)*	*Quantity*	*Total (MYR)*
ESP-32	*15.00*	*1*	*15.00*
MQ-4	*5.20*	*1*	*5.20*
MQ-135	*6.50*	*1*	*6.50*
DHT-11	*4.90*	*1*	*4.90*
PCB	*1.00*	*1*	*1.00*
Mason Jar	*10.00*	*1*	*10.00*
Total			*42.60*

4. Conclusion

The design proposed in this paper is a scalable solution to monitor the production of methane and carbon dioxide within the biogas which are important parameters to determine the efficiency of the biogas reactor. The proposed design was tested and was deemed capable in detecting the presence of biogas and carbon dioxide in the biogas reactor.

Acknowledgment

Ayu Haslija from the chemical side of the university for preparing the biogas samples. A massive thank you to Ir. Noor Idayu Mohd Tahir for supervising this project.

Abstract

This project introduces an IoT-based smart mushroom growing kit to meet the rising global demand for high-quality mushrooms. Various species of mushrooms can be efficiently grown in different environmental conditions with the help of IoT devices that enable farmers to regulate the climate condition according to the specific needs of each type of mushroom. The kit employs sensors and actuators, including temperature, humidity, MQ-135, and ultrasonic sensors, along with an ESP32 camera, controlled by a microcontroller. The collected data is transmitted to an IoT platform via Wi-Fi, facilitating real-time monitoring and control through a user-friendly dashboard on Blynk website and Blynk app. This innovative system optimizes mushroom cultivation by adjusting environmental conditions, offering efficiency and profitability. Users can remotely monitor and regulate the growth environment through their smartphones, enhancing the overall mushroom cultivation experience.

Keywords: Internet of Things; Environmental Condition Control, Mushroom Growing Kit

1. Introduction

With the growth of cities and urbanization in Malaysia, there is a growing demand for sustainable food production within the urban areas. Mushrooms are types of fungi that are known as high protein food which is beneficial for health. Mushrooms were mostly used in health supplements and used as an ingredient in meals to provide nutritional properties to the human body [1]. The demand for mushrooms in Malaysia was expected to increase due to the health awareness among the people increases [2]. Based on Hedley [3], the duration of the complete mushroom life cycle can vary from as short as one day to couple of years based on the types of the mushroom species. Thus, it is best to consume the mushroom fresh within a day. Other than that, drying, freezing, canning, pickling are the common processing and preservation methods to keep

the mushrooms fresh [4]. Despite the fact that, Malaysia is a tropical country with suitable climates condition to grow and produce various mushrooms locally, Malaysia had imported more than five tons of mushrooms every year since 2009 and has reached up to 10 million tons in 2012 which cost more than USD 3.0 million from China [2]. This shows that, the mushroom industry in Malaysia is inadequate as the local mushroom production can barely supply enough mushroom for local consumers [5]. There are several techniques that can be used in mushroom cultivation. Machine learning technique is one of the advanced technologies used in large-scale farming for crops monitoring and pest control. Fuzzy logic technique and command control programming were also used in urban farming and greenhouse to monitor the environmental parameters [6]. However, the cost of implementing advanced technology can be relatively

Ammar A.M. Al-Talib, Cynthia Kuan Jing Ting, Noor Idayu Mohd Tahir, Ain Atiqa Binti Mustafa, Tan Yong Hui

high, making it difficult for small-scale farmers to afford [7].

The paper shows the development of an IoT-based smart mushroom growing kits that allows beginners and urban farmers to monitor and remotely control the growing condition of mushroom easily through smart device without being worried or being at the presence using Blynk IoT application and sensors. The automated IoT smart mushroom growing system can help users to take care of the mushrooms and save user time while enjoying growing mushrooms at home for cooking or to earn extra income.

2. Methodology and Experimental Setup

ESP32 microcontroller was used in this project. The IoT platform chosen for this project is Blynk as it is a mobile application-based platform, easy to use and it offers a user-friendly interface to control and monitor the IoT devices. The controlling parameters and output devices of this project consist of temperature, relative humidity, carbon dioxide level, water level, LED light, fan, misting system and camera.

A. System block diagram

The IoT-based smart mushroom growing kit was designed to monitor the growth of mushrooms under the desirable environmental condition by obtaining data from the sensors and controlling the actuators using IoT technology. Fig. 1 shows the block diagram of the IoT system where the input and output devices were connected to the microcontroller and the ESP32 microcontroller communicates with Blynk IoT platform through Wi-Fi internet connection.
Fig. 1 Block diagram of the system

B. Control System wiring diagram

The control system consists of three subsystems which are the lighting, ventilation and misting system. Fig. 2 shows the wiring connection of the system which

consists of the microcontroller, sensors, actuators and power supply. A three-pin plug was used to connect the 240V AC input power generated from the power station to the house to the power supply transformer to convert voltage 240V AC to 12V DC. Then, the 12V DC output voltage positive and negative pole were connected to the terminal block to supply 12V DC to the fan, water pump, LED light and buck converter. In addition, the ESP32 microcontroller, MQ-135 air quality sensor, HC-SR04 ultrasonic sensor, ESP32-CAM and relay were connected to the output of the buck converter where 12V DC is step down to 5V DC. Lastly, the DHT22 temperature and humidity sensor was powered with 3.3V DC from the ESP32 microcontroller.
Fig. 2 System wiring diagram

C. System structure design

Fig. 3 shows the structure design of the mushroom growing kit using SolidWorks software which consists of the misting system, LED light, ESP32-CAM for video streaming, MQ-135 air quality sensor, DHT22 temperature and humidity sensor, a DC fan and an ultrasonic sensor. The material used for the mushroom growing kit structure is stainless steel with a dimension of 450mm length, 360mm width and 690mm height. The kit was designed to fit 10 mushroom bags in pyramid arrangement. The electrical component section was designed to keep the electrical components safe on top of the kit and the water tank section was used to place the plastic container used as the water tank for the misting system, while the mushroom room section was used to place the mushroom bags for mushroom development. The components used in the IoT-based smart mushroom growing kit were arranged and labeled in Fig. 3 and Fig. 4.
Fig. 3 IoT-based smart mushroom growing kit section
Fig. 4 IoT-based smart mushroom growing kit components labels

3. Results and discussion

A. *IoT-based smart mushroom growing kit prototype*

Fig. 5 shows the kit prototype when the LED light button is pressed as shown in Fig. 6. on Blynk IoT application. Blue light spectrum was used in the prototype due to blue-colored LED light is the most effective color in enhancing the development and production of the oyster mushroom [8].

Fig. 5 Mushroom growing kit prototype

Fig. 6 LED Light setting on Blynk app interface

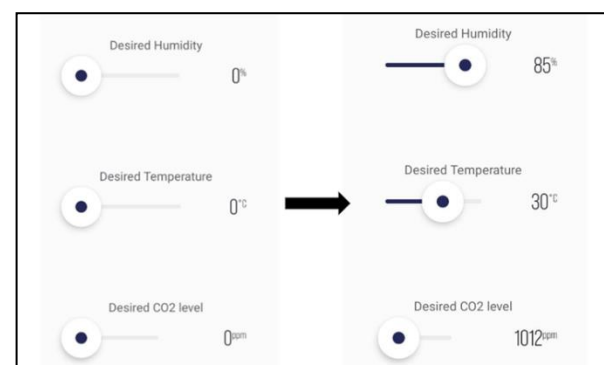
Desired value for temperature, relative humidity and CO_2 concentration can be set by user in the Blynk app as shown in Fig. 7. Once the desired values are set, the data will be read by ESP32 microcontroller, and the actuators will operate according to the command given by the ESP32 microcontroller to alter the kit environmental temperature, relative humidity and CO_2 concentration. The user is able to monitor and control the kit from the Blynk IoT application as measured readings from the DHT22, MQ-135 and ultrasonic sensors are displayed on the Blynk app IoT interface as shown in Fig. 8 and user could view the live-stream video by clicking on the video stream button on the Blynk app as shown in Fig. 9.


Fig. 7 Desired controlling variables setting on Blynk app interface

Ammar A.M. Al-Talib, Cynthia Kuan Jing Ting, Noor Idayu Mohd Tahir, Ain Atiqa Binti Mustafa, Tan Yong Hui
Fig. 8 Measured readings from sensors displayed on Blynk app interface
Fig. 9 Video stream button

B. Sensor detection accuracy results

To analyze the accuracy of the sensors, the temperature, relative humidity, CO_2 concentration level and water level readings obtained from a commercial air detector, and a ruler were compared with the ultrasonic sensors used in the kit. After eight attempts of testing, the result shown that temperature and humidity sensor (DHT22), air quality sensor (MQ-135) and ultrasonic sensors (HC-SR04) have high accuracy in detecting temperature, relative humidity, CO_2 concentration level and water level as it has low percentage error below 6%.

C. Results before and after IoT system implementation

Desired temperature value was set at 27°C. Based on Fig. 10, temperature value detected outside the prototype kit remain constant at 28°C and the temperature value measured from the DHT22 sensor inside the prototype kit reduced from 28.1°C to 27.8°C throughout the 10 minutes testing. This has proven that the prototype kit was able to work according to the microcontroller command by reading the desired value from the Blynk IoT application to turn on the fan. However, the prototype kit was only able to reduce the temperature up to 0.3°C due to there is no cooler and heater implemented in the mushroom growing kit.
Fig. 10 Temperature before and after IoT system implementation graph

Moreover, the desired value for relative humidity was set at 70%. The relative humidity value detected outside the prototype kit has a slight change from 61% to 63% as shown in Fig. 11. However, it does not reach the desired humidity value. The relative humidity value measured from the DHT22 sensor inside the prototype kit increases from 60.4°C to 69.5°C throughout the 10 minutes testing. This has proven that the misting system in the prototype kit was able to work effectively by proving sufficient humidity required for the mushroom development when the humidity detected is low.
Fig. 11 Relative humidity before and after IoT system implementation graph

D. Mushroom harvest result

A mushroom harvest cycle was conducted to observe the performance of the IoT-based smart mushroom growing prototype kit and the traditional mushroom cultivation methods. Fig. 12 shows the mushroom harvest using traditional method and Fig. 13 shows the mushroom harvest using the IoT-based smart mushroom growing prototype kit.

Fig. 12 Mushroom harvest using traditional method

Fig. 13 Mushroom harvest using prototype kit

The traditional harvest method took eight days for the primordia formation while the mushroom harvest using prototype kit only took five days which is three days faster than the traditional harvest method. Hence, the duration for the mushroom fruitbody development using traditional method is longer compared to the mushroom fruitbody development using prototype kit. Other than that, the weight of the mushroom produced using the traditional method was only 49 grams which is 11 grams lesser than the 60 grams weight of the mushroom produced using the prototype kit. The mushroom produced from the prototype kit is bigger in size and the color is more even compared to the mushroom grown with the traditional method. This shows that the mushroom harvest using prototype kit is more efficient compared to the traditional method. By using the traditional method, user must continuously damp cloth in water and place the cloth on top of the mushroom bag once the cloth is dry. The prototype kit could automatically control the environment condition to ensure the surrounding has enough moisture which could help in speeding up the mushroom development process and to produce good quality mushrooms.

4. Conclusion

The proposed IoT-based smart mushroom growing prototype kit has achieved all requirements to control the environmental condition for the mushroom's development. The kit was capable of controlling the environmental variables based on the desired value set by the user. An IoT system was created with Blynk application to control and monitor the growth of mushrooms through the smartphone. Other than that, users could obtain the data stored on the google sheet for data analysis. The kit was considered a successful innovation to support the sustainable development goals (SDGs) to reduce the use of resources and waste in the mushroom growing process and increases the efficiency and productivity of the mushroom growing operation.

Abstract

In this paper, the process of developing the reformulation equation of the Square AMC is conducted. The reformulation yielded results with less than a 5% difference for an AMC using FR-4 substrate with thickness of 3 mm. The equation for calculating capacitance was developed using the conformal mapping theory, with the assumption that inductance remains fixed at the thickness of the AMC. A comprehensive study analysis and integration of an Artificial Magnetic Conductor (AMC) tailored explicitly for metal shielding in Radio Frequency Identification (RFID) applications. The primary focus is to establish a stable and efficient communication link between RFID readers and tags, ensuring reliable data transmission within metallic environments. The proposed AMC structure exhibits a symmetrical design to facilitate seamless integration with RFID tags. This integration strategy aims to optimize communication stability and signal fidelity despite challenging metallic surroundings.

Keywords: Artificial Magnetic Conductor (AMC), RFID, Dipole Antenna.

1. Introduction

The Artificial Magnetic Conductor (AMC) belongs to the metamaterial structure group, specifically designed to enhance the performance of various antenna types, including dipole, monopole, and patch antennas [1], [2], [3]. Employing AMC as the ground plane serves to enhance the antenna's gain by minimizing undesirable back radiation and mitigating mutual coupling effects. The AMC is characterized by its high surface impedance, exceeding a thousand ohms, rendering it akin to an open circuit or lossless structure under these conditions. The reflection graph, which exhibits a phase angle of zero degrees and a magnitude of +1 when the system is in resonance, serves as a defining feature of AMC behaviour [4], [5], [6].

In [7] and [8], AMC-based antenna designs were explored to enhance gain and optimize radiation patterns by manipulating the top layer of the Perfect Electric Conductor (PEC) patch on a conductive substrate material. By applying the lumped circuit concept in [9], the modelling strategy based on characteristic modes, a generic smartphone antenna's impedance characteristic can be achieved. The research was further extended by [10], who employed a similar circuit model to calculate the resonant frequency and reflection phase of structures based on Jerusalem crosses for artificial magnetic conductors (JC-AMC) to intercept waves that would typically strike the structure.

In the paper presented by [11] includes the analysis of a new equation model of resonant frequency for absorber based on the AMC structure composed an array of square patch. Using an equivalent LC circuit model to analyse the square patch array's physical dimensions and material properties, the resonant frequency is determined. The comparable LC circuit model formula was derived using the conformal mapping theory for neighbouring co-planar square patches. While the Gauss' law and the Faraday's law are applied to the square patch that is parallel to the ground plane. This paper proposed a modification of the standard equation of square patch

Eryana Hussin, Azman Zakariya, Md. Ashraful Haque, Nur Izzati Ali

AMC for different parameters and produce smaller discrepancy between the simulated and calculated resonant frequency. The new equation was modified by introducing the correction factor based on the parametric analysis conducted. The difference of formulation for capacitive element of the proposed structure based on the parametric analysis of patch width, substrate width and gap size.

2. Methodology

The method of RFID tag for metal object detection presented in the paper is divided into two parts; single AMC design and array AMC with dipole antenna integrations.

2.1. Single 2.45 GHz AMC design

The single AMC structure consists of three layers of patch, substrate, and ground plane. The size of the patch must be smaller than the substrate to allow some gap between the patches when integrating with the dipole antenna in array arrangement. The resonant frequency and bandwidth of the standard AMC structure presented in square shape can be calculated using Eq. (1) and Eq. (2) where the L and C represents the inductive and conductive elements of the structure which determine by the Eq. (3) and Eq. (4). Fig. 1 shows the structure of the basic square AMC with square patch on a FR-4 substrate with 3 mm thickness and backed with a full ground plane.

$$f = \frac{1}{2\pi\sqrt{LC}} \quad (1)$$

$$Bw = \frac{1}{\eta_0}\sqrt{\frac{L}{C}} \quad (2)$$

$$C = \frac{w_p\varepsilon_\circ(1+\varepsilon_r)}{\pi}cosh^{-1}\left(\frac{w_s}{g}\right) \quad (3)$$

$$L = \mu_\circ h \quad (4)$$

where w_p= patch width, w_s= substrate width, g=gap around patches, ε_r=substrate permittivity, h =substrate thickness.
Fig. 1 Structure of the basic square patch AMC, SP-AMC

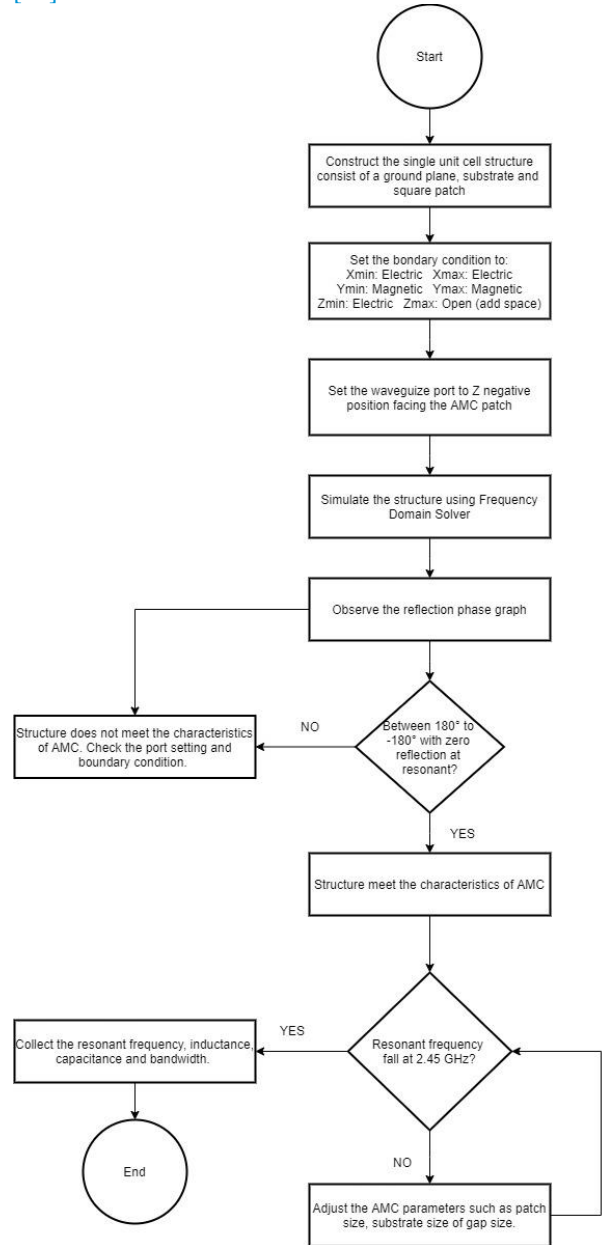
The flowchart in Fig. 2 show the design steps of designing the Square AMC using CST software. The single structure is simulated using the frequency domain solve with modified boundary setting shows in the flowchart. The simulated result should meet the characteristics of the AMC by achieving the zero-reflection phase and high impedance at resonant [12], [13].


Fig. 2 The flowchart of single unit AMC design using CST software.

2.2. Dipole antenna and Array AMC integration

The second part discussed about the proses of dipole and array AMC integration. A simple dipole antenna will be used to replicate the RFID Tag antenna. The 50Ω discrete port is used to replace the RFID chip at the center of the dipole antenna [14]. The single unit cell

AMC will be arranged in 2×2 and 3×3 arrangement and will be presented Section 3.

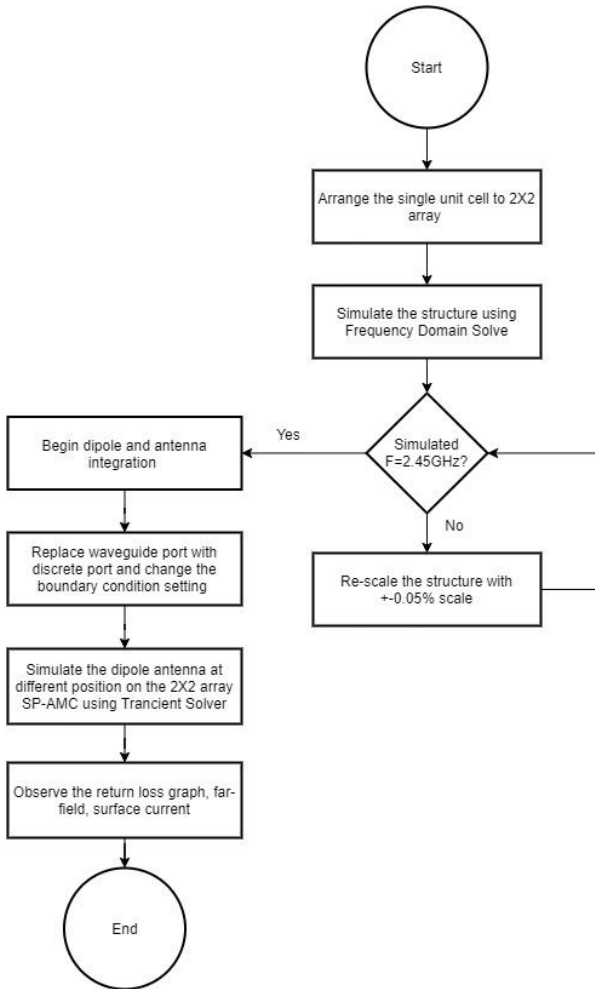
Fig. 3 shows the flow chart of the dipole antenna and array AMC integration. To maintain the symmetrical structure, the array arrangement used in this chapter will be in constant multiplication of 2×2 and 3×3 arrangement. It is important to analyze the effect of adding the dipole antenna at different positions on the two different array SP-AMC to see the effect of different metallization around the dipole antenna.


Fig. 3 Flow chart of the dipole and array AMC

3. Results and Discussion

3.1. *Analysis of single unit cell AMC*

In this section, the characteristics of the capacitive and inductive components will be investigated through the simulated frequency. Then, the capacitance value is calculated based on the resonant frequency. By applying the conformal mapping theory, the inductance of the Square AMC use in this paper will be based on the fixed thickness of 3 mm and Fr-4 as substrate. By using the Eq. (4), the inductance value is maintained at 3.77 nH. With this, the capacitance value can be calculated using the Eq. (1) and Eq. (3). The capacitance obtained from both equations will be compared and the Eq. (3) will be

reformulated again using the curve fit method. The reformulation of Square Based AMC has been conducted by [11] and produced a maximum deviation of 9.59%. In this paper, the new formulated proposed is expected to be less than 5% by using the MATLAB curve tools.

Table 1 shows the comparison of simulated and calculated resonant frequency of the AMC with substrate size of 50 mm and patch size varied from 18 mm to 21 mm. The calculated frequency using the standard formula displays a significant disparity with percentage different more than 30% when compared to the simulated frequency. The reformulation of the Eq. (5) was conducted using the curve fit tools in MATLAB. The reformulated resonant frequency (R) shown in Table 1 produce smaller discrepancy less than 1%. Fig. 4 shows the comparison between the standard formula, simulated and reformulation resonant frequency of the square AMC with different patch size.

Table 1: Comparison of the S=simulated, C=Calculated, R=Reformulated and percentage different CS= calculated and simulated and RS = reformulated and simulated.

Patch size	Frequency (GHz)			Percentage Different	
	S	C	R	CS	RS
18	3.62	4.81	3.58	33.0%	0.9%
19	3.44	4.59	3.43	33.5%	0.3%
20	3.27	4.38	3.28	34.0%	0.3%
21	3.15	4.19	3.15	33.1%	0.1%

$$C = \left(\frac{1.63 w_p \varepsilon_0 (1 + \varepsilon_r)}{\pi} \right) \times$$
$$cosh^{-1} \left(\frac{ws}{0.9(w_p - w_{s)}} \right) \quad (5)$$
Fig. 4 Comparison of frequency based on standard formula, simulated, and reformulated for the Square AMC with different patch (w_p) and gap (g) size.

The Eq. (5) is used to recalculate the frequency based on the proposed structure in [15] and [16] respectively. Table 2 shows the comparison of calculated frequency based on the proposed equation and the actual resonant frequency presented in the paper. Both use the same substrate but with different thicknesses. The comparison yields a percentage difference below 15%.

Table 2: Comparison of frequency the Square Patch AMC based on the previous papers.

Paper	Structure dimension	F_R, GHz	F_A, GHz	Percentage Different
[15]	10.8 × 12.4 × 1.6	3.40	3.90	12.8%
[16]	25.6 × 28.1 × 1.25	2.22	2.45	9.54%

where F_R = calculated frequency based proposed reformulation in Eq. (5) and F_A =actual resonant frequency

3.2. *Dipole and AMC Integration and Analysis*

This section will discuss the performance of the dipole antenna on two different AMC array integrations. Dipole antenna is placed at different positions on the array antenna to obtain optimized results in term of gain, directivity and efficiency. Fig. 5 shows the structure of dipole antenna placed at two different positions on the 2×2 array AMC. Based on the simulated graph shows in Fig. 8, the dipole antenna on the 2×2 array SP-AMC affects its interaction with the metallization components of the structure, leading to changes in impedance, radiation pattern, near-field effects, and resonance behavior. The overall structure for 2×2 array SP-AMC is measured at $92 \, mm \times 92 \, mm$.

(a)   (b)
Fig. 5 Placement of the dipole antenna with optimized performance at the top center and bottom center on the 2×2 array AMC

As the dipole antenna position changed around the 2×2 array SP-AMC, the coupling and interaction with the near-field area due to the patches of gap between the patches has different effect to the efficiency of the energy and radiation characteristics. For example, when the dipole is placed at the top center and bottom center of the 2×2 array SP-AMC, the center of the dipole is in contact

with the gap between the patches. The placement of the dipole antenna on the 2×2 array SP-AMC also affects the effective capacitance and inductance of the SP-AMC, hence modifying the mutual coupling and impedance of the structure. Based on the simulated graph, the optimized result obtained when the dipole is place at the center top and bottom of the 2×2 array SP-AMC with return loss -28.03 dB.

Fig. 6 shows the surface current distribution of the dipole antenna on the 2×2 array SP-AMC. More inducted current from the dipole antenna was distributed around the top AMC structure compared to the bottom. The AMC structure placed at the back of the dipole antenna helps to realign the surface current to be in-phase with the dipole antenna. Hence, overcome the problem of metal object detection in RFID application.
Fig. 6 Surface current distribution of the dipole antenna backed with 2×2 array AMC.

The next analysis discussed on the performance of dipole antenna on the 3×3 array AMC. The dipole is placed at the top and bottom of the gap between patched on left and right of the array the structure as shown in Fig. 7. The overall structure for 2×2 array SP-AMC is measured at $138 \, mm \times 138 \, mm$. Table 3 shows the comparison of the performance of the dipole antenna on two different square AMC array arrangements.

(a)   (b)
Fig. 7 Placement of the dipole antenna with optimized performance on the 3×3 array AMC

Table 3: Comparison of the dipole antenna performance with different AMC array arrangements.

Structure	Gain (dB)	Directivity (dB)
Dipole only	1.87	2.02
Dipole with 2×2 SP-AMC	3.32	8.21
Dipole with 3×3 SP-AMC	3.75	7.58

Fig. 9 shows the surface current distribution of the dipole antenna on the 3×3 array SP-AMC. More inducted current from the dipole antenna was distributed around the top AMC structure compared to the bottom. The induced current are lesser as the distance between the dipole and array cell increased due to the large gap used in this structure. Therefore, for structure with big gap, it is recommended to limit the array cell to achieve compact structure.

The return loss in Fig.8 shows the comparison between the dipole antenna with and without the array AMC. It is observed that the use of AMC degrades the bandwidth of the dipole antenna. However, the integration of dipole and AMC shows in Table 3 improved 77% of gain and 275% of directivity compared to dipole antenna without AMC.
Fig.8: Return loss of the dipole antenna with and without the AMC
Fig.9: Surface current distribution of the dipole antenna backed with 3×3 array AMC

4. Conclusion and Recommendations

To conclude, the first part of this paper the new reformulation of square AMC has been proposed with smaller discrepancy of less than 1% compared to the simulated resonant frequency in CST software. The second part discussed the performance of the simple dipole antenna on two different arrays with optimized results obtained at the top and bottom center of the SP-AMC structure.

The dipole and array AMC structure proposed in the paper can be used as metal shielding in RFID applications such as car detection for parking or toll-system. The use of AMC to the dipole RFID tag can improve the detection range as the AMC helps to reduce the back radiation of the dipole and improve the directivity and gain of the structure. The array arrangement in this paper is limited to 3×3 to minimize the overall structure.

A bigger array is recommended for any application which has no objection on the size limits. For low frequency such as UHF RFID, the AMC structure with slots can be introduced to achieve compact size.

Abstract

In this research, the performance of oil palm empty fruit bunch (OPEFB) fiber-reinforced epoxy composite with varying fiber orientation and stacking sequence as the material for mountain bike frame was studied utilizing ANSYS software. The choice of OPEFB fiber was motivated by the fact that the waste by-product of oil palm extraction in Malaysia alone might reach 70-80 million tons per year, with 90% of oil palm biomass lost as waste. The properties of epoxy OPEFB composite in principal 1, 2, and 3 directions were calculated using Whitney and Riley estimates. 10 stacking sequences and five loading conditions were taken. The results show that the fibre orientation of epoxy OPEFB composite on the bicycle frame had little effect on the performance contrary to the number of plies in the laminate or number of laminates which had major effects.

Keywords: Biocomposites, Bicycle frame, Oil palm empty fruit bunch, Polymer composites

1. Introduction

In the 21st century, companies and governments always push towards green technologies, eco-friendly products, and sustainability. In fact, in 2015, Sustainable Development Goals (SDGs) were established by the United Nations (UN) to push for all countries to take part in sustainability for the conservation and preservation of nature and resources for current and future generations [1]. SDGs were fully adopted by the Malaysian government and taught in universities. With this awareness, to reduce the use of resources like fuels and cut carbon emissions, bicycles become the ideal vehicle for short-distance travel.

While it is true that bicycles do not produce emissions, the manufacturing of steel, aluminium, or titanium bicycle frames produces a lot of carbon emissions. With the increasing popularity of bicycles, more bicycles are going to be manufactured and more carbon emissions are going to be produced. In Malaysia, there is also another problem involving the oil palm industry. Oil palm empty fruit bunches (OPEFB) are discarded by the industry as waste in large quantities without utilization [2]. OPEFB fibre has the potential to be used as reinforcing fibre in composite materials. Therefore, utilizing OPEFB fibre in a composite bicycle frame would ease both problems at the same time.

Many researchers have investigated the properties of OPEFB fibre and OPEFB fibre in matrix. Gunawan et al. [3] performed experiment to find out mechanical properties of 40 strands of OPEFB fibre and found that the average Young's modulus is 11.88 GPa and the average tensile strength is 156.3 MPa. Zuhri [4] experimented on just a single strand of OPEFB fibre and found that Young's modulus is 1.7 GPa and tensile strength is 71 MPa. Hassan [5] experimented on

Kok Sem Too, Nor Fazilah Abdullah, Ammar Abdulaziz Majeed Al-Talib, Cik Suhana Hassan

unidirectional OPEFB fibre-reinforced epoxy composite in 0º, 45º, and 90º directions and found that the tensile strengths are 30.5 MPa, 10 MPa, and 9.2 MPa respectively.

Utilizing unidirectional continuous OPEFB fibre in a composite bicycle frame requires the study of the fibre orientation and stacking sequence to produce a bicycle frame that can withstand all loading conditions. As investigated by the researchers, the properties of OPEFB fibre are adequate for the development of composite bicycle frames.

2. Methodology

2.1. *Mountain bicycle frame*

The dimensions and geometry of the mountain bicycle frame was adopted from a journal by Sajimsha B et al. [6]. The modelling of the frame was completed on SOLIDWORKS. Table 1 shows the parameters of dimensions and geometry of the bicycle frame.

Table 1. Parameters of dimensions and geometry of the mountain bicycle frame

Parameter	Value
Head tube angle	73.5º
Seat tube angle	73.5º
Top tube length	580 mm
Seat tube length	570 mm
Chain stay length	360 mm
Head tube length	120 mm

For composite material simulation, the shell model of the bicycle frame was exported to ANSYS. The meshing was done on ANSYS Mechanical and the completed meshed model has 12830 nodes and 12306 elements. Fig. 1 shows the completed meshed model of the bicycle frame.
Fig.1 Shell model of mountain bicycle frame

2.2. *OPEFB fiber reinforced epoxy composite properties*

Although many researchers have conducted experiments on the properties of OPEFB fibre reinforced epoxy composite, only the properties of Young's modulus, tensile strength, and flexural strength were found. Properties such as shear modulus and Poisson's ratio in principal 1-2, 2-3, and 1-3 directions and compressive strength and shear strength in principal 1, 2, and 3 directions were not found. To find the moduli and Poisson's ratios in all three directions of composite, many theoretical estimates were developed. One such theoretical estimates is Whitney and Riley estimates developed by Air Force Materials Laboratory [7-8]. The calculations of the moduli and Poisson's ratios using Whitney and Riley theory are less rigorous than other theoretical estimates and only require Young's modulus, shear moduli, bulk moduli and Poisson's ratios of the fibre and matrix. The theory also regards that the fibre and matrix are isotropic. The compressive strength and shear strength of the composite were calculated using the equations in Chapter 5 of the book of Engineering Mechanics of Composite Materials by Daniel and Ishai [9]. The properties of OPEFB fibre were obtained from an experiment done by Gunawan et al. [3] and the properties of epoxy were obtained from Appendix A in the book [9]. Table 2 shows the calculated properties of the epoxy OPEFB composite. Note that the fibre-to-matrix volume ratio is 60:40.

Table 2. OPEFB fibre properties

Young's modulus 1 (GPa)	8.848
Young's modulus 2 (GPa)	6.347
Young's modulus 3 (GPa)	6.347
Poisson's ratio 1-2	0.3184
Poisson's ratio 2-3	0.32
Poisson's ratio 1-3	0.3184
Shear modulus 1-2 (GPa)	2.899
Shear modulus 2-3 (GPa)	2.404
Shear modulus 1-3 (GPa)	2.899
Bulk Modulus (GPa)	5.937
Tensile strength 1 (MPa)	142 MPa
Tensile strength 2 (MPa)	49.46 MPa
Tensile strength 3 (MPa)	49.46 MPa
Compressive Strength 1 (MPa)	400 MPa
Compressive Strength 2 (MPa)	143.4
Compressive Strength 3 (MPa)	143.4
Shear Strength 1-2 (MPa)	70.82
Shear Strength 2-3 (MPa)	48
Shear Strength 1-3 (MPa)	70.82

2.3. *Stacking sequence*

The stacking sequences of the plies were determined from the journal of Thomas Jin-Chee LIU et al. [10] who found 10 stacking sequences of 8-ply laminate that

produced better designs for composite bicycle frames. The 10 stacking sequences are shown in Table 3. Each stacking sequence is designated with a letter with 0, 45 and 90 indicating the fibre orientation angle in the composite. Fig. 2 shows examples of 0º fibre orientation and 90º fibre orientation on the bottom bracket.

Table 3. Composite stacking sequence

Designation	Stacking Sequence
A	[0/90/45/-45]s
B	[0/90/-45/45]s
C	[90/0/45/-45]s
D	[90/0/-45/45]s
E	[-45/45/0/90]s
F	[-45/45/90/0]s
G	[45/-45/0/90]s
H	[45/-45/90/0]s
I	[0/90/90/0]s
J	[90/0/0/90]s

Thomas Jin-Chee LIU [10] used the same stacking sequence of 8-ply laminate for the entire bicycle frame. Other studies are more dynamic with having different stacking sequence and number of plies for each section of the bicycle frame. For instance, Hu et al. [11] separated the bicycle frame into two sections: section A with 8-ply laminate consisting of head tube, top tube, seat tube, and bottom bracket and section B with 5-ply laminate consisting of seat stays and chain stays. Jung et al. [12] initially used the same stacking sequence of 8-ply laminate for the entire bicycle frame then separated the bicycle frame based on the weak regions and failure indexes into three sections with different stacking sequences and 16-ply laminate only for section 3. Jung et al. [12] grouped the head tube into Group 1, top tube, seat stays, and chain stays into Group 2, and seat tube, top tube, and bottom bracket into Group 3. Similarly, Chun et al. [13] initially employed the same stacking sequence of 20-ply laminate throughout the bicycle frame and then optimised different stacking sequences for each member of the frame based on the initial results.
a. 0°   b. 90°
Fig. 2. Fibre orientation angle

2.4. *Loading conditions*

The bicycle frame design and loading conditions applied were based on Sajimsha B et al. [7] work. There were five loading conditions simulated and analysed. All the loading conditions are shown in Fig. 3. The first loading condition is static start-up. It simulates the bicycle in a resting state with a rider sitting on the saddle and the rider is about to start pedalling. A force of 700 N is applied to the top of the seat tube implying the weight of the rider and a force of 200 N is applied to the bottom bracket implying pedalling force. The head tube and rear brackets are fixed supported. The second loading condition is steady state pedalling. It simulates the bicycle is being pedalled out of saddle, meaning that the rider is not sitting on the saddle instead standing up while pedalling. Force of 1000 N is applied to the top of the head tube implying the force of the rider's hands pushing down on the steering and force of 200 N is applied to the bottom bracket implying the pedalling force. The head tube and rear brackets are fixed supported. The third loading condition is vertical impact. It is to simulate an event of impact to the top of the seat tube. Downward force of 2250 N is applied to the top of the seat tube. The head tube and rear brackets are fixed supported. The fourth loading condition is horizontal impact. Similarly to third loading condition, it simulates an event of impact to the top tube. Horizontal force of 2250 N is applied along the top tube. The head tube and rear brackets are fixed supported. The fifth loading condition is rear wheel braking. It simulates the rider is applying brake to the rear wheel when coming to a stop. Horizontal force of 750 N is applied to each of the rear bracket. The bottom bracket is fixed supported.

To analyse whether the bicycle frame fails or not in a loading condition, multiple composite failure theories were selected in composite failure tool on ANSYS. ANSYS calculates the failure theories based on inverse reserve factor (IRF) which tells a number that indicates failure. IRF between 0 and 0.99 indicates that the bicycle frame is still intact while IRF that exceeds 1 indicates the bicycle frame already fails. Composite failure theories can be divided into three groups. Limit or noninteractive theories like maximum stress and maximum strain theories disregard interaction among different stress components and only compare individual ply stresses or strain with the corresponding ultimate strengths or strains [9]. Interactive theories like Tsai-Hill and Tsai-Wu theories include all stress component in one expression without reference to particular failure modes 9. Partially interactive or failure-mode-based theories like Hashin and Puck theories give separate criteria for fibre and interfibre failures [9]. Five failure theories are chosen in the composite failure tool: Maximum stress theory, Tsai-Wu theory, Tsai-Hill theory, Hashin theory, and Puck theory.

Fig. 3. Loading conditions applied

3.   Results and Discussion

3.1.   *Initial analysis*

The initial equivalent (von-mises) stress results show good or even better performances than those of the conventional materials for some stacking sequences and loading conditions. All the stress values for corresponding stacking sequences and loading conditions are shown in Table 4. For comparison, the equivalent (von-mises) stress results produced by Deepak [14] were listed in Table 5.

Table 4.   Initial equivalent (von-Mises) stress

	Static Start-up	Steady State Pedalling	Vertical Impact	Horizon-tal Impact	Rear Wheel Braking
A	11.242	4.5884	35.034	11.127	40.049
B	11.245	4.5864	35.051	11.128	40.148
C	9.7708	3.7435	30.249	8.0981	**32.523**
D	**9.7704**	3.7417	**30.248**	8.0976	33.298
E	10.248	4.149	31.733	9.3719	34.823
F	10.259	4.2497	31.768	9.3758	35.377
G	10.235	4.1446	31.695	9.4727	38.412
H	10.245	4.2379	31.728	9.4773	38.717
I	11.196	4.6299	34.896	10.994	40.239
J	9.7798	**3.6939**	30.279	**7.9794**	32.685

Table 5.   Equivalent (von-Mises) stress of conventional materials

	Static Start-up	Steady State Pedalli-ng	Vertical Impact	Horizontal Impact	Rear Wheel Brakin-g
Steel	9.8212	6.3773	31.216	28.069	17.746
Aluminium	10.915	7.4270	33.722	30.364	17.780
Titanium	10.896	7.3168	34.607	31.071	18.022
Carbon Fibre	10.940	10.940	34.839	33.941	19.498

In static start-up, stacking sequence C, D, and J have lower stresses than all the conventional materials. Stacking sequence E, F, G, and H have lower stresses than aluminium 6061 T6, titanium grade 9 and carbon fibre while stacking A, B, and I have higher stresses than all the conventional materials. In steady state pedalling, all the stacking sequences show lower stresses than all the conventional materials. In vertical impact, stacking sequence C, D, and J have lower stresses than steel while stacking sequence E, F, G, and H have lower stresses than aluminium 6061 T6, titanium grade 9 and carbon fibre. Stacking sequence A, B, and H have higher stresses than all the conventional materials. In Horizontal impact, all the stacking sequences have lower stresses than all the conventional materials contrary to rear wheel braking

condition which displays that all the stacking sequences have higher stresses than all the conventional materials.

In each of the loading condition, the maximum stress is always concentrated at the same region despite the different stacking sequences. As can be seen in Fig. 4, the stress concentration is at the connection between seat tube and seat stays in static start-up; connection between down tube and bottom bracket in steady state pedalling; connection between seat tube and seat stays in vertical impact; connection between heat tube and top tube in horizontal impact; intersection between chain stays in rear wheel braking.

The bicycle frame will not necessarily fail at the stress concentration region. The region may be able to hold the maximum stress while other regions may not be able to hold their lower stresses. This is further seen with the location of maximum inverse reserve factor.

The initial total deformation results in Table 6 are not comparable to the results of the conventional materials in Table 7. As expected, the deformation in each loading condition and stacking sequence is way higher than the deformations for all the conventional materials. This is due to the epoxy OPEFB composite having way lower tensile and compressive moduli than all the conventional materials. Thus, producing way higher deformations. The deformations in rear wheel braking condition are unacceptable as 6 mm deformation is too high and will possibly affect riding performance and stability. As observed as well the different in deformations between the stacking sequences in each loading condition is insignificant.

Table 6. Initial total deformation induced.

	Static Start-up	Steady State Pedalling	Vertical Impact	Horizon-tal Impact	Rear Wheel Braking
A	0.29322	**0.13132**	0.8982	0.25591	6.8875
B	0.29323	0.1314	0.89823	0.25591	6.8863
C	0.29325	0.13792	0.89828	0.25626	6.8907
D	0.29325	0.13801	0.89829	0.25626	6.8895

Aluminium 6061 6T	0.023512	0.024481	0.072276	0.090021	0.52604
Titanium Grade 9	0.017838	0.018578	0.054793	0.068393	0.39739
Carbon Fibre	0.0040985	0.0042668	0.012585	0.015749	0.089395
(a) Static start-up
(b) Steady-state pedalling
(c) Vertical impact
(d) Horizontal impact
(e) Rear-wheel braking

Fig. 4. Stress concentration of each loading condition

Similarly to stress concentration, the bicycle frame deforms at the same location in each loading condition regardless of the stacking sequences. The bicycle frame always deforms the most at the highest load location if there is no fixed support at the location. The bicycle frame deforms at the tip of the seat tube where force of 700 N is applied in static start-up; bottom bracket where force of 200 N is applied in steady state pedalling; tip of the seat tube where force of 2250 N is applied in vertical impact, connection between top tube and seat tube where force of 2250 N is applied to the top tube in horizontal impact; both rear brackets where force of 750 N is applied to each in rear wheel braking.

Inverse reserve factor (IRF) is an indication if the bicycle frame will fail under the loading conditions. If the inverse reserve factor exceeds 1, the bicycle frame will fail. As can be observed in Table 8, the bicycle frame has relatively low IRF in static start-up and steady state pedalling but high IRF in vertical impact, horizontal impact, and rear wheel braking, indicating that the frame will most likely fail under these loading conditions.

0.8. General trend can be seen here is that stacking sequence A, B, G, H, and I produce lower IRF than all the other stacking sequences in all loading conditions. For initial results, stacking sequence A, B, G, H, and I are chosen to be general good stacking sequences. Table 9 shows the top five stacking sequences in each loading condition and they are composed of stacking sequences A, B, G, H and I except for steady state pedalling that swaps stacking sequence H for E. The (a), (b), (c) and (d) are indicators for the location of the maximum IRF which occurs at only four locations; as shown in Fig. 5. Location a is the connection between seat tube and chain stays; location b is the connection between bottom bracket and seat tube; location c is the connection between bottom bracket and down tube; location d is the chain stays intersection. These locations are also the weak regions of the bicycle frame. The designation inside the bracket beside the IRF value is the location of the IRF. The maximum IRF is greatly influenced by loading conditions but not the stacking sequences except for static start-up which shows variation in the maximum IRF locations based on the stacking sequences.

Table 8. Initial inverse reserve factor

The stacking sequence A, B, G, H, and I have slightly higher IRF than 0.15 compared to stacking sequence C, D, E, F, and J that have IRF higher than 0.2 in static start-up. Stacking sequence A, B and I have IRF lower than 0.1, stacking sequence E, F, G, H have IRF slight higher than 0.11, and stacking sequence C, D, and J have IRF higher than 0.12 in steady state pedalling.

Stacking sequence A, B, G, H, I have slightly higher IRF than 0.5 while stacking sequence C, D, E, F, and J have IRF around 0.8 in vertical impact. Stacking sequence A, B, G, H, and I have IRF slightly higher than 0.27 while Stacking sequence C, D, E, F, and J have IRF higher than 0.34. Lastly, Stacking sequence A, B, and I have slightly higher IRF than 0.6, stacking sequence G and H have IRF slight higher than 0.7, and stacking sequence C, D, E, F, and J have slight higher IRF than

3.2. *Optimization*

It was obvious that only one laminate of epoxy OPEFB composite cannot be feasible for a good performance bicycle frame. The deformation was too high compared to those of conventional materials and especially in rear wheel braking with one laminate. The IRFs in vertical impact, horizontal impact, and rear wheel braking were also high with one laminate. To reduce the deformation and the IRF, another laminate of 8-ply was introduced, creating two 8-ply laminates or 16 plies all together for every member of the bicycle frame.

The results, as shown in Table 10, 11 and 12, show reduction in half for all the stresses, deformations, and IRFs in all the loading conditions. The equivalent (von-Mises) stress was averagely reduced by 50.63% in static start-up; 65.39% in steady state pedalling; 49.95% in vertical impact; 41.55% in horizontal impact; 47.44% in rear wheel braking. The deformation was averagely reduced by 57.13% in static start-up; 71.56% in steady state pedalling; 57.68% in vertical impact; 51.79% in horizontal impact; 60.56% in rear wheel braking. The IRF was averagely reduced by 61% in static start-up; 70.98% in steady state pedalling; 59% in vertical impact; 63.69% in horizontal impact; 53.79% in rear wheel braking.

While all the stresses, deformations, and IRFs were reduced half by just adding an additional laminate, the bicycle frame still had the same stacking sequence throughout. Different stacking sequences for different members of the bicycle frame is proven to be beneficial for sustaining different loading conditions. Therefore, based on the weak regions, the bicycle frame was sectioned into three sections: section 1 consists of top tube, head tube, and down tube; section 2 consists of seat tube alone; section 3 consists of seat stays, chain stays, bottom bracket, and rear brackets. Section 1 would employ stacking sequence B_2 and I_2, section 2 would employ stacking sequence A_2, B_2, G_2, and I_2, and section 3 would employ stacking sequence A_2, and H_2. The combinations of all the stacking sequences of each section are clearly listed in Table 13.

Equivalent (von-Mises) stress results, as shown in Table 14, show insignificant difference between the stacking sequences except for a few stacking sequences in some loading condition. Stacking sequence Q and Y have lower stresses slightly above 4.5 MPa compared to the rest of the stacking sequences that have stresses slightly above 5 MPa in static start-up. All the stacking sequences in steady state pedalling have stresses slightly above 1.4 MPa and the difference between each other is insignificant. Stacking sequence Q and Y have stresses slightly above 14.3 MPa, stacking sequence R and Z have stresses slightly above 15.5 MPa, and all other stacking sequences have stresses slightly above 16 MPa in vertical impact. In horizontal impact, stacking sequence L, K, N,

P, R, M, O, and Q have stresses slight above 5.28 MPa and stacking sequence T, S, V, X, Z, and U have stresses slightly above 5.35. In rear wheel braking, stacking sequence K, S, M, O, Q, U, W, and Y have stresses slightly above 17.24 MPa and stacking sequence V, X, Z, N, P, R, T, and L have stresses slightly above 18.09 MPa. The stresses are not improved over the stresses of the same case of double-laminate bicycle frame.

Table 14. Equivalent (von-Mises) stress results for double-laminate sectioned bicycle frame

Similar trend is observed for the total deformation for double-laminate sectioned bicycle frame, as shown in Table 15. The deformation difference between the stacking sequences in each loading condition is very insignificant. The deformations do not see any improvement over the deformations of the same case of double-laminate bicycle frame. IRFs also do not see any improvement over the IRFs of the same case of double-laminate bicycle frame. The IRF difference between stacking sequences in each loading condition is very insignificant, as shown in Table 16.

Overall, different stacking sequence for each section of the bicycle frame does not produce any improvement at all for epoxy OPEFB composite mountain bicycle frame in this study. Major improvement of equivalent (von-Mises) stresses, total deformations, and inverse reserve factor are seen with addition of laminate or ply. Unlike other studies which found that major improvement of performance by applying different stacking sequence to different member of the bicycle frame, all the other studies used synthetic fibre such as carbon fibre and glass fibre which, in a composite, possess big difference between the Young's modulus 1 and 2, and tensile strength 1 and 2. As calculated by using Whitney and Riley theory, epoxy OPEFB composite does not have very big difference between the properties in principal 1 and 2 direction. Therefore, the fibre orientation of epoxy OPEFB composite in each section of the bicycle frame does not contribute much to the performance compared to the fibre orientation of the entire bicycle frame which saw some improvement in the initial results.

4. Conclusion

The fibre orientation and stacking sequences of epoxy OPEFB composite on mountain bicycle frame have been studied thoroughly. A total of 10 stacking sequences were adopted from previous research. It was found that of the

10 stacking sequences, five stacking sequences, [0/90/45/-45]ₛ, [0/90/-45/45]ₛ, [45/-45/0/90]ₛ, [45/-45/90/0]ₛ, and [0/90/90/0]ₛ, were found to be general good stacking sequences. But the deformations and IRFs of the five stacking sequences in some loading conditions were still high. Therefore, the additional laminate was introduced and the results showed significant reduction by half in stresses, deformations, and IRF. The bicycle frame was also sectioned for employment of different stacking sequence in each section but the results showed no improvement. Hence, for epoxy OPEFB composite bicycle frame, additional laminate or ply will improve the performance significantly but not employment of different stacking sequence in each member of the frame.

Abstract

This research paper presents the power protection study on a grid-connected Battery Energy Storage System (BESS) in a typical Malaysia low-voltage (LV) residential network. The BESS model and control algorithm is developed in MATLAB/Simulink environment. The BESS model can charge and discharge its energy with an algorithm-controlled bidirectional AC/DC converter. The paper also presents two cases for BESS short circuit evaluation to investigate stability of internal and external systems of BESS. The protection level on BESS is also optimized by introducing a time-delay characteristics model to coordinate circuit breakers in compliance with standards outlined in IEEE Std 1375-1998, IEC/EN 60898-2, IEC/EN 60947-2, UL 1077, and CSA 22.2. No.235. The paper presents BESS system stability with and without overcurrent protection. As a conclusion, BESS was interrupted within stipulated time. In case of internal short circuit protection failure, a backup protection will act on isolating BESS from the grid provided

Keywords: Battery Energy Storage System, Fault analysis, Power system stability, Protection scheme, Optimized protection

1. Introduction

Lately, more than 200 energy storage demonstration projects, at megawatt level and above, have been set up across the world, indicating huge potential for further expanded application of 154 Grid-scale energy storage systems and applications energy storage technologies [1]. According to U.S. department of energy, ESS increases grid resistant to disruptions, promotes clean electricity, and increases the economic value of wind and solar power [2]. ESS is also essential to provide power at optimal response speed to overcome the intermittence of renewable sources and contribute to the mains voltage regulation [3]. There are various types of ESS technologies proposed by [4] used for transportation, emergency, and small-to-large scale power generation. BESS may be the most versatile of the several storage systems according to [5].

BESS has three primary components: an AC grid, a battery, and a battery management system [6]. The kind of battery used in the system determines the power output and energy levels of BESS. Various research has been previously conducted for modelling of BESS. In [7], the author has proposed a detailed modelling of BESS using various power electronic components and control modules have been discussed. On the other hand, a simplified BESS model using MATLAB/Simulink logical-numerical modelling approach has been proposed by authors in [8] that can simulate the behaviors of a typical BESS.

Kong De Kang, Farah Adilah Jamaludin, Rodney H.G. Tan

Several issues have been faced by BESS due to its fault behaviours. The primary issue is the high fault current contributed from BESS [9]. The second issue is the rate of current rising [10], [11]. Regarding the two issues, the power electronic switches used with BESS may also be harmed by the current and its increasing rate [12]. The sudden decline in battery state of charge (SOC), which had an adverse effect on battery lifetime, is the final issue [13]. BESS can pose a significant safety risk to both users and installers, with the potential to cause hazards such as fire, flash burns, and explosion if it suffers from short circuit or fault if installed and used improperly [14]. Short circuits are a major contributor to the electrical and temperature risks brought on by Li-ion batteries [15]. Accordingly, it is crucial to achieve power protection of BESS to ensure its proper functions during critical time. Therefore, two main areas of BESS protection are protection of BESS itself for internal fault and isolating BESS from a system for external fault [6]. Several options to protection of stationary battery systems such as circuit breakers and fuses have also been provided in [16] to DC system designer. The paper presents an LV grid-connected BESS with and without overcurrent protection of both internal and external circuit of BESS alongside with fault analysis.

2. Methodology

2.1. *System Design*

As displayed in Fig. 1, the BESS is connected to a typical Malaysia LV network. The connection between BESS and Grid is straight forward since no load is connected to the network bus. BESS consists of a battery module and a bidirectional AC/DC converter. The BESS has utilized a battery module from manufacturer's datasheet. The battery module is referred to technical specifications outlined in manufacturer's datasheet. With the aid of a converter, the BESS can charge or discharge the battery at constant voltage and current. The BESS is protected by internal and external protection units against internal and external short circuit faults respectively. Short circuit and power system stability can be analyzed through DC and AC protection breaker monitoring interface.

research, similar fault locations have been determined in a block diagram as shown in Fig. 2. Three-phase fault blocks from MATLAB/Simulink library are placed
Fig. 1 Overview of BESS system protection model in Simulink

2.2. *BESS model*

The three primary components of BESS are an AC grid, a battery, and a battery management system as presented in [6]. The BESS consists of a Li-Ion battery and a bidirectional AC/DC converter. The nominal voltage and ratings of the battery are 450V and 33.33Ah respectively. The converter is designed using an average model based VSC as the converter bridge. A subsystem that consists of a series of mathematical blocks is built to generate pulse-width modulation (PWM) signal for the converter output as well as regulating the grid current. In addition, the subsystem also provides charging and discharging modes for BESS through current settings. The converter circuit has a DC link capacitor for smoothing the DC voltage as well as series parallel LCL filter to reduce the Total Harmonic Distortion (THD) of AC waveforms. Being the main charging source for BESS, AC grid is designed at 230V which is a typical LV residential network level in Malaysia. Simulation is run to analyse the behaviours of BESS when there is no short circuit.

2.3. *BESS short circuit evaluation*

According to previous research on protection of BESS in a DC microgrid, fault on the bus at BESS side and fault on DC terminals at battery side are the two fault locations as identified in [12]. Based on the project model in this

across the identified fault locations as shown in Fig. 3. The fault blocks are set to provide line-to-line fault as F1 and line-to-line-to-ground fault as F2. F1 and F2 are

identified as internal fault and external fault, respectively. The simulation is run to analyze the short circuit behaviors of BESS in terms of voltage, current, and SoC characteristics of its battery. The simulation is repeated

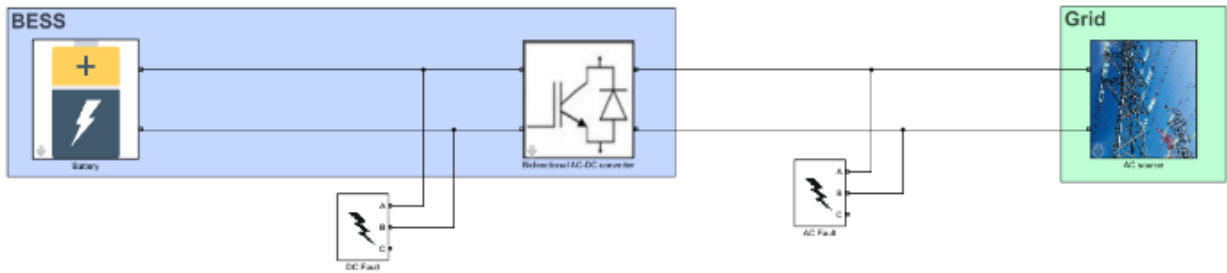
with several short-circuit resistance adjusted in the fault block parameter settings to observe the impacts of different network short-circuit levels on system stability of BESS and AC grid.
Fig. 2 Block diagram of short-circuited BESS network


Fig. 3 A short-circuited BESS model.

2.4 Proposed design of BESS protection scheme with optimization method

Circuit breaker as a main protection scheme has been provided in [6]. However, AC breaker for DC use must be modified by adjusting the magnetic trip characteristics of an AC circuit breaker [16]. In this paper, a combination of AC breaker (ACCB) and DC breaker (DCCB) are used for the external and internal power protection of BESS, respectively as shown in Fig 4. During an external fault, F2, BESS will be isolated from AC bus whereas during an internal fault, F1, battery will be isolated within the BESS system. An ideal switch is used as a basic circuit breaker to isolate battery or BESS from the short circuit when the switch is opened. A circuit breaker trips according to its trip characteristics curve based on the guidelines provided in [16]. A model that simulates B and C trip characteristics curves has been developed using look-up table block from MATLAB/Simulink library. The trip characteristics used are referenced from a manufacturer datasheet for a miniature circuit breaker (MCB). As a common practice, B type curve is employed in DCCB whereas C type curve is employed in ACCB.

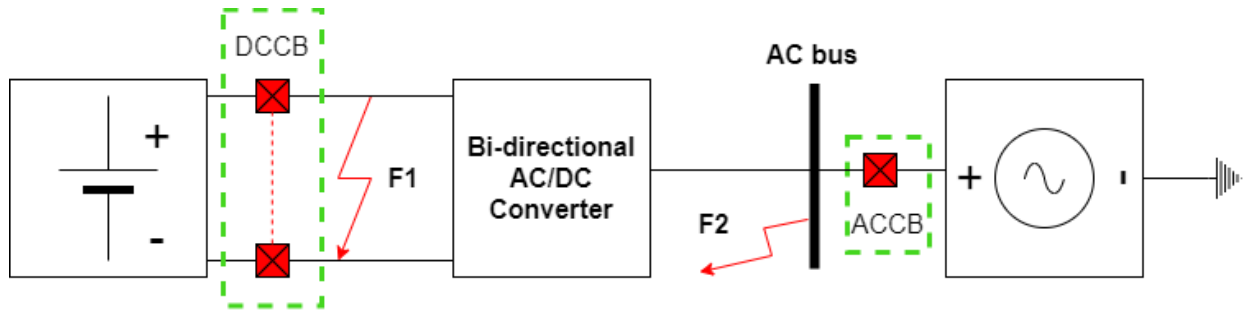
Kong De Kang, Farah Adilah Jamaludin, Rodney H.G. Tan


Fig. 4 Locations of circuit breaker.

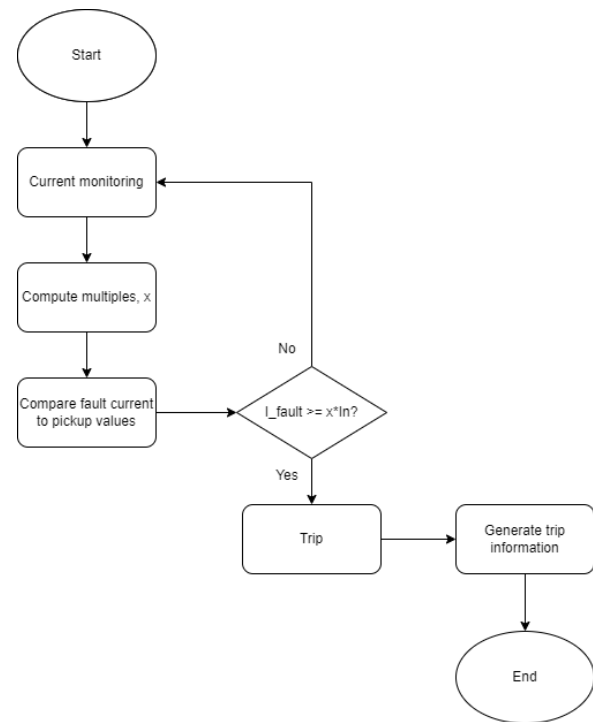
Once the trip characteristics curves are verified, the curve model is employed in a subsystem. This subsystem is built to generate signal as if it was a "relay" for opening the circuit breaker. Some of the main parameters like current ratings and breaking capacity are defined in this system. Trip time limit is used to define the maximum and minimum trip time as indicated from trip curve from manufacturer datasheet. The current ratings of a circuit breaker are defined in [16]. Based on parameters of generic battery model predefined from MATLAB/Simulink, BESS can discharge current at approximate 14.5A. Whereas based on simulation, the AC bus is regulated by the converter at approximate 6A. Therefore, the DCCB and ACCB current ratings from calculation are 18.1A and 7.5A respectively. The current ratings selection should be at least or above the calculated values for common practice. From the available range of current ratings found in datasheet, DCCB and ACCB current ratings are determined as 20A and 8A respectively. In trip signal generator, MATLAB functional codes are developed to compare the current detected on the system the breaker is connected to with current multiples of the trip curve. A time-delayed signal that indicates trip will be sent to circuit breaker model to open the switch. The tripping sequence of the circuit breaker as coordinated by the trip signal generator subsystem is summarized in a flowchart shown in Fig 5. The trip curve model with trip signal generator subsystem can optimize the protection scheme by introducing delayed tripping in circuit breaker model approved with standards outlined in IEEE Std 1375-1998, IEC/EN 60898-2, IEC/EN 60947-2, UL 1077, and CSA 22.2. No.235. After installing the protection schemes in the project model, system stability with protection is analyzed.


Fig. 5 Tripping sequence of a circuit breaker model.

3. Results and discussion

3.1 BESS behaviors under normal circumstances

Under normal circumstances, the voltage, current, and SoC of BESS are displayed on graphs shown in Fig 6(a) and Fig 6(b). From the graphs, BESS is operating at a constant voltage of 485V which is higher than its nominal voltage, 450V due to other settings assumed by default in generic battery model. However, the operating voltage is still within operating range based on datasheet. The BESS is also charging and discharging at 3A which is lower than current source from the grid due to impedance losses. The current when BESS is discharging opposes the polarity of current during charging as the direction of current flow differs in both states. The initial spike of current is due to initialization of the simulation. However, it does not effect on system stability as it happens only within 0.05s. SoC of BESS is increasing steadily during charging state whereas decreasing steadily during discharging state.
Fig. 6(a) BESS when charging.
Fig. 6(b) BESS when discharging.

As seen from Fig 6(a) and Fig 6 (b), after a fault occurs at 0.1s, the battery starts to discharge quickly as observed

from the graph of SoC during BESS charging and discharging states. Moreover, the voltage across the terminals of battery begins to decrease due to voltage drop through the resistance. The gradual decrease in voltage is caused by chemical changes occurring at the surface of electrodes. Furthermore, the battery current rises rapidly within 20ms to its peak at approximate 1.4kA. The gradual increase in the current is due to battery inductance.

3.2. Analysis of BESS under external short circuit

From the graphs in Fig 7(a) and Fig 7(b), voltage of battery remains stable after external short circuit effects at 0.1s. Therefore, the battery voltage does not drop due to lower resistance on external circuit of BESS. Moreover, the battery current decreases in both charging and discharging states of BESS. Furthermore, the rate of charge and discharge of BESS also decreases. Therefore, it is said that BESS does not display several issues as discussed in [9]–[13] by neither having high discharged current, voltage drop, nor sharp decrease in SoC except a decrease in power efficiency or performance of BESS. The converter shows current blocking effect by functioning as a diode rectifier and pass the current through only the reverse diodes. The grid filter between ac grid and converter then limits the fault current through the diodes [10].
Fig. 7(a) External short circuit of BESS during charging.

Kong De Kang, Farah Adilah Jamaludin, Rodney H.G. Tan
Fig. 7(b) External short circuit of BESS during discharging.
Fig. 8 Grid stability during BESS external short circuits under charging and discharging of BESS

As seen from Fig 8, grid voltage level drops to approximate 60V. Moreover, the grid current increases rapidly to approximate 600A. The gradual decrease and increase in voltage and current are due to grid impedance. The short circuit occurs on the AC bus which is also common point of coupling to the grid. Therefore, AC grid is directly affected by the short circuit.

4. Conclusion

A grid-connected BESS model applicable to a typical LV network in Malaysia has been developed in MATLAB/Simulink environment. The BESS can charge or discharge energy by adjusting the current settings in the converter block to achieve AC/DC bidirectional conversion. Short circuit analysis has also been conducted on the internal and external circuit of BESS. In the internal circuit, faults are conducted across the terminals of battery. Whereas in the external circuit, fault is conducted on the AC bus which is point of common couplings for BESS terminals and AC grid. Based on the fault analysis, internal short circuit causes high current discharged from BESS alongside with voltage drop and rapid decrease of SoC. These behaviors are damaging to the battery lifespan of BESS. On the other hand, external

short circuit does not cause BESS to discharge high current but operating at lower power efficiency instead due to current blocking effect of the converter. The protection scheme using a combination of ACCB and DCCB is designed for BESS power protection. The trip characteristics curve models referenced from manufacturer datasheet are developed to optimize the circuit breakers in compliance with standards outlined in IEEE Std 1375-1998, IEC/EN 60898-2, IEC/EN 60947-2, UL 1077, and CSA 22.2. No.235 according to manufacturer datasheet. AC breaker is also adjusted for DC application in the modelling. Then, fault cases are conducted son BESS to investigate the BESS system stability with power protection. The simulation results show that BESS operation is successfully interrupted in 0.02s by DCCB during an internal short circuit event. In addition, ACCB trips with longer time delay to internal fault when DCCB fails to trip. Therefore, ACCB acts as secondary protection in case of DCCB failure. During an external short circuit event, ACCB will trip to protect BESS from AC bus fault by means of BESS isolation. DCCB will never trip because the converter diodes and AC LCL filter have limited the fault current passing through converter.

Abstract

This paper presents a low-cost and user-friendly warehouse management system developed using Arduino and ESP8266 hardware. The system accurately monitors temperature, humidity, and harmful gas concentration, and acts as an intrusion detector in a warehouse environment. It also includes functions for managing and detecting goods using RFID chips and for automatic delivery using unmanned intelligent vehicles. Data is uploaded to a cloud-based relational database in real-time. The system provides a cost-effective and efficient solution for warehouse *management.*

Keywords: Arduino, ESP8266, Warehouse management system, RFID chips, Unmanned intelligent vehicles

1. Introduction

In today's fast-paced business environment, efficient warehouse management plays a crucial role in maintaining a competitive edge [1], [2]. The ability to monitor and control warehouse conditions accurately has a significant impact on the quality of stored goods and overall operational efficiency [3]. To address these needs, the development team has developed a highly extensible, comprehensive, user-friendly, quick-to-deploy, and cost-effective warehouse management system [4].

The system offers real-time monitoring of temperature, humidity, harmful gas concentration, and intrusion detection, ensuring optimal storage conditions and enhanced safety measures [5]. The collected data is seamlessly uploaded to the cloud, enabling easy access to the warehouse conditions from anywhere.

Besides monitoring capabilities, the system also uses ESP8266 and RFID chips to enable efficient goods management and detection. By scanning the RFID chips [6] attached to goods boxes, the system can obtain detailed information about the goods which includes quantity and type. This information is then uploaded to a cloud-based relational database [7], providing real-time visibility of inventory levels and facilitating streamlined inventory management.

Moreover, an experimental proportionally scaled small car model is constructed. The small car can automatically perform point-to-point transportation of goods. Through the integration of routing algorithms, the system optimizes the routing of small cars, ensuring efficient and timely transportation of goods from one location to another without the need for human intervention. This automation reduces manual labor and enhances operational efficiency.

The warehouse management system offers a cost-effective and efficient solution that aligns with the demands of modern business operations. By leveraging cloud computing, RFID, and unmanned intelligent vehicles, a comprehensive platform that enhances warehouse productivity, accuracy, and adaptability is provided.

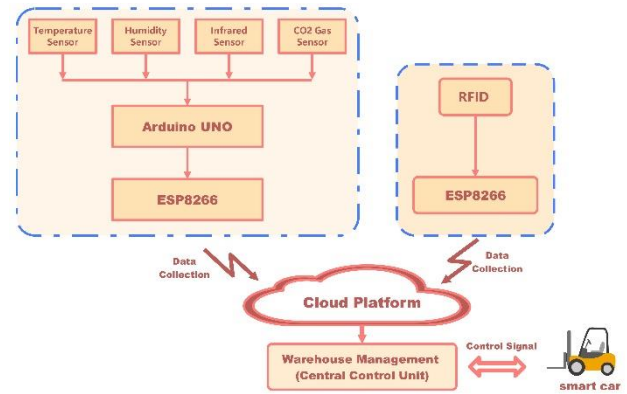
Figure 1 shows the overall structure of the system. The monitoring system and management system return the monitored data to the cloud platform, which then transfers the data to the control section for cargo management.


Figure 1 Overall system architecture diagram

2. Technical Background

The IoT-based warehouse monitoring and management system, utilizing Arduino and ESP8266 hardware, offers a comprehensive solution for real-time monitoring of crucial warehouse parameters. By continuously tracking temperature, humidity, harmful gas concentration, and intrusion detection, the system ensures optimal storage conditions and enhanced safety measures.

To enable seamless data integration and management, the system leverages the Alibaba Cloud IoT platform. This cloud-based infrastructure allows for the efficient uploading and storage of data, providing a centralized hub for monitoring and analysis. The platform also facilitates easy integration with third-party applications, thanks to Alibaba Cloud's well-documented APIs, enabling rapid expansion and deployment of new features.

In addition to real-time monitoring, the system incorporates a cloud inventory management system based on RFID recognition. By utilizing RFID technology, the system enables efficient and accurate goods tracking and management. Each item is equipped with an RFID tag, which allows for quick and reliable identification, inventory updates, and location tracking. This streamlines the

Zhongheng Sun, Yue Zhou, Xun Sun, Wenzhuo Fan, Wenxuan Zhou

inventory management process, reduces manual labor, and minimizes errors.

To facilitate the movement of goods within the warehouse, the system included smart delivery cars. In our experimental system, a proportional scaled small car model is implemented. This automatic car operates based on predefined algorithms and navigates through the warehouse to transport goods to their designated locations. The cars are also able to operate manually using control from Android devices. By automating this process, the system minimizes human intervention, reduces handling costs, and improves overall operational efficiency.

The integration of IoT in warehouse management systems has enabled users to manage their data in real time and proceed with accurate inventory tracking, demand forecasting, and other crucial operations.

To develop the software for the system, Arduino IDE is utilized and Arduino UNO and ESP8266 development chip are used and programmed using C language and Arduino language, creating a robust and reliable software solution that connects seamlessly with the Alibaba Cloud IoT platform using the WebSocket protocol. This protocol ensures low latency, long-lasting connections, and power-efficient environment monitoring.

3. Literature Review

Zhang, B. et al. developed an intelligent warehouse management system utilizing the L298N chip, RC522 for near-field communication, and W5500 module for network communication [8]. The MSP430F5529 microcontroller acts as the central control unit, overseeing tasks such as motor control, data reading, and network communication. The system facilitates smart cargo management, including card activation, encrypted data transmission, and remote monitoring. This innovation streamlines warehouse operations, saving resources, optimizing space, and ensuring reliable security. Particularly beneficial for small to medium enterprises and courier companies, it enhances efficiency and reduces costs.

Christos Spandonidis et al. developed a smart container monitoring system based on the Internet of Things [9]. Key challenges such as weight reduction, fire smoke detection, hardware safety, and logistics maintenance are addressed. By integrating low-cost, low-power sensors, the system is able to track container status and detect critical events such as fire/smoke, impacts, and accidental misuse. Provides better and safer control over cargo loading/unloading operations and flight processes. The experimental results show that the system can make a breakthrough in the current technical level of container technology and aircraft cargo operation.

Xu Zhijie et al. took account of clear and real-time video streams simultaneously [10]. They put forward hybrid multichannel video stream transmission strategies for a remote surveillance system, in which high-quality panoramic video and real-time interactive video are combined together to satisfy surveillance system requirements of high data stream quality and interactive operation.

4. Monitoring System Design

For the monitoring system, Arduino Uno and ESP8266 in conjunction are chosen with the Arduino IDE to implement its functionality. The Arduino Uno is a microcontroller board based on the ATmega328P, while the ESP8266 is a low-cost Wi-Fi microchip with a full TCP/IP stack and microcontroller capability. These devices were chosen for their ease of use, low cost, and versatility compared to other options. Figure 2 and Figure 3 show the monitoring system.
Figure 2 Picture of the monitoring system

In terms of specific functionality, a DHT11 temperature and humidity sensor, an infrared human body sensor, and a harmful gas concentration sensor is connected to Arduino Uno. The DHT11 sensor measures temperature and humidity using a capacitive humidity sensor and a thermistor. The harmful gas sensor detects the presence of harmful gases such as carbon monoxide and methane. Both sensors are connected using serial ports by the software serial port function of Arduino. The infrared sensor detects the presence of humans by measuring changes in infrared radiation. It uses an analog input to transmit data to the Arduino.
Figure 3 Hardware implementation map of the monitoring system

After reading data from the sensors, the Arduino UNO board hardware serial port transmits the data in real-time to the ESP8266 for processing and transmission. The ESP8266 is responsible for processing the data and transmitting it to a cloud server for storage and analysis.

For the logic design of the ESP8266, MQTT and WebSocket protocols are used for transmitting data. MQTT is a lightweight messaging protocol for small sensors and mobile devices, while WebSocket is a protocol for full-duplex communication over a single TCP connection. ESP8266 chip will receive data from the Arduino serial port in bit storage format and perform simple frame header and tail check and bit processing. Then the ESP8266's 2.4G Wi-Fi module is used for establishing a connection to a provided wireless network and to establish a connection with the Alibaba Cloud server using the MQTT protocol over WebSocket. The data is uploaded and displayed in real-time on a front-end page. Figure 4 shows the front-end web page and Figure 5 shows the Hardware implementation diagram of management module.

Figure 4 Picture of the front-end web page

Figure 5 Hardware implementation diagram of management module

5. Management System Design

RFID technology is applied to scan and track goods within the warehouse. The scanned information is then uploaded to a cloud platform, where it is organized into visualized tables, enabling real-time management. Additionally, a feature on the platform that allows us to send instructions to automated cars is implemented by the team, enabling them to transport goods efficiently. Figure 6 shows the management module and small car are shown below.

Figure 6 Photos of the RFID system and car

The implementation of RFID technology in the warehouse management system has significant positive impacts on management efficiency. By scanning RFID tags attached to each item, users are able to accurately track the quantity, name and other relevant information of the cargo. This data can then be transmitted to the cloud-based back-end server, where it is processed and transformed into user-friendly visualizations. This allows warehouse managers and personnel to have a clear overview of inventory levels, stock movement, and overall warehouse performance at any given time.

Furthermore, users can send instructions to the cars, directing them to specific locations within the warehouse to pick up or deliver goods. The system optimizes the routes of the car and ensures that goods of the same category are stored together, maximizing efficiency and minimizing the time required for manual handling.

With the integration of real-time data analytics and automated car operations, the smart warehouse solution provides a comprehensive and efficient approach to inventory management. The combination of RFID technology, cloud-based computing, and automation streamlines processes, reduces errors and enhances overall productivity. As a result, warehouse operations become more agile, cost-effective, and adaptable to changing business demands.

In summary, the warehouse management module leverages RFID scanning, cloud-based data processing, and intelligent delivery car systems to enable real-time inventory tracking, visualization, and streamlined operations. This intelligent solution empowers businesses to achieve higher levels of efficiency, accuracy, and scalability in their warehousing processes.

6. Effectiveness Validation

To verify the effectiveness of the system, the team conducted an on-site verification. The average number of backlogged items in the warehouse for incoming/outgoing shipments is recorded over two weeks, as well as the number of instances where the warehouse's humidity and temperature exceeded the standards (the temperature and humidity test data is collected every hour in a day). The system was not installed in the first week and then installed in the second week. Data changes in these two weeks were monitored and analyzed, and the results are shown in Table 1. The graph of average data for using the warehouse management system as shown in Figure 7.

Table 1 The effect of using our warehouse management system

7. Backend Cloud Service

The backend cloud service offers a comprehensive set of features designed to streamline and optimize users' operations. With a wide range of functionalities, the service serves as an effective tool to enhance the efficiency and effectiveness of management and monitoring processes.

The main function of the cloud service is storing and displaying data. It provides a secure and reliable storage infrastructure that ensures all the data are safely preserved. The intuitive user interface allows for easy access to stored data, enabling quick retrieval and analysis. By centralizing the data of cargo to the cloud service, users can eliminate the hassle of managing multiple data sources and improve data consistency.

Moreover, the cloud service is designed to handle connections between different terminals and data sources, which facilitates seamless integration with various data stream outputs, enabling real-time data synchronization and updating. This functionality ensures that users have instant access to real-time information, enabling timely decision-making and accurate analysis.

One of the most prominent features of the cloud service is its algorithmic path calculation capability. This feature enables users to exercise semi-automatic control over robots or unmanned cars within their operations. The service can calculate optimized paths for the robots, guiding them to transport goods to designated locations with minimal human intervention. By automating this process, handling costs can be significantly reduced, errors minimized, and overall operational efficiency improved.

In addition, the cloud service acts as a transition layer, allowing for seamless integration with third-party secondary data analysis and prediction services. By leveraging these external resources, users can gain deeper insights into their data, identify patterns, and make more informed decisions. This integration enhances the analytical capabilities of the system, enabling users to extract valuable insights and drive continuous improvement in their operations.

8. Conclusion

The study successfully developed a cost-effective, user-friendly and expandable warehouse management system using Arduino and ESP8266 hardware, which has unique advances compared with similar systems [11]. It accurately monitors temperature, humidity, gas concentration, and intrusions. The system utilizes RFID chips for goods management and detection and unmanned intelligent vehicles for automated delivery. Real-time data is uploaded to a cloud-based database, providing an efficient and cost-effective solution for warehouse management [12], [13], and also being effective for monitoring and making decisions for controlling the carbon footprint of the venue under monitoring.

Overall, this system enhances operational efficiency, safety, and reliability. Further research can expand its functionality and applicability in warehouse management.

Abstract

Supermarket shopping is an experience that everyone has in life. This project aims to design an intelligent and user-friendly shopping cart and interactive web page, to elevate the overall customer shopping experience. The shopping cart designed in this project integrates multiple functionalities that allow users to access information about the items within the cart via the interactive web page and exert control over the movement of the cart. While moving, the shopping cart can autonomously detect obstacles in its path and navigate around them. Simultaneously, users can check the total cost of their selected items by reviewing the cart's contents, enabling them to decide whether the cart should continue following them. The project primarily utilizes an ultrasonic module to determine the cart's location and trail a specific customer. The shopping cart employs automatic barcode scanning to identify various products, and the WiFi module facilitates communication with the server via the MQTT protocol, enabling seamless interaction. The fruition of this project serves as a tangible representation of the Internet of Things application, demonstrating how connectivity through the internet enhances people's lives with greater convenience.

Keywords: Internet of Things, ultrasonic ranging, STM32singlechip, smart shopping cart

1. Introduction

The widespread of information, and communication technology, coupled with the advancements in Internet of Things technology, has brought our life into the stage of a smart city. The increase in electronic devices and applications has significantly improved convenience in our daily lives. With the increasing prevalence of mobile devices, the development of smart cities naturally falls toward this technological landscape. Therefore, it is necessary to develop intelligent equipment [1].

In the shopping scene, an intelligent shopping cart can greatly enhance the shopping experience. Essential and fundamental functions of an intelligent shopping cart include automatic following the user as well as automatic obstacle identification and avoidance. Another convenient feature is the automated calculation of the total price of items in the shopping basket. This enables customers to view the items and their respective prices on the web page from their mobile phones, eliminating the need for manual price calculations.

2. Literature Review

In the past, numerous researchers have conducted diverse studies on smart shopping carts. Supermarket owners benefit from these innovations in terms of time savings, reduced manpower, and space efficiency, leading to decreased investments. The smart shopping trolley can be used in all retail shopping malls, supermarkets, hypermarkets, and clothing showrooms [2].

Several innovative concepts have emerged to revolutionize shopping cart design, aiming to enhance the overall shopping experience and reduce human efforts. Sadia *et al.* [3] proposed the integration of RFID technology to bolster the durability of product identification tags. They suggest the implementation of RFID in shopping carts, creating an intelligent shopping system where all supermarket carts are equipped with RFID tags to reduce wait times during the checkout process and improve the customer purchasing experience.

Gunawan et al. [4] installed an IOIO microcontroller and an Android smartphone together with sensors and a controller in a shopping cart. The basket is configured in the shape of a two-wheeled mobile robot.

Yao Chen, Jiacheng Du, Bo Peng, Ningfei Wang, Zehan Huang, Wei Hong Lim, Sew Sun Tiang, Mastaneh Mokayef, Chin Hong Wong

Tai *et al.* [5] also utilized the ultrasonic sensor because of the advantages include a wide detection area, reduced sensitivity to light, the ability to detect glass and shiny surfaces, compact size, lightweight construction, minimal memory usage, cost-effectiveness compared to Laser Range Finder (LRF) or cameras, and lower power.

These investigations into shopping cart functionality and application technology have significantly expanded the research landscape of intelligent shopping carts. As a result, tasks have become more focused and precise, yielding results that align smart shopping carts more closely with people's evolving needs.

3. Methodology

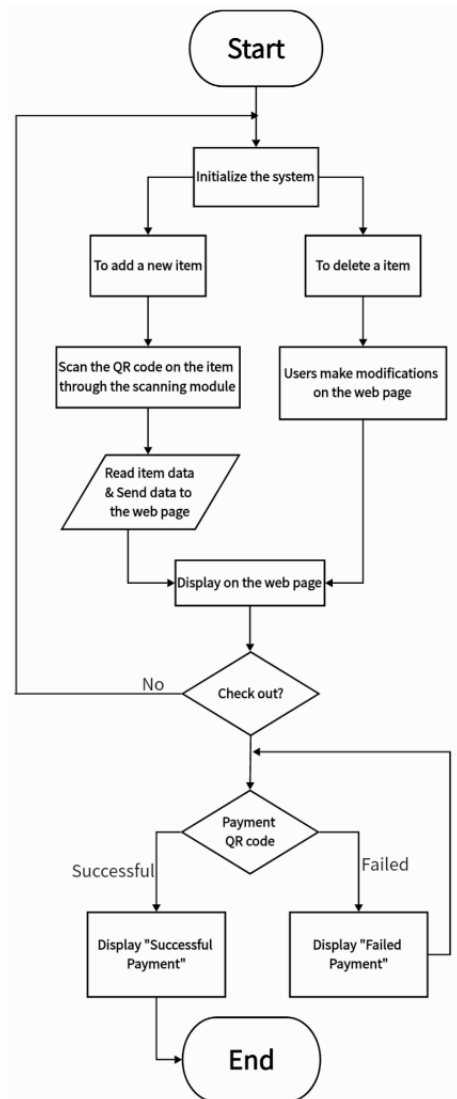
Figure 1Figure 1 shows a flow chart for the smart shopping cart system from the user side whereas Figure 2 illustrates a flow chart for the operation of the shopping cart.


Figure 1 Flow chart for the smart shopping cart system from the user side
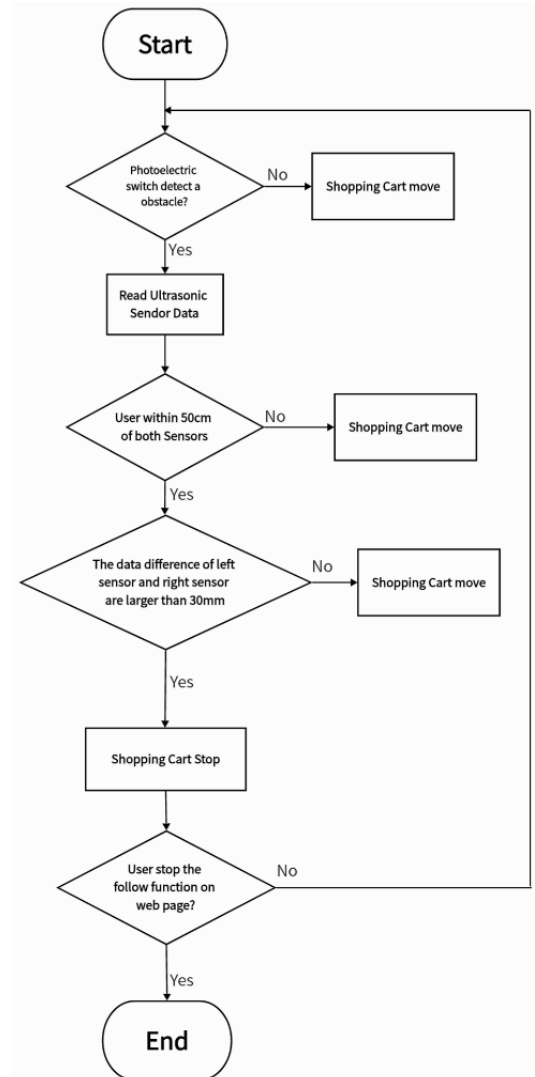

Figure 2 Flow chart for the operation of the shopping cart

When the shopping cart is started, it will detect obstacles by photoelectric switches and avoid them. The ultrasonic sensor will provide real-time feedback on the distance between the user and the shopping cart. If the distance between the shopping cart and the user, as well as the orientation of the shopping cart, exceeds the set range, the shopping cart will move and adjust the distance and direction. The mobile function of the shopping cart will continue until the user stops the function on the webpage. In addition, users can use the QR code scanning module on the shopping cart to scan the QR code of the product and add it to the shopping list on the webpage, to manage the list and settle the payment on the webpage.

3.1. Microcontroller

STM32 F407 ZET6 is used as the main controller of the shopping cart. By handling the information obtained from sensors and servers, the controller is able to control the movement of the shopping cart and communicate with the user.

3.2. PCB Module

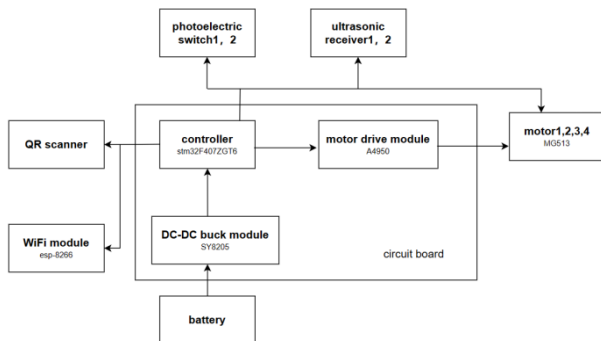
The PCB circuit board consists of STM32 F407ZET6 main control board, DC-DC buck module, A4950 dual motor drive module, ultrasonic sensor, photoelectric switch sensor, two-dimensional code module and motor encoder as shown in Figure 3 and Figure 4. The circuit board is highly integrated and the modular design makes it easy to update and repair.
Figure 3 Connection between the main board, sensors, and wheels


Figure 4 Block diagram for the circuit connection

3.3. DC-DC Antihypertensive Module

The DC-DC antihypertensive module employs the SY8205 chip, a high-efficiency synchronous stepdown DC-DC converter capable of delivering a 5 A output current. The SY8205 operates over a wide input voltage range from 4.5 V to 30V and integrates the main switch and synchronous switch with very low RDS(ON) to minimize the conduction loss. The module consists of two voltage outputs, one 5V voltage and another output to meet the diverse voltage requirements of various modules.

The chassis for the shopping cart is crafted from a 6 mm thick POM plate through laser cutting as shown in Figure 5(a). The chassis is used to hold the shopping cart bracket, circuit board and various sensors. Furthermore, 3D

printing technology is used to print the clamp to hold the ultrasonic sensors as shown in Figure 5(b).
Figure 5 (a) The chassis and (b) the ultrasonic clamp

3.4. Mecanum Wheel

The outer ring of the Mecanum wheel as shown in Figure 6 is equipped with rollers arranged a 45° to the axle and contact with the ground. During rotation, the friction generates a 45° reverse thrust force along the axle. This oblique thrust force can be divided into two vectors which are longitudinal and transverse. The entire vehicle is propelled by two pairs of Mecanum wheels, each featuring a mirrored arrangement of rollers. Each wheel generates its own vector, and the combined force of these vectors determines the final motion of the car [6].
Figure 6 Mecanum wheel

Omnidirectional motion is achieved by installing four Mecanum wheels at the corners of the chassis. The overall velocity, V, can be obtained through Eq (1), where V_x, and V_y indicate velocity in the x-direction and y-direction respectively and ω is the angular velocity, as shown in Figure 7.
Figure 7: The direction of velocity.

$$\rightarrow \quad \rightarrow \quad \rightarrow \quad \rightarrow \tag{1}$$

Yao Chen, Jiacheng Du, Bo Peng, Ningfei Wang, Zehan Huang, Wei Hong Lim, Sew Sun Tiang, Mastaneh Mokayef, Chin Hong Wong

$$\vec{V_1} = \left|\vec{V_X}\right| - \left|\vec{V_Y}\right| - \left|\vec{\omega} \times (a+b)\right|$$
$$\vec{V_2} = \left|\vec{V_X}\right| + \left|\vec{V_Y}\right| - \left|\vec{\omega} \times (a+b)\right|$$
$$\vec{V_3} = \left|\vec{V_X}\right| + \left|\vec{V_Y}\right| + \left|\vec{\omega} \times (a+b)\right|$$
$$\vec{V_4} = \left|\vec{V_X}\right| - \left|\vec{V_Y}\right| + \left|\vec{\omega} \times (a+b)\right|$$

3.5. Ultrasonic Ranging

To measure the distance between the user and the shopping cart, two ultrasonic sensors were positioned at the front end of the shopping cart as illustrated in Figure 8. These sensors were positioned roughly parallel to the user's waist.
Figure 8: Overall view of the shopping cart.

By taking an ultrasonic transmitter in users' hands, the receivers can receive the ultrasonic waves and calculate the distance between the transmitters and receivers. These distances are denoted as X_1 and X_2 respectively [7]. The concept of the transmitters and the receivers is illustrated in Figure 9.
Figure 9: The concept of the transmitters and the receivers

3.6. Cascade PID

Cascade control is one of the most successful methods for enhancing single-loop control performance, particularly when the disturbances are associated with the manipulated variable and the final control element exhibits nonlinear behavior [5].

In the controlling of the Mecanum wheelbase, two desired distances between the ultrasonic transmitter and receivers are denoted as X_3 and X_4 serve as the input of the cascade PID. To control the distance between the user and the shopping cart, the distance $(X_1 + X_2)/2$ is considered as the feedback and 0.5 m is set as the desired input for the Position PD control. To ensure the front of the cart always faces the user, $(X_1 - X_2)$ is considered as the feedback and zero difference as the desired input of the Angle Loop PD control. With position control and angle control, V_x, V_y and ω can be calculated. By utilizing the calculated V_x, V_y and ω as the input for the Velocity Loop PID, the final PWM signal is conveyed to the motor as shown in Figure 10.
Figure 10: Block diagram of PID control.

3.7. Obstacle Avoidance

Two E18-D80NK photoelectric switches are placed on the front of the cart as illustrated in Figure 8. Upon any obstacle is detected, the cart will stop following the user and overtake the obstacle. As soon as the cart overtakes the obstacle and no other obstacles exist, the cart will continue the job.

3.8. Server Communication

Advancements in the Internet of Things (IoT) have enabled innovations in smart home and industrial automation, offering possibilities for remote monitoring and controlling devices. These solutions contribute to energy efficiency and cost saving, as appliances are monitored and controlled by small, resource-constrained embedded devices [8].

To establish communication with the server, an esp-8266 WiFi module is connected to the microcontroller board. By using the Message Queuing Telemetry Transport (MQTT) protocol, the controller is able to publish topics containing commodity information to the server and subscribe to topics conveying user input from the server.

In this system, the server initiates requests to the front-end controller through HTTP and utilizes the MQTT protocol for communication with the embedded device. The back-end is developed in Java, leveraging the SpringBoot framework to simplify the complexity of the

development, and incorporates MySQL for database connectivity and data persistence. In practical scenarios, the server needs to establish a long connection with a large number of embedded devices. The traditional blocking I/O involves threading, and the frequent switching between threads can lead to significant overhead. Therefore, domestic smart sockets are employed as the underlying I/O container to address these challenges.

A prototype incorporating these features has been successfully implemented and tested within a simple home automation network to validate its functionalities. The results demonstrate that the system responds rapidly, preventing overconsumption and electrocution hazards. This capability positions the technology to contribute to creating safer and smarter homes in the next generation [9].

The multiplexing of threads is achieved using thread pool and asynchronous callback technologies. This approach effectively reduces the overhead associated with thread creation and destruction, resulting in a substantial improvement in the system's load capacity.

3.9. QR Code Scanner

QR codes are a cost-effective technique because they are easily created and printed on a surface for distribution, often being incorporated into existing print materials. This is why the QR code was selected as a fundamental component in the design of this shopping cart [10]. The packaging of the goods is equipped with a corresponding QR code. To identify commodity information, a QR code scanner is employed, and the gathered data is transmitted to the microcontroller. The QR scanner is attached to the back of the shopping basket as shown in Figure 11.
Figure 11: QR code scanner

3.10. Interactive Webpage

Users can communicate with the shopping cart and decide whether to enable the shopping cart to follow. Alternatively, even when the shopping cart is not set to follow during the shopping process, it can still be utilized for remote communication, allowing the shopping cart to

resume following the user as needed, achieving the effect of remote communication.

There is also a shopping cart commodity settlement interface where users can view the product information in the shopping cart through the web page. Additionally, each time a product is added, users can monitor the total cost and the quantity of items in the shopping cart through the settlement function. This process allows users to easily track if they exceed their estimated budget, minimizing the need for users to independently calculate commodity prices. Users can also modify the quantity of goods on the webpage or remove items from the shopping cart, contributing to a smoother shopping experience as illustrated in Figure 12. In short, this system enhances the user's shopping experience by streamlining the checkout process and providing greater control over the shopping cart contents.

Figure 12: Example of web interface.

4. Results and Discussions

To assess the stability and accuracy of the shopping cart in actual operation, conducting relevant tests becomes imperative.

4.1. Maximum Start Distance

To evaluate the maximum distance capability of the shopping cart's following function, a test involves initiating the following function in front of the shopping cart while it is in a static state. This method allows the observation of the shopping cart's following stability under varying distances between individuals and the cart.

Under unchanged conditions, the start distance between the user and the shopping cart was set to 10 cm, 50 cm, 100 cm, and 200 cm with the desired follow distance maintained at 40 cm. Figure 13, Figure 14, Figure 15 and Figure 16 show the results of the distance between the cart and the user against time. In the legend, 'Left'

Yao Chen, Jiacheng Du, Bo Peng, Ningfei Wang, Zehan Huang, Wei Hong Lim, Sew Sun Tiang, Mastaneh Mokayef, Chin Hong Wong

represents the data from the left ultrasonic receiver, and 'Right' indicates the data from the right ultrasonic receiver.
Figure 13: 10 cm starting distance between the user and the shopping cart against time.
Figure 14: 50 cm starting distance between the user and the shopping cart against time.
Figure 15: 100 cm starting distance between the user and the shopping cart against time.
Figure 16: 200 cm starting distance between the user and the shopping cart against time.

From the test results, when the distance between the user and the shopping cart is between 10 cm to 200 cm, the shopping cart can quickly adjust the distance to the user after the start of the follow function. When the distance between the user and the shopping cart exceeds 200 cm, the ultrasonic module experiences unstable data reception. This instability prevents the shopping cart from promptly adjusting itself after activating the follow function, resulting in a failure to follow accurately. Therefore, the effective start distance for the shopping cart is set between 20 cm and 200 cm.

4.2. Turning Test

To test the follow function of the shopping cart during the user's turning process, two circular experiments were conducted. The tester walked along circles with radii of 1m and 2m at normal speeds, while the shopping cart followed. Figure 17 and Figure 18 show the turning test results.
Figure 17: Distance between the user and the shopping cart against time for the tester walking along a circle with a radius of 1 m.
Figure 18: Distance between the user and the shopping cart against time for the tester walking along a circle with a radius of 2 m.

According to the test results, it is observed that when the turning radius is greater than 1 m, the shopping cart promptly adjusts its distance to the user.

4.3. Walking Test

To evaluate the follow function in a shopping scenario, two circular experiments were conducted. The tester

walked at speeds of 1.5 m/s and 3 m/s, representing normal walking and jogging speeds, while the shopping cart followed. The test results are illustrated in Figure 19 and Figure 20.
Figure 19: Distance between the user and the shopping cart against time with 3 m/s walking speed.
Figure 20: Distance between the user and the shopping cart against time with 1.5 m/s walking speed.

Based on the test results, when walking at a normal speed and activating the follow function, the shopping cart can successfully follow the user throughout the shopping process.

5. Conclusion

This paper highlights the accomplishments in developing a smart shopping cart system with automatic following, obstacle avoidance, and web interface-generated shopping lists. The acknowledgement of potential improvements, such as performance optimization and enhanced user interfaces, adds a realistic and forward-looking perspective. The mention of future research directions, including adaptability to different shopping scenarios, demonstrates an awareness of potential advancements.

Abstract

This paper introduces a compact four-port MIMO antenna for ultrawideband (UWB) applications measuring 60×60 mm^2. Printed on a single layer flame resistant (FR-4) substrate (permittivity of 4.3, thickness 1.6mm), the antenna features four microstrip cells, each orthogonal to its neighbor for improved isolation. It includes a rectangular patch with staircase slits and a stepped feed line. Square stubs at the top center enhance isolation. The antenna boasts a significant return loss (-43.75dB), wide impedance bandwidth (1.967-12GHz), and an isolation below -15dB. Its envelope correction coefficient (ECC) is under 0.02 with a moderate 4.4dBi gain. Although its 63% radiation efficiency could be enhanced, the antenna's ultrawide bandwidth and compactness make it suitable for UWB wearable IOT applications.

Keywords: UWB antenna, MIMO antenna, MIMO performance.

1. Introduction

The frequency of ultra-wideband (UWB) technology was set to 3.2-10.6GHz by the Federal Communication Commission (FCC) which garnered great attention of researchers due to its promising solution to scarcity of spectrum resources. Compared to traditional narrowband technology, UWB offers more advantages and several capabilities including short range, high transmission, high bandwidth, low energy usage, low complexity, and good radiation. With this, UWB positions itself to being useful in applications such as short-range communications, sensor networks, tracking, and positioning systems [1], [2].

In a multi-path environment, UWB systems are prone to signal fading which degrades the performance of the entire system. To address this issue, Multi-Input-Multi-Output (MIMO) technology has been used to provide a multi-element patch antenna for signal transmission and reception. This implementation significantly increases spectral efficiency, reliability, and channel capacity without utilizing additional power and spectrum. The enhanced features of MIMO UWB antennas such as high data rate and exclusion from interference make it a perfect candidate for wearable and IoT applications especially in healthcare industries. Radiation exposure from the antenna is heavily monitored to be as small as possible to ensure that it does not harm human tissues since it is in close contact with human skin [2].

However, the usage of more than one radiating element, closely arranged to one another in MIMO may lead to high signal correlation and reduce the overall antenna efficiency. Therefore, appropriate decoupling needs to be done between antenna elements for better isolation in modern communication. The challenging part is to design UWB-MIMO with low isolation by keeping minimum distance between antennas. In [1], a UWB-MIMO antenna with square shaped decoupler and rectangular metallic stubs was designed to reduce mutual coupling and improve isolation. The antenna offers stable gain with peak gain at 6.8dBi, low ECC value of 0.001 and high diversity gain of 9.9. Besides, flexible substrates such as polymer, paper, and Kapton are important in the designing of wearable UWB. In [3], a wristband MIMO antenna is designed that covers frequency range of 2.75-12GHz with silicone rubber as substrate material that is used to monitor children and patients, ensuring user safety. In [4], the author proposed the use of liquid crystal polymer (LCP) that operates between 2.9-10.86GHz which results in a flexible MIMO antenna that performs well in bending and on-body conditions, suitable in wearable fields. Another result obtained from [5], uses bendable substrate FR-4 that operates up to 17GHz from 3.89GHz with stable gain.

Jia Wei Tan, Sew Sun Tiang, Kim Soon Choong, Mohammad Arif bin Ilyas, Mastaneh Mokayef, Zhi Ying Yeoh, Wei Kang Lai, Wei Hong Lim

Moreover, the design of UWB is very challenging to achieve optimized frequency and time, stable polarization, as well as low dispersion. In [6], the author proposed a methodology that introduces slotted ground structure which is a widely used technique to improve the impedance bandwidth and minimize the ground plane effects in UWB. In [7], 4 ports rectangular monopole antennas with step etching on ground plane and arrow-shaped slot on radiating patch using FR-4 substrate operates at frequency 3.1-10.6GHz, has high isolation of -17.4dB, ECC less than 0.001 which in turn decreases mutual coupling. In the medical field, wearable devices are achieving profound recognition when designed using MIMO antenna due to their quality signal and high capacity without increasing transmitted power.

This paper proposes the design of four port UWB-MIMO antenna suitable for wearable and IoT applications which is done by utilizing the CST software that involves careful selection of flexible substrate properties, structure of microstrip patch, and feed network. The design uses copper conductor for patch and FR-4 as substrate material that covers wider bandwidth and higher efficiency characteristic with low dielectric loss and high thermal endurance. The width of the microstrip and gap between the patches are adjusted to obtained impedance matching of 50 Ohm. The finalized antenna is measured at different parameters such as reflection coefficients, gain, radiation pattern, current distribution, ECC, DG, radiation and total efficiency for further analysis and improvements. Table1 shows summary of comparison between existing UWB-MIMO antennas and proposed work.

2. Material and Methods

2.1 Single Element Antenna Design

The configuration of the proposed UWB single element microstrip antenna shown in Fig. 1. The fundamental structure of the antenna consists of three layers which are metal layer on top and bottom with substrate material, in between. The design begins with a rectangular radiating patch that uses a 50Ohm transmission line feeding technique to feed signal to the resonating patch. The ground plane size is decreased for low profile and optimization for attaining enhanced impedance bandwidth. Two symmetrical staircase-shaped slits are introduced on both sides of the radiating patch to further enhance the impedance bandwidth.

a. Front view of antenna design

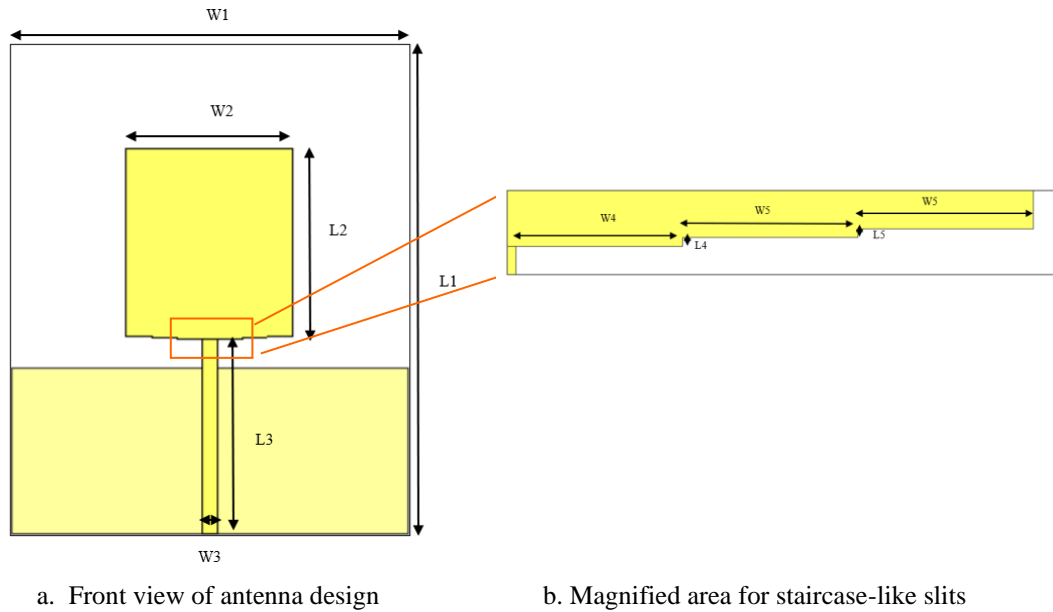
b. Magnified area for staircase-like slits


Fig. 1 Geometry of proposed antenna design.

Table 2. Optimized Parameters for the Proposed Four Port MIMO Antenna.

Parameters	W1	W2	W3	W4	W5
Values (mm)	31	13	3	1.65	2
Parameters	L1	L2	L3	L4	L5
Values (mm)	42	15.6	15.3	0.1	13

Table 2 shows the optimized parameters for the proposed four port MIMO antenna. The material chosen for the antenna patch is copper (annealed) because it is much softer and malleable which makes it easier to shape during the fabrication stage. On the other hand, the flexible dielectric substance used is flame-resistant (FR4) with dielectric constant of 4.3 and tangent loss of 0.019. Some key features of this substrate material include low cost, easily available and relative mechanical and electrical stability. It is mostly found in microstrip and stripline circuits, as well as point-to-point digital radio antennas. The thickness of the UWB microstrip antenna is 1.8mm with copper (annealed) 0.1mm and substrate as 1.6mm respectively. Overall, the FR4 substrate based UWB antenna, and its resonating patch has sizes of $31 \times 42 \times 1.7$ mm^3 and fed by a $3 \times 17 \times 0.1$ mm^3 transmission line.

The operating range of antenna generated is 2.74-10.59GHz shown in Fig. 2 which fulfills the requirement of UWB but is lesser compared to the values from the article [14] which obtain 2.9-11GHz.
Fig. 2 Simulation results of return loss (S11) for single-slot antenna

2.2 Four-Element Flexible UWB Antenna

From the single element in Fig. 1, a four-port flexible MIMO antenna array was designed as shown in Fig. 3 (b) with a square-shaped stub inserted between orthogonal element antennas for better isolation performance.

a. Without isolator

b. With isolator branch
Fig 3. Four Port UWB MIMO antenna

3. Result and Discussion

The layouts were designed and simulated using CST software to determine the antenna performance in different aspects.

The S11 parameter graph is a measure of how well devices or lines are matched. A high return loss is desirable for lower insertion loss. The simulated result for return loss from the proposed UWB four-port antenna is displayed in Fig. 4 (a). The first antenna result without branch isolator (green line) shows much narrow impedance bandwidth with frequency range of 3.925-12GHz for S11 < -10dB. Besides, the return loss value is acceptable, which is -22.49dB at resonant frequency of 4.42GHz but can be improved to reduce power reflected to the system. This leads to the addition of a branch isolator (red line) to improve both return loss and bandwidth values. The S11 value almost increased twofold with value highest return loss value of -43.94dB at resonant frequency of 8.124GHz, larger bandwidth, and wider frequency range of 1.926-12GHz. The rest of the resonant frequencies for S11 below -10dB are recorded at 2.292GHz, 4.14GHz, 6.6GHz and 11.076GHz.

The remaining parameters are also compared such as S12, S13 and S14 to determine the isolation as shown in Fig 4 (b), (c), (d). The measured operating frequency covers 2.0-12GHz. The implementation of branch isolators affects S12, S13, and S14 whereby most of them are below -15dB (red line) and this shows good isolation properties. With an almost similar isolation design, the result from A. A. Ibrahim, et al [13] shows better isolation which is greater than -20dB when the isolation ports are added.

(b) Directivity at resonant frequency of 8.124GHz.

Fig 5. Gain and directivity at resonant frequency of 8.124GHz.

Fig. 6 (a), Fig. 6(b), Fig. 6(c), Fig. 6(d), and Fig. 6(e) shows the radiation pattern of the proposed four-port flexible antenna on H-plane and E-plane at different resonant frequencies. The simulation and test results were obtained when port 1 was used as excitation. The H-field and E-field exhibit a directional pattern whereby the energy is concentrated and focused on specific directions at degrees of 44° and 178° for all resonant frequencies. It allows far-distance communication due to higher gain and directivity.
(a) Radiation pattern at 2.292GHz.
(b) Radiation pattern at 4.414GHz.
(c) Radiation pattern at 6.6GHz.
(d) Radiation pattern at 8.124GHz.
(e) Radiation pattern at 11.076GHz.

Fig 6. Radiation pattern on H-plane and E-plane of four port MIMO UWB antenna at different resonant frequencies

The surface current distribution is measured at port 1, 2, 3 and 4 with resonant frequencies at 2.292GHz, 4.14GHz, 6.6GHz, 8.124GHz and 11.076GHz and tabulated in Table 4. Fig. 7 shows the pattern of the selected resonant frequency, 8.124GHz, where the rest have similar current diagrams. The current density is most evident at the antenna feedline denoted by warm colors of red and orange color map which contributes to stronger radiation and better performance but can result in higher potential for losses and prone to heating easily due to high dissipation of electromagnetic fields and energy. The rest of the areas that are mostly displayed in blue or green colors experience low current density whereby it has

Jia Wei Tan, Sew Sun Tiang, Kim Soon Choong, Mohammad Arif bin Ilyas, Mastaneh Mokayef, Zhi Ying Yeoh, Wei Kang Lai, Wei Hong Lim

weaker radiation and signal strength but less susceptible to losses.

Table 4. Surface Current Value at Port 1 to 4 at Different Resonant Frequencies.

Resonant Frequency (GHz)	Port 1 (A/m)	Port 2 (A/m)	Port 3 (A/m)	Port 4 (A/m)
2.292				
4.14	37.0092	37.9358	38.3408	37.0869
6.6				
8.124	29.5007	33.4613	30.3317	34.7738
11.076	37.0092	37.9358	38.3408	37.0869
Fig. 7 Surface current distribution of four-port UWB MIMO antenna at resonant frequency, 8.124GHz.

The average radiation and total efficiency of the antenna is only recorded between 6GHz-12GHz due to mesh limitation in frequency domain. Fig. 8 shows the value in dB (magnitude) which is approximately 55% and 54% after converted to percentage form. These values are considered marginally acceptable because good antenna design can reach up to 80%. Hence, the design can still be further improved by careful calculation of geometry and dimensions, matching networks to achieve maximum performance whereby it provides better signal strength and reduces interference which are important factors for improving the reliability and operability of wearable devices in IoT applications.
Fig. 8 Radiation efficiency and total efficiency of four-port UWB MIMO antenna.

The diversity performance of the UWB-MIMO antenna was evaluated by Envelope Coefficient Correlation (ECC) and diversity gain (DG). ECC parameters reflect the degree of correlation between adjacent elements of MIMO antennas and are expected to be less than 0.5. The ECC parameters between the antenna's ports are shown in Fig. 9 (a) which are less than 0.02 in the operating frequency band and indicate good isolation between ports.

DG evaluates the quantified improvement in signal-to-noise ratio when antenna in the MIMO system receive the RF signal. The DG parameters between different ports are given in Fig. 9 (b) It shows that satisfying DG values are achieved with values above 9.938 for the whole operating frequency band (1.926-12GHz) which gives better diversity characteristics.
(a) ECC
(b) DG

Fig 9. ECC and DG values for four-port UWB MIMO antenna.

Conclusion

This paper proposed a small, compact, and flexible four-port UWB MIMO antenna designed for wearable and IoT applications with overall dimensions of $60 \times 60 \times 1.8$ mm^3. The proposed antenna was arranged orthogonally to each other to form a four-port MIMO antenna structure and the final design shows that the antenna can operate in the whole UWB band covering from 1.926 to 12GHz with moderate isolation of -15dB. The isolation was achieved by adding a square-shaped stub at the top center with elongated strips extending to the edge of the substrate. It

has a high return loss value of -43.65dB, total efficiency of approximately 60%, gain of 4.4dBi, and good diversity performance, with ECC less than 0.02 and DG larger than 9.93dB. In summary, the proposed antenna can be considered as a viable candidate for UWB-MIMO wireless applications.

Abstract

In power electronics, accurately assessing simulation tools is key for precise, reliable electronic system designs. This study compares MATLAB Simulink and PLECS in modeling a 5W USB charger's power characteristic. The charger, using an AC-DC full bridge rectifier and DC-DC flyback topology, delivers a stable 5VDC at 1A. The analysis focuses on power efficiency and thermal characteristics, incorporating real-life components for detailed insights. Results show PLECS, specialized in power electronics, surpasses MATLAB in accuracy and consistency. This research aids in understanding simulation tools' effectiveness, guiding engineers and researchers in power efficiency evaluations for electronic systems.

Keywords: Power electronics conversion, MATLAB Simulink, PLECS, USB charger, simulation, power efficiency, thermal analysis.

1. Introduction

Power electronics conversion is an essential technology utilized in the landscape of modern technology, permeating various aspects of daily life applications. Power electronics converters serve as a transformative agent in the regulation and control of electric energy flow.

A static power converter is a converter made up with the architecture of electrical components such as transformers, diodes, capacitors, and inductors. Electrical components work together transforming electrical energy from one form to another. From Fig. 1, notable ideal power converter can be observed, controlling the flow of power between two sources aiming to enhance the power efficiency [1]. Power conversion can delve into four categories which are DC to DC converter, AC to AC converter, DC to AC converter and AC to DC converter.
Fig. 1 Power converter topologies.

In recent years, significant improvements in power electronics technology. These advances include breakthroughs in converter topologies, control strategies, and power semiconductor devices, which together have contributed to the continuous improvement and widespread application of modern power conversion systems [2].

USB chargers are one of the illustrations of daily life, where the fundamental principles of power conversion. USB chargers are ubiquitous for charging electronics devices such as laptops and smartphones. In contemporary times, USB chargers are designed with emphasis on fast charging of electronics devices [3]. However, this design of faster charging rates can lead to increased energy

Zhi Ying Yeoh, Kim Soon Chong, Sew Sun Tiang, Mohammad Arif Ilyas, Jia Wei Tan, Wei Kang Lai, Wei Hong Lim

loss and heat generated, potentially diminishing the performance of power efficiency.

This paper focuses on using a USB 5-Watt charger as an evaluation method to evaluate the performance of MATLAB Simulink and PLECS software in accurately modeling and predicting the power characteristics of the charger. By conducting a detailed comparative analysis, this study aims to elucidate the disparities in results obtained from each software, shedding light on the strengths and limitations of MATLAB Simulink and PLECS in the context of power efficiency simulations.

The outcomes of this research will not only contribute to a better understanding of the capabilities of these simulation tools but will also assist engineers and researchers in making informed decisions when assessing power efficiency in various electronic systems.

2. Related Work

In the pursuit of advancing understanding of power electronics and simulation tools, a comprehensive review of related work lays the groundwork for our exploration. This section begins by exploring the AC-DC bridge converters, and DC-DC Flyback converter, essential components in designing the 5-Watt USB charger. By continuously adjusting the Proportional-Integral value to fine-tune and achieve the desired output voltage in the 5-Watt USB charger. Understanding converters is crucial for operating and evaluating their role in enhancing power efficiency, and thermal analysis.

2.1. *AC-DC Bridge Converter*

The AC-DC bridge converter, also known as the dual active bridge (DAB) converter, is a power electronic device used for converting alternating current (AC) to direct current (DC) and vice versa and the process known as rectification. The DAB converter, as outlined in Fig. 2 utilizes a bidirectional power flow and high-frequency isolation with a bridge topology featuring two sets of switches and a transformer [4].
Fig. 2 DAB Converter Topology.

The DAB converter operates by modulating the phase-shift of the switches to control the power flow and achieve AC-DC or DC-AC conversion. It implements both frequency and time-domain analysis to capture the transient behavior of the converter, offering the advantages of steady-state frequency-domain analysis [5]. The converter can be configured to achieve full soft-switching operation, high efficiency, minimize distortion in input current, and provide output short-circuit protection [6]. One notably advantage of DAB is seamless four-quadrant operation [6], [7], [8], [9].

2.2. *DC- DC Flyback Converter*

A Flyback converter, specifically DC-DC converter is a type of power converter that uses a transformer to transfer energy from the input to the output.

The working principles of flyback converter is storing energy in the transformer during on time switching transistor, and then releasing it to the output during off time of switching transistor, as outlined in Fig. 3. This allows for voltage conversion and isolation between the input and output. The flyback converter can be used in various applications, such as AC-DC power supplies, power factor correction circuits, and active-clamp flyback converters [10].
Fig. 3 The Operation of Two States of Flyback Converter.

2.3. *Proportional-Integral*

A Proportional-Integral (PI) controller is a type of feedback control system commonly used in power electronics to regulate the output of the power converters. It combines proportional (P) and integral (I) control actions to achieve the desired output.

The P value generates an output proportional to the current error, while the I value aids eliminating any residual steady-state error by integrating the error over time. In this project, the PI controller is implemented in the DC-DC Flyback converter in regulation to achieve desired output of USB charger.

2.4. *Thermal Analysis*

Thermal analysis is an important aspect of power USB charger configuration, due to it bringing effect on the reliability and safety of the system. The proper working of the charger's thermal considerations is a basic part of power electronics design. Several studies have been conducted on the thermal design of wireless chargers for electric vehicles [11], miniaturization and thermal design of battery chargers [12], and thermal analysis of transformers in on-board chargers for electric vehicles [13]. These studies use simulation tools to predict losses and temperature and establish thermal networks of heating components to calculate hotspot temperatures.

2.5. *Power Efficiency*

Power efficiency in USB chargers can be described as the charger's ability to convert electrical power from the source to the device, allowing it to be charged with minimal loss. It is a critical factor in determining the charging time and energy conservation.

Achieving high conversion efficiency is essential for optimal operation and robustness under varying conditions, as seen in the context of mobile battery charger ICs, where techniques like zero current switching (ZCS) are employed [14]. Therefore, power efficiency in USB chargers is essential for improving device charging, energy conservation, and the development of innovative charging technologies.

3. Materials and Methods

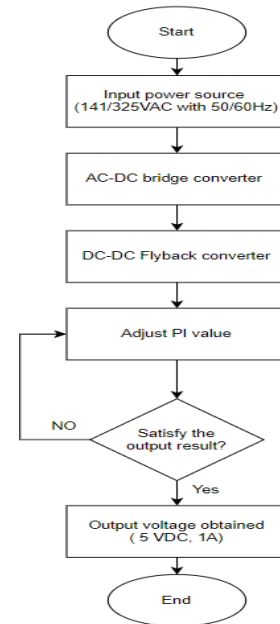
Overview of 5-Watt USB charger described overall input AC voltage to output DC voltage, as outlined in Fig. 4. The process begins with an input of 141/325 VAC with a frequency of 50/60Hz. This input voltage is directed through the AC-DC bridge converter. In this stage, the AC input voltage undergoes rectification, transforming it into a pulsating DC voltage. Subsequently, the pulsating DC voltage undergoes filtering and smoothing to ensure a stable waveform. The smoothed DC voltage then progresses through the DC-DC flyback converter, where it is stepped down to the desired level, providing isolation and regulation in the transformation process. To fine-tune and optimize the output results, a PI controller is applied, ensuring that the output voltage remains regulated at 5V DC with a current capacity of 1A.


Fig. 4 Overview of 5-Watt USB Charger.

3.1. *The Design Procedure of 5-Watt USB Charger*

The design and implementation of a 5-Watt USB power charger involves the integration of an AC-DC full bridge rectifier employing a DC-DC flyback topology.

The primary objective of this charger is to deliver a maximum output current of 1A with a consistent output voltage of 5VDC. Achieving this goal requires the inclusion of a 5-ohm load resistor in the circuit.

To ensure the charger's adaptability for global use, it accepts two AC input voltages (V_{in}), as outlined in Table 1, providing corresponding output DC voltage, (V_{out}). The switching frequency, (f_{sw}) is set at 40kHz to optimize the performance of the charger.

Table 1. The Calculation of AC Voltage Input with Frequency.

AC Voltage	Input Voltage	Frequency
100V	100 x $\sqrt{2}$ = 141.42V	50/60Hz
230V	230 x $\sqrt{2}$ = 325.26V	50/60Hz

The Flyback equation was employed to calculate the winding ratio (n), critical inductance (Lc), and critical capacitance (Cc) for component selection in the high-frequency transformer and Flyback circuit capacitor. This calculation involves utilising known variables such as resistance (R), duty cycle (D) and output ripple voltage (ΔVo).

Number of turns ratio of transformer in flyback converter to calculate the value of Lc and Cc.

$$n = \frac{N2}{N1} = \frac{V_{out}(1-D)}{V_{in} * D} \qquad (1)$$

Critical Inductance and critical capacitor for Flyback circuit.

$$L_c = \frac{(1-D)^2 * R}{2 * f_{sw}} (\frac{N2}{N1})^2 \qquad (2)$$

$$C_c = \frac{D * V_{out}}{R * \Delta V_o * f_{sw}} \qquad (3)$$

Following the calculation of Lc and Cc using the Flyback equation, the appropriate high-frequency transformer, and inductor was selected.

To mitigate ripple voltage and ensure converter stability, a higher capacitor value was subsequently chosen in accordance with the formula. The selection of a higher capacitor value is essential for reducing ripple voltage, even though it may result in a higher peak current at the input. These components specifications are outlined in Table 2.

Table 2. The Specification of the Converter.

Converter Type	AC-DC Bridge Rectifier, DC-DC Flyback Topology
Switching Device	MOSFET (C3M0120065J by CREE was used)
Switching Frequency	20kHz -100kHz
HF Transformer	EE Series (EE16 74091 Flyback Transformer by MYRRA was used)
AC to DC Diode	IN5819
Capacitor	250uF
Inductor	6000uH
Controller Type	PWM PI Feedback Control (No overshoot and 0,1 Second Settling)
Input Voltage	Region Independent (230/100 VAC at 50/60Hz)
Output Voltage	5 VDC
Output Current	1A
Load Type	Resistor (5-ohm)

The proportional-integral (PI) value was tuned for a settling time within 0.1 seconds without overshooting.

For diode selection, the circuit's maximum current was observed on an oscilloscope, guiding the choice of a diode capable of withstanding the surge forward current. Finally, measurements were conducted to assess metal-oxide-semiconductor field-effect transistor (MOSFET) temperature and power efficiency.

3.2. *The Simulation on MATLAB Simulink and PLECS*

MATLAB Simulink and PLECS were utilized for running simulations, which play a significant role in the selection of components for the power converter. The design overview of the AC-DC 5-Watt USB charger on MATLAB Simulink and PLECS software are shown on Fig. 6 and Fig. 7. Additionally, the PWM PI feedback control was implemented to address steady-state error, requiring lower forward gain.

The PI controller ensures a stable 5V output under varying input voltages by generating a corrective signal to address system faults. Manual adjustments to the proportional and integral values of the PI controller were made until the desired output was stabilized without overshooting.

The flyback capacitor is adjusted to 250 microfarads during PI value tweaking to prevent excessive ripple. The PI value should be at P=0.06 and I=16, it was subsequently found.

The MATLAB Simulink environment is configured with the solver ode23t (modified Stiff/Trapezoidal), as outlined in Fig. 5 to facilitate analysis before conducting performance tests.

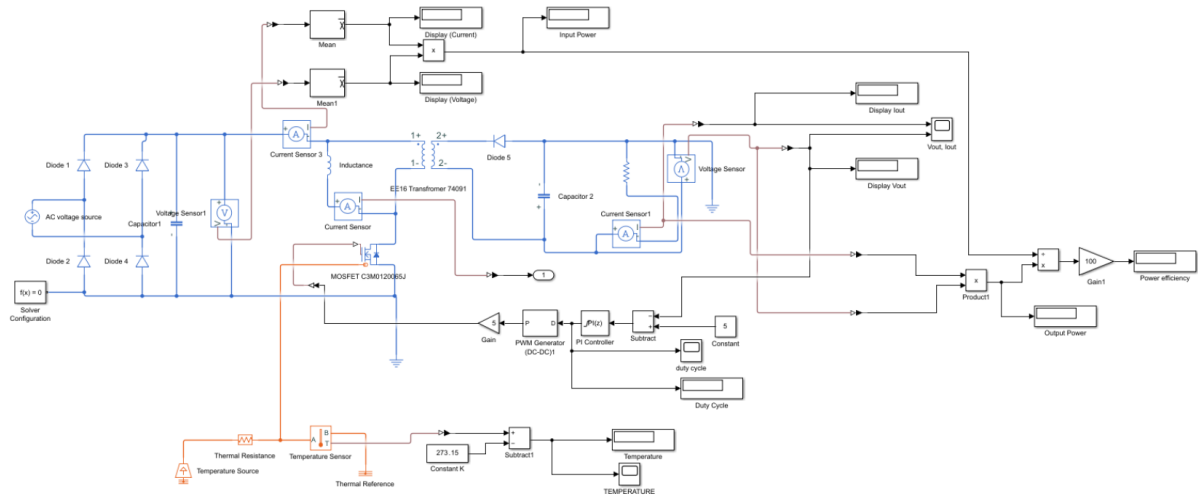
Fig. 5 The Configuration Parameters of the Simulink Solver.


Fig. 6 The MATLAB Model of the AC – DC 5-Watt USB Charger.
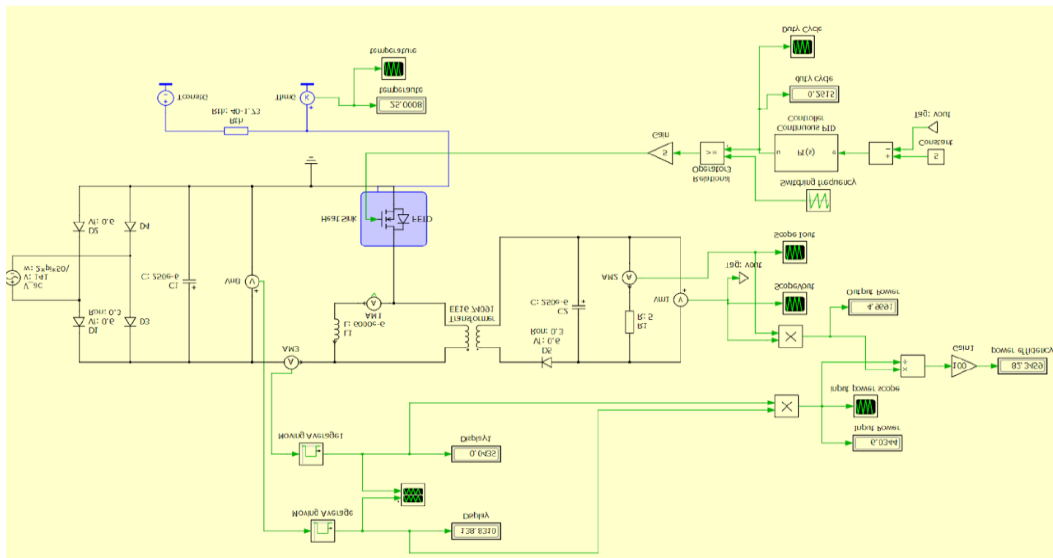

Fig. 7 The PLECS Model of the AC – DC 5-Watt USB Charger.

4. Results and Discussion

The 5-Watt USB Charger simulation results, as detailed in Table 3, are presented utilizing both MATLAB Simulink and PLECS. The simulations were conducted using a f_{sw} value of 40kHz and a PI value of P=0.06 and I=16. The results from both simulations are tabulated and compared to each other.

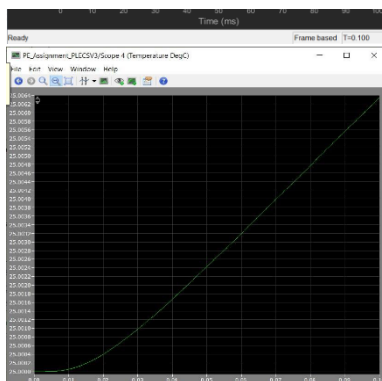
Table 3. Comparison of the Simulation Results of the AC – DC 5-Watt USB Charger.

Voltage Region	Frequency	Input Voltage Input Current Input Power		Output Voltage Output Current Output Power	
		MATLAB	PLECS	MATLAB	PLECS
141V	50Hz	138.9V 45mA 6.31W	138.83V 43.5mA 6.03W	5.002V 1.00A 5.003W	4.985V 997mA 4.969W
	60Hz	138.9V 45mA 6.307W	138.9V 43.4mA 6.034W	5.002V 1.00A 5.004W	4.985V 997mA 4.970W
325V	50Hz	323.1V 22.6mA 7.307W	323.23V 18.5mA 5.989W	4.996V 999mA 4.992W	4.987V 997mA 4.973W
	60Hz	323.2V 22.5mA 7.302W	323.25V 18.5mA 5.989W	4.996V 999mA 4.992W	4.987V 997mA 4.974W

4.1. *The Output Voltage, Current and Power*

The result indicates that the USB charger produces an output voltage of 5VDC and an output current of 1A and shown in Fig. 8.
Fig. 8 The Scope of Voltage, Current, and Power Output at 325/100V AC with 50/60Hz.
(a)


(b)

Fig. 9 The scope thermal analysis at 230/100VAC at MATLAB Simulink (a) and PLECS (b).

4.2. *Thermal Analysis*

Fig. 9 performs the scope thermal analysis of the input voltage at 230/100 VAC in MATLAB Simulink (a) and PLECS (b). The result of MOSFET temperature reaches a steady-state value of 25 °C in MATLAB Simulink and 25.06 °C in PLECS, after a simulation time of 0.1 seconds.

Table 4 performs detail comparison on the MOSFET temperature after simulation at different voltage regions and frequencies.

The MOSFET temperature is slightly higher in PLECS than in MATLAB Simulink. This is consistent with the results of the simulation setup, which showed that PLECS software utilized a more detailed thermal model of the MOSFET. As can be seen from Fig. 9 (a) and (b), the MOSFET temperature is slightly higher in PLECS than in MATLAB Simulink.

Table 4. The MOSFET Temperature After Simulation

Voltage Region	Frequency	MOSFET Temperature	
		MATLAB	PLECS
141V	50Hz	25 °C	25.06 °C
	60Hz	25 °C	25.06 °C
325V	50Hz	25 °C	25.01 °C
	60Hz	25 °C	25.01 °C

4.3. *Power Efficiency*

Power efficiency results can be observed on differences input voltages and frequencies in Table 5. The table showed power efficiency was also compared with using MATLAB and PLECS software. The results in the MATLAB are between 68% and 79%. On the other hand, the power efficiency in PLECS is more consistent at 82.35% to 83.04%. It is notably underscoring the difference in the power efficiency in both software.

Table 5. Power Efficiency After Simulation.

Voltage Region	Frequency	Power Efficiency	
		MATLAB	PLECS
141V	50Hz	79.29%	82.35%
	60Hz	79.35%	82.37%
325V	50Hz	68.31%	83.04%
	60Hz	68.37%	83.04%

Comparing to MATLAB Simulink, the performance of PLECS on simulation power efficiency USB charger exhibits a 3.06% improvement at 141 VAC with 50/60Hz. Moreover, PLECS further outperforms, demonstrating a significant 14.73% increase in power efficiency with a 325V AC input voltage at 50/60Hz frequency.

MATLAB is a general-purpose software used in engineering fields for numerical analysis, data visualization, and simulation of complex systems, using a discrete-time simulation method. MATLAB's general approach to simulation may not be as accurate in modelling power electronics components, resulting in less consistent power efficiency results.

PLECS is designed specifically for simulating power electronics systems, using a continuous-time simulation method with specialized models for simulating power electronic components. The different simulation methods and models used by these two software tools could result in variations in simulation outcomes, including power efficiency.

PLECS specialized models accurately represent the behaviour of power electronic components leading to more precise simulations and consistent power efficiency results.

While the same datasheet was implemented, this does not demonstrate that the MATLAB Simulink software is superior for simulating the circuit because the MOSFET's specific parameter differs from that of the PLECS Software. This is because the MOSFET in the PLECS Software is based on the characteristics of the actual MOSFET that have been implemented by the manufacturer, CREE. On the other hand, the parameters for the MOSFET in the MATLAB/Simulink Software are manually entered based on the datasheet.

When simulated in 0.1 seconds, the MOSFET temperature of each software is slightly comparable. Nevertheless, the temperature of the simulation in PLECS Software is slightly higher than that of the simulation in MATLAB Simulink Software. This is because MOSFET's specific parameter varies depending on the software.

In MATLAB Simulink software, the MOSFET is manually inserted based on the datasheet, which may result in less precision than the model used in the PLECS software. Whereas in PLECS software, MOSFET is based on the manufacturer, CREE. The parameters and thermal model of MOSFET are needed to add into PLECS thermal library.

The ways to solve the numerical methods involved to solve the system of equations also can impact the outcome of simulations in both MATLAB Simulink and PLECS Software, which might result in some degree of error throughout the simulation results.

Step size, solver parameters, and the accuracy of the used models are only a few of the variables that affect how accurate the simulation is. It is advised to decrease the step size or raise the solver accuracy in both MATLAB and PLECS software and evaluate if the simulation results converge to improve the accuracy of the simulation results.

5. Conclusion

This paper successfully constructs a 5-Watt USB power charger, exploring AC to DC full bridge rectifier and DC-to-DC Flyback converters. Each circuit component's parameter adjustments produce the 5VDC, 1A output, necessitating a PI controller for stability. This controller manages P = 0.06 and I=16, minimizing the difference between reference and actual voltage. Two simulation software were compared for their performance and outcomes. PLECS excels, designed specifically for power electronics, offering greater accuracy and faster, memory-efficient, showing a 3.06% advantage at 141V and 50/60Hz. Moreover, at 325V AC input voltage with 50/60Hz frequency, PLECS excels further, exhibiting 14.73% increase in power

Zhi Ying Yeoh, Kim Soon Chong, Sew Sun Tiang, Mohammad Arif Ilyas, Jia Wei Tan, Wei Kang Lai, Wei Hong Lim

efficiency compared to MATLAB Simulink. The simulation study provides a comprehensive understanding of converter interactions and highlights PLECS Software advantages in power electronics simulations over MATLAB Simulink Software.

Abstract

In Malaysia's rapidly urbanizing landscape, sustainable energy for small, tall buildings is increasingly vital. This study addresses this need through the design, simulation, and performance analysis of grid-connected photovoltaic systems tailored for these unique structures. Utilizing AutoCAD and PVSyst for design and simulation, the research details rooftop array dimensions, PV panel wiring, and system components aligned with MS 1837-2018 standards. Results indicate the designed system can save 526.70MWh annually, costing RM 339,306.98, with a 9.8% return on investment (ROI) and a 13-year breakeven point, emphasizing its sustainability and economic viability.

Keywords: PVSyst, AutoCAD, Cost saving, ROI, Breakeven point

1. INTRODUCTION

In recent years, as non-renewable energy sources such as coal, oil, natural gas, chemical energy, and nuclear fuel have begun to run out and sustainable development has begun to be threatened, the use of renewable energy has become increasingly important. All these energy sources are also harmful to the environment and can lead to environmental problems such as greenhouse gas (GHGs) emissions and hazardous chemical waste [1], [2], [3]. Therefore, research and development of renewable energy sources is crucial.

Among various renewable energy options, rooftop solar photovoltaic (PV) systems are a popular and effective method for collect solar energy [1]. A grid-connected rooftop solar photovoltaic system is a solar power generation system that is connected to the grid and can transmit excess energy back to the grid. In addition, Malaysia is one of the countries with the greatest potential for solar energy utilization due to its strategic location near the equator. Through the research, the monthly solar irradiance for Malaysia is estimated at 400-600 MJ/m^2 as well as its hot and sunny weather throughout the year, thus the potential for solar power is very large [4]. However, the design and implementation of a grid-connected rooftop solar PV system requires careful consideration of several factors, including the selection of appropriate solar panels, system sizing, inverter selection, and system integration with existing electrical infrastructure.

In Malaysia, the rapid growth of urbanization has led to an increased demand for sustainable energy solutions. Despite the potential benefits of grid-connected photovoltaic (PV) systems in meeting this demand, there is a lack of comprehensive research addressing the design, simulation, and performance analysis tailored specifically for the unique challenges posed by small, tall buildings in the Malaysian context. The main objective of this paper is to bridge this gap by investigating the optimal design parameters, conducting detailed simulations, and performing a thorough performance analysis of grid-connected PV systems. The outcomes of this study are expected to provide valuable insights into the feasibility and efficiency of implementing grid-connected PV systems in this specific urban setting, contributing to the advancement of sustainable energy solutions for the region.

2. METHODOLOGY
2.1. *Calculation and Selection for Solar Panel*

In this study, one of the buildings in the UCSI university was selected for installing the PV panels. The selected building, named Block C, located at No. 1, UCSI Heights, Jalan Puncak Menara Gading, Taman Connaught, 56000 Cheras, Federal Territory of Kuala Lumpur. As shown in Fig. 1, the satellite view shows that there are 12 faces on the rooftop

Wei Kang Lai, Kim Soon Chong, Mohammad Arif Bin Ilyas, Sew Sun Tiang, Zhi Ying Yeoh, Jia Wei Tan, Wei Hong Lim

with the tilts of 30 degrees in each azimuth. The area of the rooftop was calculated to be $3194m^2$. However, only 8 faces are decided to install the PV panels which is $2129m^2$ and the other 4 faces are for cleaning and technical maintenance. These data were then used to create a 3D model of the rooftop in 3D AutoCAD, and the appropriate PV array size was decided using 1120 modules of SunPower X22-360 solar panels based on calculated by using expected power for each orientation which is 50kW and spaces on the rooftop. Below is the calculation:

$$Area\ for\ placing\ PV\ panels = \frac{3,194m^2}{12} \times 8$$
$$= 2,129m^2$$

$$No.\ of\ PV\ panels = \frac{50,000W}{360W}$$
$$= 140\ modules$$

$$Total\ no.\ of\ PV\ panels = 140\ module\ \times 8$$
$$= 2,129m^2$$

$$Power\ generated = 1,120\ modules\ \times 8$$
$$= 403,200W$$

Apart from that, to convert the DC power generated by the solar panels into AC power, the model of Goodwe GW50KLV-MT inverter had been selected.

The SunPower X22-360 Solar panel is a high-performance solar panel designed for residential and commercial applications. In a six-story building, SunPower's X22-360 solar panels can be used to generate renewable energy to offset the building's energy consumption. The electricity generated by the solar panels can be used to power lighting, heating, ventilation, and air conditioning (HVAC) systems and other electrical equipment in the building, while excess energy can be fed back to the grid to generate revenue for the university through a net metering program. Additionally, the X Series panels have a 25-year warranty and are made to be long-lasting and robust. This long-term durability improves X-Series panels a cost-effective, sustained producing electricity for many years [5].

The Goodwe GW50KLV-MT is a three-phase grid-tied inverter intended to transform the direct current (DC) power produced by the solar panel arrays into alternating current (AC) power that can be supplied into the utility system. Goodwe GW50KLV-MT has also built-in safety features like ground fault protection (GFP) and surge protection devices (SPDs) for both DC and AC inputs, which provide both the safety of the solar PV system and the building's occupants [6].

The inverters of the system were installed at exterior placement to create a more spacious indoor environment and address safety concerns related to preventing electrical hazards. Placing the inverters at exterior placement not only minimizing energy waste from cable resistance but also enhance efficiency by reducing the length of the DC wire between the solar panel and the inverter.

Figure 1: Satellite view of a building's rooftop

2.2. *Solar panel layout design*

The floor plan of the roof PV panels was construct based on the Google Maps satellite images as shown in Fig. 1. The dimensions of the SunPower X22-360 were obtained from the data sheet in order to arrange the panels in the most effective and aesthetically acceptable way possible. The route of the DC wires from the PV panels to the inverter and the AC cables from the inverter to the electrical panel was also determined at this point. Thorough the analysis, a 3D model of PV system design on the rooftop was showed in 3D AutoCAD shown in Fig. 2.
Figure 2: 3D Modelling rooftop design

2.3. Wire Connection

Leapfrog chain wiring, as outlined in Fig. 3 is the best and suitable wiring design for string panels that are not organized in a straight line due to its simplicity, ease of use, cost saving and electromagnetic loop reduction which represent less voltage drop [7], [8].
Figure 3: Leapfrog Wiring

According to the MS 1837-2018 standard, single-line diagram of the system shown in Fig. 4 was designed and outlined the minimum

requirements for the installation of grid-connected PV systems. This diagram provides a clear and concise representation of the system components, including the arrangement of PV array, inverters, DC and AC disconnects, and electrical panels. It also includes details on the system grounding and protection devices, such as surge protectors and overcurrent devices [9].

Figure 4: Single-line diagram

In Fig. 4, the direct current (DC) electricity produced by the 5 strings of 7 solar panels was routed through DC surge protective devices (SPDs) positioned before and after the PV DC switch. The DC SPDs safeguard the system against surges and overvoltage. The DC electricity was then routed through the PV DC switch to the eight generators. Each inverter has four MPPT (maximum power point tracking) sources to optimize electricity production from the panels.

The wires before and after the PV DC switch and the wires before and after the PV AC switch were selected as MC4 compatible for the head and tail of the wire and through calculation. Due to the design of 7 module of solar panels in series connection and each module can generate 60.6V at maximum power point, the output of the voltage will be 424.2V.

Through the calculation, the voltage for the wires required to withstand is at least 424.2V. Thus, due to the critical safety aspect, THHN/THWN-2 wire which can withstand 600V was selected to prevent the wiring from overheating and overload that may cause fire hazard and short circuit. While the other reason for choosing THHN/THWN-2 wire was the temperature rating for this wire is 90 degrees Celsius and could use in wet conditions [10].

2.4. Selection in PVsyst software

In Fig. 5, it depicts the desired tilts and azimuths. Azimuths of 0°, 30°, 90°, 120°, 180°, -120°, -90°, -30° have been selected for placing the solar panels on the rooftop.

Figure 5: Orientations (Tilts and Azimuths)

In the PVSyst software, the selection and application of dimensions, photovoltaic modules and inverters are shown in Fig. 6. The SunPower X22-360 model for the solar panel and the Goodwe GW50KLV-MT model for the inverter were chosen

for each orientation in PVSyst software. The inverters will conduct 4 MPPTs each, as the operating DC voltage needs to fall within the MPPT voltage range of the inverter. Therefore, 5 strings that are connected in parallel will be connected to one of the MPPT for the inverter. A total of 20 strings, each consisting of 7 solar panels per string, will be subject to application based on the expected power determined in PVSyst software, which is 50 kW.

After all the values and the selection was applied, the voltage maximum power point obtained is 367V and 418V at 60 degrees and 20 degrees, while AC voltage is 531V. Moreover, the value of array nominal power at Standard Test Conditions (STC) also determine as 50.4kWp.

Besides, to account for the various variables that may influence the system's real performance as opposed to the idealized circumstances anticipated in laboratory testing, the Thermal Losses, Ohmic Losses, Power Loss at Maximum Power Point(MPP), Soling Loss, and Aging Losses has been applied in the PVsyst software. These variables may include shading, weather, soiling, inefficient modules, and inverters, among other practical and environmental problems that could eventually result in a drop in power production. It is possible to get a more accurate estimate of the system's real energy yield and financial success by including these losses in the simulation. It is also possible to find prospective areas for optimisation and development.

Figure 6: Sizing and system applied in PVSys

2.5. *Arrangement of Solar Panels*

The spacing between the solar panels is an essential factor in the design of solar photovoltaic systems, as shown in Fig. 7. The rationale behind providing adequate space was to ensure that there is proper ventilation and air flow around the panels. This aids to keep the panel cool, subsequently enhances performance.

Minimizing shading is imperative, it can significantly reduce the output of photovoltaic systems. Therefore, by leaving space between panels, can mitigate the risk of shading, which occurs when one panel casts a shadow on another panel.

The accumulation of dust or debris can also degrade the panel's performance [11]. Therefore, leaving space between panels is essential, providing convenient for maintenance and cleaning. Overall, allocating sufficient space for solar panels is vital, ensuring optimal performance, power efficiency, and longevity of solar photovoltaic systems.

Figure 7: Spacing between Solar panels

2.6. *Budget of the project*

An expenditure of 911,192 dollars, equivalent to RM 4,309,026.97, as shown in Table 1, was anticipated for the acquisition of PV panels and solar inverters utilized in this project.

Table 1: Total cost of material

Product	Model	Total unit	Single unit price (dollar)	Total price of all units (dollar)
PV panel	SunPower X22-360	1,120	800	896,000
Solar inverter	Goodwe GW50KLV-MT	8	1,899	15,192
Total				911,192

3. RESULT AND DISCUSSIONS
3.1. *PVsyst Analysis*

The array loss analysis simulated by PVSyst software as outlined in Fig. 8. The series diode typically exhibits a default voltage drop of 0.7 V. Concurrently, ohmic losses emerge from the resistance in wires and connectors, contributing to a potential decline in the solar system's output power.

To quantify these losses within the subfield, the loss fraction was specified as STC which is 2%. In this scenario, the solar system achieves a total power output of 400 kW at STC and ohmic losses are stipulated at 2%, the resultant power loss due to ohmic factors amounts to 2 kW.

Apart from that, the yearly soiling loss factor indicates the decrease in solar panel energy production caused by dust and dirt accumulation on the surface. It varies depending on the location and environmental conditions of the solar panel installation such as rainfall frequency, wind patterns, and proximity to dust sources can affect the rate of soiling. The annual soiling loss factor was found to be 3% analysed by PVSyst software, reducing solar panel's performance. This outcome can be used to determine the cleaning frequency needed to ensure the solar panel performing optimally.

The PVSyst module analysis revealed an average degradation of 0.4% per year with a 10-year loss factor. This indicates that the module's efficiency is expected to decrease by 0.4% each year over the course of 10 years.

The analysis also revealed a mismatch due to degradation and resulting in Root Mean Square of Current (Imp RMS) and Root Mean Square of Voltage (Vmp RMS) dispersions of 0.4% per year. Owing to the degradation of the panels, the current and voltage output from the solar panels will experience slight deviations over time. These findings highlighted the importance of regular maintenance and monitoring of the solar panels to ensure optimal performance and efficiency over the long-term.

Figure 8: Array Loss analysis

Within the total PV power characteristic, the total number of utilized PV modules is 1,120, generating a nominal (STC) output of 403 kWp as shown in Fig. 9, which is consistent with the calculated value. The covered module area and unit area are 1,826m^2 and 1,648 m^2 respectively.

The total power of the inverters that have converted was 400kWac and the number of the converter used is 8 units. The ratio of PV to inverter power is measured as the DC/AC ratio whereby ideal value is 1.25. Nevertheless, the simulation analysis indicates the power nominal (Pnom) ratio is 1.01, falling short of the recommended healthy ratio for the PV system.

Total PV power

Nominal (STC)	403 kWp
Total	1120 modules
Module area	1826 m²
Cell area	1648 m²

Total inverter power

Total power	400 kWac
Number of inverters	8 units
Pnom ratio	1.01
No power sharing	

Figure 9: Total PV power and inverter power

In Fig. 10, it shows the total global horizontal irradiation (GlobHor) for the given area was found to be 1,783.4 kWh/m^2, whereas the total horizontal diffuse irradiation (DiffHor) was calculated to be 963.42 kWh/m^2. During this period, the average ambient temperature (T_Amb) was 27.72℃. The total global incidence in coll. plane (Globinc) was calculated to be 1,641.8 kWh/m^2, indicating a reduction in the total energy incident on the module due to the tilt angle and orientation.

According to the PVSyst analysis the obtained results affirm that the PV system was performing well in terms of energy production. The high specific production or high output of 1,306 kWh/kWp/year indicates that the system was well-designed and well-maintained, which was a positive sign. In addition, the total energy injected into the 526,695kWh grid indicated a critical commitment to the overall electricity supply on site.

The analysis of the results indicates that, in the given location, the PV module tilt point and the degree of inclination are not optimally configured. This was reflected in the comparatively lower value of Globinc in comparison to GlobHor.

By focusing on the DiffHor value of 963.42 kWh/m2, the location of the PV system is not highly shaded, which was a positive factor for energy production. The average ambient temperature during the study period of 27.72℃ was considered within the cycle and is also within the ideal temperature range for photovoltaic system performance.

Apart from that, the average performance ratio (PR) that indicates the efficiency of the system in converting the solar energy into electrical energy was calculated to be 0.796, equivalent to 79%, which is close to 80%. Nevertheless, for the year 2010 is found to be between ~70 and ~90% and shows a median PR of 84%. However, the analysis shows that it does not getting 84% the PV system due to the imperfection of tilts. To solve this problem, it is recommended to add an adjustable mounting system for optimal tilt and performance [12].

Figure 10: Balance and main results

In this study, the efficiency of the PV system has comprehended by the system output power distribution graph as shown in Fig. 11. The graph shows that the system operates at optimum efficiency, with a peak energy injection of 9 MWh/class of 2.5 kW, corresponding to a power injection of 240 kW. Notably, the majority of the energy injected into the grid falls within a stable range of 5 to 7 MWh/class of 2.5 kW, suggesting efficient and consistent operation. The distribution graph provides useful insights into the system's performance that can be used to find potential areas for development and optimize the functioning of the PV system. By knowing the power levels at which the system produces the most energy, the system can be operated to maximize energy output at these power levels.
Figure 11: Power distribution graph

3.2. *Estimate Cost Saving, Breakeven point and Return of Investment (ROI)*

According to the analysis, 526.70 MWH can be generated throughout the year, with an average of 43.891 MWH per month. The electricity bill is calculated using the formula provided by Tenaga National Berhad (TNB), as shown below:

Electricity Bill = (Consumed electricity x First 200 kWh rate) + (Consumed electricity x Next 100 kWh rate) + (Consumed electricity x Next 300 kWh rate) + (Consumed electricity x Next 300 kWh rate) + (Consumed electricity x Next 901 kWh onwards per month) *(6% tax)

Wei Kang Lai, Kim Soon Chong, Mohammad Arif Bin Ilyas, Sew Sun Tiang, Zhi Ying Yeoh, Jia Wei Tan, Wei Hong Lim

Table 2: Year of the ROI

	Electricity Bill
Per Month	RM 28,146.24
Per Year	RM 339,306.98

Through the calculation, user can save minimum up to RM 28,146.24 per month and RM 339,306.98 per year as shown in Table 2. Besides, the use of electricity from the solar panels are prioritised instead of using electricity from the TNB grid whereby surplus electricity will not be wasted and exported back to TNB.

$$ROI = \frac{Net\ profit}{Cost\ of\ Investment} \times 100$$

$$Year\ 1 = \frac{RM339,307 - RM4,350k}{RM4,350k} \times 100$$
$$= -92\%$$

Table 3: Year of the ROI

Year	ROI = (Net profit / cost of investment) x 100
1	-92%
2	-84.4%
3	-76.6%
4	-68.8%
5	- 61%
6	-53.2%
7	-45.4%
8	-37.6%
9	-29.8%
10	-22%
11	-14.2%
12	-6.4%
13	1.4%
14	9.2%

Breakeven point (in year)
= Fixed Costs / Gross Profit Margin
= RM 4,309,026.97/ RM 339,306.98
= 12.69 year

At the beginning of the investment, it resulted in a net loss and no returns due to the high upfront cost of the system which is RM 4,309,026.97 [13]. In Year 13, the ROI has become positive after 12 years as shown in Table 3. Beyond the 13th year, it is expected to be in a profit-making state, where the saving from the electrical bill exceeds the total cost of panels ordered. Regarding the breakeven point analysis, it shows this project needs to take 12.69 year which is almost 13 years to reach the breakeven point.

4. CONCLUSION

This study examines the potential of installing a solar photovoltaic (PV) system at a small, tall building in Malaysia. The analysis considers factors such as the building's energy demand, available space, and the financial feasibility of the proposal. The findings of the analysis reveal that a 403-kW solar PV system has the capacity to generate approximately 526695 kWh of electricity and helps to save up to RM 339,306.98 per year which can satisfy the building's power requirements.

Apart from cost saving and power supply, the performance of PV systems is not optimal. In order to take full advantage of the potential capabilities of the system and reduce performance differences, key recommendations for the future include the adoption of adjustable mounting systems. This technology facilitates dynamic tilt regulation, ensuring optimal alignment of photovoltaic panels with incoming sunlight, thereby improving overall energy conversion efficiency. However, the calculation of the ROI and the breakeven point shows it takes 13 years to reach profit-making state with no expenses. This is because of the upfront cost of the system is high to begin with.

Abstract

A dual-band coplanar waveguide (CPW) printed antenna for IoT application is proposed, mounted on a low-profile RT/Duroid 5880 substrate with dielectric constant of 2.2, loss tangent of 0.0009 and a standard height of 0.787mm. This design aims to cover the major frequency bands from LTE to Bluetooth/Wi-Fi band/WiMax/Zigbee, Extended IMT and 5G whereby the bandwidth range between 1.7 GHz to 3.6 GHz. The antenna is miniaturized through the CPW technique and has a rectangular size of $60 \times 30 \times 1.187$ mm^3. The design and simulation of the result records a return loss of -25.12dB, peak gain of 4.23dBi, voltage standing wave ratio (VSWR) close to 1, omnidirectional radiation, and current distribution. Radiation efficiency reaches approximately 94%, with a total efficiency of 89.4% between 1.9GHz-3.6GHz.

Keywords: Dual-band CPW, Internet of Things, impedance bandwidth, reflection coefficient, radiation pattern, current distribution

1. Introduction

With increasing world population and the incorporation of Internet of Things (IoT) in multiple computer networks, microelectronics and modern communication, there are higher demands for better, flexible, and advance antenna module to support the embedded systems [1]. Antennas play a primary role in supporting such systems because they enable long-distance communication and efficient use of frequency spectrum that allows maximization of data transmitted over a given frequency band. An example is the dual-band antenna which is designed to support two frequencies that can cover multiband applications and provide sufficient bandwidth for the operating frequencies as well as reduced interference by neighbor devices.

In recent years, coplanar waveguide (CPW) has garnered immense attention across the globe especially in modern wireless communication systems due to their simple integration with microwave integrated circuits, low radiation loss and reduced dispersion as compared to microstrip antenna [2]. This type of waveguide has an additional third conductor centered in the slot region and specifically useful in developing active circuitry. The presence of the additional strip can support even or odd quasi-TEM mode at low frequencies as well as TE mode at high frequencies [3]. The modification of the dimensions of the signal strip or ground plane such as thickness, length and width play a vital role in determining the characteristics of a CPW-fed antenna [2].

There are a few main challenges in designing a dual-band CPW antenna which include miniaturization, large gain, high bandwidth coverage, low return loss, impedance matching, power, and radiation efficiency. Some of the techniques introduced to satisfy the abovementioned criteria includes the usage of metamaterials and complementary split ring resonator (CSRR) to increase gain or implementation of a magneto electric (ME) to achieve wider impedance bandwidth, higher gain, and compatible radiation patterns on both electric and magnetic plane [3].

Hence, in this paper, the design of this waveguide is done by utilizing the CST software which involves careful selection of substrate properties, structure of CPW, and feed network. The simulation result allows optimization and evaluation of antenna performance over a desired frequency range. The proposed antenna presents a dual-band coplanar waveguide using copper

Jia Wei Tan, Sew Sun Tiang, Kim Soon Choong, Mohammad Arif bin Ilyas, Mastaneh Mokayef, Zhi Ying Yeoh, Wei Kang Lai, Wei Hong Lim

conductor and RT/Duroid 5880 as substrate material. The width of the microstrip and gap between the sides of the ground is adjusted to obtained impedance matching of 50 Ohm. The main consideration of the paper is to develop a design that operates on all major frequency bands from LTE (1900MHz) to Extended LTE (2100MHz), Bluetooth/Wi-Fi band/WiMAX/Zigbee (2.4GHz) and 5G (3.4-3.6GHz). Table 1 shows the summary of comparison between existing CPW-fed antennas and proposed work.

2. Related Works

The configuration of the proposed antenna shown in Fig. 1 is inspired by the basic design from S. Das, H. Islam, T. and Bose, N. Gupta [7]. The fundamental structure of the antenna consists of two layers which are antenna layer on top and dielectric substrate at the bottom. Our design assumes no ground plate is placed underneath the dielectric which means it is of free space or air.

a. Front View b. Bottom View
Fig 1. Structure of proposed antenna design.

The material chosen for the antenna patch is copper (annealed) because this form of copper is much softer and malleable which makes it easier to shape during the fabrication stage. On the other hand, the dielectric substance used is the RT/duroid 5880 with dielectric constant of 2.2 and tangent loss of 0.0009. Some key features according to the datasheet of this substrate material include low moisture absorption, resistance towards chemicals, isotropic and uniform chemical properties over frequency. It is mostly found in microstrip and stripline circuits, as well as point-to-point digital radio antennas. The thickness of the dual-band CPW is 1.187mm with copper (annealed) 0.4mm and substrate as 0.787mm respectively.

The detailed geometry of the proposed antenna is shown in Fig. 2. Some of the parameters such as length and width of the main rectangular patch were taken from the values by S. Das, H. Islam, T. and Bose, N. Gupta [7] and is progressively modified to fit the requirements of our antenna. The characteristic impedance of the feed line can be calculated with a certain formula, however, in this paper, we considered utilizing the coplanar waveguide calculator found online which requires value including substrate thickness, width of antenna strip, ground plane spacing, and dieletric substrate [11]. We ran a couple of trials and errors to achieve matching impedance of 50 Ohm and the result was to adjust

antenna width to 2mm while spacing between the edge of feed element and ground plane is 0.1933mm. The calculator equations are based on the 'Coplanar Waveguide Circuits, Components, and Systems' textbook written by R. N. Simons [12].

The equations applied in the online calculator are just an approximation of the CPW impedance as it does not consider the thickness of antenna strips, hence may not display the most accurate results. When creating critical design, the usage of 3D electro-magnetic analysis of

CPW needs to be considered. The gap between the ground plates and antenna feed line is calculated to be 0.193mm which is less than half of the substrate thickness to control leakage of electromagnetic energy in free space. The antenna design is gradually modified to fulfil the required frequency range and the evolution of the proposed antenna design is shown in Fig. 3. The detailed antenna parameters of the final design are depicted in Table 2.
Fig 2. Geometry of proposed antenna.

3. Result and Discussion

The different layout of CPW antennas were designed and simulated to determine the antenna performance in different aspects including S11-parameter (return loss), reflection coefficients, gain, radiation pattern, current distribution, , and voltage standing wave ratio (VSWR).

The S11 parameter graph shows the return loss of the antenna design which is a measure of the reflection coefficient. The simulated result for return loss from the first to the final proposed antenna is displayed in Fig. 4. The first antenna result (red line) shows a narrow impedance bandwidth less than 30% (2.0-2.6GHz) for S11 < -10dB threshold. Besides, the return loss value is fairly small, which is -13.88dB and this may cause more power reflected back to the system which is not desirable.

This leads to our second antenna (green line) which is designed to increase the return loss as can be seen in Fig. 4. By adding two rectangular patches with 1mm width on each side of the ground plate as shown in Fig. 3 (b), the return loss improved to -21.47dB.

Moving on, the goal of antenna 3 (blue line) is to increase the impedance bandwidth to fulfill the criteria for IoT applications which covers all major frequency bands between 1.7GHz to 3.6GHz. By changing the length between the newly added rectangular strips with the ground plate, the bandwidth coverage improved from the initial antenna design which is 2.0GHz-2.6GHz to 1.97GHz-3.58GHz with more than 80% of the desired spectrum. This design also produces two resonant frequencies at 2.215GHz and 3.28GHz.

Lastly, the addition of circular slots on the corner of the rectangular patches further decreases the return loss to -25.12dB (orange line) and improved the impedance bandwidth to 1.88GHz-3.62GHz. However, one of the major frequency spectrums failed to be covered by this design, which is the LTE with frequency of 1.7GHz.

More detailed parametric studies need to be done such as modifying the major length and width of antenna and dieletric substrate, positions of rectangular strips, separation distance between feed line and ground plates to achieve wider frequency spectrum. Additional tuning and optimization are also needed to attain the appropriate frequency response.
Fig 4. Simulation result of S11 parameter (return loss) for all four antennas.

The gain for final proposed antenna is shown in Fig 5 with the peak gain captured at 4.23dBi when the operating frequency is around 3.6GHz. At resonant frequencies of 2.215GHz and 3.28GHz, the gain observed is 2.59dBi and 3.92dBi respectively.
Fig 5. Simulation result of gain for final proposed antenna.

The radiation pattern of the final proposed antenna at 2.215GHz and 3.28GHz frequencies viewed in 3D is shown in Fig. 6 (a) and (b). Based on the results, the antenna design is omnidirectional, or commonly referred to as 'omni' whereby its shape is similar to a bagel. This type of antenna radiates and receives signal in all directions equally. Along its axis, this antenna evenly emits electromagnetic radiation in all directions. An omnidirectional antenna has the benefit of being able to send and receive signals from any direction without the requirement for exact targeting. The directivity recorded at 2.2GHz and 3.28GHz is 2.665dBi and 3.28dBi respectively. The radiation pattern in E-field and H-field can also be viewed in 2D for operating frequency at 2.215GHz and 3.28GHz as shown in Fig. 6 (c) and (d).

a. 3D radiation pattern at 2.215GHz.

b. 3D radiation pattern at 3.28GHz.
c. Far field radiation pattern at 2.215GHz.
d. Far field radiation pattern at 3.28GHz.

Fig 6. Radiation pattern of final proposed antenna.
The surface current distribution is measured at both resonant frequencies of 2.215GHz and 3.28GHz as shown in Fig 7 (a) and (b). In both figures, the current density is most evident at the antenna strip denoted by red and orange color map which has higher potential for losses and prone to heating easily due to high dissipation of electromagnetic fields and energy. Some methods to reduce these losses include having proper grounding and optimizing the feed network as well as geometry design. The rest of the areas that are mostly drawn in blue or green area experience low current density whereby it indicates that the performance of the antenna still has room for improvement.

Jia Wei Tan, Sew Sun Tiang, Kim Soon Choong, Mohammad Arif bin Ilyas, Mastaneh Mokayef, Zhi Ying Yeoh, Wei Kang Lai, Wei Hong Lim
a. Current distribution at 2.215GHz.
b. Current distribution at 3.28GHz.

Fig 7. Current distribution on final proposed antenna.
Fig 8. Smith chart of the final proposed antenna.

Smith chart is shown in Fig. 8. The VSWR value plotted at 2.215GHz is 1.11 and at 3.28GHz is 1.38 as shown in Fig. 9 whereby both values can be considered close to 1. This value of VSWR indicates a well-matched antenna with the transmission line and also reduces power loss due to impedance mismatch.
Fig 9. VSWR graph of the final proposed antenna.

Based on Fig. 10, efficiencies are recorded in terms of magnitude (dB). The highest radiation efficiency and total efficiency converted into percentage are 98% and 92.4% respectively at 2.35GHz. The radiation and total efficiency for resonant frequencies of 2.2GHz and 3.28GHz are mostly above 90% and values are tabulated in Table 3.

Table 3. Radiation efficiency and total efficiency of different resonant frequencies.

Resonant Frequency (GHz)	Radiation efficiency (%)	Total efficiency (%)
2.2	92.2%	86.6%
3.28	94.6%	90%
Fig 10. Radiation efficiency and total efficiency of dual-band CPW.

4. Conclusion

In this proposed paper, the rectangular dual-band CPW antenna structure with RT/duroid 5880 as substrate that has standard height of 0.787mm and dieletric constant of 2.2 is designed and simulated using CST software. The design can be classified for the usage on the applications of Internet of Things as it can satisfy most of the major frequency bands from LTE to Bluetooth/Wi-Fi band/WiMax/Zigbee, Extended IMT and 5G. However, it is also worth mentioning that the proposed design fails to cover a lower bandwidth spectrum of LTE which is 1.7GHz and this can be due to various factors such as dimensions, size, and layout of the antenna design as well as substrate material. The final antenna design has a wide impedance bandwidth of 1.9GHz-3.6GHz, improve in overall antenna gain with highest peak value at 4.23dBi in the two working bands and VSWR approximately close to 1. The final antenna design demonstrates monopole radiation patterns (omnidirectional) characteristics and high radiation efficiency up to 98% between the stated impedance bandwidths. The proposed antenna also exhibits moderate return loss of -29.54dB with an acceptable size of 1800m^2 and total efficiency of approximately 92.4% which makes it a comparable candidate for portable handheld communication devices.

Abstract

Semiconductor defect inspection is crucial for yield improvement but is hindered by manual inspection's subjectivity and error. This paper employs Convolutional Neural Networks (CNNs) for automated wafer defect classification, addressing the challenges of time-intensive training and complex hyperparameter tuning. We propose the Arithmetic Optimization Algorithm (AOA) to efficiently optimize CNN hyperparameters like momentum, initial learning rate, maximum epochs, and L2 regularization. Our method reduces the trial-and-error in hyperparameter tuning. Using the AOA-optimized ResNet-18 model, our simulations show superior performance in defect classification compared to the unoptimized model, demonstrating its effectiveness and practical potential.

Keywords: Arithmetic optimization algorithm, Convolutional neural networks, Hyperparameter optimization, Wafer defect classification

1. Introduction

The advent of the fourth industrial revolution (IR4.0) has escalated the need for semiconductor industries to produce increasingly complex integrated circuit chips. This complexity arises from the need to pattern and etch more components on semiconductor wafers, catering to diverse chip specifications like lifespan, size, memory storage, and access speed. Consequently, this escalation in production demands heightens the likelihood of process-induced defects on wafer surfaces, adversely affecting the manufacturing yield. A key step in mitigating this yield reduction involves the identification and classification of wafer defect patterns, which often correlate with various manufacturing stages, including contamination, robot handoff, and flow leakages. Accurate identification of these defects enables engineers to pinpoint and rectify the underlying issues, thereby enhancing chip production yield [1].

Most semiconductor industries currently depend on manual visual inspection for detecting wafer defects, a method plagued by subjectivity and a high risk of erroneous classifications due to long-term fatigue. To address these limitations, there is a growing need for an automated machine vision system, integrated with an optimized deep learning model, for reliable wafer defect classification. Convolutional Neural Networks (CNNs) are a widely used deep learning technique [2], [3], [4], [5], [6], [7]. particularly effective in wafer defect

classification [8], [9], owing to their capability to learn the nonlinearity between inputs and outputs by automatically extracting relevant information from raw data. Pre-trained CNN architectures like GoogleNet [10]. AlexNet [11], VGG [12], and ResNet [13] have been successfully adapted using transfer learning to tackle new tasks, benefiting from reduced data and training time requirements. The efficacy of these pre-trained networks in addressing new tasks through transfer learning process is heavily influenced by the hyperparameter settings employed during their training phase.

In conventional practice, the fine-tuning of CNN hyperparameters relies on a labor-intensive and time-consuming trial-and-error approach. To streamline this process, metaheuristic search algorithms (MSAs), drawing inspiration from various natural phenomena [14]—including swarm intelligence, natural evolution, physics, mathematical principles, and human activities—have been developed. These algorithms are effective in addressing complex problems [15], [16], [17], [18], [19], [20], [21], [22] and are particularly adept at hyperparameter tuning in CNNs [23], thanks to their robust global search capabilities. One such algorithm is the Arithmetic Optimization Algorithm (AOA) [24], which derives its strategy from the distribution behaviors of basic arithmetic operations such as addition, subtraction, multiplication, and division.

In this study, we employ a pre-trained network, ResNet-18, retrained on new datasets using transfer learning for

the purpose of wafer defect classification. The AOA is utilized to optimize four critical hyperparameters of the CNN: momentum, initial learning rate, maximum epochs, and L2 regularization. The efficacy of this optimized CNN model in classifying wafer defects is then assessed and benchmarked against the performance of a corresponding unoptimized CNN model.

2. Related Works
2.1. *Conventional CNN and ResNet-18*

A typical CNN architecture comprises three fundamental components: convolutional layers (Conv) for feature extraction, pooling (Pool) layers for reducing the size of feature maps, and fully connected (FC) layers for classification. Table 1 illustrates an example of a standard CNN model.

Table 1. Architecture of a typical CNN.

Layer	Layer Type	#Feature Maps	Feature Map Size	Filter Size
1	Input	1	14×14	
2	Conv 1	6	7 × 7	5×5
3	Pool 1	6	4×4	2 ×2
4	Conv 2	16	4×4	5 × 5
5	Pool 2	16	2 × 2	2 × 2
6	FC 1	1	120	
7	FC 2	1	84	

He et al. [13] introduced ResNet models, known for their deep architectures, which have exhibited remarkable convergence and high accuracy. In 2015, ResNet models achieved first place in the ImageNet Large Scale Visual Recognition Challenge (ILSVRC) and the Common Objects in Context (COCO) classification challenge. ResNet is characterized by multiple stacked residual units and comes in various configurations, including 18, 34, 50, 101, 152, and 1202 layers, each with specific operations tailored to its architecture. ResNet-18, a model offering an optimal balance between depth and performance, comprises five convolutional layers, one average pooling layer, and a fully connected layer with SoftMax activation. ResNet-50 includes 49 convolutional layers, culminating in a fully connected layer. Considering the balance between computational efficiency and performance, ResNet-18 is chosen for this study.

2.2. *Arithmetic optimization algorithm (AOA)*

In 2021, Abualigah et al. [24] introduced the AOA, a MSA inspired by the characteristics of the four basic arithmetic operations: addition, subtraction, multiplication, and division. The AOA operates through three primary phases: initialization, exploration, and exploitation, strategically navigating the solution space to address optimization challenges effectively.

In the initialization phase of the AOA, a set of potential solutions is generated, each falling within predefined dimensional boundaries, to address specific optimization problems. Subsequently, the algorithm calculates the Math Optimizer Accelerated (MOA) value, which dictates the search strategy between exploration and exploitation phases. The MOA function is mathematically expressed as:

$$MOA(C_{Iter}) = Min + C_{Iter} \times \left(\frac{Max - Min}{M_{Iter}}\right) \quad (1)$$

where C_{Iter} denotes the current iteration number, M_{Iter} is the maximum number of iterations, and *Min* and *Max* are the lower and upper limits of the accelerated function, respectively. The AOA enters the exploration phase if the MOA value is lower than a randomly generated number between 0 and 1; otherwise, it proceeds to the exploitation phase.

During the exploration phase of the AOA, both Multiplication and Division operators are employed to enhance the search space coverage and introduce a diverse array of solutions. This approach leverages their potential for high dispersion and distributed values. The position of each *i*-th AOA solution in the *d*-th dimension is updated as follows:

$$x_{i,j}(C_{Iter} + 1)$$
$$= \begin{cases} x_j^{best} \div (MOP + \varepsilon) \times \left((UB_j - LB_j) \times \mu + LB_j\right), \\ \qquad\qquad r1 < 0.5 \\ x_j^{best} \times MOP \times \left((UB_j - LB_j) \times \mu + LB_j\right), \\ \qquad\qquad otherwise \end{cases}$$
$$(2)$$

where $x_{i,j}(C_{Iter} + 1)$ denotes the *j*-th dimension of the *i*-th solution in the next iteration ($C_{Iter} + 1$), with *j* ranging from 1 to *D*, *i* ranging from *1* to *I*, and *I* is the population size; C_{Iter} ranges from 1 to M_{Iter}, the latter is the algorithm's maximum iteration number; x_j^{best} is the *j*-th dimension of the best solution; UB_j and LB_j are the upper and lower boundaries in the *j*-th dimension; $r1$ is a random number between 0 and 1; μ adjusts the search range. Define the Math Optimizer Probability (MOP) as:

$$MOP(C_{Iter}) = 1 - \frac{C_{Iter}^{\frac{1}{\alpha}}}{M_{Iter}^{\frac{1}{\alpha}}} \quad (3)$$

where $MOP(C_{Iter})$ represents the function value at iteration C_{Iter}, and α controls the exploitation accuracy.

In the exploitation phase of the AOA, Subtraction and Addition operators are utilized to precisely target the search regions identified by the most promising AOA solution. This step leverages the operator's characteristic of being densely concentrated yet having low dispersion. The position of each *i*-th AOA solution in the *d*-th dimension is updated as follows during this phase:

$$x_{i,j}(C_{Iter} + 1)$$
$$= \begin{cases} x_j^{best} - MOP \times \left((UB_j - LB_j) \times \mu + LB_j\right), \\ \qquad\qquad r2 < 0.5 \\ x_j^{best} + MOP \times \left((UB_j - LB_j) \times \mu + LB_j\right), \\ \qquad\qquad \text{otherwise} \end{cases}$$

$$(4)$$

Here, $r2$ represents a randomly generated number between 0 and 1, following a uniform distribution.

The AOA algorithm iteratively executes these exploration and exploitation processes until predefined stopping criteria are met. The optimal solution generated by AOA at the end of the optimization process is adopted as the best set of hyperparameters for training the ResNet-18 network to classify wafer defects.

3. Proposed Optimized Deep Learning Model
3.1. *Preprocessing of dataset with wafer defects*

The optimized ResNet-18 architecture undergoes training and evaluation for wafer defect classification utilizing the WM-811K dataset [25]. This particular dataset is noted for its significantly imbalanced distribution across various classes. To mitigate potential biases and overfitting stemming from this imbalance, we formed a new dataset using an under-sampling method. This approach involved compiling 30,000 images classified as 'None defect' from the WM-811K dataset, along with all other images categorized as defects. The resultant dataset, balanced in terms of defect and non-defect images, is detailed in Table 2, providing a comprehensive breakdown of the image categories.

Table 2. Number of defect and non-defect wafer images after preprocessing stage

Layer	Defect Type	#Labeled Images
1	Center	4,294
2	Donut	555
3	Edge-Loc	5,189
4	Edge-Ring	9,680
5	Loc	3,593
6	Near-Full	149
7	Random	866
8	Scratch	1,193
9	None	30,000

3.2. *Hyperparameter tuning of ResNet-18 with AOA*

The revised WM-811K dataset, detailed in Table 2, is used to train the chosen deep learning model, ResNet-18, for wafer defect classification via transfer learning. To tailor the pre-trained network for this specific classification task, several modifications are made to both the input datasets and the configuration of ResNet-18. The size of each input image is increased from 48×48×1 to 224×224×3, the padding size of the initial convolution layer is adjusted to align with the new input size, and the output size of the fully connected layer is altered to 9 to reflect the nine defect types identified in this study.

Additionally, to enhance ResNet-18's performance in classifying wafer defects, the AOA is implemented to optimize the network's training hyperparameters during the transfer learning process. The AOA generates solution vectors representing four key decision variables: momentum, initial learning rate, maximum epochs, and L2 regularization. The ranges for these variables are specified in Table 3. The effectiveness of each AOA solution is assessed based on the classification accuracy achieved. Fig. 1 illustrates the AOA-optimized ResNet-18 framework developed for wafer defect classification.

Table 3. Lower and upper bounds of training hyperparameters to be optimized.

Hyperparameter	Lower Limits	Upper Limits
Momentum	0.5	0.9
Initial Learning Rate	0.01	0.1
Maximum Epochs	5	10
L2 Regularization	1×10^{-4}	5×10^{-4}

AOA-Optimized ResNet-18 for Wafer Defect Classification

Input: N, D, UB_j, LB_j

```
01:   Initialize C_Iter = 0;
02:   for i =1 to I do
03:       Randomly generate solution x_i;
04:       C_Iter = C_Iter + 1;
05:   end for
06:   while C_Iter ≤ M_Iter do
07:       Decode the hyperparameters from x_i;
08:       Train the ResNet-18 using transfer learning based on
          hyperparameters decoded from x_i;
09:       Evaluate the accuracy f(x_i) of ResNet-18;
10:       Calculate MOP using Eq. (3);
11:       Calculate MOA using Eq. (1);
12:       for i =1 to I do
13:           for j =1 to D do
14:               if rand > MOA then
15:                   Update x_{i,j}(C_Iter + 1) with Eq. (2);
16:               Else
17:                   Update x_{i,j}(C_Iter + 1) with Eq. (4)
18:               end if
19:           end for
20:           Decode the hyperparameters from x_i;
21            Train the ResNet-18 using transfer learning
              based on hyperparameters decoded from x_i;
22:           Evaluate the accuracy f(x_i) of ResNet-18;
21:           Update x_i, f(x_i), x^{best}, f(x^{best})
22:           C_Iter ← C_Iter + 1;
23:       end for
24:   end while
```

Output: Optimal values of momentum, initial learning rate, maximum epochs and L2 regularization decoded from the best AOA solution represented as x^{best}.

Fig.1 Pseudocode of optimizing the hyperparameters of ResNet-18 using AOA for wafer defect classification.

4. Performance Studies
4.1. *Simulation settings*

The pre-processed WM-811K dataset is randomly partitioned into three subsets for the purposes of training, validation, and testing. Specifically, the dataset allocation

comprises 70% for training, 10% for validation, and 20% for testing. Additionally, all input images are uniformly resized to a dimension of 224×224×3, and the minimum batch size for processing is set as 32.

4.2. *Performance comparisons*

The classification effectiveness of both unoptimized ResNet-18 and AOA-Optimized ResNet-18 in identifying wafer defects is evaluated using several key metrics: recall, accuracy, precision, F1 score, and AUC. Consider *TP*, *TN*, *FP*, and *FN* as the true positive, true negative, false positive, and false negative counts, respectively, generated by the deep learning model during the classification process. Recall, reflecting the model's capability to detect positive samples, is calculated as:

$$Recall = \frac{TP}{TP + FN} \quad (5)$$

Accuracy, indicating the proportion of correctly predicted data, is defined as:

$$Accuracy = \frac{TP + TN}{TP + TN + FP + FN} \quad (6)$$

Precision, measuring the model's accuracy in predicting a sample as positive, is expressed as:

$$Precision = \frac{TP}{TP + FP} \quad (7)$$

The F1 score, the harmonic mean of precision and recall, is calculated by:

$$F1\ Score = 2 \times \left(\frac{Precision \times Recall}{Precision + Recall} \right) \quad (8)$$

Lastly, AUC, representing the area under the receiver operating characteristic curve, provides an overall effectiveness measure. The quantitative performance of both the unoptimized and AOA-Optimized ResNet-18 models is detailed in Table 4. Additionally, their qualitative performance is analyzed based on the confusion matrices depicted in Fig. 2.

Table 4. Quantitative performance comparison between optimized and unoptimized ResNet-18

Metrics	Unoptimized ResNet-18	AOA-Optimized ResNet-18
Validation Accuracy	0.8560	**0.8983**
Testing Accuracy	0.8388	**0.8923**
Recall	0.8482	**0.8956**
Precision	0.8751	**0.9059**
F1 Score	0.8523	**0.8972**
AUC	0.9002	**0.9397**

Table 4 illustrates that the AOA-optimized ResNet-18 surpasses the unoptimized model in all assessed metrics. It shows a higher validation accuracy of 0.8983 compared to the unoptimized model's 0.8560, and a testing accuracy of 0.8923 versus 0.8388. Additionally, the recall score of the AOA-optimized model stands at 0.8956, outperforming the unoptimized model's 0.8420. In terms

of precision, the AOA-optimized model achieves a score of 0.9059, exceeding the unoptimized model's 0.8751. The F1 score and AUC for the optimized model are 0.8972 and 0.9397, respectively, both higher than the unoptimized model's scores of 0.8523 and 0.9002. The enhanced validation accuracy of the AOA-optimized ResNet-18 indicates its superior performance in predicting classes of unseen samples during training, while its greater testing accuracy suggests a more accurate prediction of new, unseen data classes. The improved recall and precision scores signify the model's heightened ability to correctly identify more true positive samples and effectively reduce false positives.

(a)

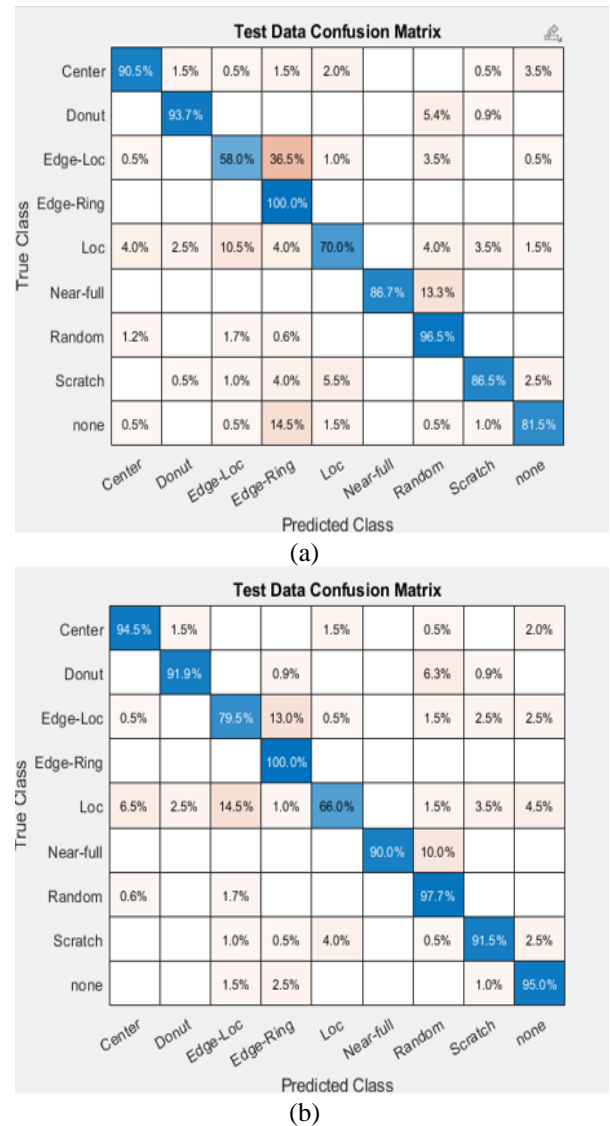
(b)


Fig.2 Confusion matrices produced by: (a) Unoptimized ResNet-18 and (b) AOA-Optimized ResNet-18 when classfying wafer defects.

Qualitative results, derived from confusion matrices of both the AOA-optimized and unoptimized ResNet-18 models as depicted in Fig. 2, align with the quantitative findings in Table 4. The AOA-optimized model demonstrates superior accuracy in classifying various

wafer defects, including Center, Edge-Loc, Near-Full, Random, and Scratch, compared to the unoptimized version. Notably, the unoptimized model frequently misclassifies Edge-Loc defects as Edge-Ring, leading to significant errors, and incorrectly labels 14.5% of 'No defect' cases as Edge-Ring defects. Both the quantitative and qualitative analyses suggest that optimizing ResNet-18's hyperparameters through AOA effectively corrects the misclassification issues observed in the unoptimized model, resulting in a marked enhancement in the model's ability to classify wafer defects accurately and efficiently.

5. Conclusion

This study is designed to demonstrate the effectiveness of optimizing hyperparameters in deep learning models for wafer defect classification. In our approach, the Arithmetic Optimization Algorithm (AOA) is employed to fine-tune four key hyperparameters—momentum, initial learning rate, maximum epoch, and L2 regularization rate—of the ResNet-18 model. This model, initially pre-trained on ImageNet, was further refined on a wafer defect dataset via transfer learning. Our extensive simulation studies indicate that the AOA-optimized ResNet-18 model surpasses the unoptimized version in recall, accuracy, precision, F1 score, and AUC, showcasing enhanced capabilities in accurately identifying and classifying wafer defects.

The findings reveal the significance of hyperparameter optimization in developing deep learning models for wafer defect classification. Future research could investigate the applicability of AOA in fine-tuning other deep learning models within this domain. Additionally, exploring AOA for identifying optimal deep learning network architectures offers promising avenues for robust wafer defect classification. Incorporating more features and diverse data sources could further refine the proposed method's efficacy. Finally, subsequent studies should assess the practicality of implementing these optimized deep learning models in industrial settings for real-world wafer defect classification applications.

Authors Introduction

Mr. Koon Hian Ang

He received the Bachelor of Mechatronics Engineering with Honours in Faculty of Engineering, Technology and Built Environment, UCSI University, Malaysia, in 2023. His research interests are machine learning, deep learning, and optimization algorithm.

Dr. Koon Meng Ang

He received the B.Eng. degree in Mechatronic Engineering with Honours and PhD in Engineering from UCSI University, Malaysia, in 2019 and 2023, respectively. His research interests are swarm intelligence, machine learning and deep learning.

Dr. Chin Hong Wong

He is a Lecturer in Maynooth International Engineering College at Fuzhou University in China. He received his PhD in Electrical and Electronic Engineering from Universiti Sains Malaysia in 2017. His research interests are Energy harvesting and control system.

Dr. Abhishek Sharma

He is a Research Assistant Professor at Graphic Era Deemed to be University in India. He received his PhD from University of Petroluem & Energy Studies in 2022. His research interests are artificial intellgence and power electronics.

Dr. Chun Kit Ang

He is the Dean and Associate Professor in Faculty of Engineering at UCSI University in Malaysia. He received his PhD in Mechanical and Manufacturing Engineering from Universiti Putra Malaysia in 2014. His research interests are artificial intelligence, soft computing, robotics and mechatronics.

Dr. Kim Soon Chong

He is an Assistant Professor in Faculty of Engineering at UCSI University in Malaysia. He received his PhD in Electrical, Eleronics & System Engineering from Universiti Kebangsaan Malaysia in 2022. His research interests are biomedical and healthcare technoologies.

Dr. Sew Sun Tiang

She is an Assistant Professor in Faculty of Engineering at UCSI University in Malaysia. She received her PhD in Electrical and Electronic Engineering from Universiti Sains Malaysia in 2014. Her research interests are optimization and antenna design.

Dr. Wei Hong Lim

He is an Associate Professor in Faculty of Engineering at UCSI University in Malaysia. He received his PhD in Computational Intelligence from Universiti Sains Malaysia in 2014. His research interests are optimization and artificial intelligence.

Tackling Photovoltaic (PV) Estimation Challenges: An Innovative AOA Variant for Improved Accuracy and Robustness

Abstract

Optimizing photovoltaic (PV) cell/module modeling is key to advancing solar power and achieving net zero carbon goals. Challenges in accurate PV parameter estimation arise from environmental variability, aging, and incomplete manufacturer data. Traditional Arithmetic Optimization Algorithm (AOA) often struggles with premature convergence due to imbalanced exploration and exploitation. This paper presents an enhanced AOA variant, incorporating chaotic maps and oppositional-based learning to better balance the optimization process. Our extensive simulations show that this improved AOA variant significantly enhances accuracy and robustness in PV cell/module parameter estimation compared to the conventional method.

Keywords: Photovoltaic module/cell, Parameter estimation, Arithmetic optimization algorithm

1. Introduction

The Intergovernmental Panel on Climate Change (IPCC) has underscored the urgent necessity to address global warming, advocating for significant efforts to attain net zero carbon emissions by 2050. This imperative demands a transition to renewable energy sources, with solar power emerging as a key player due to its sustainability and minimal environmental footprint [1]. Solar energy, captured through photovoltaic (PV) cells and modules, offers versatility, catering to a range of applications from residential heating to extensive solar farms [2]. Yet, the efficacy of solar systems is critically dependent on the performance of PV arrays, which are prone to degradation under harsh outdoor conditions.

Precision in PV system modeling is crucial for enhancing performance. This process encompasses various models, including single-diode, double-diode, and triple-diode, each demanding distinct parameter such as photocurrent and resistances [3]. Often, these parameters are not readily available from manufacturers, necessitating their estimation from experimental data. This task is further complicated by the aging of PV systems and fluctuating environmental factors [3]. The intricate and multimodal characteristics of PV parameter estimation, especially under diverse irradiance and temperature conditions, pose considerable challenges.

Existing photovoltaic (PV) cell/module parameter estimation approaches are broadly categorized into deterministic and metaheuristic methods. Deterministic methods, simpler and less computationally intensive, often fall short in accuracy under varied environmental conditions [3]. In contrast, metaheuristic methods, drawing inspiration from natural phenomena, exhibit superior global search capabilities, ease of implementation, and scalability. Consequently, they have become highly effective for diverse global optimization challenges [4], [5], [6], [7], [8], [9], [10], [11]. These metaheuristic methods also excel in addressing complex, multimodal PV cell/module parameter estimation problems [12], [13], [14], [15], [16]. Despite substantial progress using metaheuristic approaches, challenges persist due to the intricate, nonlinear interplay of PV module parameters and variable operating conditions. Therefore, developing robust metaheuristic methods for more precise PV parameter estimation is vital. Such advancements will enhance PV system optimization, maximizing solar energy utilization and contributing to a sustainable future.

Arithmetic Optimization Algorithm (AOA) [17] is a mathematics-inspired metaheuristic method that employs four basic arithmetic operations (division, multiplication, addition, and subtraction) with varying exploration and exploitation strengths for solving optimization problems.

Rayan Mohammed Noor Mohammed Bakhit, Abhishek Sharma, Tiong Hoo Lim, Chin Hong Wong, Kim Soon Chong, Li Pan, Sew Sun Tiang, Wei Hong Lim

In PV cell/module parameter estimation, the AOA population signifies diverse diode parameter combinations. Since its introduction, AOA and its variants have been effectively applied to various real-world optimization problems [18], [19], [20], [21], [22]. However, AOA, like many metaheuristic methods, relies on a conventional approach for generating its initial population, which often lacks intelligent, systematic initialization. This approach tends to produce initial solutions that are either trapped in local optimum or distant from the global optimum, thus impacting the solution's accuracy and the algorithm's convergence speed [23]. This limitation affects AOA's efficiency in complex, multimodal challenges such as PV cell/module parameter estimation.

In this paper, we introduce an enhanced variant of AOA, termed AOA with Modified Initialization Scheme (AOA-MIS), specifically designed to tackle complex and multimodal PV cell/module parameter estimation problems. The MIS module combines chaotic map strengths and dynamic oppositional learning (DOL) to generate a higher-quality initial population with improved fitness and diversity. Utilizing the non-repetitive and ergodic nature of chaotic maps, the MIS module enhances initial population diversity, thereby increasing the algorithm's robustness for complex issues. Concurrently, the DOL mechanism within MIS module effectively accelerates AOA's convergence by generating opposite solutions for those significantly distant from the global optimum. The efficacy of AOA-MIS, using various diode modeling techniques, is then benchmarked against the original AOA.

2. PV Cell/Module Parameter Estimation Problem

The electrical properties of PV systems can be modeled using different approaches: single diode model (SDM), double diode model (DDM) and triple diode model (TDM) as shown in Fig. 1. Let $j = 1, \ldots, J$ be the diode index in the model, where $J = 1$ is for SDM, $J = 2$ for DDM and $J = 3$ for TDM. For a given output voltage V, the output current I each diode model is determined as:

$$I = I_{ph} - \frac{V + IR_s}{R_{sh}} - \sum_{j=1 \to J} I_{ssdj} \left[e^{\left(\frac{q(V+IR_s)}{n_j kT} \right)} - 1 \right] \quad (1)$$

where I_{ph} and I_{sh} are the photogenerated line current and shunt resistor line current, respectively; I_{ssdj} is the saturation current of the j-th diode, R_s and R_{sh} are the series and shunt resistances, respectively; n_j is the ideality factor of the j-th diode, T is the absolute temperature, k is Boltzmann's constant, and q is the unit charge. Accurate modeling using SDM, DDM, and TDM necessitates the accurate estimation of parameters such as I_{ph}, R_s, R_{sh}, I_{ssdj} and n_j for $j = 1, \ldots, J$.

In PV cell/module parameter estimation using metaheuristic methods, appropriate objective functions are formulated based on the discrepancy between the experimental current and the model's predicted current. Considering X as a candidate solution with undetermined diode parameters, the error function for PV cells is expressed as:
Fig.1 Equivalent circuit of PV using TDM with $J = 3$.

$$\begin{cases} f(X) = I_{ph} - \frac{V + IR_s}{R_{sh}} - \sum_{j=1 \to J} I_{ssdj} \left[e^{\left(\frac{q(V+IR_s)}{n_j kT} \right)} - 1 \right] - I \\ X = [I_{ph}, R_s, R_{sh}, I_{ssdj}, n_j], \quad \text{for } j = 1, \ldots, J \end{cases} \quad (2)$$

Root mean square error (RMSE) is commonly employed as the objective function, defined as:

$$RMSE = \sqrt{\frac{1}{K} \sum_{k=1}^{K} f^2(X)} \quad (3)$$

where k and K represent the indices and total count of measured current data points, respectively. The aim is to find a solution that minimizes the RMSE in PV cell/module parameter estimation.

3. AOA-MIS
3.1. *Proposed MIS module*

The process of generating an initial population in the proposed MIS module is described as follows. Initially, a chaotic population of size N is generated using a modified sine chaotic map, a departure from the traditional initialization schemes. This map, based on deterministic equations, can display stochastic behavior at external levels. The ergodic and non-repetitive nature of chaotic map promotes a more comprehensive search in the solution space, preventing initial solutions from being trapped in local optima and thus enhancing the diversity and robustness of the initial population against premature convergence. Define ϑ_t as the output of a chaotic variable at the t-th iteration, for $t = 1, \ldots, T$, updated as per the modified sine chaotic map with a bifurcation coefficient $\mu = \pi$:

$$\vartheta_{t+1} = \sin(\mu \vartheta_t) \quad (4)$$

The final iteration output ϑ_T initializes the d-th dimension of each n-th chaotic solution, as in Eq. (5), where X_d^L and X_d^U are the lower and upper bounds of the d-th decision variable, respectively. This results in a chaotic population $\mathbf{P^C} = [X_1^C, \ldots, X_n^C, \ldots X_N^C]$.

$$X_{n,d}^C = X_d^L + \vartheta_T (X_d^U - X_d^L) \quad (5)$$

Despite its advantages, chaotic map may still generate initial solutions far from the global optimum, potentially slowing algorithm convergence. To mitigate this, a DOL operator is applied to the chaotic population $\mathbf{P^C}$ to

produce opposite solutions for each *n*-th chaotic solution. This DOL operator broadens the initial population's coverage of the solution space, enhancing the chance of finding fitter solutions. The opposite solution for each dimension, i.e., $X_{n,d}^O$, is calculated using Eq. (6), corresponding to $X_{n,d}^C$, where $r_1, r_2 \in [0,1]$ are randomly generated numbers. This results in an opposition population, $\mathbf{P^O} = [X_1^O, \dots, X_n^O, \dots X_N^O]$.

$$X_{n,d}^O = X_{n,d}^C + r_1 \left[r_2(X_d^U + X_d^L - X_{n,d}^C) - X_{n,d}^C \right] \quad (6)$$

The two populations, $\mathbf{P^C}$ and $\mathbf{P^O}$, are combined into a single set $\mathbf{P^C} \cup \mathbf{P^O}$, resulting in a total population size of $2N$. Each solution within this merged population set is evaluated for fitness using Eq. (3), focusing on RMSE. The solutions are then rearranged based on their fitness values, from the best to the worst. The top N solutions from this sorted set $\mathbf{P^C} \cup \mathbf{P^O}$ are selected as the initial population for the AOA-MIS algorithm, denoted as $\mathbf{P} = [X_1, \dots, X_n, \dots, X_N]$.

3.2. *Iterative Search Mechanisms of AOA-MIS*

After generating the initial population $\mathbf{P}$ with the proposed MIS module, each *n*-th solution of AOA-MIS is iteratively updated using search mechanisms akin to those in the original AOA.

At each iteration, the Math Optimizer Accelerated (MOA) function value is updated for the proposed AOA-MIS to toggle between exploration and exploitation:

$$MOA(C_{Iter}) = Min + C_{Iter} \left(\frac{Max - Min}{M_{Iter}} \right) \quad (7)$$

where C_{Iter} and M_{Iter} represent the current and maximum iteration numbers, respectively; Min and Max are the minimum and maximum values of MOA. Concurrently, the Math Optimizer Probability (MP) function, guiding the search range for each solution and influenced by the critical parameter θ for exploitation efficiency, is updated:

$$MP(C_{Iter}) = 1 - \left(\frac{C_{Iter}}{M_{Iter}} \right)^{1/\theta} \quad (8)$$

Based on MOA's value, a random number $\mathbf{rand1}$ decides the search strategy (exploration or exploitation) at each iteration for updating every *d*-th dimension of the *n*-th solution, $X_{n,d}$. In the exploration phase ($\mathbf{rand1 > MOA}$), Multiplication or Division is randomly chosen:
$X_{n,d}(C_{Iter} + 1)$
$$= \begin{cases} best_d \div (MP + \varepsilon) \times [(X_d^U - X_d^L)\mu + X_d^L], rand2 < 0.5 \\ best_d \times MP \times [(X_d^U - X_d^L)\mu + X_d^L], \quad \text{Otherwise} \end{cases}$$
$$(9)$$

where $rand2$ is a random number between 0 and 1; $best_d$ is the *d*-th dimension of the current best solution; ε is a small positive number preventing division by zero; μ is a control parameter.

In the exploitation phase ($rand1 \leq MOA$), Addition or Subtraction operator updates $X_{n,d}$:

$X_{n,d}(C_{Iter} + 1) =$
$$\begin{cases} best_d - MP \times [(X_d^U - X_d^L)\mu + X_d^L], rand2 < 0.5 \\ best_d + MP \times [(X_d^U - X_d^L)\mu + X_d^L], \quad \text{Otherwise} \end{cases} \quad (10)$$

The proposed AOA-MIS iterates through this search process, following Eqs. (7) to (10), until predefined termination criteria are met, as illustrated in Fig. 2. Upon completion, the optimal diode parameters in the best solution are decoded to address the PV cell/module parameter estimation problems.

AOA-MIS for PV Cell/Module Parameter Estimation

Inputs: $D, N, M_{Iter}, T, Max, Min, \theta$
01:     Initialize $\mathbf{P^C} \leftarrow \emptyset$, $\mathbf{P^O} \leftarrow \emptyset$ and $C_{Iter} \leftarrow 0$;
02:    **for** each *n*-th solution **do**
03:      **for** each *d*-th dimension **do**
04:       Randomly generate $\vartheta_t \in [0,1]$, where $t = 0$;
05:       **while** $t \leq T$ **do**
06:        Update ϑ_t using Eq. (4);
07:        Update $t \leftarrow t + 1$;
08:       **end while**
09:       Calculate $X_{n,d}^C$ with Eq. (5);
10:       Calculate $X_{n,d}^O$ with Eq. (6);
11:      **end for**
12:      Update $\mathbf{P^C} \leftarrow \mathbf{P^C} \cup X_{n,d}^C$ and $\mathbf{P^O} \leftarrow \mathbf{P^O} \cup X_{n,d}^O$;
13:    **end for**
14:    Merge two populations as $\mathbf{P^C} \cup \mathbf{P^O}$;
15:    Fitness evaluation of all solutions stored within the merged population set of $\mathbf{P^C} \cup \mathbf{P^O}$ using Eq. (3);
16:    Sort the solutions within $\mathbf{P^C} \cup \mathbf{P^O}$ from best to worst based on their fitness values;
17:    Select the top N solutions from the sorted $\mathbf{P^C} \cup \mathbf{P^O}$ as the initial population, i.e., $\mathbf{P} = [X_1, \dots, X_n, \dots, X_N]$.
18:    Assign the first solution of $\mathbf{P}$ and its fitness as *best* and $f(best)$, respectively;
19:    **while** $C_{Iter} \leq M_{Iter}$ **do**
20:      Update *MOA* and *MP* with Eqs. (7) and (8);
21:      **for** each *n*-th solution **do**
22:       **if** $rand1 > MOA$ **then** /*Exploration*/
23:        Update $X_{n,d}(C_{Iter} + 1)$ with Eq. (9);
24:       **else** /*Exploitation*/
25:        Update $X_{n,d}(C_{Iter} + 1)$ with Eq. (10);
26:       **end if**
27:       Fitness evaluation of $X_n(C_{Iter} + 1)$ with Eq. (3);
28:       Update the X_n, $f(X_n)$, *best* and $f(best)$, with greedy selection method;
29:      **end for**
30:      $C_{Iter} \leftarrow C_{Iter} + 1$;
31:    **end while**
Output: *best* and the corresponding PV model;

Fig.2 Workflow of proposed AOA-MIS in solving the PV cell/module parameter estimation problems.

4. Results and Discussions
4.1. *Simulation settings*

In this section, the proposed AOA-MIS is applied to solve the PV cell parameter estimation problem involves the test case of R.T.C. France solar cell using SDM, DDM and TDM approaches. The proposed AOA-MIS and original AOA are implemented in MATLAB 2021a on a personal computer consisting of an Intel® Core™

Rayan Mohammed Noor Mohammed Bakhit, Abhishek Sharma, Tiong Hoo Lim, Chin Hong Wong, Kim Soon Chong, Li Pan, Sew Sun Tiang, Wei Hong Lim

i7-HQ CPU, 2.50 GHz, and 16 GB RAM laptop. For all compared techniques, the population size and maximum iteration numbers are set as 30 and 1000, respectively.

4.2. *Performance analysis*

The current and voltage experimental values for the R.T.C. France solar cell were recorded under standard conditions: 1000 W/m² at 33°C. This subsection applies the proposed AOA-MIS to estimate five and seven unknown parameters of the SDM and DDM, respectively, representing the R.T.C. solar cell at these conditions. The AOA-MIS results are compared with those from the original AOA. RMSE serves as the performance index to evaluate AOA-MIS's effectiveness.

Table 1 and Table 2 showcase the optimized parameters derived from AOA-MIS and the original AOA for the R.T.C. France solar cell, using the SDM and DDM, respectively, along with their corresponding RMSE values. Parameters yielding better results, as indicated by lower RMSE values, are highlighted in bold. Table 1 reveals that AOA-MIS's estimation of the five parameters (i.e., I_{ph}, R_s, R_{sh}, I_{ssd} and n) for the SDM leads to higher modeling accuracy for the R.T.C. France solar cell, as evidenced by lower RMSE values, compared to the original AOA. Similarly, Table 2 shows that AOA-MIS's estimation of the seven parameters (i.e., I_{ph}, R_s, R_{sh}, $I_{ssd,1}$, $I_{ssd,2}$, n_1 and n_2) for the DDM yields more competitive RMSE values.

Table 1. Optimized parameters obtained for R.T.C France solar cell using SDM.

Parameters	AOA	AOA-MIS
I_{ph}	0.75483	0.75822
R_s	0.052023	0.039672
R_{sh}	97.805	69.689
I_{ssd}	1.5746×10^{-8}	1.5411×10^{-7}
n	1.2485	1.4316
RSME	5.3572×10^{-3}	$\mathbf{3.2507\times10^{-3}}$

Table 2. Optimized parameters obtained for R.T.C France solar cell using DDM.

Parameters	AOA	AOA-MIS
I_{ph}	0.73552	0.80916
R_s	0.0044392	0
R_{sh}	2.668	1.7305
$I_{ssd,1}$	0	0
$I_{ssd,2}$	0	0
n_1	1.1428	1.0141
n_2	1.9816	1.235
RSME	1.7449×10^{-1}	$\mathbf{1.705\times10^{-1}}$

To further assess the effectiveness of the proposed AOA-MIS in addressing the PV cell/module parameter estimation problems, Table 3 provides a statistical analysis of the RMSE values for the R.T.C. France solar cell using both SDM and DDM models, comparing AOA-MIS and the original AOA. This analysis includes performance metrics such as the minimum (Min), maximum (Max), mean (Mean), and standard deviation (SD) of the RMSE values from multiple simulation runs

for both algorithms. The data in Table 3 reveal that AOA-MIS consistently outperforms the original AOA in terms of Max, Min, and Mean RMSE values. Additionally, AOA-MIS shows superior consistency in achieving lower RMSE values, as evidenced by lower SD values in both SDM and DDM test cases.

Table 3. Statistical results of the RMSE values of R.T.C France solar cell represented by different diode modelling methods

Model	RSME	AOA	AOA-MIS
SDM	Min	5.3572×10^{-3}	$\mathbf{3.2507\times10^{-3}}$
	Mean	3.0009×10^{-2}	$\mathbf{2.4830\times10^{-2}}$
	Max	1.4549×10^{-1}	$\mathbf{6.7476\times10^{-2}}$
	SD	4.2432×10^{-2}	$\mathbf{2.0059\times10^{-2}}$
DDM	Min	1.7449×10^{-1}	$\mathbf{1.7050\times10^{-1}}$
	Mean	1.9299×10^{-1}	$\mathbf{1.7875\times10^{-1}}$
	Max	2.1688×10^{-1}	$\mathbf{1.8938\times10^{-1}}$
	SD	1.2098×10^{-2}	$\mathbf{5.8922\times10^{-3}}$

The superior performance of the proposed AIA-MIS over the original AOA can be attributed to several factors. PV cell/module parameter estimation is a complex, multimodal real-world optimization problem, largely due to the nonlinear relationship between model parameters and varying operating conditions such as temperature and irradiance levels. The complexity of this problem escalates with the number of diodes used in modelling (e.g., five parameters in SDM, seven parameters in DDM and so on), further complicating the optimization task. Table 1, Table 2, and Table 3 suggest that the quality of the initial population is crucial in enabling AOA to accurately model PV cell/module parameters. The original AOA, using a conventional initialization scheme, tends to generate the initial solutions in local or non-optimal regions, leading to premature convergence due to the absence of intelligent methods and knowledge of the surrounding search environment. Moreover, there is a significant risk of initializing solutions far from the global optimum, slowing down the algorithm's convergence speed. In contrast, the MIS module in AOA-MIS generates an initial population of higher quality in terms of fitness and diversity. The chaotic map's non-repetitive and ergodic nature in the MIS module promotes a more comprehensive search of the solution space, minimizing the risk of local optima entrapment and premature convergence. DOL, another key mechanism in MIS, accelerates convergence by enhancing the exploration of search range through generating opposite solutions from those initialized by the chaotic map. This synergistic effect of the chaotic map and DOL in the MIS module bolsters AOA-MIS's robustness in navigating complex, multimodal search spaces, thereby enhancing its accuracy in solving PV cell/module parameter estimation problems.

5. Conclusion

In this paper, we introduce an enhanced version of the Arithmetic Optimization Algorithm, termed AOA-MIS, to address the complex and multimodal challenges of PV

cell/module parameter estimation. The innovation of AOA-MIS lies in integrating chaotic maps and DOL mechanisms into the Modified Initialization Scheme (MIS) module, thereby generating an initial population with improved fitness and diversity. Simulation results reveal that AOA-MIS, with its superior initial population quality, outperforms the original AOA in estimating parameters for the SDM and DDM in representing the R.T.C. France solar cell, tested under standard conditions of 1000 W/m² at 33°C. As one of the future works, AOA-MIS could be further enhanced by incorporating an adaptive search mechanism, potentially increasing its robustness and efficacy in addressing various complexities in PV cell/module parameter estimation.

Authors Introduction

Mr. Rayan Mohammed Noor Mohammed Bakhit

He received the Bachelor of Mechatronics Engineering with Honours in Faculty of Engineering, Technology and Built Environment, UCSI University, Malaysia, in 2023. His research interests are renewable energy, and optimization algorithm.

Dr. Abhishek Sharma

He is a Research Assistant Professor at Graphic Era Deemed to be University in India. He received his PhD from University of Petroluem & Energy Studies in 2022. His research interests are artificial intellgence and power electronics.

Dr. Tiong Hoo Lim

He is a Senior Assistant Professor and Director of Planning Development Office at Universiti Teknologi Brunei in Brunie Darussalam. He received his PhD in Computer Science from University of York, United Kingdom. His research interests are artificial intelligence, advanced technology, competitive and forecasting analysis.

Dr. Chin Hong Wong

He is a Lecturer in Maynooth International Engineering College at Fuzhou University in China. He received his PhD in Electrical and Electronic Engineering from Universiti Sains Malaysia in 2017. His research interests are Energy harvesting and control system.

Dr. Kim Soon Chong

He is an Assistant Professor in Faculty of Engineering at UCSI University in Malaysia. He received his PhD in Electrical, Eleronics & System Engineering from Universiti Kebangsaan Malaysia in 2022. His research interests are biomedical and healthcare technoologies.

Ms. Li Pan

She received her Master of Engineering in Computer Technology degree from Huazhong University of Science and Technology, China in 2008. She is currently a Doctoral research student in UCSI University, Malaysia.

Dr. Sew Sun Tiang

She is an Assistant Professor in Faculty of Engineering at UCSI University in Malaysia. She received her PhD in Electrical and Electronic Engineering from Universiti Sains Malaysia in 2014. Her research interests are optimization and antenna design.

Dr. Wei Hong Lim

He is an Associate Professor in Faculty of Engineering at UCSI University in Malaysia. He received his PhD in Computational Intelligence from Universiti Sains Malaysia in 2014. His research interests are optimization and artificial intelligence.

Deep Learning in Manufacturing: A Focus on Welding Defect Classification with CNNs

Abstract

Welding is integral to modern manufacturing, yet the complex process often leads to defects, impacting the quality of the final product. Recent advances in deep learning, particularly Convolutional Neural Networks (CNNs), have shown remarkable results in applications like defect recognition. This study evaluated AlexNet, ResNet-18, ResNet-50, ResNet-101, MobileNet-v2, ShuffleNet, and SqueezeNet for their effectiveness in identifying welding defects, using accuracy, precision, sensitivity, specificity, and F-score as metrics. The dataset covered defects like cracks, lack of penetration, porosity, and a no-defect class. Our analysis shows that most of these architectures deliver promising results in accuracy, sensitivity, specificity, precision, and F1-score, highlighting their potential in defect recognition.

Keywords: Convolutional neural network, Classification, Deep learning, Welding defects

1. Introduction

Welding is a crucial industrial process integral to various production sectors, including high-performance industries like aerospace, automotive, marine, and power generation. This complex process involves multiple parameters that directly impact the quality of the weld joint. Factors such as welding procedures, methods, environmental conditions, and the operator's skill level can lead to various defects during the welding of pipelines and pressure vessels [1]. Common defects include blowholes, cracks, incomplete fusion, incomplete penetration, slag inclusions, and undercutting, which significantly compromise the sealing and strength of the products. In addition to welding parameters, unforeseen events in the manufacturing process can also cause weld defects. Therefore, rigorous welding quality inspection and testing are essential during manufacturing, especially for products like pipelines and pressure vessels. This is critical to identify the root causes of welding defects and implement targeted corrective measures to ensure product quality and safety [1].

Considerable research has been devoted to addressing the challenges of weld defect detection and identification. These defects are typically detected using non-destructive testing (NDT) techniques, favored for their non-invasive interaction with specimens. Common NDT methods for weld defect detection fall into various categories, including visual or manual inspection, radiographic testing with ionizing radiation sources (such as gamma rays or X-rays), eddy current testing, ultrasonic testing, and dye penetrant testing [2], [3]. However, each of these techniques has inherent limitations. For example, eddy current testing is only applicable to metallic specimens, while X-ray radiographic testing poses potential health risks due to prolonged exposure to radiation. Additionally, the majority of current weld surface defect recognition relies on manual inspection by NDT experts analyzing these radiographic images. This manual process of interpreting and evaluating images can be complex, subjective, inconsistent, time-consuming, labor-intensive, and prone to errors, particularly when distinguishing between defects with similar features [4]. Consequently, developing an automated inspection solution that offers more efficient and accurate recognition of weld surface defects is essential to overcome the drawbacks of manual inspections.

The adoption of automated machine vision systems, integrating deep learning techniques, offers a promising solution for weld surface image classification challenges. Convolutional Neural Networks (CNNs), renowned for their ability to learn nonlinear relationships between inputs and outputs, mimic the human brain's learning process and have been effectively applied in various real-world scenarios. These applications include signal/image classification [5], [6], [7], cybersecurity [8], [9], medical diagnosis [10], [11], [12], fault detection [13], [14], [15]

Tin Chang Ting, Hameedur Rahman, Tiong Hoo Lim, Chin Hong Wong, Chun Kit Ang, Mohamed Khan Afthab Ahamed Khan, Sew Sun Tiang, Wei Hong Lim

and prediction [16], [17]. Encouraged by deep learning's success, numerous network architectures have been developed, such as AlexNet [18], ResNet-18 [19], ResNet-50 [19], ResNet-101 [19], MobileNet-v2 [20], ShuffleNet [21], and SqueezeNet [22]. Transfer learning, a method for adapting these existing CNN architectures to new tasks, has gained popularity. It utilizes smaller datasets and reduces training time, making it an efficient approach for training CNNs in new application domains.

While previous studies [4], [23], [24], [25], [26], [27] have explored welding defect classification using deep learning, the optimal selection of CNN architectures remains relatively unexplored, leaving many architectures yet to be assessed. Addressing this gap, our paper presents an extensive study evaluating the performance of seven popular CNN architectures: AlexNet, ResNet-18, ResNet-50, ResNet-101, MobileNet-v2, ShuffleNet, and SqueezeNet, in classifying weld defects from digital radiographic images. Our aim is to objectively identify the most effective CNN architecture using various performance metrics. This study could lead to replacing manual inspection methods with a more accurate automated weld defect classification system, potentially reducing production costs and increasing throughput.

2. Methodology
2.1. *Data acquisition and preprocessing*

This study focuses on training and evaluating a deep learning model using the RIAWELC welding defect dataset [28]. Unlike other commonly used datasets such as GDXRay [29] and WDXI [30], RIAWELC offers a larger, open-source dataset, which is beneficial for training CNNs without the risk of overfitting.

The RIAWELC dataset comprises 24,407 radiographic images, each of size 224×224 pixels, categorized into four classes of welding defects: lack of penetration (LP), cracks (CR), porosity (PO), and no defect (ND). A representative image for each defect type is displayed in Fig. 1, and Table 1 details the distribution of images across these classes. The substantial size of RIAWELC dataset supports the development of automated methods for identifying and classifying welding defects, crucial for reliable inspection and quality control.
Fig.1 Sample of radiographic images for each welding defect class from RIAWELC dataset: (a) LP, (b) CR, (c) PO and (d) ND.

Table 1. Data distribution of RIAWELC dataset for each welding defect class.

Defect Types	CR	PO	LP	ND
No. of Image	7,635	6,320	4,452	6,000

To facilitate deep learning model training, the RIAWELC dataset is divided into three subsets: 70% for training, 10% for validation, and 20% for testing. Additionally, all radiographic images from the dataset are resized to match the input requirements of the selected pretrained network, as outlined in Table 2, ensuring compatibility with the network architectures.

Table 2. Summary of seven pretrained networks

Pretrained Networks	Depth	Size (MB)	Parameter (Millions)	Input Size
AlexNet	8	227	61.0	224×224
ResNet-18	18	44	11.7	224×224
ResNet-50	50	96	25.6	224×224
ResNet-101	101	167	44.6	224×224
MobileNet-v2	53	13	3.5	224×224
ShuffleNet	50	5.4	1.4	224×224
SqueezeNet	18	5.2	1.24	227×227

2.2. *Transfer learning of pretrained networks*

Training CNNs from scratch for specific tasks presents challenges due to significant resource requirements, such as training time, infrastructure, and input datasets. Transfer learning offers a viable solution by transferring knowledge from one or more source domains to a different target domain. In this study, we utilize transfer learning to extract the learnable parameters from selected pretrained network architectures (namely, AlexNet, ResNet-18, ResNet-50, ResNet-101, MobileNet-v2, ShuffleNet, and SqueezeNet) for the welding defect radiographic images classification tasks.

Specifically, the last three layers of these pretrained networks are replaced with a new fully-connected layer, a SoftMax layer, and a classification output layer. Additionally, the original output layers are substituted with new output layers tailored to four classes: lack of penetration (LP), cracks (CR), porosity (PO), and no defect (ND). These modified networks are then trained using the RIAWELC dataset, as detailed in Table 1.

2.3. *Hyperparameter tuning*

Stochastic Gradient Descent (SGD) is a popular optimizer in deep learning training, valued for its ability to effectively balance accuracy and efficiency. In this study, SGD is employed to train selected pretrained network architectures with the RIAWELC dataset, aiming to minimize the cross-entropy loss function. However, the performance and convergence of SGD are influenced by various training hyperparameters, including momentum, initial learning rate, L2 regularization, maximum epoch, and batch size.

Specifically, the initial learning rate dictates the step sizes in the parameter update process. L2 regularization helps to prevent network overfitting by adding a penalty term to the loss function. The maximum epoch limits the number of iterations to avoid overfitting, and the batch size determines the number of samples used per iteration, impacting the stability, speed, and memory usage of SGD.

To facilitate a fair comparison in performance evaluations, the hyperparameters for all selected pretrained networks are standardized. This includes setting the momentum to 0.9, the initial learning rate to 2×10^{-3}, L2 regularization to 0.5, the maximum epoch to 5, and the batch size to 32.

2.4. *Performance metrics*

The overall performance of all pretrained CNN networks in classifying welding defect radiographic images is evaluated using five key metrics: accuracy, sensitivity, specificity, precision and F1 score. These metrics are derived from the true positive (TP), true negative (TN), false positive (FP), and false negative (FN) outcomes produced during the testing phase of the CNN architectures. The mathematical formulations for each performance metric employed in this study are as follows.

Accuracy, indicating the overall correctness of the CNN architecture's predictions, is calculated as:

$$Accuracy = \frac{TP + TN}{TP + TN + FP + FN} \quad (1)$$

Sensitivity, measuring the CNN architecture's ability to correctly identify positive results, is computed as:

$$Sensitivity = \frac{TP}{TP + FN} \quad (2)$$

Specificity, gauging the CNN architecture's capacity to accurately identify negative results, is determined as:

$$Specificity = \frac{TN}{TN + FP} \quad (3)$$

Precision, assessing the accuracy of positive predictions among all positive cases identified, is calculated as:

$$Precision = \frac{TP}{TP + FP} \quad (4)$$

F1 Score, the harmonic mean of precision and sensitivity, is defined as:

$$F1\ Score = 2 \times \left(\frac{Sensitivity \times Precision}{Sensitivity + Precision} \right) \quad (5)$$

The abovementioned five performance metrics provide a comprehensive assessment of the CNN architectures' capabilities in distinguishing different classes of welding defects.

3. Results and Discussions

The performance of all selected pretrained networks, including AlexNet, ResNet-18, ResNet-50, ResNet-101, MobileNet-v2, ShuffleNet, and SqueezeNet, in classifying radiographic images of welding defects is comprehensively evaluated. To facilitate a quantitative comparison, each CNN architecture's effectiveness in the welding defect classification task is assessed using the five performance metrics previously mentioned, namely accuracy (Acc.), sensitivity (Sens.), specificity (Spec.), precision (Prec.) and F1 score. The simulation results are detailed in Table 3, where the highest values attained by each CNN architecture for these metrics are highlighted in boldface.

Table 3. Quantitative performance evaluation of all selected CNN architectures for welding defect classification task

CNN architecture	Acc. (%)	Sens. (%)	Spec. (%)	Prec. (%)	F1 (%)
AlexNet	71.43	71.43	90.48	80.21	70.92
ResNet-18	78.57	78.57	92.86	80.56	78.92
ResNet-50	82.14	82.14	94.05	83.93	82.49
ResNet-101	**85.71**	**85.71**	**95.24**	**87.50**	**86.06**
MobileNet-v2	71.43	71.43	90.48	69.00	69.06
ShuffleNet	75.00	75.00	91.67	80.63	75.98
SqueezeNet	71.43	71.43	90.48	75.00	70.92

Table 3 reveals a significant observation across all CNN architectures: the identical values of accuracy and sensitivity when classifying the RIAWELC dataset. This uniformity implies that the models' ability to correctly predict positive instances (sensitivity) significantly impacts their overall accuracy. Among these, ResNet-101 (85.71%) and ResNet-50 (82.14%) stand out with the best and second-best performance in both accuracy and sensitivity, highlighting their superior detection capabilities for welding defects in radiographic images. Conversely, architectures with lower complexity, such as AlexNet, MobileNet-v2, and SqueezeNet, demonstrate less effectiveness, each recording 71.43% in both accuracy and sensitivity.

Moreover, Table 3 indicates that all selected CNN architectures consistently achieve higher specificity and precision compared to their accuracy and sensitivity. This suggests they are more effective in correctly identifying true negatives (specificity) and ensuring accurate positive predictions (precision). Specifically, ResNet-101 exhibits the highest specificity (95.24%), while AlexNet shows the lowest (90.48%), indicating a broad capability across these models to identify non-defective instances accurately. Precision, however, varies more across the models, with ResNet-101 leading at 87.50%, suggesting its higher accuracy in classifying weld defects. Conversely, MobileNet-v2, despite similar accuracy and sensitivity to other models, records the lowest precision (69.00%), implying a higher rate of false positives.

The F1 score, reflecting the harmonic mean of precision and sensitivity, offers a more balanced evaluation of model performance. ResNet-101 and ResNet-50 achieve

Tin Chang Ting, Hameedur Rahman, Tiong Hoo Lim, Chin Hong Wong, Chun Kit Ang, Mohamed Khan Afthab Ahamed Khan, Sew Sun Tiang, Wei Hong Lim

the highest F1 scores (86.06% and 82.49%, respectively), confirming their robust overall performance in classifying the radiographic images of welding defects. In contrast, AlexNet, MobileNet-v2, and SqueezeNet exhibit lower F1 scores (70.92%, 69.06%, and 70.92%, respectively), indicating a compromise between sensitivity and precision in these models.

Analysis of the simulation results in Table 3 reveals that more complex CNN architectures, such as ResNet-101 and ResNet-50, consistently outperform simpler ones like AlexNet and SqueezeNet across all performance metrics. This superior performance of advanced models like ResNet-101 and ResNet-50 highlights the significance of choosing the right model for complex image classification tasks, such as welding defect classification. It suggests that deeper networks are more adept at extracting essential features necessary for accurately identifying welding defects. The enhanced capability of these complex CNN models to discern intricate patterns in data meets the expectations associated with deeper network architectures.

However, it is important to note that while these sophisticated CNN architectures offer improved classification accuracy, they also demand greater computational resources. In contrast, simpler CNN models, despite being less precise, are more computationally efficient and may be preferable in scenarios with limited resources. In practical applications, factors like available computational power, latency considerations, and the criticality of accurately detecting defects should guide the selection of CNN architectures. Balancing these considerations is key to effectively deploying CNNs in real-world tasks.

4. Conclusions

This paper introduces a deep learning-based machine vision inspection algorithm that combines pretrained CNN architectures and transfer learning for classifying four types of welding defects—lack of penetration, cracks, porosity, and no defect—using radiographic images from the RIAWELC dataset. The objective is to thoroughly analyze the efficacy of seven different pretrained CNN architectures: AlexNet, ResNet-18, ResNet-50, ResNet-101, MobileNet-v2, ShuffleNet, and SqueezeNet, in addressing welding defect classification tasks. This analysis employs various performance metrics, including accuracy, sensitivity, specificity, precision, and F1 score. Simulation studies reveal that these pretrained networks exhibit diverse performance levels in defect classification, with ResNet-101 emerging as the most effective, achieving 85.71% accuracy, 85.71% sensitivity, 95.24% specificity, 87.50% precision, and an F1 score of 86.06%. In contrast, MobileNet-v2 shows the least effectiveness, with the lowest scores across all metrics: 71.43% accuracy and sensitivity, 90.48% specificity, 69.00% precision, and an F1 score of 69.06%. These results offer valuable insights into the applicability of pretrained deep learning networks for welding defect classification, providing a significant benefit to

manufacturing companies seeking to enhance their quality control processes. In this study, the hyperparameter settings for all pretrained networks are manually configured. It is anticipated that their classification performance could be further improved by employing advanced metaheuristic search algorithms to optimize these hyperparameter settings, thereby refining the training process of the pretrained networks.

Authors Introduction

Mr. Tin Chang Ting

He is currently pursuing the Bachelor of Mechatronics Engineering with Honours in Faculty of Engineering, Technology and Built Environment, UCSI University, Malaysia. His research interests are machine learning, deep learning, and optimization algorithm.

Dr. Hameedur Rahman

He is an Associate Professor in Faculty of Computing and AI at AIR University in Pakistan. He received his PhD in Computer Science from Universiti Kebangsaan Malaysia in 2018. His research interests are Virual/Augmented Rality, Image Processing, Data Mining, Artificial Intelligence, Natural Language Processing and CyberSecurity.

Dr. Tiong Hoo Lim

He is a Senior Assistant Professor and Director of Planning Development Office at Universiti Teknologi Brunei in Brunie Darussalam. He received his PhD in Computer Science from University of York, United Kingdom. His research interests are artificial intelligence, advanced technology, competitive and forecasting analysis.

Dr. Chin Hong Wong

He is a Lecturer in Maynooth International Engineering College at Fuzhou University in China. He received his PhD in Electrical and Electronic Engineering from Universiti Sains Malaysia in 2017. His research interests are Energy harvesting and control system.

Abstract

Arithmetic Optimization Algorithm (AOA) is widely used to solve global optimization problems. However, it often faces premature convergence challenges in complex optimization scenarios. A key factor affecting AOA's performance is the solution quality of the initial population. The conventional initialization scheme, despite its prevalence, lacks reliability in ensuring high-quality solutions due to inherent stochastic processes. To address this issue, we propose a modified initialization scheme that improves initial population quality by integrating chaotic maps and oppositional-based learning. Through extensive simulation studies, we demonstrate that the enhanced AOA, equipped with this new initialization scheme, exhibits superior performance in solving a range of benchmark functions with improved accuracy.

Keywords: Arithmetic optimization algorithm, Population initialization, Chaotic map, Oppositional-based learning

1. Introduction

Optimization is pivotal in real-life engineering design, where it seeks the most effective solutions while accommodating various stakeholders' criteria. Accurate problem definition and modeling are essential for resolving these design challenges. This process includes establishing clear objectives, identifying both technical and non-technical constraints, and optimizing decision variables. Nonetheless, real-world engineering design problems frequently present complexity and challenges due to factors like high dimensionality, numerous constraints, conflicting objectives, and data uncertainty.

In the era of Industrial Revolution 4.0 (IR 4.0), engineering systems have become more intricate, often involving non-differentiable, nonlinear, multimodal, and non-continuous functions. While traditional optimization methods such as Newton's method are prevalent, they face limitations in addressing these complex, real-world engineering design challenges. These methods often depend heavily on initial solutions and are typically suited to specific problem types, limiting their scalability for diverse, complicated optimization tasks [1]. Most traditional methods also rely on gradient information to identify optimal solutions, which is not always feasible in real-world scenarios that frequently present as black box functions [2]. Furthermore, the limited global search capability of traditional optimization methods increases the risk of premature convergence.

Recognizing the limitations of traditional optimization methods, there is an urgent need in the Industrial Revolution 4.0 era to develop more intelligent and robust optimization algorithms. These algorithms must be capable of providing efficient solutions to a broad spectrum of increasingly complex optimization problems. Metaheuristic Search Algorithms (MSAs) have emerged as effective solutions, drawing on search mechanisms inspired by natural phenomena. Existing MSAs fall into four categories based on their natural inspirations [3]: evolutionary algorithms, swarm intelligence, human-based algorithms, and physics-based algorithms. Compared to traditional methods, MSAs offer several advantages, including potent global search capabilities, straightforward implementation, and enhanced scalability. They exploit the unique strengths of their respective inspirations, enabling them to effectively address a variety of complex optimization challenges as outlined in [4], [5], [6], [7], [8], [9], [10], [11], [12], [13].

The Arithmetic Optimization Algorithm (AOA) [14], introduced in 2021, is a physics-based algorithm with search mechanisms inspired by the four basic arithmetic operations: division, multiplication, addition, and subtraction. These operations vary in their exploration and exploitation strengths, essential for solving optimization problems. Like other MSAs, achieving a proper balance between exploration and exploitation is crucial for enhancing AOA's performance. Consequently, several enhancement schemes, including hybridization

Tin Chang Ting, Hameedur Rahman, Meng Choung Chiong, Mohamed Khan Afthab Ahamed Khan, Cik Suhana Hassan, Farah Adilah Jamaludin, Sew Sun Tiang, Wei Hong Lim

[15], [16], [17], the introduction of new learning mechanisms [18], [19], [20] and others, have been developed to improve the balance in AOA variants. Since its introduction, both the original AOA and its enhanced variants have been successfully applied to a wide array of engineering optimization problems [15], [16], [19], [21], [22], [23], [24], [25].

The quality of the initial population is a key factor in determining the performance of MSAs. Despite numerous variants of the AOA being introduced in recent years, many still rely on conventional methods to randomly generate their initial populations. This conventional approach, while simple to implement, does not intelligently leverage environmental information around the solution regions during initialization [3]. As a result, it often mistakenly places some solutions in local or suboptimal regions, leading to premature convergence. Additionally, if initial solutions are far from the global optimum, the algorithm's convergence speed may be compromised. These drawbacks can significantly impact the robustness and effectiveness of AOA in addressing complex real-world optimization challenges.

This paper presents the Multi-Chaotic Dynamic Oppositional Learning (MCDOL) module as an enhancement to the AOA's population initialization scheme, culminating in a new variant named MCDOL-AOA. The MDCOL module is designed to produce an initial population with enhanced solution quality, both in terms of accuracy and convergence rate, by harnessing the strengths of multiple chaotic maps and the dynamic oppositional-based learning (DOL) mechanism. Notably, the diverse ergodic properties of various chaotic maps are employed for a comprehensive solution space search, enhancing population diversity and mitigating the risk of initializing solutions in local optima. Additionally, the inclusion of DOL in MCDOL module promotes more rapid global optimum identification by expanding the exploration of solution regions. The effectiveness of MCDOL-AOA is evaluated through benchmarking against the original AOA across a range of benchmark functions with varying characteristics.

2. Methodology
2.1. *Proposed MCDOL module*

In this subsection, we detail how the proposed MCDOL module generates an initial population of superior quality. The MCDOL module leverages multiple chaotic maps to create a diverse set of initial solutions, forming a chaotic population. This approach contrasts with conventional initialization schemes, which often result in poorly distributed initial solutions. The deterministic nature of chaotic maps, coupled with their ability to exhibit stochastic behavior through ergodic properties, allows for a more comprehensive exploration of the solution space. Unlike some prior studies [26], [27], [28] that rely on a single chaotic map, this paper explores the benefits of using multiple chaotic maps for population initialization. We hypothesize that each map's unique ergodic characteristics can enhance the algorithm's performance

for specific optimization problems. Therefore, the synergistic integration of multiple chaotic maps promises to significantly improve the algorithm's robustness in addressing various complex problems.

The MCDOL module incorporates five distinct chaotic maps — Circle, Logistic, Piecewise, Sine, and Tent — for generating a chaotic population. Each chaotic map is randomly chosen to generate different dimensions of the initial solutions within this population. To facilitate this, define ϑ_t as the output of a chaotic variable at the t-th iteration, where $t = 1, \ldots, T$. The population initialization in the MCDOL module, using these multiple chaotic maps, follows five criteria: (a) the Circle map is used if $0 \leq \vartheta_0 < 0.2$, (b) the Logistic map for $0.2 \leq \vartheta_0 < 0.4$, (c) the Piecewise map for $0.4 \leq \vartheta_0 < 0.6$, (d) the Sine map for $0.6 \leq \vartheta_0 < 0.8$, and (e) the Tent map for $0.8 \leq \vartheta_0 \leq 1.0$. The specific equations for these five chaotic maps, Circle, Logistic, Piecewise, Sine, and Tent, are detailed in Eqs. (1) to (5).

$$\vartheta_{t+1} = \mathrm{mod}\left(\vartheta_t + 0.2 - \left(\frac{0.5}{2\pi}\right)\sin(2\pi\vartheta_t), 1\right) \quad (1)$$

$$\vartheta_{t+1} = 4\,\vartheta_t(1 - \vartheta_t) \quad (2)$$

$$\vartheta_{t+1} = \begin{cases} \dfrac{\vartheta_t}{P}, & 0 \leq \vartheta_t < P \\ \dfrac{\vartheta_t - P}{0.5 - P}, & P \leq \vartheta_t < 0.5 \\ \dfrac{1 - P - \vartheta_t}{0.5 - P}, & 0.5 \leq \vartheta_t < 1 - P \\ \dfrac{1 - \vartheta_t}{P}, & 1 - P \leq \vartheta_t < 1 \end{cases} \quad (3)$$

$$\vartheta_{t+1} = \sin(\pi\vartheta_t) \quad (4)$$

$$\vartheta_{t+1} = \begin{cases} \dfrac{\vartheta_t}{0.7} & \vartheta_t < 0.7 \\ \dfrac{10}{3}(1 - \vartheta_t) & \vartheta_t \geq 0.7 \end{cases} \quad (5)$$

Let X_d^L and X_d^U denote the lower and upper bounds of the d-th dimensional decision variable, respectively, for $d = 1, \ldots, D$. At the final iteration $t = T$, a chaotic value ϑ_T is generated from a randomly selected chaotic map. This value initializes the d-th dimension of each n-th chaotic solution, as outlined in Eq. (6). The resulting chaotic population, denoted as $\mathbf{P^C} = \left[X_1^C, \ldots, X_n^C, \ldots X_N^C\right]$, encompasses all solution members formed using multiple chaotic maps.

$$X_{n,d}^C = X_d^L + \vartheta_T (X_d^U - X_d^L) \quad (6)$$

While various chaotic maps exhibit differing levels of robustness to local optima, they may still generate initial solutions distant from the global optimum, potentially slowing the algorithm's convergence. To address this issue, a DOL operator is applied to the chaotic population $\mathbf{P^C}$, generating opposite solutions for each n-th chaotic solution. This DOL operator is expected to broaden the initial population's coverage of the solution space,

increasing the likelihood of identifying fitter solutions. The opposite solution for each dimension, denoted as $X_{n,d}^O$, is determined using Eq. (7), corresponding to $X_{n,d}^C$, with $r_1, r_2 \in [0, 1]$. Consequently, this generates an opposition population, $\mathbf{P^O} = [X_1^O, \dots, X_n^O, \dots X_N^O]$.

$$X_{n,d}^O = X_{n,d}^C + r_1 \left[r_2(X_d^U + X_d^L - X_{n,d}^C) - X_{n,d}^C \right] \quad (7)$$

The two populations, one generated using multiple chaotic maps ($\mathbf{P^C}$) and the other using the DOL operator ($\mathbf{P^O}$), are merged to form a combined population set $\mathbf{P^C} \cup \mathbf{P^O}$ with a total size of $2N$. The fitness of each solution member in this merged population set is evaluated according to the predefined objective function. These solution members are then ordered based on their fitness values, from the best to worst performing ones. The top N solution members from this ordered population set $\mathbf{P^C} \cup \mathbf{P^O}$ are chosen as the initial population for the proposed MCDOL-AOA algorithm, represented as $\mathbf{P} = [X_1, \dots, X_n, \dots, X_N]$.

2.2. *Iterative Search Processes of MCDOL-AOA*

After generating an initial population $\mathbf{P}$ of superior quality using the MCDOL module, each n-th solution in MCDOL-AOA is iteratively updated through search mechanisms similar to those in the original AOA.

During each iteration, the Math Optimizer Accelerated (MOA) function value is adjusted in MCDOL-AOA to alternate between exploration and exploitation phases:

$$MOA(C_{Iter}) = Min + C_{Iter} \left(\frac{Max - Min}{M_{Iter}} \right) \quad (8)$$

where C_{Iter} and M_{Iter} represent the current and maximum iteration counts; Min and Max are the minimum and maximum values of MOA. Simultaneously, the Math Optimizer Probability (MP) function, which dictates the search range for each solution and is influenced by the critical parameter θ for exploitation efficiency, is updated as:

$$MP(C_{Iter}) = 1 - \left(\frac{C_{Iter}}{M_{Iter}} \right)^{1/\theta} \quad (9)$$

A random number $\mathbf{rand1}$ determines the search strategy (exploration or exploitation) at each iteration for updating the d-th dimension of the n-th solution, $X_{n,d}$. During the exploration phase ($\mathbf{rand1} > \mathbf{MOA}$), either the Multiplication or Division operator is selected:

$$
X_{n,d}(C_{Iter} + 1)
$$
$$
= \begin{cases} best_d \div (MP + \varepsilon) \times [(X_d^U - X_d^L)\mu + X_d^L], rand2 < 0.5 \\ best_d \times MP \times [(X_d^U - X_d^L)\mu + X_d^L], \quad \text{Otherwise} \end{cases}
$$
$$(10)$$

where $rand2$ is a random number between 0 and 1; $best_d$ denotes the d-th dimension of the current best solution; ε is a small positive number to prevent division by zero, and μ is a control parameter.

In the exploitation phase ($rand1 \le MOA$), either the Addition or Subtraction operator is used to update $X_{n,d}$:

$$
X_{n,d}(C_{Iter} + 1) =
$$
$$
\begin{cases} best_d - MP \times [(X_d^U - X_d^L)\mu + X_d^L], rand2 < 0.5 \\ best_d + MP \times [(X_d^U - X_d^L)\mu + X_d^L], \quad \text{Otherwise} \end{cases} \quad (11)
$$

As illustrated in Fig. 1, MCDOL-AOA continues this iterative search, following Eqs. (8) to (11), until pre-set termination criteria are fulfilled. Upon completion, optimal decision variables in the best solution are decoded to solve the specific optimization problems.

MCDOL-AOA for Global Optimization
Inputs: $D, N, M_{Iter}, T, Max, Min, \theta$
01: Initialize $\mathbf{P^C} \leftarrow \emptyset, \mathbf{P^O} \leftarrow \emptyset$ and $C_{Iter} \leftarrow 0$;
02: **for** each n-th solution **do**
03: **for** each d-th dimension **do**
04: Randomly initialize $\vartheta_t \in [0,1]$, where $t = 0$;
05: **if** $0 \le \vartheta_0 < 0.2$ **then**
06: Select Circle map in Eq. (1);
07: **elseif** $0.2 \le \vartheta_0 < 0.4$ **then**
08: Select Logistic map in Eq. (2);
09: **elseif** $0.4 \le \vartheta_0 < 0.6$ **then**
10: Select Piecewise map in Eq. (3);
11: **elseif** $0.6 \le \vartheta_0 < 0.8$ **then**
12: Select Sine map in Eq. (4);
13: **elseif** $0.8 \le \vartheta_0 \le 1.0$ **then**
14: Select Tent map in Eq. (5);
15: **end if**
16: **while** $t \le T$ **do**
17: Update ϑ_t with the selected chaotic map;
18: $t \leftarrow t + 1$;
19: **end while**
20: Generate $X_{n,d}^C$ using Eq. (6);
21: Generate $X_{n,d}^O$ using Eq. (7);
22: **end for**
23: Update $\mathbf{P^C} \leftarrow \mathbf{P^C} \cup X_{n,d}^C$ and $\mathbf{P^O} \leftarrow \mathbf{P^O} \cup X_{n,d}^O$;
24: **end for**
25: Merge the two population sets as $\mathbf{P^C} \cup \mathbf{P^O}$;
26: Evaluate the fitness values of all solutions stored within $\mathbf{P^C} \cup \mathbf{P^O}$;
27: Rearrange the solutions stored within $\mathbf{P^C} \cup \mathbf{P^O}$ from best to worst based on their fitness values;
28: Select the top N solutions from the sorted $\mathbf{P^C} \cup \mathbf{P^O}$ as the initial population, i.e., $\mathbf{P} = [X_1, \dots, X_n, \dots, X_N]$.
29: Assign the first solution of $\mathbf{P}$ and its fitness as $best$ and $f(best)$, respectively;
30: **while** $C_{Iter} \le M_{Iter}$ **do**
31: Update MOA and MP with Eqs. (8) and (9);
32: **for** each n-th solution **do**
33: **if** $rand1 > MOA$ **then** /*Exploration*/
34: Update $X_{n,d}(C_{Iter} + 1)$ with Eq. (10);
35: **else** /*Exploitation*/
36: Update $X_{n,d}(C_{Iter} + 1)$ with Eq. (11);
37: **end if**
38: Fitness evaluation of $X_n(C_{Iter} + 1)$;
39: Update the $X_n, f(X_n)$, $best$ and $f(best)$,
40: with greedy selection method;
41: **end for**
42: $C_{Iter} \leftarrow C_{Iter} + 1$;
43: **end while**
Output: $best$ and $f(best)$

3. Results and Discussions

3.1. *Simulations settings*

In this section, we compare the performance of MCDOL-AOA with the original AOA using 23 benchmark functions, each with distinct characteristics as outlined in [17]. Functions F1 to F7 are scalable unimodal functions, while F8 to F13 are scalable multimodal functions, all set at a dimension size of $D = 100$. Functions F14 to F23, on the other hand, are fixed-dimension multimodal functions with D ranging from 2 to 6. Both MCDOL-AOA and the original AOA were implemented on MATLAB 2021a, running on a personal computer equipped with an Intel® Core™ i7-HQ CPU at 2.50 GHz and 16 GB RAM. For both algorithms, the population size and maximum number of iterations are set at 30 and 1000, respectively.

3.2. *Performance analysis*

The evaluation of MCDOL-AOA's performance, and its comparison with the original AOA across all 23 benchmark functions, is detailed in Table 1. We employ two performance metrics: mean error (E_{mean}) and standard deviation (SD), to assess the algorithms' accuracy and consistency in solving these functions. Lower values of E_{mean} and SD are preferable, indicating the algorithm's consistent and accurate resolution of the given benchmark functions.

Table 1. Performance comparison of MCDOL-AOA and original AOA using 23 benchmark functions with different characteristics.

Fun	Original AOA		MCDOL-AOA	
	E_{mean}	SD	E_{mean}	SD
F1	2.048e-04	5.662e-05	**1.938e-04**	5.371e-05

F23	-8.590	3.094	**-8.751**	3.091

The results in Table 1 showcase MCDOL-AOA's impressive accuracy, outperforming or matching the original AOA in 16 of the 23 benchmark functions, as

evidenced by lower E_{mean} values. In the scalable unimodal function's category (F1 to F7), MCDOL-AOA surpasses the original AOA in 5 of the 7 functions based on E_{mean}. For the 6 scalable multimodal functions (F8 to F13), MCDOL-AOA demonstrates superior E_{mean} values in 4 functions (F8, F9, F12, and F13) and equals the original AOA in one function (F10). When dealing with the fixed-dimension multimodal functions (F14 to F23), MCDOL-AOA outperforms the original AOA in 4 functions (F15, F18, F22, and F23) and equals its performance in 3 other functions (F16, F17, and F19).

Analysis of the simulation results in Table 1 indicates that MCDOL-AOA significantly outperforms the original AOA in solving larger-scale benchmark functions (F1 to F13) with $D = 100$, evidenced by lower E_{mean} values in 9 out of 13 functions. However, the performance of MCDOL-AOA is relatively on par with the original AOA in fixed-dimension problems (F14 to F23) with smaller dimensions ($D = 2, 3, 4$, and 6). These findings suggest that the MCDOL module in MCDOL-AOA effectively produces initial populations with superior fitness and diversity compared to the original AOA, yielding enhanced optimization results. The benefits of the MCDOL module are particularly notable in larger dimensional sizes (e.g., $D = 100$), as utilized in this study. The multiple chaotic maps' non-repetitive and ergodic properties within the MCDOL module facilitate a more exhaustive exploration of the solution space across various problem types, thereby minimizing the risk of local optima entrapment and premature convergence. Additionally, the DOL mechanism within the MCDOL module contributes to faster algorithmic convergence by broadening solution space exploration through the generation of opposite solutions from those initiated by the chaotic maps.

4. Conclusion

In this paper, we introduce an enhanced version of the AOA, termed MCDOL-AOA, designed to solve complex global optimization problems with improved accuracy. The novelty of MCDOL-AOA resides in its integration of multiple chaotic maps and DOL mechanisms into a modified initialization scheme, the MCDOL module. This module aims to generate an initial population of superior quality, focusing on fitness and diversity. Simulation results demonstrate that MCDOL-AOA, benefiting from the enhanced initial population quality provided by the MCDOL module, surpasses the original AOA in solving 23 distinct benchmark functions. Notably, the performance gains of MCDOL-AOA are more pronounced in solving functions with larger dimensions, specifically $D = 100$. This underscores the efficacy of the multiple chaotic maps and DOL mechanisms within the MCDOL module in boosting the algorithm's robustness against premature convergence and enhancing its convergence speed. Future work will explore the application of MCDOL-AOA to real-world engineering optimization problems, including machine

learning model training and scheduling optimization, to assess its practicality and effectiveness.

Authors Introduction

Mr. Tin Chang Ting

He is currently pursuing the Bachelor of Mechatronics Engineering with Honours in Faculty of Engineering, Technology and Built Environment, UCSI University, Malaysia. His research interests are machine learning, deep learning, and optimization algorithm.

Dr. Hameedur Rahman

He is an Associate Professor in Faculty of Computing and AI at AIR University in Pakistan. He received his PhD in Computer Science from Universiti Kebangsaan Malaysia in 2018. His research interests are Virual/Augmented Rality, Image Processing, Data Mining, Artificial Intelligence, Natural Language Processing and CyberSecurity.

Dr. Meng Choung Chiong

He is an Assistant Professor in Faculty of Engineering at UCSI University in Malaysia. He received his PhD in Chemical Enigneering from Universiti Teknologi Malaysia. His research interests are artificial intelligence, mechatronics and alternative fuels combustion.

Dr. Mohamed Khan Afthab Ahmed Khan

He is an Assistant Professor in Faculty of Engineering at UCSI University in Malaysia. His research interests are artificial intelligence, robotics, control, medical rehabilitation and power electroncs.

Dr. Cik Suhana Hassan

She is an Assistant Professor in Faculty of Engineering at UCSI University in Malaysia. She obtained her PhD in PhD in Mechanical Engineering from Universiti Putra Malaysia. Her research interests are artifical intelligence, bio composite and finite element analysis.

Dr. Farah Adilah Binti Jamaluddin

She is an Assistant Professor in Faculty of Engineering at UCSI University in Malaysia. She obtained her PhD in PhD in Eletrical Power Engineering from Universiti Putra Malaysia. Her research interests are artifical intelligence, electrical insulation and high voltage engineering.

Dr. Sew Sun Tiang

She is an Assistant Professor in Faculty of Engineering at UCSI University in Malaysia. She received her PhD in Electrical and Electronic Engineering from Universiti Sains Malaysia in 2014. Her research interests are optimization and antenna design.

Dr. Wei Hong Lim

He is an Associate Professor in Faculty of Engineering at UCSI University in Malaysia. He received his PhD in Computational Intelligence from Universiti Sains Malaysia in 2014. His research interests are optimization and artificial intelligence.

Enhancing Precision Object Detection and Identification for Autonomous Vehicles through YOLOv5 Refinement with YOLO-ALPHA

Abstract

Advancing swiftly in contemporary society, the rapid growth of autonomous driving technology suggests its potential adoption across continents. The realization of fully autonomous driving relies on proficiently detecting, classifying, and tracking road objects such as pedestrians and vehicles. This research employs the YOLOv5 neural network, enhancing it with YOLO-ALPHA. Modifications, encompassing freeze and attention mechanisms, serve to refine accuracy and expedite training. Furthermore, adjustments to the activation function aim to stabilize precision and recall. The integration of an FCN based on semantic segmentation theory contributes to improved accuracy in detecting road conditions during autonomous driving. Consequently, this enables the successful and highly accurate functionality of automatic identification.

Keywords: Object detection, Autonomous vehicle, YOLOv5, FCN, Attention mechanism, Freeze mechanism, Activation function

1. Introduction

In recent years, the rapid advancement of technology has led to a surge in the popularity of autonomous driving systems. Real-time image processing is a pivotal technology in autonomous driving. Despite reaching an advanced stage, autonomous driving technology faces persistent challenges in low recognition accuracy and sluggish real-time image processing, giving rise to safety concerns. These issues give rise to safety concerns. Although automated driving technology has reached a certain level of maturity, it encounters limitations in adverse weather conditions, complex environments, and nighttime operations. automatic driving sensor recognition accuracy tends to decline, compromising autonomous vehicle safety. Consequently, there is a pressing need to enhance automatic driving technology to bolster autonomous vehicle reliability and safety.

This paper introduces an attention mechanism into the object detection algorithm, fine-tunes activation functions, adds a freezing mechanism and conducts a comparative analysis with the FCN (Fully Convolutional Networks) algorithm. This algorithm offers an enhanced detection speed and accuracy. The implications of this research are highly relevant to the enhancement of autonomous driving safety.

Utilizing the PASCAL VOC (The PASCAL Visual Object Classes) dataset, this study systematically alters various modules and introduces distinct mechanisms, this paper changes a different module and adds a disparate mechanism each time. Then, by evaluating precision, recall, mAP, and mAP0.5 indices of the adapted models, it identifies the optimal placement for incorporating an attention mechanism, freezing layers to prolong training duration, and selecting the activation function that demonstrated superior performance on the PASCAL VOC dataset.

This paper presents a novel detection technique named YOLO-ALPHA. The approach involves incorporating an attention mechanism at various layers within the YOLO network. Specifically, inserting the Squeeze-and-Excitation (SE) attention mechanism (Self-Attention Mechanism) after the Concat module on the 16th layer of the network could enhance both the precision and recall of the model. Additionally, adding a freeze mechanism in the YOLO backbone could accelerate curve fitting. Moreover, replacing the combined structure of SiLU (Sigmoid-weighted Linear Units) and LeakyReLU with the SiLU activation function contributes to a smoother precision and recall curve, thereby, improving the stability of the model by 0.169%.

2. Literature Review

Guandong Li, Yanzhe Xie, Yuhao Lu, Zongyan Wen, Jingzhen Fan, Yuankui Huang, Qinghong Ma, Wei Hong Lim, Chin Hong Wong

Convolutional neural networks (CNNs) often suffer from information loss, resulting in gradient disappearance and detection inaccuracies during image processing. Researchers continuously strive to mitigate semantic information loss and enhance overall network performance. Lan et al. [1] conducted research to improve the YOLO network, focusing on addressing losses in pedestrian information during image processing. They introduced additional passthrough layers, including a Route layer and Reorg layer, or reconstructed the primitive YOLOv2 network. The resulting YOLO-R network specializes in pedestrian detection, effectively improving accuracy and reducing false detection rates. Wu et al. [2] presented a vehicle detection system in CARLA, introducing YOLOv5-Ghost with adjusted layer structures for reduced computational complexity. The study achieved improved detection accuracy and speed. Lu et al. [3] enhanced a YOLOv5-based model for crack and vehicle detection datasets, addressing sample imbalance and small object presence. Dodia and Kumar [4] compared modern object detectors with YOLO for vehicle detection, suggesting enhancements to improve vehicle prediction capacity. Kaloev et al. [5] investigated activation functions in deep learning, emphasizing their role in introducing nonlinearity. Xiao et al. [6] proposed intelligent layer freezing during training to accelerate training on various networks. Zhao et al. [7] improved an infrared detection model based on YOLOv5s, adding an SE-Net module. Kaymak et al. [8] experimented with FCN architectures in the context of autonomous driving. The study concludes that applying YOLO to vehicle detection faces challenges, leading researchers to improve the algorithm through various modifications.

3. Design Methodology

Fig. 1 shows the flow chart to tackle imminent challenges related to object identification, classification, and tracking in the domain of autonomous driving. Given the effectiveness of YOLOv5 in object identification tasks, as evidenced by Xiao [9] and Kaymak [8], and recognizing the utility of FCN in autonomous driving scenarios, this research chooses to employ both methods for real-time image processing in autonomous driving contexts. To ensure a fair comparison of results across different networks using the control variate method, a consistent dataset, PASCAL VOC 2012, was used to train and validate both YOLO and FCN networks. PASCAL VOC 2012 encompasses 20 classes commonly encountered in autonomous driving scenarios, such as bicycle, bus, car, motorbike, and person.

Following multiple rounds of training and prediction in YOLO, this work collects and scrutinizes detection and classification outcomes using TensorBoard, relying on index curves such as precision, recall, mAP, and mAP0.5 curvature. Higher precision values denote the network's proficiency in accurately classifying items, while elevated recall signifies the network's efficacy in rectifying previous classification errors. The mAP and mAP0.5 metrics evaluate the detection accuracy across

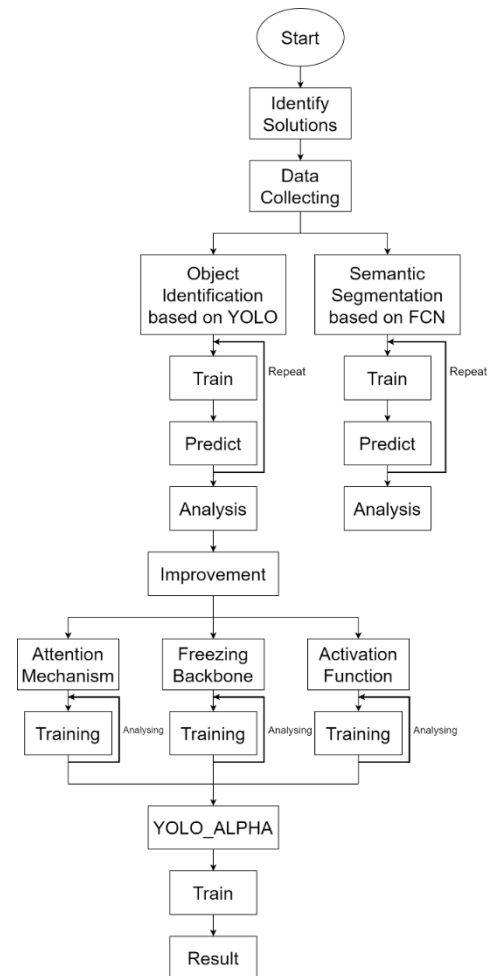
all classes present in the dataset. A lower curvature in the curve indicates enhanced stability and a more consistently changing trend, signifying ideal model training stability and convergence.


Fig. 1 Flow chart

Then, the project aims to enhance the YOLO algorithm by adding an attention mechanism, freezing backbone, and activation function.

Incorporating an attention mechanism enables the network to focus on crucial input features while disregarding inconsequential ones. Through the integration of SE attention mechanisms in different layers of the YOLO structure and subsequent training, the research evaluates the performance enhancement trend by scrutinizing index curves and determining the optimal location for implementing the SE attention mechanism.

Freezing the backbone is a training strategy aimed at expediting training speed by halting parameters in the backbone upgrade. By comparing the result indexes of modules employing freezing backbone, freezing all layers, and not freezing layers separately, the project seeks to identify the optimal freezing method.

Activation functions amplify the nonlinearity of convolutional neural networks. By replacing the original activation function with SiLU, Mish, LeakyReLU, and ReLU in the modified YOLOv5s, the project utilizes the

average curvature of the precision curve to compare and assess the smoothness and stability of the network.

Ultimately, the study amalgamates the proven optimal strategies from the preceding analysis to formulate YOLO-ALPHA, an enhanced version of YOLOv5. The performance of YOLO-ALPHA is then juxtaposed with that of YOLOv5 to affirm its improvement.

4. Results and Discussions

The object detection output images from YOLOv5s depict vehicles on the road using bounding boxes. However, these bounding boxes lack information regarding the distance between vehicles, a crucial consideration in congested road scenarios, particularly during peak commuting hours, a vital aspect of autonomous driving. To precisely discern the outlines of nearby vehicles and pedestrians, pixel-wise object detection and classification with FCN are employed. Fig. 2 illustrates the contrast in detection results between YOLOv5s and FCN. The depiction from YOLOv5s shows vehicles with pink bounding boxes, outlining the edges of cars as straight lines that do not accurately match the actual boundaries. On the other hand, FCN, with pixel-wise detection, unveils the precise boundaries of cars, enabling autonomous vehicles to effectively avoid collisions.
Fig. 2 Detection result between YOLOv5s and FCN

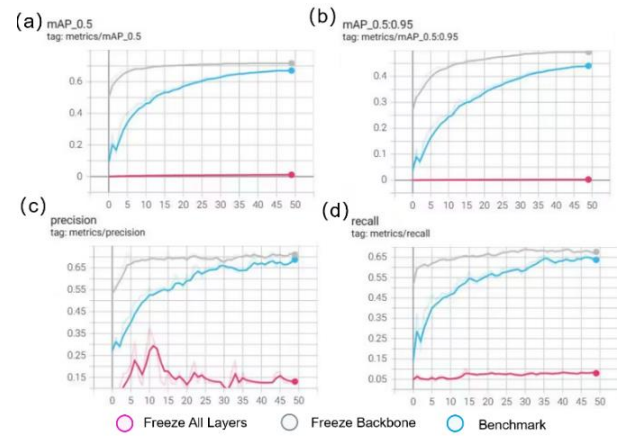
Fig. 3 shows minimal differences observed between the frozen backbone curve and the original model curve in terms of mAP, precision, and recall at the highest training rounds. Despite a reduction in training time by 2 hours, image accuracy slightly decreases from 0.7166 to 0.6716. The key conclusion drawn is that freezing trained parameters enhances training speed without compromising accuracy. Freezing all layers completely leads to virtually no accuracy, emphasizing the importance of trained parameters. Freezing the backbone during training enhances training efficiency, as the unchanging feature extraction network consumes less memory, leading to faster training.


Fig. 2 Freezing Mechanism graphs for (a) mAP_0.5, (b) mAP_0.5:0.95, (c) Precision and (d) Recall

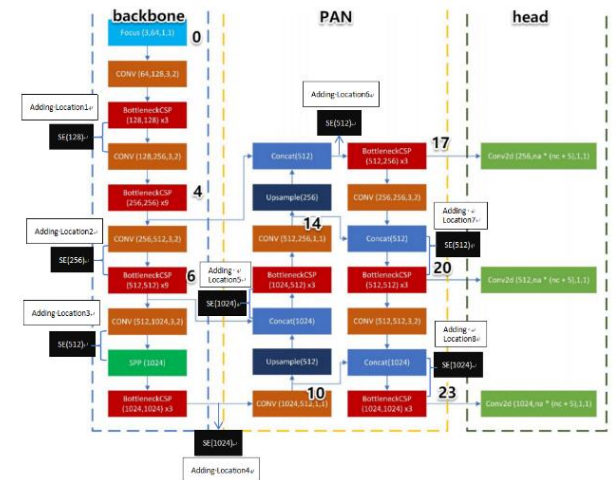
Experimental results suggested that adding the SE attention mechanism to the bottom or middle layers of the network yields optimal outcomes. Fig. 4 illustrates that adding the attention mechanism between layers 16 and 17 achieves higher accuracy than the original version, validating the hypothesis. Fig. 5 further confirms that placing the SE attention mechanism between the middle and bottom layers produces the best results.


Fig. 3 SE adding locations in the original YOLOv5 network

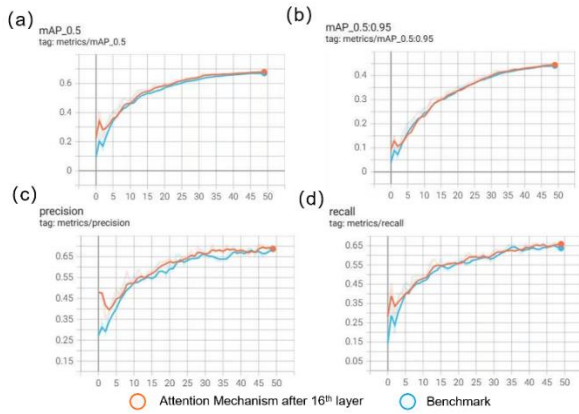
Guandong Li, Yanzhe Xie, Yuhao Lu, Zongyan Wen, Jingzhen Fan, Yuankui Huang, Qinghong Ma, Wei Hong Lim, Chin Hong Wong


Fig. 4 Attention Mechanism graphs for (a) mAP_0.5, (b) mAP_0.5:0.95, (c) Precision and (d) Recall

Five activation functions (ReLU, Leaky ReLU, Mish, SiLU, and the original activation function) undergo comparative analysis. Fig. 6 displays the precision, recall, mAP, and mAP0.5 indexes at epoch 50 for networks employing various activation functions. The SiLU activation function is selected for the PASCAL VOC dataset due to its smoother curve and increased stability, as tabulated in Table 1.
Fig. 5 Activation Function

Table 1 Activation Function Data

Epoch = 50	mAP	mAP0.5	Precision	Recall
benchmark	0.6716	0.4426	0.7064	0.6286
LeakyReLU	0.6437	0.4114	0.6531	0.6238
Mish	0.6649	0.4397	0.6783	0.6363
ReLU	0.6353	0.4058	0.7007	0.5739
SiLU	0.6694	0.4426	0.6961	0.6270

Fig. 7 depicts a less satisfactory outcome when combining the optimal freezing mechanism, attention mechanism, and activation function. The precision initially starts high but continuously decreases, indicating performance degradation. Removing the attention mechanism results in Fig. 8 that surpass those of the original YOLOv5 network, affirming the performance enhancement of the upgraded YOLO-ALPHA network.

5. Conclusion

In this investigation, YOLOv5s is employed to carry out object detection, classification, and tracking, with the FCN (Semantic Segmentation) technique serving as a supplementary method to precisely delineate object

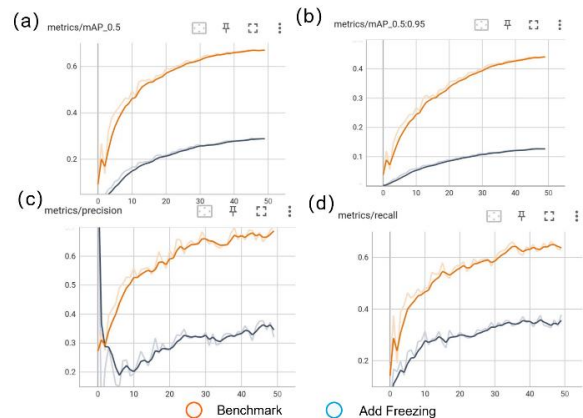
boundaries. Enhancements, including the incorporation of attention mechanisms, freezing the network's backbone, and modifying the activation function, are evaluated based on precision, recall, mAP, and mAP0.5 curves. These identified mechanisms and modules, known to augment the performance of YOLOv5s, are amalgamated into an upgraded version referred to as YOLO-ALPHA. However, the collective optimal modules identified in previous research resulted in a degradation of performance. Following meticulous analysis, the freezing backbone mechanism is pinpointed as the cause. Subsequent refinement by removing the freezing backbone mechanism reveals that YOLO-ALPHA showcases performance improvements in comparison to the original YOLOv5s.


Fig. 6 Unsuccessful Result for (a) mAP_0.5, (b) mAP_0.5:0.95, (c) Precision and (d) Recall
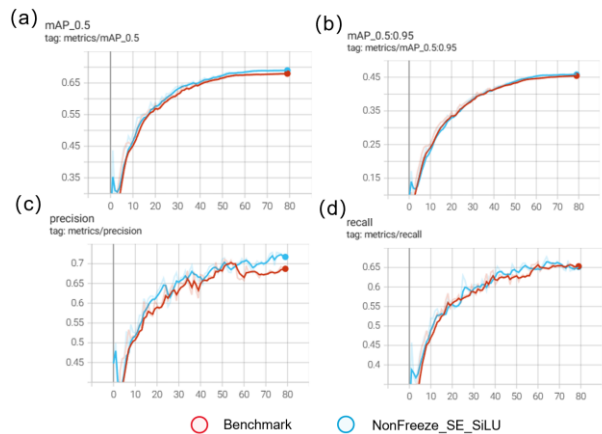

Fig. 7 Result of Applying SE and SiLU excluding Freezing Mechanism graph for (a) mAP_0.5, (b) mAP_0.5:0.95, (c) Precision and (d) Recall

Abstract

From 2022, when Russia began its invasion of Ukraine, to the present, the number of speeches and information directly/indirectly related to Russo-Ukrainian war has continued to increase in mass communication venues such as SNS and TV. This study proposes the idea of a game system that simulates the spread of disinformation by focusing on the information published by Ukraine as a list of disinformation speakers, especially on the topics they talk about. The game system is intended to provide players with psychological immunity against disinformation by simulating the spread of disinformation.

Keywords: Disinformation, Russo-Ukrainian war, Game System

1. Introduction

Russo-Ukrainian war has two parts. On February, 2014, Russia annexed Crimea. Also, in February 2022, Russia has invaded the Donbass region of Ukraine. In this war, the discourse and information directly and indirectly related to Russo-Ukrainian war continues to grow in mass communication spaces such as social networking sites and television. In this context, Russia sees the information space as another battlefield, with NATO [1] and Ukraine (https://cpd.gov.ua/) reporting on the situation. Ogata [2], [3], [4], [5] has collected discourses on Russo-Ukrainian war and summarized them as "Russo-Ukrainian War as Narrative Warfare"[6], while Ono and Ogata have published articles on this war, proposing the concept of a narrative-generating game based on Russo-Ukrainian war[7], [8].

This study proposes the idea of a game system (we call the game system as simply "game" in the following description) that simulates the spread of disinformation by focusing on the discourses compiled by Ogata [2], [3] [4] [5] and published by Ukraine as a disinformation speaker list, especially the topics that the speakers talk about. The game is designed to help players develop psychological immunity to disinformation by simulating the spread of disinformation.

2. Background

Disinformation is information that influences a person's perception and distorts their decision making.

For example, fake news, which spreads sensational or conspiratorial content, including falsehoods, is a typical example of disinformation. Today, battles that make full use of disinformation, in addition to the conventional domain of warfare, are positioned as a new domain of warfare and are called cognitive warfare [9]. On the other hand, Ogata, who believes that falsehood is not the only means of attacking opponents in battles that affect the perception of the target, has proposed the term "narrative warfare" as a domain in which attacks are made regardless of whether the content is true or false [6]. For example, one method might be to present a distorted conclusion as the conclusion of a logic that only mentions the truth about individual elements. Maan have focused on narrative warfare, and they have been exposed to it from the time of the emergence of the Islamic State to the present day [10]. Narrative warfare in Russo-Ukrainian war has also received attention [11].

Attempts to position players on the disseminators of disinformation have been experimented with by Roozenbeek and Linden [12] with *Bad News* [13]. *Bad News* is a web game that provides a virtual experience of a fake news speaker. In this game, each player follows the game's instructions and gradually increase their influence on public opinion by selecting one of fake new candidates. The player can efficiently increase their influence by selecting more appropriate fake news, and their influence decreases if they select an inappropriate fake for the occurred event. Roozenbeek and Linden found that this game allows each player to "cognitive resistance against fake news strategies." There are similar games on the market, such as *Plague Inc.* [14]. *Plague Inc.* is a simulation game. Each player in the game becomes an

epidemic and aims to wipe out humans. The player can select the game mode of fake news.

3. Proposed Game System

The structure of the game is presented after an overview of the proposed game. At last, an example of the game play is shown.

3.1. Overview of the proposed game

The game proposed in this paper is a game in which the player is a Russian spreading disinformation about the Ukrainian model. The goal of each player is to convert more Ukrainian faction to the Russian faction ("faction" in this paper does not mean a particular political party, people who believe in the state.). The game presents the player with events that occurred during Russo-Ukrainian War, and the player chooses the disinformation to spread accordingly. The Ukrainian faction is a set of non-player characters (NPCs) that are not controlled by the player, and each NPC has a trust parameter. This trust represents the level of trust in Ukraine, and the disinformation chosen by the player will fluctuate this value. The Ukrainian faction will switch to the Russian faction if the trust parameter falls below a certain value.

This work does not include factors such as the spread of misinformation ("misinformation" is false information that is spread without malicious intent), the phenomenon of disinformation having a greater impact due to biased information on social networking sites, or the range of influence of disinformation or the number of people affected. These elements are considered important for simulating disinformation and will be discussed as future topics.

3.2. The flow in a game play

A player becomes the sender of disinformation and changes the parameters of non-player characters (NPCs) made up of several people, to change the NPC's faction.

The game repeats the turn as many times as the number of events that make up the scenario, with (i) the generation of events, (ii) the selection of disinformation, and (iii) the calculation of effects as a single turn. At the end of the turn, the amount of trust in the Ukrainian faction of NPCs is scored.

When choosing disinformation, the player chooses one of the disinformation candidates. The mechanism changes the parameters of all NPCs based on the selected disinformation.

3.3. Components of the proposed game

The proposed game has non-player characters (NPCs), events, and disinformation. These attributes are used to calculate the score that evaluates the player, or are values related to the game play.

Non-Player Character (NPC)

- Trust: if this value is 0, the NPC has completely lost trust in the faction. This value also indicates resistance to false information.
- Characteristics: What personality traits the NPC has. If there are no characteristics worth mentioning, it is set to null. Currently, it indicates if the NPC has conspiracy theorist traits.

Event

- Characteristics: Classification of the event. Disinformation is more influential if it matches the "Characteristics" in the disinformation.

Disinformation

- Strength: The degree to which the disinformation affects the NPC's trust.
- Reality: The degree to which the disinformation is factual, indicating the likelihood that the NPC will accept the disinformation; if this value is low, the likelihood of acceptance is low.
- Characteristics: Classification of the disinformation. If the disinformation is appropriate to the nature of an event, it will have a greater influence on the NPC's trust.

Disinformation in the proposed game based on *СПІКЕРИ, ЯКІ ПРОСУВАЮТЬ СПІВЗВУЧНІ РОСІЙСЬКІЙ ПРОПАГАНДІ НАРАТИВИ* (*Speakers who promote narratives that are in tune with Russian propaganda*, https://cpd.gov.ua/reports/spikery-yaki-prosuvayut-spivzvuchni-rosijskij-propagandi-naratyvy-2/). This list was revised once, and before and after the revision, excluding duplicates, the list contained 89 speakers. In this paper, if the same speaker sent the same disinformation before and after the revision, it was classified as a single source, and if different speakers sent the same disinformation, they were classified as different sources. The classification was then done in a bottom-up fashion and organized as disinformation used in the game. Each classification and the example of its breakdown are provided as the Appendix.

The trust value of the NPC is reduced based on the following Eq. (1) and. Eq. (2) First determine whether the NPC is affected by the disinformation (Eq. (1)), and then determine the degree of influence (Eq. (2)). If the NPC is committed to a conspiracy theory, the trust value used in the Eq. (1) and Eq. (2) Regarded as half the value.

$$P = 100 + (R - T) \qquad (1)$$
$$A = S - T/4 \qquad (2)$$

P: Probability of decreasing trust, A: Amount of trust decreases, R: Reality in selected disinformation, T: Trust that the NPC has, S: Strength in selected disinformation

3.4. A game session example and a short discussion

The following shows the example of a game session. There are five NPCs. One NPC in the five NPCs believes in the conspiracy theory. The session has six events. "Disinformation" in the following description means the fake information selected by a player. "NPCs" in the description includes the changed "Trust" in the respective NPC ("Number").

Event 1: "Russia have launched an invasion."
Disinformation: "The U. S. is provoking/inspiring Russia."
NPCs: Number 0: Trust 82 (conspiracy thinking) / Number 1: Trust 95 (nil) / Number 2: Trust 95 (nil) / Number 3: Trust 95 (nil) / Number 4: Trust 95 (nil)
Average: 92.4, Total trust: 462/500

Event 2: "Russia occupied a city."
Disinformation: "Russia has not attacked civilians."
NPCs: Number 0: Trust 62 (conspiracy thinking) / Number 1: Trust 88 (nil) / Number 2: Trust 88 (nil) / Number 3: Trust 88 (nil) / Number 4: Trust 88 (nil)
Average: 82.8, Total trust: 414/500

Event 3: "A massacre occurred."
Disinformation: "The massacre in Bucha is a fake."
NPCs: Number 0: trust 9 (conspiracy thinking) / Number 1: trust 50 (nil) / Number 2: trust 88 (nil) / Number 3: trust 50 (nil) / Number 4: trust 50 (nil)
Average: 49.4, Total trust: 247/500

Event 4: "The war continues."
Disinformation: "Ukraine/Zelensky wants war."
NPCs: Number 0: trust 0 (conspiracy thinking) / Number 1: trust 32 (nil) / Number 2: trust 80 (nil) / Number 3: trust 32 (nil) / Number 4: trust 32 (nil)
Average: 35.2, Total trust: 176/500

Event 5: "The war continues."
Disinformation: "Russia will win the war."
NPCs: Number 0: trust 0 (conspiracy thinking) / Number 1: trust 10 (nil) / Number 2: trust 70 (nil) / Number 3: trust 10 (nil) / Number 4: trust 10 (nil)
Average: 20.0, Total trust: 100/500

Event 6: "Russia has retreated."
Disinformation: "They should not hunt down Russia."
NPCs: Number 0: trust 0 (conspiracy thinking) / Number 1: trust 0 (nil) / Number 2: trust 57 (nil) / Number 3: trust 0 (nil) / Number 4: trust 0 (nil)
Average: 11.4, Total trust: 57/500

In the above session, the value of trust to Ukraine of the conspiracy theorist (Number 0) is rapidly reduced. In the other NPCs, the NPC of Number 2 continues to have the value of trust to Ukraine. However, the values of trust of the other NPCs, Number 1, 3, and 4, finely become 0. When we see the entire process, we know the accelerated growth of suspicion to Ukraine.

In the game, the value of trust is also the power to resist the influence of disinformation. NPCs are repeatedly exposed to some type of disinformation and the influence of disinformation for all NPCs are gradually increased.

4. Conclusion

In this paper, we proposed the idea of a game system related to disinformation in the context of Russo-Ukrainian war and developed a simple prototype dealing with disinformation. We used one pattern of disinformation used actually in Russo-Ukrainian war. This game framework, including several NPCs and a human player, simulates the spreading process of disinformation. The goal of a player in one session is to change NPCs from Ukrainian faction to the Russian faction. The player may acquire the knowledge to prevent influences of disinformation through the game process. In the future, we would like to extend the scale of the game.

Abstract

With the development of AI, AI may substitute for physicians in radiological interpretations in the future. The purpose of this paper is to identify factors that could form the foundation for algorithms enabling AI to explore pathological findings. This study focuses on the "angles of gaze trajectory" and conducts a comparative analysis between veteran and novice. The results indicate commonalities and variances in the angles of gaze trajectory between veteran and novice, particularly 10, 350, and 180 degrees. Both Veteran and Novice have a relatively higher frequency of gaze movement around 10 and 350 degrees compared to other angles. Veteran has a relatively higher frequency of gaze movement around 180 degrees compared to other angles, while novice has a relatively lower frequency around 180 degrees.

Keywords: Eye-tracking, Angles of eye trajectory, Artificial Intelligence (AI)

1. Introduction

Machine learning and deep learning advancements, coupled with high-performance GPUs, have led to a significant breakthrough in the field of artificial intelligence [1]. Particularly in image recognition, AI is considered to surpass human capabilities [2]. In the realm of healthcare, a critical application of AI's image recognition capabilities is evident, with one prominent example being the interpretation of CT images. Given the current shortage of radiologists, AI is expected to achieve a level of expertise in image interpretation that can serve as a viable alternative to human physicians. To attain this capability, various factors contributing to the training of AI in image interpretation must be identified. One such factor is the ocular movement of physicians during image interpretation. This paper aims to discuss the significance of physicians' gaze patterns as one of these factors, emphasizing the need to uncover and understand these aspects to enhance the learning process of AI in image interpretation.

2. Previous Research

Numerous studies have explored gaze measurements of physicians during the interpretation of radiographic images, a certain cue is presented on the screen, and an analysis is conducted on how participants can detect this cue in terms of gaze trajectory and movement velocity [3]. Studies comparing the gaze patterns of veteran and novices are also prevalent. For instance, an analysis of gaze fixation points during chest X-ray image interpretation shows that experts promptly identify lesions and repeatedly confirm their presence while also scanning other areas, whereas novices tend to fixate on structurally complex regions [4]. In research on overlooking and missing findings during medical image interpretation, it has been demonstrated that experts thoroughly observe photographs, strongly focusing on the accurate location of anomalies, while novices exhibit more inconsistent observation patterns, with their gaze often diverted to complex positions where organs overlap [5]. This line of research on tacit knowledge and expertise in skill-demanding scenarios has unveiled that veterans and novices differ in terms of "where to look," influencing their subsequent performance [6]. As a preliminary step, it is necessary to extract and quantitatively analyze the gaze patterns of experts before linguistically formulating such characteristics. Therefore, the purpose of this paper is to conduct a comparative analysis between novices and veterans regarding the angles of gaze trajectories, which could serve as the foundation for algorithms exploring findings in artificial intelligence (AI). Furthermore, the objective is to propose recommendations for AI to learn

from the disparities in gaze trajectories between novices and veterans, ultimately enabling more accurate and effective image diagnostics in the future.

3. Experiment

The gaze measurement experiment was carried out as follows.
● Participants: One veteran radiologist (with over 10 years of experience) and one novice radiologist (with 1~3 years of experience).
● Data:15 cases with abnormal findings.
● Experimental method: Tobii Pro Lab eye-tracking software was employed. The camera was fixed. Participants were presented with CT images on a computer screen and performed interpretation of CT images by scrolling through the images using a mouse, following their usual reading methods.

4. Analysis Methods

Duchowski provides guidelines regarding data collection and interpretation in the context of eye tracking. The book introduces applications and instances of success in fields such as medicine, psychology, and human factors engineering, underscoring the effectiveness of employing eye tracking in the medical domain [7]. Furthermore, Holmqvist et al. offer an in-depth exposition of data analysis methods in eye tracking research. Of particular note, fixation points serve as a frequently employed metric [8]. However, the analyzed metric in this paper is the angle of the gaze movement as it sequentially moves from one fixation point to the next in succession. (Henceforth, this shall be referred to the angle of eye movement.) The reason for this is to confirm whether the direction of eye movement, namely the trajectory of the gaze, when radiologists interpret CT images is consistent with the characteristics of everyday human gaze as elucidated in previous research [9]. The characteristics of human eye movement elucidated in this previous research are detailed in the subsequent discussion section. The employed eye-tracking software in this study automatically aggregates parameters such as fixation points, fixation counts, fixation duration, and coordinates of fixation points, subsequently generating this information as output data. The trajectories connecting successive fixation points (hereinafter referred to as gaze trajectories) are visually indicated by red lines, enabling direct observation.

The angles of gaze movement were defined based on the eye-tracking data obtained using Tobii Pro Lab and analyzed using a custom-developed program. In this context, angles of gaze movement refer to the direction changes of gaze trajectories as it progresses across different fixation points. The concept is illustrated in the Fig. 1, where black circles represent fixation points (pixel), and connecting lines depict the gaze trajectory between these points. When the coordinate shifts from

(971, 810) to (988, 867), and subsequently to (974, 816), the angle of gaze movement is denoted by Angle 1 in Fig. 1. The directional movement is measured clockwise. Similarly, when moving from (988, 867) to (974, 816) and further to (1013, 837), the angle of gaze movement is represented as Angle 2 in Fig. 1.

Fig.1 Angles of gaze movement

5. Results

The results of the measured angles of gaze movement, as captured by the software, are presented in Fig. 2 and Fig. 3.

Fig.2 Angles of gaze movement in veteran (with abnormal findings)

Fig.3 Angles of gaze movement in novice (with abnormal findings)

A comparison between veteran and novice revealed notable differences in angles of gaze movement. In the graphs, the numbers displayed on the outer circumference represent the angles, while the numbers within the circumference, namely the radii, indicate the

frequency of the corresponding angles. Skilled practitioners exhibited a higher frequency of gaze movement angles around 180 degrees within the 360-degree spectrum. This is demonstrated in Fig. 2. In Fig. 2, angles such as 10 degrees, 350 degrees, 190 degrees, and 180 degrees were observed with higher frequencies. When examining the results for novice, as shown in Fig. 3, angles such as 350 degrees and 10 degrees were more pronounced in their gaze movement. Comparing the results presented in Fig. 2 and Fig. 3, it is evident that veteran frequently exhibit gaze movement angles near 180 degrees, a pattern not as pronounced in novice practitioners. This suggests that veteran tend to pause and carefully observe between fixation points when shifting their gaze, while novice appear to transition their gaze more promptly from one point to another.

6. Discussion

The paper highlighted differences in gaze movement between veteran and novice during interpretation. The analysis of angles of gaze movement, a hypothesis was formulated. The hypothesis suggests that skilled practitioners pause for careful observation between fixation points when shifting their gaze, whereas novices shift their gaze more promptly from one point to another, lacking this intermediate pause.

Considering that novices possess less experience than skilled practitioners, they might find it challenging to predict the location of anomalies. This could potentially explain why novices tend to survey the entire CT images thoroughly and quickly. In contrast, veteran can infer the approximate location of anomalies, allowing them to concentrate on specific areas. Interviews with experienced practitioners aligned with this explanation. Inexperienced individuals may have attempted to observe a broad area as much as possible. As a result, the gaze of novice may have exhibited movements along the Z-axis (the head-foot direction in CT images), while simultaneously surveying the XY plane comprehensively. Conversely, veteran tend to direct their gaze along the Z-axis (head-foot direction). Therefore, in a series of similar CT images, should an anomaly be detected, it could be recognized as a flicker. According to the previous research [9], the characteristics of human gaze encompass distinct roles for central vision and peripheral vision, where grasping stimuli occurs through peripheral vision and subsequently confirming details via central vision constitutes a fundamental process. Veterans shift their gaze along the Z-axis (head-foot direction) with peripheral vision, and subsequently enhance the resolution with their central vision when anomalies are detected. This phenomenon aligns with the description provided by adept physicians as "recognizing anomalies as flickers."

Additionally, the gaze patterns of veteran revealed repeated back-and-forth movements along lines near 180 and 360 degrees. Similar repetitive movements along horizontal and vertical lines have been observed

in previous studies [9]. The research has been elucidated that repetitive movements along horizontal lines are more frequent than those along vertical lines. In other previous research [10], it has revealed that the capability to accurately perceive information is higher in the horizontal direction of eye movements compared to the vertical direction. This paper also found that novice exhibited more frequent back-and-forth movements along horizontal lines than vertical ones. This phenomenon can be attributed to reasons such as the relatively easier execution of horizontal movements compared to vertical ones, as well as the cautious tendency of novices due to the difficulty in anticipating the location of abnormal findings. Consequently, novices may opt to observe a broader scope of the CT image.

7. Conclusions

The purpose of this paper is to conduct a comparative analysis between novices and veterans regarding the angles of gaze trajectories, which could serve as the foundation for algorithms exploring findings in artificial intelligence (AI). Furthermore, the objective is to propose recommendations for AI to learn from the disparities in gaze trajectories between novices and veterans, ultimately enabling more accurate and effective image diagnostics in the future. This paper specifically analyzed the angles of gaze movement and speed of veteran and novice radiologists. However, it is important to note that this research had limitations in terms of a limited number of participants and sample size. Future studies should involve a larger sample size to further investigate the elements of algorithms during radiological interpretation.

Abstract

In association with the change of work style to remote, the home environment should be considered in terms of carbon dioxide concentration (CDC) which has negative effects on the human body, such as less cognitive abilities. To challenge this problem, the authors developed an alert system that supports remote workers to be notified of an increase in CDC, by combining Raspberry Pi, CDC sensor, and Slack. As a result, the developed alert system was able to support the user in keeping the CDC in the room below the set threshold. In addition, the system shows that a significant increase in CDC can be observed in the room when it comes to insufficient ventilation.

Keywords: Carbon Dioxide Concentration (CDC), Raspberry Pi, Working Productivity

1. Introduction

In recent years, the spread of the Internet and the coronavirus have prompted many companies to adopt remote work. According to the Pew Research Center (2022), remote work rates have not declined much even after the peak of the pandemic [1]. In addition, many workers have a favorable attitude toward remote work after the pandemic (Da Silva et al., 2023) [2]. Therefore, remote work will likely continue to be promoted after the end of pandemic.

In consideration of the situation mentioned above, working productivity is noteworthy. Generally, the promotion of remote work in the wake of the coronavirus is interpreted as an increase in productivity of work. In fact, there is an argument that the shift to remote work leads to increased productivity, by thinking from the perspective of the amount of work, work-life balance, and job satisfaction (Kurdy, 2023) [3]. However, most of the papers referring to productivity in remote work simply compare productivity before the introduction of remote work with after doing that. In other words, there is little discussion from the perspective of changes in productivity caused by the home environment.

When pursuing productivity in remote work, a home environment that has become the working environment should be focused. Krivonossova (2022) points out that distractions in remote work are caused by the home environment, such as TVs,

books, and beds [4]. However, different from the perspective above, this paper focuses on the composition of indoor air. According to Azuma (2018), increased indoor CDC due to human breathing and other factors can cause negative impacts on the human body, such as dizziness, headaches, and reduced cognitive and problem-solving abilities [5]. Therefore, remote workers need to maintain indoor air quality by ventilating and other ways. However, the increase in CDC cannot be perceived easily, and it is difficult to know the appropriate timing to ventilate. Therefore, there is a possibility that the increase in CDC is causing a decrease in working productivity even if remote workers do not perceive it.

The purpose of this paper is to prevent an increase in CDC and a decrease in working productivity by using the system developed to notify the appropriate timing of ventilation.

2. Previous Research to Set Threshold

The unit used to express CDC is the "ppm (parts per million)". To determine the CDC threshold for the notification, it should be referred to the indoor CDC standards published by various public agencies.

The Wisconsin Department of Health Services (2023) states that 400 to 1,000 ppm is a reasonable standard for CDC indoors. Moreover, it points out that from 1,000 to 2,000 ppm will cause complaints

Yohei Kamoda, Jun Nakamura

of drowsiness and poor air quality, and from 2,000 ppm and above will cause health problems such as headaches, drowsiness, decrease in concentration to work, and mild nausea [6]. In addition, Japan's Ministry of Health, Labour and Welfare (2016) has set the environmental health management standard for CDC at 1,000 ppm in its Building Sanitation Law because CDC levels above 1,000 ppm cause fatigue, headaches, tinnitus, and breathlessness in the human body [7].

From the above, it is reasonable to set the threshold used in this paper at 1,000 ppm. Thus, the standard for notification used in the developed system in this paper can be set at 1,000 ppm.

3. Specifications of Developed System

3.1. System Overview

Fig. 1 shows a photograph of the overall CDC measurement and notification system created in this paper, and Fig. 2 shows a wiring diagram of the system. The system consists of a small computer called "Raspberry Pi model 4B" and two modules called "MH-Z19C" and "LCD 1602". The computer and display are connected by an i2c communication interface, "PCF8574".

Fig. 1. Overall Picture of CDC Measurement and Notification System

Fig. 2. Wiring Diagram of the System

The functions implemented in this system can be divided into measurement and notification. These two functions are intended to solve the problem stated in Chapter 1.

3.2. Measurement Function

The CO2 sensor module, MH-Z19C, was used to measure CDC. In terms of the program code to measure CDC, the function from the library

available on GitHub created by Ueda (2018) is utilized to simplify source code [8]. There are two measurement functions using this. The first is to record measurement results as csv file for analysis. The second is to immediately check the results at any given time through a small display.

3.3. Notification Function

In the system, Slack, the communication tool in business, was used for the CDC notifications. The purpose of this is to send a notification to the user to urge them to ventilate when the CDC value exceeds the threshold level of 1,000 ppm.

In addition, three conditions were set for notification. First, the Raspberry Pi must be connected to the Internet. Second, the notification is sent when the measured CDC value exceeds 1,000 ppm. Third, the judgment on whether to send a notification is made every five minutes.

4. Methods of Evaluation and Data Measurement

4.1. Environment during Measurement of Carbon Dioxide Concentration Data

The data measurements in this paper were conducted by the authors in their room. A simplified figure of the room where the data measurements were taken is shown in Fig. 3. To measure CDC as close as possible to the air that a person breathes, the sensor was placed close to the person. At this time, the position of the sensor was adjusted to avoid direct contact with the exhaled breath to obtain accurate data. Also, the "natural ventilation system" in this paper refers to the 24-hour ventilation system in the bathroom outside the "door", and the room is ventilated by taking in fresh air through the gaps around the "door" in the experimental environment.

When measuring data, test measurements were conducted under the same environment for at least 60 minutes prior to the start of the measurement to confirm that the CDC remained stable at less than 1,000 ppm. In addition, the working human was not away from the seat during the measurement and was assumed to be engaged in constant breathing activity.

Fig. 3. Environment of Room during Measurement

4.2. System Evaluation

In the evaluation of the system, the effect of the notification system on the increase in CDC is evaluated. Assuming a situation of inadequate ventilation, the "natural ventilation system" is stopped. Then, the "Window" in Fig. 3 is opened at the time of the notification to urge the user to ventilate the room. As a result, the system will be evaluated whether it has been able to contribute to reducing the CDC in the room below 1,000 ppm.

5. Results

Under the environment and conditions described in Chapter 4, an experiment was conducted by opening the "Window" and ventilating the room when the measured CDC value in the room exceeded 1,000 ppm, and a Slack notification was received. Table 1 shows the date and time of the measurement and the total measurement time, and Table 2 shows the elapsed time until when the notification was sent and the conducted ventilation time. Also, the CDC transition obtained from this measurement is shown in Fig. 4. In Fig. 4, the period during which the ventilation was conducted is colored.

Table 1. Date and Total Time of Measurement for Fig. 1

Start date and time	End date and time	Total Time
2023/9/27 19:00	2023/9/28 0:00	300 minutes

Table 2. Elapsed Time from Start of Measurement to Notification and Ventilation Time

Elapsed Time (minutes)	Ventilation Time (minutes)
65	15
95	15
120	30
190	35

Fig. 4. Transition of Carbon Dioxide Concentration when Ventilation is Conducted at the Time of Notification

As shown in Table 2 and Fig. 4, it can be said that ventilation at the time of the notification contributes to keeping the CDC in the room below 1,000 ppm. However, when the "Window" was closed, the CDC rapidly rose and exceeded 1,000 ppm. In the end, 135 minutes of ventilation time was required out of 300 minutes. However, it would be fair to say that positive results were obtained for the question, "Can the notification system help to keep the CDC in the room below 1,000 ppm?"

6. Discussion

It is fair to say that the system developed in this paper can help to prevent the increase of CDC in a room, as shown in the results of Chapter 5. In addition, it also showed that a room with inadequate ventilation has a high possibility of increasing CDC causing not only reduced productivity but also health problems. In other words, the system developed in this paper can prevent the decline in working productivity by knowing the adequate timing to ventilate. Also, the social value of this system in realizing the goal of improving productivity in remote operations can be well recognized.

However, this paper does not actually compare working productivity. Therefore, it is necessary to consider the possibility that Slack notifications may interfere with concentration on work. From this viewpoint, this system will not necessarily lead to increased working productivity based on the only verification in this paper.

In addition, the system developed in this paper only notifies the user of appropriate ventilation timing. Thus, the control of CDC in the room depends on the opening and closing of windows by the user. This is sufficient for remote work but needs further expansion to be utilized in other locations. As Fig. 4 shows, in rooms with inadequate ventilation, ventilation by opening and closing windows only becomes a temporary measure. Considering that the CDC rose

immediately after the window was closed, a ventilation system that automatically adjusts the CDC independent of user behavior would be needed to maintain the appropriate working environment.

Also, according to OPEN ACCESS GOVERNMENT (2021), since the COVID-19 pandemic, workers' awareness of flexible work styles and better working environments has increased [9]. Therefore, the system developed in this paper can be used to improve the working environment at a more advanced stage than the promotion of remote work. The importance of this system will be recognized, and its demand will rise in the current situation that COVID-19 has promoted not only remote work but also awareness of the work environment.

7. Conclusion

The purpose of this paper is to prevent an increase in CDC and a decrease in working productivity by using the system developed to notify the appropriate timing of ventilation.

The CDC notification system developed in this paper could be utilized to improve the working environment for remote workers. As shown in Fig. 4, the system was able to help keep the CDC in the room below 1,000 ppm by encouraging ventilation at the appropriate time. However, it does not indicate whether it was possible to prevent working productivity decline. Therefore, further verification of working productivity will be necessary in the future.

The data measurements in this paper were conducted in the limited environment of the authors' room, and the number of experimental subjects is insufficient. Therefore, it will be necessary in the future to acquire a large amount of data and to consider detailed environmental conditions such as the location of ventilation fans, actual flow of air, the number of people, room size, and temperature. This would provide detailed findings and suggestions for ventilation.

Abstract

This study examines gaze movement differences in diagnosis between skilled and beginner physicians, aiming to identify factors influencing diagnostic speed and developing human resource and enhance artificial intelligence's diagnostic capabilities. Results reveal that experienced physicians, on average, spent 61% less diagnostic time than beginners, covering 49% of the gaze distance on the X and Y-axes. (comparison of the cumulative distance of gaze on the screen). Despite increased movement on the Z-axis (comparison of the scrolling speed of the CT scan results), skilled physicians moved 2-3 times faster, effectively narrowing attention and identifying specific areas.

Keywords: Experimental Economics, Eye-tracking, Cognitive Science, Artificial Intelligence (AI)

1. Introduction

Examination work in the medical industry is generally considered time-consuming and highly labor-intensive to train one CT service technician to acquire the knowledge necessary to prepare interpretation reports [1]. In addition, a nationwide survey of the actual status of the reading system for chest interpretation of radiograms for medical examinations, based on a questionnaire targeting 239 radiologists in 2018 [2], also indicated that it is difficult to train radiologists in a short period of time and requires a certain level of clinical and reading experience. In addition, the results of the survey indicated that the burden on radiologists is increasing due to the aging of the workforce and that the spread of CT scans will further reduce the manpower needed for the interpretation of radiograms, which may lead to the breakdown of the current radiogram system.

This has led to increased awareness of human resource development and medical AI development. Medical AI is being developed using deep learning. However, because deep learning has a black box problem in which the decision-making process cannot be identified by humans, the development of medical AI that can explain the process is being explored in the medical field, where safety is a high priority [3].

Considering the above issues, this study does not aim to contribute to the development of medical AI based on deep learning. This study aims to understand humans through the diagnosis of skilled physicians, and based on the understanding, aims to contribute to the realization of diagnosis like that of skilled physicians by beginner physicians and AI.

Diagnosis using imaging test results requires time and effort to master, resulting in a difference in the speed at which skilled physicians and beginner physicians can make a diagnosis. This is thought to be due to the difference in knowledge and experience between skilled and beginner physicians based on previous research [2]. This paper visualizes and analyzes the eye movement of both physicians resulting from the difference in knowledge and experience.

Humans are thought to possess the property of being able to make automatic inferences about stimuli with which they have frequent contact through practice, and this process of developing automaticity in judgment through practice is called procedural processing [4]. Procedural processing has been found to enable quicker decisions, improve reaction speed, and emphasize rational and practiced judgment [5]. It is thought that such procedural judgment is also made by experienced physicians when they use imaging test results to make diagnoses.

It is difficult to verbalize and provide effective guidance for diagnoses that are made unconsciously using such procedural judgments. Therefore, in this paper, by using a method [6] to visualize the eye movements of experienced physicians and beginner physicians during diagnosis by measuring eye gaze and to analyze the differences from a cognitive perspective, this paper aims to clarify the factors that lead to the speed with which

Taiki Sugimoto, Jun Nakamura, Yoshinobu Ishiwata

experienced physicians make diagnoses.

2. Purpose

The purpose of this paper is to contribute to human resource development and Medical AI development by clarifying factors that lead to the speed of making a diagnosis through a cognitive approach, such as measuring the eye movement of experienced physicians and beginner physicians during the interpretation of radiograms.

This paper is a study of novelty and academic significance. Conventional economics has focused on the results of decision-making and attempted to understand human behavior through mathematical decision-making models. However, this paper attempts to understand human behavior through a cognitive approach such as eye measurement by visualizing and analyzing the diagnostic process during the interpretation of a radiogram by using imaging tests. In addition, unlike previous studies that analyzed decision-making by comparison, this paper is unique in that it analyzes decision-making in the process of developing automaticity [4] as mentioned above.

This paper has social significance in that it aims to contribute to the development of beginner physician and development of medical AI by making the gaze at the time of diagnosis visible and clarifying factors that lead to the speed of giving a diagnosis.

3. Hypothesis

The hypothesis was developed as differences in the way experienced physicians and beginner physicians move their gaze during the interpretation of radiograms.

Experienced physicians have a narrower range of eye movement when searching for the presence or absence of symptoms/points of symptoms compared to beginner physicians. Since both interpretations of radiograms by experienced physicians and batting by experienced hitters have in common that they are performed using procedural judgment [4], a process in which the aforementioned automaticity of judgment has developed, previous studies [7] in which the gaze of experienced hitters while batting was studied were consulted. The results showed that experienced batters fix their gaze on the entire pitcher in their peripheral vision, fixing their gaze by on the point of attention prediction, rather than on a wide area as beginner batters gaze at a wide range. Based on this finding, it was hypothesized that the gaze movements of experienced physicians would be narrower than those of beginner physicians.

4. Methods

In this paper, experiments were conducted under the following conditions.

Yokohama City University Hospitals
- Experienced (more than 10 years career) 1 person

- Beginner (1~3 years of career) 1 person

With the cooperation of 2 physicians
- Abnormal findings 15 people (cases)
- No findings 15 people (cases)

A total of 30 people (cases) were tested for interpretation of head CT scan results, and eye gaze was measured using Tobii Pro Lab Screen Edition.

When interpreting the 30 cases, both physicians were not informed of the findings, the examination images were random, and both physicians diagnosed the cases in the same order, beginning and ending the diagnosis of each case at the physician's own discretion.

In comparing the experienced physician and beginner physician in this paper, the following two types of analyses were conducted.
- Comparison of the cumulative distance of gaze on the screen (X-axis and Y-axis movement): Abnormal findings - 15 cases.
- Comparison of the scrolling speed (Z-axis movement) of CT scan results: Abnormal findings - 3 cases.

The cumulative distance of the gaze (movement of the X-axis and Y-axis) was performed with reference to the velocity-detection method [6], which measures the distance of gaze movement on the screen. In addition, in this paper only analyzed abnormal findings (15 cases) from 30 cases.

The scrolling speed of the imaging test results (movement of the Z-axis) is an analysis unique to this paper; the movement of the Z-axis is an expression also used in the interpretation of radiogram and corresponds to the scrolling speed (diagnostic time and movement) between images of CT test results that capture cross sections. In the analysis, the diagnostic time for each image was recorded at the time the examination images were switched. The recording was done manually, and the error in the timing of when the physician switched images was kept within a range of 0 microseconds to 4 microseconds or less. If the physician did not change the scroll direction within 5 images, the time was recorded at intervals of 5 images, and if the physician did change the scroll direction within 5 images, the time was recorded each time an image was switched.

Both analyses were conducted with the purpose of focusing on gaze movements in the X-axis, Y-axis, and Z-axis to investigate whether the range of gaze movements of the hypothesized experienced physician's eye would be narrower than the range of gaze movements of the beginner physician's eye.

5. Results

Comparison of cumulative distance of gaze (X-axis and Y-axis movements)

Fig.1, Fig.2 below shows a comparison of the cumulative distance of gaze when the same case was diagnosed by an experienced physician and a beginner physician. Due to space limitations, the figures for each case are not shown here, but rather the total cumulative distance and the total normalized diagnosis time for all

cases, table summarizing their sum, mean, and variance, and figure showing the mean cumulative distance for the cases with findings (15 cases). The horizontal axis represents the time of diagnosis.

Table 1. X-axis and Y-axis movement in Abnormal Finding cases.

	Experienced_normalized time	Experienced_cumulative distance of gaze	Beginner_normalized time	Beginner_cumulative distance of gaze
Case1	66.99	31042.43	100	100626.18

Fig.1. Average of X-axis and Y-axis movement

Fig.2. Case 4 X-axis and Y-axis movement

The horizontal axis represents diagnostic time. Among the diagnoses made by experienced physician and beginner physician diagnosticians, the diagnosis completion time of the one with the longest diagnosis time was set to 100 and normalized. The vertical axis represents the cumulative distance of eye movements until the end of the diagnosis, calculated by dividing all eye movements in the screen where the examination image is displayed in Tobii Pro Lab by the coordinates of the X-axis and Y-axis.

A comparison of the results for 15 cases revealed the following three points.

- Experienced physician require an average of 61% of the diagnostic time of beginner physician for all 15 cases. (Table 1, Fig.1).
- Experienced physician will require an average of 49% of the cumulative gaze distance of the beginner physician for all 15 cases except Case 4 (Fig.2).

- Experienced physician never exceeded the cumulative distance of the beginner physician's gaze for more than half of the diagnostic time in all 15 cases except Case 4 (Fig.2).

Comparison of scrolling speed (Z-axis movement) of imaging test results

Fig.3 below is representative Figure that shows a comparison of the representative Z-axis gaze shift of the gaze when the same case was diagnosed by an experienced physician and a beginner physician.

Fig. 3. Z-axis movement

The following two points were clarified.

- Experienced Physician move back and forth 1~1.5 times between imaging test results until beginner physician confirm all imaging test results (Fig.3).
- Compared to the Beginner Physician, who tended to move back and forth along the Z-axis at many points and was not able to narrow down the range of attention, the Experienced Physician tended to identify the points of attention and gradually narrow down the range of attention along the Z-axis (Fig.3).

6. Discussion

The purpose of this paper is to contribute to human resource development and medical AI development by clarifying factors that lead to the speed of making a diagnosis through a cognitive approach, such as measuring the eye movement of experienced physicians and beginner physicians during the interpretation of radiograms.

In analyzing the gaze, this paper hypothesized that Experienced physicians would have a narrower range of eye movement when searching for the presence or absence of symptoms and the location of symptoms than beginner physicians.

As a result of the analysis, it can be said that the hypothesis is valid according to the following two analysis results for the movement of the X-axis and Y-axis.

- Experienced physician will require an average of 49% of the cumulative gaze distance of the beginner physician for all 15 cases except Case 4 (Fig.2).

Taiki Sugimoto, Jun Nakamura, Yoshinobu Ishiwata

- Experienced physician never exceeded the cumulative distance of the beginner physician's gaze for more than half of the diagnostic time in all 15 cases except Case 4 (Fig.2).

In addition, about Z-axis,

- Compared to the Beginner Physician, who tended to move back and forth along the Z-axis at many points and was not able to narrow down the range of attention, the Experienced Physician tended to identify the points of attention and gradually narrow down the range of attention along the Z-axis (Fig.3).

This is related to the hypothesis that the range of eye movement of Experienced physicians is narrower than the range of eye movement of beginner physicians.

However, in all the cases investigated in this paper, the number of eye movements back and forth on the Z-axis for Experienced physicians was greater than that for beginner physicians Thus, in addition to substantiating the hypothesis, the experienced physicians made fewer eye movements between the X-axis and Y-axis than the beginner physicians, but made more eye movements in the Z-axis, suggesting that the experienced physician may perceive and diagnose imaging test results in a three-dimensional rather than a planar manner.

These findings and discussions in this paper will lead to human understanding through the skilled physician's diagnosis and contribute to the future development of human resource training and medical AI.

7. Conclusions

The purpose of this paper was to contribute to human resource development and medical AI development by focusing on the differences in eye movement between experienced physicians and beginner physicians during diagnosis and to identify factors that lead to the speed at which they make a diagnosis.

As a result of analyzing eye movement during diagnosis in two ways: cumulative distance of eye movement (movement on the X-axis and Y-axis) and scrolling speed of imaging test results (movement on the Z-axis), it was found that experienced physician was faster than beginner physician in making a diagnosis, moving less distance on the X and Y axes, and usually moving less than the distance of beginner physician. On the Z-axis, however, they tended to identify the area of focus and gradually narrow the range of attention but traveled more distance and in a shorter time than the beginner physician.

Next, the limitations of this paper are discussed. Due to technical problems, this paper has not been able to analyze the Z-axis shift of all cases. Besides improving the reliability of the analysis results, it would be desirable to continue analyzing the Z-axis shift, which may lead to new discoveries. In addition, this paper only compares one experienced physician and one beginner physician each. In the future, it is desired to increase the number of subjects and to include intermediate physicians who are between the levels of the two physicians in this paper to increase the reliability of the results.

Finally, in terms of future prospects, this paper will share the results of this analysis with physicians, and by deepening the discussion, explore effective human resource development methods and way of developing medical AI.

Toward Temporal Taste Sensing: Contrasting Human Experience with Machine Perception in Food Appreciation

Hiroki Fxyma

Kobe University, 1-2 Tsurukabuto, Nada-ku, Kobe, Japan

Abstract

This paper explores the temporal aspects of food and beverage appreciation, particularly focusing on the interplay between taste sensors and human sensory experiences. It begins by discussing the fundamental principle of taste sensors, which analyze chemical substances but often fail to capture the complexities of human taste perception. To address this limitation, the concept of "artificial tongues" is introduced, aiming to replicate human taste perception more accurately. The paper then delves into the temporalities inherent in our eating experiences, categorized into three dimensions: the time of the object, the time of embodied cognition, and the time of the phenomenon. Four temporal aspects of the phenomenon are proposed: non-temporal, linear temporality, circular temporality, and point temporality, which are shaped by the eater's attention. The discussion further examines the motivations behind the temporality of food, highlighting cognitive and physical constraints such as memory and oral capacity. Additionally, the paper investigates temporalities in dessert appreciation, using the example of a strawberry mille-feuille to illustrate how the arrangement of ingredients and the sequence of consumption create unique temporal experiences. Finally, it concludes by emphasizing the need for philosophical and theoretical advancements to bridge the gap between human sensory experiences and machine sensing, thereby enhancing our understanding of taste perception in both realms.

Keywords: Temporality, Artificial tongues, Taste sensors, Aesthetics

1. Introduction

1.1. *Taste sensor and the temporality*

The basic principle of taste sensors is to analyze chemical substances that are taste components. Sugar meters and salt meters are the most basic of such sensors. However, a precise analysis of the chemical composition of food does not represent the taste that humans perceive. The characteristics of human taste perception include, for example, the fact that humans perceive different chemical substances (sucrose and aspartame) as the same taste stimulus ("sweetness") as well as the inhibitory/synergistic effect of one taste on the perceived intensity of another taste. To reflect such cognitive characteristics of human perception and output "the taste perceived by humans" instead of simply detecting taste substances, sensors are referred to as artificial tongues. As Toko [1] reviews, there are two types of commercialized electronic tongues in the world. One is the taste sensing systems SA402B and TS-5000Z, commonly known as the taste sensor, and the other is the Astree II e-tongue.

These electronic tongues are intelligent sensors that reflect the human taste perception system in their component analysis as information processing, but their detection of temporality is limited to a small portion. The SA402B and TS-5000Z developed by Toko et al. can analyze taste as it is perceived on the tongue (initial taste) and the taste that remains after swallowing (aftertaste). These are computed based on the ease with which taste components detach from the lipid membrane, which is a taste sensor, thereby detecting, for example, a rich aftertaste. However, none of the current taste sensors measure changes in perception over time, such as fatigue with the same taste. Also, effects such as contrast between ingredients (e.g., strawberry after cream) must be measured separately and evaluated by humans.

1.2. *Temporalities in our eating experience*

Taste and smell are gaining status in aesthetics, but theories concerning their basic appreciation are insufficient. Fxyma [2] proposed the basic theory for temporality of food and beverage appreciation. According to the study, the temporality underlying food appreciation is classified into three categories: the time of the object, the time of the embodied cognition, and the time of the phenomenon. Next, Fxyma proposed four aspects of the time of the phenomenon: non-temporal, linear temporality, circular temporality, and point temporality. These four temporalities are not determined a priori but generated by the eater's attention.

2. Motivations of the Temporality of food

Temporality as a phenomenon in the human eating experience arises from cognitive and physical constraints. In this section, I outline the primary constraints: memory

(cognitive constraints) and oral capacity (physical constraints).

The first constraint is memory. Memory is generally divided into sensory memory, short-term memory, and long-term memory. The retention period of sensory memory varies by sensory modality, but is short, ranging from less than one second to several seconds. In contrast, its retention capacity is larger than that of short-term memory. Sensory information is then stored as short-term memory, medium-term memory, and then long-term memory. Human senses cannot reproduce stimuli. We can recall pain and taste, but this is not a reproduction of the pain or taste "itself. If it were possible to reproduce the pain itself, we would experience intense pain again every time we explain the situation of a serious injury.

On the other hand, a machine's sensors can reproduce the stimuli as numerical values; the values measured 10 years ago can once again be input into the sensors; the wine opened 10 years ago and the wine opened now can be tasted "at the same time". The human being seems to be comparing the two, but one is the sensor data of the actual wine in front of us, while the other is the edited and partly erased/enhanced long-term memory of the wine of 10 years ago.

This means that the time possessed by the machine is basically point temporality in Fxyma's temporality classification. The present and the past appear simultaneously in the here and now. It is not Linear temporality because there is no passage of time or order. It is also different from Circular temporality because it recreates the same stimulus in the past. Circular temporality is about finding repetition in different experiences. For example, spring is repetitive, but the content of the spring experience is not identical every year. The reproduction of exactly the same stimuli is different from the concept of Circular temporality. Thus, the simultaneous appearance of the here and now as a condensed time of the present and the past is Point Temporality.

This constraining characteristic of human memory to be edited, forgotten, and reinforced over time gives rise to Linear Temporality or Circular temporality. When eating a parfait, the first strawberry, the next taste of cream, and the subsequent strawberries are not experienced separately, but have a linear continuity or a circular temporality structure as repetitions of strawberries. When a person eats a parfait, temporal memory is passed on from one bite to the next; if the same taste continues in the mouth, the person becomes bored, and if the sweet flavor of the cream is followed by the sour jam, there is a contrast. In the repetition of strawberries and cream, the strawberry is presented with a different role each time it appears. Here, more than the summation of the elements, an aesthetic experience emerges.

The second constraint is the physical structure of the nasal and oral cavities. Generally, the volume of the oral cavity is smaller than that of the stomach, and humans divide food during meals, sending the entire amount of

one meal to the stomach in several to several tens of times. In the case of eating the entire amount of food at once, there is no temporality. The division of food itself becomes the basic unit of temporality, such as order and repetition. For example, beef steak is divided into several pieces with a knife, finely crushed with several times the number of chewing, and sent to the stomach.

Human meals are embedded in multiple cyclical temporalities. The time span ranges from seconds, such as repeated chewing and swallowing, to levels such as three meals a day (rise and fall of blood sugar in some hours), and complex cyclical cycles such as food aversion/preference learning (in some hours to days), or seasonal foods (in a year). When analyzing food with taste sensors, it is liquefied with a mixer and the composition of flavor components is analyzed. Here, temporalities such as division with a knife or repetitive chewing are disregarded, and analysis is conducted as timeless, ignoring point time or time passage.

The analysis times increase significantly when the number of steps in the implicit integral is expanded. In the implicit method, the solutions of simultaneous equations are obtained by inserted Newton-Raphson method, and numerical substitutions into symbolic matrix within this process require the computation processing time. The symbolic matrix is enlarged by increasing the number of implicit stages, which takes more computation time. Therefore, it is important to implement an efficient substitution process into a symbolic matrix for the implementation of higher order implicit methods in MBD analysis.

3. Temporalities in Dessert Appreciation

In this section, I will examine the process by which humans experience food, using one dish of dessert as an example. This dessert shown in Fig. 1 is provided at the pastry shop *Assiette Dessert Maruyama*, located in Nishinomiya City, Japan.

Fig.1 The Strawberry Millefeuille of *Assiette Dessert Maruyama.*

The strawberries scattered on the plate play different roles in the beginning and the end of the dish. Of course, they also play a role in giving an impact at the moment

they are presented. However, this function is a visual one. The strawberries eaten at the beginning of the meal function to tell the taste of the strawberries or to introduce the flavor of the strawberries used as an ingredient. In order to understand the function of the strawberries in the latter stages, it is necessary to interpret the flavor of the millefeuille in the main body of the dish. The millefeuille is characterized by the horizontal structure of the cut layers, rather than the more common style in which layers of pie and cream are piled up vertically.

In a typical layered millefeuille, one must cut the pastry with a fork to achieve the intended size, which is not only cumbersome but also risks disrupting the balance between the pie pastry and the strawberries by causing cream to spill out. However, in *Maruyama*'s millefeuille, a bite-sized portion is pre-cut, allowing one to enjoy the pie pastry, cream, and strawberries atop without compromising their balance.

In *Maruyama*'s mille-feuille, the meticulous calculation behind this bite-sized composition becomes fully evident as one progresses through consuming it. As the layers of cream and pastry are meticulously arranged side by side, defying the conventional definition of a mille-feuille, scooping up a set with a fork automatically results in an accompanying strawberry, completing a mouthful. The pastry is not of the rigid variety but rather consists of delicate, thin layers stacked upon one another. When pressed against the custard cream with the tongue and teeth, the pastry dissolves effortlessly without requiring a bite, instantly enveloping the tongue in the smoothness of the cream. There is no sensation of strawberry juice separating from the custard cream and flowing out. While the strawberries provide a fibrous texture and a refreshing acidity to the tip of the tongue, the carefully controlled juice harmoniously melds with the pastry and cream, creating an impression of "strawberry custard cream" rather than separating out.

The perfect harmony of pastry, cream, and strawberries creates an impression of "strawberry custard cream" where everything melts together in the mouth, to the extent that one might almost forget the awareness of "eating strawberries" as they progress through the middle and later stages. To prevent this forgetting, the role of the strawberries scattered on the plate from the middle to the end comes into play. The strawberries scattered on the plate ensure a return to the main theme that might otherwise be lost due to the remarkable harmony.

This mille-feuille is likely intended to be consumed from left to right. Evidence of this can be found in the absence of cream at the right end, indicating a progression. In the overall linear progression of time, each bite-sized millefeuille forms a condensed, Point Temporality through the perfect harmony of its ingredients. While the repetition of millefeuille layers from left to right introduces a recursive Cyclical Temporality, there comes a moment when continuity threatens to turn into monotony and a sense of timeless monotony (i.e., Atemporality). At this juncture, the strawberries scattered on the plate serve as "privileged moments [3], bringing the consciousness of the eater back to the cyclical time.

4. Conclusion

This paper examines the differences between human sensory experiences and machine sensing through the description of the experience of eating a dessert on a plate. I argue that the human experience of eating is temporal in nature, primarily motivated by two constraints: the limitations of memory and oral capacity. In contrast, machine taste sensing, without these constraints, is an experience characterized by "point time" or "timelessness," where past, present, and future information are analyzed homogeneously.

The current limitations of sensing in reflecting the temporal aspects of the human eating experience, especially linear or cyclical time, do not stem from inadequacies in sensor capabilities or the scientific knowledge supporting them.

Rather, the deficiency lies in the philosophical and theoretical understanding of what should be sensed. We lack theories to explain the experience and phenomena of consuming a dessert or savoring a glass of wine, which limits taste sensing to mere component analysis. Taste sensors themselves are capable of detecting taste components more "accurately" than humans, "objectively" across various conditions, and with an unparalleled sensitivity to subtle taste components. If taste sensors are to transcend mere component analysis and aim to reproduce "eating" as an intellectual behavior of machines, what is required is philosophical and theoretical leadership in science.

Abstract

Cooling methods based on boiling have attracted attention as a thermal solution for electronic equipment. In this situation, it is necessary to measure the heat transfer coefficient (HTC) to design more efficient cooling systems. In this paper, we propose a method to predict of the HTC from boiling sound data using deep learning techniques. The accuracy improved by 1.12% compared to the conventional method through the development of Convolutional Neural Network (CNN) incorporate Convolutional Block Attention Module (CBAM).

Keywords: Boiling Sound, Heat Transfer Coefficient (HTC), Convolutional Neural Network (CNN), CBAM.

1. Introduction

The heat generation density of CPUs and GPUs is increasing year by year as they become more highly integrated [1]. Under these circumstances, the cooling method using water boiling is currently attracting attention. Boiling cooling has a high heat transfer coefficient (HTC) compared to gas forced convection cooling using heat sinks and fans [2], which is still in use today. Furthermore, since water serves as the boiling medium, it is environmentally friendly and economical. Since the boiling absorbs heat through the evaporation of the boiling liquid and the convection induced by the bubble motion [3], the HTC significantly depends on the number and size of the bubbles. In fact, the measured HTC shows a significant change when the number and shape of the bubbles are varied, as shown in Fig. 1. Therefore, it is important to accurately measure the HTC to develop more efficient and reliable cooling systems.

This paper proposes a method for predicting the HTC from spectrogram images of the boiling sound using Convolutional Neural Network (CNN). This method is based on the idea that there is a relationship between boiling sound and HTC. We conduct a classification task by categorizing the HTCs obtained through experiments into five classes. Then, we apply Convolutional Block

Fuga Mitsuyama, Ren Umeno, Tomohide Yabuki, Tohru Kamiya

Attention Module (CBAM) [4] to a CNN model to improve the classification accuracy.

2. Method

2.1. *Creation of dataset*

We experimented with sound data acquisition to create a dataset of spectrograms. Then, this acquired sound data was transformed into a spectrogram using the Fast

Fig. 1. Boiling state transitions and associated changes in the quantity and shape of bubbles

Fourier Transform (FFT) [5] to generate a 200 x 200 [pixels] image. Fig. 2 gave an overview of the

Fig. 2. Overview of experimental setup for sound data acquisition

experimental setup. A 1-mm-thick, 10-mm-square copper plate soldered to the top of a copper heater block into which cartridge heaters are inserted was used as a heat-transfer wall. Thermocouples inserted in the copper block were used to the surface measure temperature and heat flux. Before the boiling experiment, the pure water used as the boiling medium was degassed for more than 1 hour. Boiling sound was measured using Miniature Hydrophone Type 8103® [6] at a sampling frequency of 50 [kHz]. Table 1 shows the number of data for each the HTC class.

2.2. *Classification by CNN*

The model is based on the CNN model developed by Tabata et al [7] and Sinha, K.N.R et al [8]. A basic block of CNN in Fig. 3 consists of a convolution layer (with a kernel size of 3 x 3 and 96 channels), batch normalization, ReLU functions (as activation functions) and average pooling (with a kernel size of 2 x 2). Then, four stacks of these blocks downsample the input images and construct

a robust model against noise. We specify the labels for each class ranging from 10–20, 20–30, 30–40, and 40–50 [kW/m^2/K]. These label numbers represent the HTC.

2.3. *Convolutional Block Attention Module (CBAM)*

In order to improve the accuracy of the conventional CNN model, we incorporate CBAM and compare its accuracy with that of the conventional model. The structure of the CNN model with CBAM is shown in Fig. 3. The CBAM architecture is based on the paper by S. Woo et al [4], where it is found that higher accuracy results can be obtained by connecting the Channel Attention Module and the Spatial Attention Module in series. The Channel Attention Module is a mechanism that learns and weights the importance of information in each channel based on the correlation of features between channels. The Spatial Attention Module is a mechanism that learns and weights the importance of information in the spatial axis, allowing the extraction of important information in the spatial direction in the feature map.

3. Experimental Result and Discussion

3.1. *Evaluation*

The evaluation method is the Five-Fold Cross Validation and average accuracy, which is the average of the accuracy of each class in the five-class classification and the average of the accuracy for all data in each dataset.

Table 1 The number of data in each class

Class [kW/m^2/K]	Number
10–20	880
20–30	440
30–40	440
40–50	900
50–60	420
Total	3080

Fig. 3. Configuration of the proposed model with CBAM

(Accuracy is defined as the proportion of correct and predicted labels that match).

3.2. *Result*

The results of the proposed method using the datasets obtained from the experiments in Section 2.1 are shown in Table 2 and compared with the those of the conventional method. The accuracy in each class decreased by 1.09% in the 10–20 [kW/m^2/K] class and by 0.95% in the 30–40 [kW/m^2/K] class but increased significantly in the other classes. In particular, the accuracy in the 40–50 [kW/m^2/K] class improved by 3.38%. The average accuracy of the proposed method is 91.61% compared to 90.49% for the conventional method. That's an improvement of 1.12%.

3.3. *Discussion*

The main reason why the average accuracy was improved except for the 10–20 [kW/m^2/K] and 30–40 [kW/m^2/K] classes is that CBAM was able to extract the response of the constant-frequency component of the horizontal line, which is unique to each HTC. That allowed CBAM to maintain high accuracy even for noisy data sets. On the other hand, the inaccuracy could be attributed to the presence of various noises added during the creation of dataset, which aimed to construct a model that can be robust to noise. We have concluded that the spectrograms obtained from the experiments in Section 2.1 may not reflect the unique frequency characteristics found at each HTC. The spectrograms shown in Fig. 4

provide typical data for these classes, and we can recognize horizontal lines of constant frequency near the center of the images. On the other hand, Fig. 5 is an example of images that could not be classified correctly, showing that the features appeared in Fig. 4 are not clearly represented or are faded due to noises in Fig. 5. The CBAM mechanism may have made it more difficult to classify images like those in Fig. 5 by over-extracting features from data with typical features like those in Fig. 4.

4. Conclusion

In this paper, the incorporation of CBAM into the conventional CNN model decreased accuracy by 1.09% in the 10–20 [kW/m^2/K] class and by 0.95% in the 30–40 [kW/m^2/K] class, but significantly increased accuracy in the other classes, with the average accuracy improving by 1.12%. Future work will include increasing the number of experiments to build a CNN model that is more robust to noise, as one reason for the decrease in accuracy is the limited number of datasets. In addition, we will identify features common to each class and build a model that takes these features into account, with the aim of predicting the HTC in more detail and further improving accuracy.

Abstract

Classification of sound has its usage in various fields in today's world. In this paper we will go through the sound classification techniques for the detection of faulty machines with the help of the sound data produced by the machine. The focus is towards determining the pertinency of audio classification methods to detect faulty motors by their sounds; both in noisy and noise-free scenarios; so that the requirement of human inspection can be reduced in factories and industries. Noise reduction plays such an important role in improving accuracy of detection some researchers simulated data by adding noise for benchmarking their models. Hence noise reduction is widely used in audio classification tasks. Among various available methods, we have implemented an autoencoder for noise reduction. We have conducted the classification tasks on both noisy and denoised data using Convolutional Neural Network. Accuracy of classification on the data denoised using autoencoder is compared with the noisy ones. For classification, we used spectrogram, Mel-frequency cepstral co-efficient (MFCC) and Mel-spectrogram images. These processes yield promising results in distinguishing faulty motors by their sound.

Keywords: Faulty motor detection, autoencoder, convolutional neural network (CNN), audio classification

1. Introduction

Audio data is one of the most common multimedia types used in almost every sector of modern life throughout the past decades. The availability of audio recording devices has also been increased and the usage of audio data can be found in security surveillance systems, health monitoring systems, and various autonomous systems along with the inseparable usage in daily human life [1], [2], [3], [4]. Successful utilization of audio resources depends on the efficiency of classification (process of identification of pre-defined label for audio signals [5]), transcription, and perception of underlying contents through a bunch of transforming algorithms and machine learning approaches carried out on various sources of audio data, as in, voices, music, environmental sound, traffic sound etc. [1]. Our research aimed at distinguishing the faulty motors from the normal ones by means of the soundwave processing followed by training with convolutional neural network so that it can be used in factories to reduce the requirement for human inspection, and in preventing hazards. As the adequacy of classification often gets drastically affected by noise [6], we also have incorporated an autoencoder based noise reduction model in parallel to the classification process. CNN has many proven outcomes in the field of audio classification [7], [8], [9]. Convolutional neural networks have been used widely for classification since it has been found competent for both image classification e.g. vehicle classification [9] and sound classification [10] on various fields namely environmental sound classification (ESC) [11], animal sound classification [10], [12], vehicle classification [7], [13], emotion detection [14], violence detection [15] etc.

In this paper we will be showing results of applying Lenet-5 on image transforms of the audio signal. Lenet-5 was developed on the context of classification of images especially text [16]. However, while we can transform sound data into various image representations it can be an auspicious tool for classification of audios as well. We found approaches with applying CNN for the task of Environmental sound classification [11] and deploying Lenet for acoustic scene detection [17]. Despite the time consumption issues with large scale datasets CNNs are well suited for classification tasks within a few parameters [18]. For our research we have used Lenet-5 for classifying audios by means of transforming audios into feature images. We have used 3 types of feature-

Md Shafayet Jamil, Praveen Nuwantha Gunaratne, Hiroki Tamura

Fig. 1 Overview of faulty motor classification

images (Mel-Frequency Cepstral Coefficient, Mel-spectrogram, and Spectrogram) from both the noise-free original and smoothed (with an Autoencoder) audio chunks. Finally, we fed the classifier with both (noisy and smoothed) type of feature images separately and compared the resultant accuracy for noise association and the above mentioned 3 types of feature images as well. The process yields promising results. The whole process is shown in Fig. 1.

2. Dataset and Preprocessing

Our dataset is comprised of 890 samples of motor sounds, divided into two classes, 645 normal sound and 245 samples of abnormal sound; both are of variable length audio file in the form of '.wav' file at 48000Hz. The audio data was acquired using electronic stethoscopes. In preprocessing we split 3 seconds long chunks from the audio samples, having a length of 3 * 48000; and the samples which's lengths are less than 144000 (3 * 48000) were zero padded. Finally, each datapoint is normalized in such a way that the underlying values of the data stream contain real numbers ranging from -1.0 to 1.0 only.

3. Methodology

For classifying the uniform length audios of normal and abnormal motor sound; derived from the preprocessing; we divided the task into 2 standalone pipelines. The first one involves smoothing with autoencoder and the second one doesn't incorporate any noise reduction measure. In the later sections we have discussed these steps.

3.1. Noise reduction

Autoencoders are used for noise reduction in various audio recognition experiments [19]. An autoencoder is a composition of an encoder and a decoder block having convolutional and transpositional layers respectively. It can reconstruct the input without noise through a series of compressions and then decompressions [20]. We optimized the autoencoder model described in [20] by accompanying 4 convolutional layers and 4 transposition or deconvolutional layers as shown in Fig. 2. Also, in the transposition layers hyperbolic tangent activation (tanh) is used instead of PRelU for keeping the negative elements [21] in the resultant audios and to preserve a near-zero mean [22]. The results showing the smoothing with both types of activations are shown in Fig. 3 and Fig. 4 by superimposing the smoothed wave (yellow) onto the original one (blue).

```

Transpose (16, k=3)
Transpose (32, k=5)
Transpose (128, k=7)
Output
```

Fig. 2 Autoencoder Model

3.2. Feature extraction

The selection of features has significant influence on classification accuracies [4]. That is why we fed both the noisy and smoothened audios through a transformation process which yield 3 types of feature images- a. Spectrogram, b. Mel-spectrogram, c. Mel-frequency cepstral coefficient (MFCC). We used a Python-based library called Librosa [23] for these processing.

a. Spectrogram
Transforming one dimensional audio signal into matrix like representation makes them suitable for training with neural networks [4]. Spectrograms are such visual depictions of frequency-wise strength of an audio which can improve classification results [24]. A sample spectrogram of a 3-second-long normal motor sound is shown in Fig 5 (a).

b. Mel-spectrogram
Mel scaled spectrograms can represent the signal analogous to the human auditory system. The formula for converting f Hz into m mel is $m = 2595 \log_{10}(1 + \frac{f}{700})$ [4]. The mel-spectrogram of a 3 second sound of abnormal motor looks like Fig. 5 (b).

c. Mel-frequency cepstral coefficient (MFCC)
MFCC incorporates Discrete Cosine Transform and has a compressed representation signal [4] so it is quite useful for training audio features. We have put an MFCC image of a smoothened normal motor sound (3 second) in Fig. 5 (c).

3.3. Classification

Image classification networks also have good results on sound data [24]. So, we trained these feature images with a CNN based model Lenet-5 (shown in Fig. 6) [16] which was proposed for classifying handwritten characters with requiring low preprocessing. Our implementation of Lenet-5 has an identical structure. It has 2 convolutional layers working as feature extractors followed by 3 fully connected layers working as classifier, as it appears in Fig. 7.

Fig. 7 Structure of the implemented Lenet-5 model.

Fig. 8 Loss function of the autoencoder

4. Results

The results derived from the various experiments can be divided into 4 parts. Firstly, the performance of the autoencoder in terms of loss function (refers to Fig. 8). We have trained the autoencoder model up to 1.6% of loss using the metrics of mean squared errors (MSE), but the autoencoder model with 2.3% loss yield the best result during classification. Secondly, the straight-forward performance comparison between MFCC, Mel-spectrogram, spectrogram image-based classification of the model. Thirdly, comparison between the performance with and without using autoencoder smoothing, results of second and third steps are summarized in Table. 1. Fourthly, reviewing the impact of different dataset combinations, amounts data, and biases as shown in Table. 2. The best accuracies (%) found in these three steps are shown in Table 1 and Table 2. To put it in a nutshell, we can deduce that at least 97% accuracy could be expected from this approach in classifying 2 classes of motors (normal and abnormal) where a totally unknown type of motor sound is not present in the testing data. And as for noise reduction, it is not evident to have positive influence on classification accuracy with the current configuration of the model of the autoencoder that has been used for smoothing.

5. Conclusion

Sound classification with the help of CNN could be a feasible solution to various realistic problems especially in automation of maintenance and monitoring scenarios in large scale factories. It can reduce the need for manpower and improve Mean time to response (MTTR) by providing automated detection of faulty machines in industries. The scope of this paper could also be easily extended to other fields where a small number of classes are needed to be classified with high precision.

Table 1. Performance with and without autoencoder

Feature	With Autoencoder	Without Autoencoder
Spectrogram	98.39871898	98.71897518

Abstract

Active ankle joint orthosis is an artificial wearable device that is closely fitted to the human ankle and combines human intelligence and intentions with the powered robot joints. However, most of the existing designs have only focused on one degree of freedom (DOF) of the ankle joint: namely plantarflexion-dorsiflexion. Alternatively, a modular power-assist flexible active ankle orthosis is proposed, addressing anthropomorphic architecture of design, and supporting multiple DOFs of ankle for locomotion assistance of the physically weak individuals. The proposed ankle joint orthosis was designed with the aid of CAD tools followed by fabrication of a working model. Electrically powered systems with gear transmissions were adapted to support the principal motions during normal Gait. In parallel, the design of the control algorithm was carried out based on the EMG signals. The future advancements have been focused on developing a novel control method that provides sufficient flexibility to assist a wide variety of lower-limb motions.

Keywords: Active ankle orthoses, power-assist robots, anthropomorphic design, joint axes mapping, rehabilitation

1. Introduction

Every human being would prefer to spend their entire lifetime as an independent individual without becoming dependent on others for locomotion. According to statistics around the globe, the elderly population exceeds 10% of the total population and conversely, the number of people suffering from neurological or muscular disorders is on the rise. As such, the medical industry has shown a growing interest in using exoskeleton robots for restoring patients' mobility and to alleviate health care issues arising from locomotion difficulties.

With the continuous development in biomedical engineering field over the past few decades, the robotic orthosis devices have been used for many different applications. The active orthosis/ robotic exoskeleton is an artificial wearable device that is powered by the means of electric motors, pneumatics, hydraulics, or linear actuation methods. In the current market, active orthoses are classified as upper extremity systems, lower-extremity systems, and full-body systems. The lower extremity exoskeletons (LEE) are designed to support anatomical functions of different joints of the lower extremity. In general, hip, knee and ankle joints have seven degrees of freedom (DOF) per limb. The LEEs are primarily developed for three main types of applications such as gait rehabilitation (i.e. helping patients with mobility disorders in the rehabilitation of musculoskeletal strength, motor control, and gait), human locomotion assistance (i.e. targeted at paralyzed patients who have lost motor and sensor function in their lower limbs) and human power augmentation (i.e. enhance human strength and endurance during locomotion and enable individuals to perform tasks that they cannot easily perform by themselves).

The ankle joint complex is concerned, encompassing the lower leg and foot, serves as the crucial link facilitating interaction between the lower limb and the ground. Especially the essential aspect for activities like walking and daily tasks. Despite experiencing significant compressive and shear forces during walking, the ankle's robust structure provides a high level of stability. The key ankle joint complex movements include sagittal plane, plantarflexion-dorsiflexion, transverse plane, abduction-adduction, and frontal plane, inversion-eversion [1].

While commonly referred to as the 'ankle joint,' the foot's movement is facilitated by several articulations. The ankle joint complex comprises the subtalar joint (talocalcaneal), tibiotalar joint (talocrural), and transverse-tarsal joint (talocalcaneonavicular) [1]. The subtalar joint's geometry permits ankle inversion and eversion, with a primary role in these movements. Although other motions are possible, the bulk of foot inversion and eversion occurs here. The talocrural joint acts as a hinge, mainly contributing to plantar- and

dorsiflexion. The transverse tarsal joint is considered part of the functional unit with the subtalar joint, sharing a common axis, and contributing to foot inversion-eversion. The combining motions at the subtalar and talocrural joints results in three-dimensional supination and pronation [2], [3].

While some suggest the talocrural joint is multi-axial due to internal rotation during dorsiflexion and external rotation during plantarflexion, evidence indicates it may be uniaxial. The observed simultaneous motions are attributed to its oblique axis. Similar to the talocrural joint, the subtalar joint has an oblique axis, contributing to multiple motions during plantar- and dorsiflexion, leading to pronation and supination [4].

In the past, there was a traditional belief that dorsiflexion and plantarflexion were exclusively associated with the motion of the talocrural joint, while inversion and eversion were thought to occur solely at the subtalar joint. However, recent perspectives have rejected the idea of completely segregating these motions to each joint. Although the majority of plantar and dorsiflexion is still attributed to the talocrural joint, there is now acknowledgment that a few degrees of these motions also involve the subtalar joint [5].

Despite some of the research efforts aimed at creating active ankle orthoses to aid human movements, challenges persist in effectively supporting natural human motions. These challenges revolve around the goal of enabling limbs to move freely and comfortably, particularly in relation to the corresponding oblique axes.

2. Design Considerations

Designing a device that will effectively interact with the human dynamic conditions is a difficult task to accomplish, especially at the distal end of limbs. Gait analysis can be used as an objective tool for quantifying motion of lower limb joints and forces that act upon these joints. However, gait analysis cannot separate it joint wise due to the major limitation of accurately measuring talus motion using skin-mounted markers. Fig. 1 depicts example gait analysis data of the ankle joint complex kinematics [6]. During a normal gait cycle, the stance phase begins at heel strike, where the dorsiflexors are eccentrically contracting to lower the foot to the ground based on the sagittal motion of the ankle. Then the ankle moves from plantarflexion to dorsiflexion during which the shank rotates forward around the ankle and after that the foot rotates around the forefoot phase continuing until maximum plantarflexion (approximately 14°) being achieved at toe-off. In the swing phase of walking, the ankle undergoes dorsiflexion, allowing the foot to lift off the ground and then transitioning to a slight plantarflexion upon heel strike. Simultaneously, there is motion at the subtalar joint, involving around 15° of

inversion and eversion to complement this flexion movement [7].

As illustrated in Fig. 2, the anatomical axes of talocrural and subtalar joints are placed in an oblique sense that cause foot to move across all three planes allowing pronation and supination to occur during walking [6], [8]. Hence, constraining motions to a single plane can lead to abnormal joint movements, poor muscle recruitment and increasing overall energetic cost. Therefore, it is essential to facilitate multiple DOF to improve exoskeleton performance by active or passive means.

Fig. 4. The axis of rotation and osteo-kinematics at the plantar-/dorsiflexion assembly a) component axis (red) [8]; b) developed plantar-/dorsiflexion assembly.

Fig. 5. The axis of rotation and osteo-kinematics at the inv-/ eversion assembly a) component axis(red) [8]; b) developed inv-/ eversion assembly.

3. Mechanical Design

This flexible active ankle joint orthosis is a multipurpose robotic ankle exoskeleton that can perform rehabilitation exercises as well as locomotion assistance. It is worn as a bilateral system and supports all three DOF of the ankle.

The two significant DOF, namely, plantarflexion-dorsiflexion and inversion-eversion are externally powered using electrical actuators and remaining DOF, namely, internal- external rotation is passively supported. In addition, with the intention of maximizing user compatibility and performance, the mechanisms proposed in the mechanical design have compatible joint axes for each DOF. The CAD model of the flexible active ankle joint orthosis is shown in Fig. 3.

3.1. Plantarflexion/ dorsiflexion assembly

The movement of the ankle predominantly takes place in the sagittal plane, where plantarflexion and dorsiflexion are mainly observed at the talocrural joint. Various research studies have suggested a range of motion (ROM) in the sagittal plane, typically falling between 65° and 75°. This encompasses a span from 10° to 20° of dorsiflexion to 40°–55° of plantarflexion [9]. Here the plantarflexion-dorsiflexion axis of the suggested ankle joint brace is accurately aligned with the talocrural axis of the natural joint. Fig. 4 illustrates the plantar-/dorsiflexion assembly with the component axis.

3.2. Inversion/ eversion assembly

In the frontal plane, the complete range of motion is around 35°, consisting of 23° of inversion and 12° of eversion [10]. The axis of inversion-eversion in the flexible active ankle joint brace is accurately aligned with the subtalar axis of the natural joint. The assembly indicated in Fig. 5 has been mechanically formed and positioned normal to the subtalar axis of ankle.

3.3. Internal/ external rotation assembly

The internal/external rotation mechanism is crafted and adjusted to closely align with the ankle's axis of rotation. A stabilizer system is employed to maintain the assembly in its neutral position.

4. Prototype Development

The prototype incorporates tri-planar motion with oblique axes. The spacing between the two motion axes (sagittal and frontal plane motion) is adaptable to accommodate the wearer, making it one of the most human-like structures among the initial design concepts. Following multiple manufacturing processes at the production facility, the final prototype was successfully assembled. Fig. 6 illustrates the conclusive form of the active ankle orthosis device, while Table 1 provides detailed specifications outlining the design features of the developed prototype.

Fig. 6. Prototype of the proposed mechanical structure

Table 1. Design specifications of the flexible active ankle joint orthosis

Characteristic	Plantar-Dorsiflexion	Inversion-Eversion
ROM (Degree)	55/20	35/25
Actuation method	Motor driven	Motor driven
Transmission	Bevel and spur gear system	Spur gear system
Max. torque output (Nm)	22.3	2.3

5. Conclusion

The distinctive feature of the design for the flexible active ankle joint brace lies in its capability to meet the functional and ergonomic demands of the natural ankle joint. This is accomplished through precise alignment of the orthosis axes of rotation with the oblique axes of rotation found in the talocrural and subtalar joints of the ankle. The innovative mechanism, inclusive of the drive units, is situated anteriorly to the shank and foot segments. The proposed active ankle brace is easily adaptable for performing ankle rehabilitation exercises, serving as a robotic therapy module to aid paralyzed individuals in regaining or enhancing their functional mobility, or assisting those with physical weakness in their motion. Future work will involve creating an EMG-based controller for the flexible active ankle joint orthosis. This aims to enable real-time control by accurately anticipating the patient's intended motion through precise predictive capabilities.

Abstract

Lumbar region is susceptible to strain and stress due to various physical activities and occupational task. To study about the lumbar burden, researchers have developed many tools but most of existing design can only use static imaging or doesn't provide real-time update. The proposed system records and examines the change of body posture in real time by utilizing the capabilities of stereoscope cameras. By using MediaPipe algorithms, 2D key-points representing body joint can be extracted from images. Afterward, using the Direct Linear Transform (DLT) the corresponding 3D key-points can be calculated using obtained 2D key-points. With the 3D key-points the body angles can be computed and used to calculate the wight of the lumbar burden using JACK calculation. Finally, the proposed system reached to its aim to study about lumbar burden and adjust the person needs in real-time.

Keywords: Lumbar burden, real-time biomechanical analysis, computer vision

1. Introduction

The lumbar region of the spine, commonly referred to as the lower back, is susceptible to strain and stress due to various physical activities and occupational tasks. Around 577.0 million people worldwide, or approx. 7.5% of the total population, were projected to have low back pain at any given time in 2017, and that number is continuing to rise [1]. This incident occurs due to doing the same activities that affect the lumbar region over a long period of time. Examples of activities that cause this include agricultural work, nursing, construction, etc. Therefore, this needs to be monitored and corrected before it gets exaggerated. One of the consequences that can occur due to ignoring pain in the lumbar region is disability [2], [3].

Therefore, many researchers are trying to monitor and improve body movements with various approaches. Among these methods, the approach that is often to be seen is using smartphones and Kinect sensors [4], [5], [6], [7], [8]. The approaches have already taken their respective advantages. However, when it is applied on real scenarios, such approaches demand several additional features. For example, smartphone-based approach, it employs gyro and accelerator sensors embedded on the smartphone to measure changes in body inclination [4]. This change in body inclination will then be used to estimate the lumbar burden that occurs on the body and classify the movements the body makes [5]. On the other hand, the Kinect sensor [6-8] uses a camera to capture human images and a depth sensor to measure the depth of key-points captured by the camera. This data will then be used to obtain 3-dimensional body key points. Afterward, the 3D key-points are being used to estimate the body posture, angles, and the biomechanical of the human body. Each approach has its own advantages and disadvantages. for example, smartphones can be used in all conditions. However, based on the measurement criteria, several devices need to be attached to the body and cannot be monitored in real-time. As for Kinect sensor, the sensor can find out various information on parts of the body at once, but Kinect sensor cannot be used under sunlight.

The proposed system is designed for real-time biomechanical analysis of the body, considering the use in different environmental conditions. This research employs a camera stereoscope to analyze the body and carry out comprehensive calculations in order to identify the lumbar burden in real time.

Taufik Hidayat Soesilo, Praveen Nuwantha Gunaratne, Hiroki Tamura

allows the system to effectively detect movements within a 10-meter range while minimizing noise interference.

2.2. *Data Acquisition*

Data collection is carried out according to the flowchart depicts Fig.2. In order to carry out biomechanical analysis, the system needs to obtain 3D key-points so that monitoring of the desired body parts can be obtained [9]. Initially, the camera captures an image of the subject positioned in front of it. Then the obtained image undergoes processing via the MediaPipe algorithm to extract 2D key-points. Given that the images are derived from two distinct perspectives through two cameras, a pair of key-point perspectives right and left cameras, illustrated in Fig.3. To achieve 3D key-points, some calculations are conducted using DLT method. However, calibration is needed to derive the translation and rotation parameters of the camera in order to carry out DLT calculation. The obtained 3D key-points serve as foundational data for extracting biomechanical insights from the body. Afterwards, in order to compute lumbar burden, it's necessary to deepen the understanding of body posture, one of which is through the body angle. This angle is obtained through vector calculations utilizing the known 3D key-points coordinates. This process involves presenting the 3D key-points within a three-dimensional environment, as visualized in Fig.4.

Fig. 1. Camera setup

Fig. 2. System Flowchart

Fig. 3. 2D key-points from left and right cameras

2. Methodology

2.1. System setup

The study employed a stereoscope system comprising two cameras to investigate the activities. The cameras were strategically placed on a 1-meter-high camera support with a 1-meter separation, as depicted in Fig. 1. Distance between the two cameras was carefully addressed, as overly close placement could constrain the view, leading to more noise and less precision. Use of stereoscopic approach creates a three-dimensional image, and it leads to a comprehensive understanding of complex movement patterns involved in walking and the factors that influence them. Further, this configuration

Fig. 4. 3D key-points

2.3. *Lumbar burden calculation*

The estimation of lumbar burden involves the computation of body posture angles, as illustrated in Fig.5. Calculations are performed according to formulas Eq. 1, 2, 3, 4, 5, 6.

$$A = (x_1, y_1, z_1) \tag{1}$$

$$B = (x_2, y_2, z_2) \tag{2}$$

$$C = (x_3, y_3, z_3) \tag{3}$$

$$a = (x_a, y_a, z_a) = ((x_1 - x_2), (y_1 - y_2), (z_1 - z_2)) \tag{4}$$

$$b = (x_b, y_b, z_b) = ((x_3 - x_2), (y_3 - y_2), (z_3 - z_2)) \tag{5}$$

$$\theta = \cos^{-1}\left(\frac{(x_a x_b + y_a y_b + z_a z_b)}{\left(\sqrt{x_a^2 + y_a^2 + z_a^2} \cdot \sqrt{x_b^2 + y_b^2 + z_b^2}\right)}\right) \tag{6}$$

This angle calculation can then be used to carry out biomechanical analysis by applying JACK calculations. The JACK computation demands data on body posture (such as body angle), subject-specific information such as height and weight, and the weight of the object intended for lifting. Fig.6 represents the coordinates involved, and Table 1 provides a detailed description of the corresponding angles denoted by its abbreviations.

In this study, the height of the participated subject was 160 cm with a body weight of 50 kg, with different load settings of objects, ranging from 0 kg (absence of a load) to 2.5 kg and 5 kg. The proposed system records the computed results in an Excel file, facilitating comprehensive post-analysis.

3. Results and Discussion

In order to know the effect of load on lumbar burden, a comparison is needed by providing different loads. In recent research, the load given was divided into 3 loads, namely 0 kg or no load, 2.5 kg load, and 5 kg load. The movement carried out by the subject is the same movement as shown in Fig 7. but the system simulates the target of lifting a different load. The results of the lumbar burden analysis can be seen in the Fig. 8.

Based on the results, it can be observed that the system can analyze the lumbar burden according to the movements made by the subject. Moreover, the load that occurs in the lumbar region is directly proportional with the load that being lifted. The maximum load that occurs in the lumbar region when the subject was at the lowest point and tries to lift the weight; 2098 N for 0 kg, 2843 N for 2.5 kg, and 3612 N for 5 kg (Table 2). Further, minimum, and average values can also be found in Table 2.

Fig.8. Lumbar burden analysis

Table 2. Lumbar burden Max, Min, and Average

Load (kg)	Lumbar Burden (N)		
	Max	Min	Average
0	2098	790	1655
2.5	2843	1299	2327
5	3612	1770	2974

4. Conclusion

Based on the results it can be concluded that the proposed system can carry out biomechanical analysis to determine the lumbar burden effectively. The procedure was executed in real-time, also enabling monitoring of the system within any occupational settings. Further, the system demonstrated a robust performance under sunlight, showing its adaptability to diverse environmental conditions.

For future work, the observed results will undergo a validation process using an established system to assess the efficacy of the developed system. Furthermore, as a system constraint, the current study is limited to the detection of a single person. Therefore, in order to conduct real-time analysis of lumbar burden for multiple persons, the system requires further development.

Abstract

The purpose of this research is to clarify the cause of failure and to improve the accuracy of abnormality detection by predicting the noise added to the machine tool from the results of the convolutional autoencoder. Data obtained from an acceleration sensor mounted on the machine tool are reconstructed using a convolutional autoencoder, and the average absolute error is calculated. The maximum value of the average absolute error of the training data is used as the threshold value for abnormality detection. Multiple simulated data with different amplitude values based on a composite sine wave with a specific frequency and random numbers within a specified amplitude value were verified. In this paper, the characteristics of each type of noise and the parameters of the optimal model were examined from error rate and error distribution.

Keywords: machine tools, deep learning, anomaly detection, convolutional autoencoder, noises

1. Introduction

In factories, machine failures can be categorized as sudden breakdowns and deteriorating faults [1]. Preventing failures proactively during maintenance is exceptionally challenging, and excessive maintenance or machine breakdowns can result in significant losses for companies. Examples include production downtime leading to manufacturing time losses, increased labor costs due to stoppages, and the generation of defective products. The purpose of this study is to reduce losses and enhance productivity by providing maintenance timing suggestions and early detection of abnormalities in machining equipment.

In collaboration with businesses, this research involved installing acceleration sensors on machining equipment used in semiconductor manufacturing. The data acquired from the sensors is in the form of continuous time-series data. Since explicit abnormal judgments are significantly fewer than normal data, it is necessary to perform anomaly detection without explicit labels for normal and abnormal data. Consequently, anomaly detection was conducted using a convolutional autoencoder [2].

Initially, the machine with the attached sensor experienced a breakdown, and there were no prospects for its reprocessing. Subsequently, the sensor was transferred to a similar type of machining equipment. After the transfer, only normal data was obtained from the factory's machines. As abnormal data obtained before the transfer exhibited specific frequency components, simulated data resembling those characteristics was generated. Parameters for multiple models were created based on different numbers of training data, and abnormal detection was verified by introducing specific noise to the training data [3] to assess how much noise is required to detect anomalies. Moreover, considering the possibility of identifying malfunctioning machine components by pinpointing the noise, we investigated the distribution of reconstruction errors.

2. Proposed method

The proposed method consists of two steps: Learning and parameter saving, and Testing validation.

2.1. Learning and parameter saving

Initially, a convolutional autoencoder was created by referencing the Keras tutorial [4] for parameter

Yuta Sumoto, Praveen Nuwantha Gunaratne, Hiroki Tamura

Fig. 1. Flowchart of learning and parameter saving

inheritance (Fig. 1). The training data was standardized using the mean and standard deviation of the data. A sequence with a timestep of 100 was generated using a sequential model, and training was conducted. A callback was implemented to halt training if the validation loss did not improve for five consecutive epochs. The hyperparameters were set as follows: epochs = 5, batch size = 4096, and validation split = 0.1.

After training, the parameters were saved, and the model was used to reconstruct the training data. The absolute mean error between the actual data and the reconstructed data for each sequence was calculated, and the maximum value was set as the threshold for testing.

2.2. Testing validation

The process involves extracting one CSV file at a time from the dataset. The training data is then standardized using the mean and standard deviation of the respective file. Test data is reconstructed using the specified model parameters. For each sequence, the absolute mean error between the test data and the reconstructed data is calculated. Instances where this error exceeds the predefined threshold are considered anomalies. (Fig. 2)

3. Experiment

The sampling frequency of the experimental data was 500Hz, and each file contained 600,000 data points (equivalent to 20 minutes) with columns for time (s), x

(m/s²), y (m/s²), and z (m/s²). For this study, only the time (s) and x (m/s²) columns were utilized. To assess the accuracy of each parameter, twelve CSV files were utilized for training. The process depicted in Figure 1 was repeated twelve times, and the resulting parameters were saved. The model parameters were denoted as model_1, model_2, ..., model_n corresponding to the number of training data (n). With an epoch count of 5 per training, a total of 60 training iterations were conducted as the process was repeated 12 times. (Fig. 3).

Analyzing the frequency components of normal and abnormal data obtained from the machine before the transfer revealed that normal data covers a wide frequency range, whereas abnormal data is concentrated in the high-frequency band. The results of the FFT (Fast Fourier Transform) applied to normal and abnormal data are shown in Fig. 4.

Based on these results, a composite wave of sine waves with specific frequencies was added to the initial training data to create simulated abnormal data. The added composite waves consisted of low frequencies at 40Hz and 90Hz, and high frequencies at 410Hz and 460Hz.

Fig. 2. Flowchart of testing validation

Fig. 3. Loss function

Fig. 4. Frequency analysis results of normal and abnormal data

Additionally, simulated data was generated by adding random numbers within specified maximum and minimum values. The specified absolute values for amplitude and random numbers ranged from 0.1 to a maximum of 0.8.

3.1. Testing validation

Test the three types of simulated data using twelve parameters (model_n) with varying amounts of training data. Based on the results, examine the optimal amount of training for anomaly detection.

3.2. Testing validation

Detect the three types of simulated data using the best parameters. Based on the results, evaluate how well anomalies are detected when various levels of noise are added and investigate the threshold for anomaly detection.

3.3. Testing validation

When the three types exhibit the same error rate, illustrate the distribution of the mean absolute errors between the actual data and the reconstructed data for each type. Compare the mean absolute errors when the

error is approximately 10% and investigate whether there are any distinctive features in the distribution due to the added noise.

4. Results
4.1. Parameter Comparison

The order of accuracy in detecting anomalies for abnormal data is as follows:
- Low-frequency components: model_3, model_5, model_11, model_2 (Fig. 5)
- Random noise: model_3, model_11, model_12, model_5 (Fig. 6)
- High-frequency components: model_11, model_12, model_10, model_3 (Fig. 7)

For data with added low-frequency components and random noise, the parameters of Model_3, trained using three datasets, exhibited the most effective anomaly detection. Regarding data with added high-frequency component noise, Model_11, trained using eleven datasets, demonstrated the most proficient anomaly detection.

Fig. 5. Parameter comparison (Low-Frequency component)

Fig. 6. Parameter Comparison (Random Data)

Yuta Sumoto, Praveen Nuwantha Gunaratne, Hiroki Tamura

Fig. 7. Parameter Comparison (High-Frequency Component)

Fig. 8. Comparison of Model_3

4.2. Simulated Data Comparison

Based on the results from 4.1, a comparison of the three types of simulated data was performed using model_3 (Fig. 8). For all three types, errors reached 10% when the additional amplitude and specified absolute values ranged from 0.3 to 0.4. Additionally, it was observed that errors sharply increased for values equal to or greater than 0.4.

4.3. Noise Identification

When the error is approximately 10%, the distribution of actual data and reconstructed data for the three types is shown. Additionally, when the error is approximately 10%, the amplitude of the synthesized wave for low-frequency is 0.325, for high-frequency is 0.35, and the specified absolute value for random data is 0.3 (Fig. 9, Fig. 10 and Fig. 11). Differences in items such as mean, median, standard deviation, minimum, 25th percentile, 75th percentile, and maximum, based on the obtained basic statistical information, are on the order of one-thousandth. It can be observed from the distribution that when the anomaly rate is the same, there is little difference.

5. Conclusion

In the experimental data, step count, and hyperparameters employed in this study, the parameters of model_3 and model_11 demonstrated high accuracy in anomaly detection. From this, it was found that under the current conditions, abnormalities could be detected with high accuracy if three or 11 or more pieces of normal data, each with a total of 600,000 pieces of data, were trained.

From experiments using parameters trained three times, it was observed that, irrespective of whether the noise is periodic, high-frequency, or low-frequency, anomalies were detected when noise with an amplitude value or specified absolute value exceeding 0.3 was introduced. While it was not possible to identify the characteristics of the noise from the distribution of reconstruction errors, it is possible to estimate the amplitude of the added noise from the error percentages.

Currently, data is being measured in the factory and saved in specific files. Processing is set to analyze the second-to-last CSV file every 20 minutes. If anomalies are detected above 10%, the number 1 is added to the array; if below 10%, the number 0 is added. An alert is triggered when anomalies are detected continuously three times, and the array is output daily.

Abstract

In recent years, many researchers have focused on enhancing the current situation of home healthcare systems. In this paper, we developed a system that uses AI to quickly determine whether auscultation sounds are normal or not. In our analysis, heart sounds were imaged, and their abnormalities were identified using machine learning tools. The proposed approach uses a Yolo_v7 model-based anomaly detection and the Wavelet Transform was employed to analyze the acquired heart sound data. Proposed system resulted with an 90% accuracy rate or over on the basis of 5 seconds of heartbeat data, in various recording environments.

Keywords: Auscultation sounds, abnormality identification, YOLO_v7, Wavelet Transform

1. Introduction

In today's society, the demand for home medical care is rapidly increasing due to the aging population. However, home medical care requires a physician to visit the patient in person to make a diagnosis, which poses problems such as securing time for physicians. A possible solution to this problem would be to make medical equipment readily accessible to ordinary households, enabling individuals to personally use and evaluate the effectiveness of the equipment. However, as proficiency in medical knowledge is crucial for operating medical equipment, the current situation hinders its widespread utilization. To identify an approach suitable for the general public, eliminating the necessity for a visit to a physician or medical expertise, our team has attempted to create a system capable of swiftly assessing the normality of heart sound data obtained through auscultation.

In this paper, machine learning tools were employed to analyze the heart sound data. Heart sound data from diverse recording environments was utilized in this paper. The acquired heart sound data was transformed into images through wavelet transforms, and the yolov7 model was employed for abnormality detection. Additionally, a *k*-fold approach was applied to a limited dataset to enhance accuracy. The findings revealed a 90% accuracy rate based on 5 seconds of heartbeat data. This paper compares Yolo model with different durations of phonocardiography data and elucidates strategies for achieving higher confidence scores.

2. Methodology

Initially the Speech data, illustrating frequency features of heart sounds, went through wavelet transformation at various intervals to generate images. Afterwards, the transformed images were utilized to train multiple Yolo models, facilitating a comparative analysis to identify the superior model. Here, the assessment was conducted based on confidence scores assigned to the normal and abnormal classes. For the Yolo training data set, the images were divided into three parts: training data, valid data, and test data. Table 1 illustrates the learning environment used in this analysis, and the Fig. 1 depicts the experimental procedure in brief.

3. Experiment

In the section 3.1, the ratio of training data to validation data and test data was set at 7:2:1 in the Yolo model. The subsequent phases, starting from section 3.2, the ratio was adjusted to 6:2:2. The offline datasets used were heart sound data auscultated by Sono-Support clinical

Riku Nakashima, Praveen Nuwantha Gunaratne, Hiroki Tamura

technologists (dataA – 10 healthy subjects and 40 sick subjects), heart sound data from former laboratory members (dataC - 23 healthy subjects), and heart sound data of few laboratory members (jibun - 2 healthy subjects). The data from physioNet (dataB~dataB_F), comprising 2558 healthy subjects, 665 sick subjects was used as online data [1].

Table 1. Learning environment of the YOLO model

Learning environment	
Memory	32GB
CPU	Intel(R) Core(TM) i7 – 10700 CPU@2.90GHz
GPU	NVIDIA GeForce RTX 3070
CUDA	11.2

Fig. 1. Experimental Procedure

Fig. 2, 3, and 4 illustrate the images generated by the wavelet transform used in this paper. The vertical axis represents frequency, the horizontal axis signifies a specific time width of the experimental data, and the color bar indicates amplitude. The wavelet transform is output as an image after being processed using the Morlet function with MATLAB. A one second shift was used to increase the number of data by shifting the image by few data. Due to the variation in the number of seconds in heartbeat, the number of images produced varies as well. The *k*-fold method involves creating *k* splits of the training data images and training them *k* times (*k*=5 in this case). The splits were randomly divided into 8 for the training data and 2 for the validation data. Those with a confidence score of less than 0.1 between normal and abnormal were excluded due to their classification falling within gray zones as lacking in reliability. The formulas for calculating the percentage of correct answers Eq. (1) and the percentage of target hits Eq. (2) are presented below.

$$Percentage\ of\ correct\ answers = \frac{Number\ of\ correct\ images}{Total\ number\ of\ images} \times 100 \quad (1)$$

$$Percentage\ of\ target\ hits = \frac{true\ positive}{true\ positive + false\ negative} \times 100 \quad (2)$$

3.1. Experiment 1

In experiment 1, multiple Yolo models (Yolo_v2, Yolo_v5, and Yolo_v7) were employed to jointly train normal and abnormal heart sound images and assess the superiority of each model.[2], [3].

3.2. Experiment 2

Multiple Yolo models with favorable confidence scores were employed, and machine learning was conducted on each of them for varying durations (3, 5, and 10 seconds), comparing their performance in terms of the percentage of correct responses. However, a 10-second wavelet transform could not be generated due to insufficient seconds in imaging dataB_B. Fig. 3, 4 was generated by performing a wavelet transform on a single speech sample, cut out for a fixed time width of 1 second intervals and converting it to an image.

Fig. 2. Wavelet transform 3 sec.

Fig. 3. Wavelet transform 5 sec.

3.3. *Experiment 3*

In Experiment 3, the accuracy of the 5-second wavelet transforms, identified as the best on real data in Section 3.2. was enhanced by employing the *k*-fold method. This method involved covering a small data set and increasing the number of training patterns.

Fig. 4. Wavelet transform 10 sec.

4. Results
4.1. Results of Experiment 1

The correctness of machine learning responses for each Yolo was determined based on the agreement between the label and the test judgment. A comparison of the mean confidence scores of the correct answers revealed the superiority of Yolo_v7, as illustrated in Table 2.

Table 2. Confidence score results of each YOLO

	Yolov2	Yolov5	Yolov7
Confidence Score	0.957	0.973	0.997

4.2. Results of Experiment 2

Machine learning with Yolo_v7 was carried forward, as it came out as the best among the other Yolo models based on the results of Section 4.1. Consequently, the correct response rates were as follows: 3 seconds, 90.6% for normal and 89.2% for abnormal (as shown in Table 3); 5 seconds, 86.8% for normal and 90.6% for abnormal (Table 4); and in 10 seconds, 68.7% for normal and 94.4% for abnormal (Table 5). These three results demonstrate that the 3-second cutout yields the highest average correct response rate. However, upon comparing with actual data (dataA), the 5-second wavelet transform exhibits the best results. While deciding which result to adopt presents a doubt, move forwarded with k-fold using the 5-second wavelet transform, as it yields the best results on real data.

4.3. Results of Experiment 3

The outcomes obtained through k-fold training on a 5-second wavelet transform revealed accuracy rates of 90.3% on normal and 93.6% on abnormal, which are over 90%.

5. Conclusion

Yolo_v7 enhanced the accuracy to 90% in diverse recording environments, achieved by optimizing a

limited dataset and enhancing learning patterns through k-fold techniques. Future research will focus on strategies to enhance accuracy by expanding the dataset. Further, considering the satisfactory average accuracy of the 3-second wavelet transform, experiment with k-fold on the 3-second version will be continued.

Abstract

The radiation belt, where the high-energy particles are predominant in near earth space from the low earth orbit (LEO) to the geostationary orbit (GEO), sometimes causes satellite malfunction. Therefore, the objective of this study is to predict the high-energy electron flux at GEO with the energy above 2 MeV after 24 hours with higher accuracy for the safety satellite operation in terms of the space weather science. In this study the various kinds of solar wind data from satellite observations and ground geomagnetic observation data in 1999 were used for the Recurrent Neural Network (RNN). Prediction results were evaluated by the prediction efficiency, which is derived from both predicted and actual variation data. As a result, the prediction using combined data of solar wind and geomagnetic data shows highest prediction efficiency of 0.72.

Keywords: Neural network, Spacecraft, High-energy electron flux

1. Introduction

The region in space where high-energy particles are concentrated is called the radiation belt, and the electrons that exist there are called radiation belt electrons. The radiation belts consist of the inner and outer belts. In particular, the outer belt sometimes extends into geostationary orbit, where many satellites are operated [1], [2], [3]. High-energy electrons with energies above MeV are known to cause satellite malfunctions and failures [4], [5].

So far, several studies have been conducted to predict fluctuations in high-energy electron flux by using only ground-based observation data as input parameters or combining ground-based observation data with solar wind data observed in space [6]. Fukada *et al.* [7] used only ground-based AE index and D_{st} index data during magnetic storms as input data and made predictions using a neural network. In their study, predictions were made from 2 to 12 hours later, and the prediction efficiency was as high as 0.71. However, since only the case of magnetic storms was used as training data, it was not practical because it could not predict the starting point where the high-energy electron flux fluctuates significantly. Nakamura *et al.* [8] used seven solar wind data as input data: V_{sw}: solar wind velocity, Bx: solar direction component of solar wind magnetic field data, B_z: north-south component of solar wind magnetic field data, E: electron flux with energy above 2 [MeV], and AE index, D_{st} index, and UT: universal standard time as ground observation data, The same neural network was used to make predictions. In their study, data from 1999 to 2006 were used to predict the energetic electron flux 24 hours later by combining space-based and ground-based data, and the prediction efficiency was 0.61. There is room to further improve this prediction efficiency by the number of input data and the way they are combined.

In this study, with the aim of further improving the prediction accuracy, we use various combinations of ground-based observation data and solar wind data as input data to predict the energetic electron flux over the next 24 hours. The results are also evaluated using prediction efficiency (PE).

2. Dataset

In this study, solar wind velocity (V_{sw}), north-south component of the solar wind magnetic field (B_z), and high-energy (>2 MeV) electron flux (E), which are solar wind data, and AE index, AU index, AL index, D_{st} index, and Universal Time (UT), which are ground-based observation data, as input parameters. AE, AU and AL indices are used as a proxy of the Auroral activity, and

Dst index apparently represents the intensity of the Magnetic storms. We also used Akasofu ε parameter calculated by Eq. (1) [9], which efficiently represent a total energy transported from the solar wind into magnetosphere. V_{sw} and B_z were obtained from the solar wind probe ACE, which was acquired from Omni Web, and E was obtained from the geostationary satellite GOES10, which was acquired from the Space Weather Prediction Center (NOAA) of the U.S. National Oceanic and Atmospheric Administration. The AE, AU and AL indices, and D_{st} index, which are ground-based observation data, were obtained from the Kyoto University Geomagnetic World Data Analysis Center.

In this study, one year of data in 1999 was used, of which 80% was for training data and 20% was for test data. The respective parameters are shown in Fig. 2-1.

$$\text{Akasofu } \varepsilon = V_{sw} \times |B|^2 \times f(t) \times (7Re)^2 \quad (1)$$

Re：Earth radius

B：Solar wind magnetic field average

where $f(t) = \left\{ \sin\left(\frac{t}{2}\right) \right\}^4$, and the value of t is determined by Bz using the following equation.

$$B_z > 0 \quad t = \arctan \left| \frac{B_y}{B_z} \right|$$

$$B_z < 0 \quad t = \pi - \arctan \left| \frac{B_y}{B_z} \right|$$

Fig.2-1 Data for each parameter in 1999

Fig.2-1 shows that the temporal variations of solar wind parameters are basically correlated with that of the high-energy electron flux. However, in the short time-scales, the relationship is not necessarily a one-to-one correspondence, but rather a mixture of correlated and uncorrelated portions, indicating a complex relationship among various parameters.

3. Recurrent Neural Network (RNN)

Neural networks are systems that mimic the mechanisms of the human brain in order to perform processes such as recognition, memory, and judgment on a computer. There are two main types of neural networks: supervised learning and unsupervised learning, and supervised learning is used in this study. Supervised learning is a learning method in which an input signal is given and the output signal is repeatedly compared with a teacher signal, and the coupling loadings of each neuron are modified to reduce the error and adapt to a given problem [10].

In this study, a recurrent neural network (RNN) was employed to learn and predict the data. Here, RNN is a neural network that recursively repeats learning in each unit and is suitable for use on continuous data, as shown in Fig.3-1.

Fig.3-1 Structure of RNN

4. Results

In this study, predictions were made for various combinations of parameters as shown in Table 4-1, and the results were evaluated using the prediction efficiency (PE) shown in Eq. (2),

$$PE = 1 - \frac{MSE}{VAR} \quad (2)$$
$$MSE = \frac{1}{N} \sum_{i=1}^{N} (f_i - x_i)^2$$
$$VAR = \frac{1}{N} \sum_{i=1}^{N} (x_i - \bar{x})^2$$
$$\bar{x} = \frac{1}{N} \sum_{i=1}^{N} x_i$$

where x_i in each equation is the actual observed value and f_i is the predicted value.

Predictions were made five times for each epoch in each case. The results for each case are shown in Fig.4-1 to Fig.4-5. The horizontal axis is the number of epochs, the vertical axis is PE, and the average value of the five predictions in each epoch is shown as a dot.

Table 4-1 Input data for each forecast

Case 1	V_{sw}, E, B_z, D_{st} index, AE index
Case 2	V_{sw}, E, B_z, D_{st} index, AE index, UT
Case 3	V_{sw}, E, D_{st} index, AEindex, Akasofu ε
Case 4	V_{sw}, E, B_z, D_{st} index, AU index, AL index
Case 5	V_{sw}, E, B_z, D_{st} index, AU index,

Fig.4-1 PE for case 1

Fig.4-2 PE for case 2

Fig.4-3 PE for case 3

Fig.4-4 PE for case 4

Fig.4-5 PE for case 5

From Fig.4-1 to Fig.4-5, it seems that there is no correlation between the number of epochs and prediction efficiency between epochs 50 and 100.

Next, Table 4-2 shows the average prediction efficiencies obtained from the results for all epochs in each case.

Table 4-2 Comparison of average PE in each case

Case	1	2	3	4	5
Average PE	0.61	0.51	0.61	0.57	0.57

Table 4-2 indicates that Case 2, in which UT (the proxy of the satellite position) was added as input data to Case 1, shows the worst PE, while the case 1 shows the highest PE. On the other hand, Case 3, in which Akasofu ε (the total energy inflow from the solar wind) was added, had the same PE as Case 1.

Case 1 with an epoch number of 70, PE shows the highest value of 0.72. The prediction results for this case are shown in Fig.4-6 and Fig.4-7.

Fig.4-6 Comparison of predicted and observed data at the highest PE

Ami Iwabu, Kentaro Kitamura

Fig.4-7 Comparison of predicted and observed data at the highest PE

In Fig.4-6 and Fig.4-7 show the comparison of the temporal variations for both predicted and observed high-energy electron flux. The horizontal axis shows the date and the vertical axis shows the energetic electron flux. The blue line shows the actual observed data, and the orange line shows the predicted data. The more the orange line, the predicted data, overlaps the blue line, the observed data, the higher the prediction efficiency and accuracy.

Fig.4-6 shows that the forecast results are largely consistent for large changes. Fig.4-7 shows that the predicted values are lower than the actual observed values in many areas where the value of E is small.

5. Discussion

In Case 2, in which UT (the positional information of the satellite) was added as input data to Case 1, resulted PE is lower than that in Case 1. On the other hand, PE in Case 3 is almost same as that in Case 1, while Case 3 is added one parameter (the Akasofu ε which is the total number of energy inflows from the solar wind) to Case 1 same as Case 2. The difference of the added parameters causes significant difference in consequent result. This suggests that the spatial information might reduce the PE, rather than the increasing of number of input parameters. Especially, using one parameter that include the integrated several information can efficiently improve PE, rather than superposing several parameters that has individual information. On the other hand, the input parameters of solar wind data might have potential to improve the PE compared to that of ground data.

6. Conclusion

In each case, there is no correlation between the number of epochs and the PE, which means that the PE is not dependent on the number of epochs between 50 and 100, and there is no need to set the number of epochs above 100.

From the comparison of the average prediction efficiency for each case, the accuracy of prediction is higher when the parameters to be used as input data have integral information rather than when the number of input data is increased.

From the prediction results, the trend of the change in high-energy electron flux is captured. In addition, in the short time scale, we find that the prediction shows a little underestimation at the time of decreasing of E, but during E has an energy of 10^4 or more (alert level for the satellite malfunction), the prediction is highly accurate. In conclusion, the current result suggests that the RNN method proposed in this study is able to predict the periods considered important for the safe operation of the satellite.

Abstract

This paper presents image gradient-based monocular visual-inertial odometry (VIO) algorithm, using image gradient measurements, robust to illumination change. We expand the measurements from the reprojected feature locations on the image coordinates to the corresponding image gradients. The iterated EKF and low-pass pyramid are adapted to reduce the linearization error in the multi-state constraint Kalman filter (MSCKF) measurement update process. We verify that our proposed algorithm outperforms both conventional indirect and direct MSCKF-based VIO algorithms by evaluating the pose estimation performance.

Keywords: Illumination Change, Image Gradient, Iterated Extended Kalman Filter, Low-pass Pyramid, Visual-Inertial Odometry

1. Introduction

An accurate ego-motion estimation of a vehicle in a global navigation satellite system (GNSS) denied environment has been a challenging task in robotics and autonomous driving for several decades [1]. To tackle this issue, the ego-motion estimation algorithm using camera information, so-called Visual Odometry (VO), has been studied [2], [3], [4]. VO incrementally estimates a relative 6-DOF pose between consecutive images.

The most representative fusion of camera and alternative sensors is visual-inertial odometry (VIO), which additionally uses IMU; accelerometers, and gyroscopes. Despite various VIO algorithm studies, several challenging environments exist for ego-motion estimation, still being tackled. One representative environment is where the photometric consistency assumption is violated due to the illumination change.

The main contribution of this paper is threefold. First, inspired by the studies on image gradient-based VO algorithms [5]. we adapted the novel measurement, image gradient, to the VIO framework. Image gradient is known to be robust to illumination change. We utilize image gradients in the horizontal and vertical image directions as measurements of the multi-state constraint Kalman filter (MSCKF)-based VIO algorithm. Second, unlike the conventional MSCKF-based VIO algorithm,

we apply iterated extended Kalman filter (EKF) and low-pass pyramid to minimize linearization error. Lastly, we evaluate our proposed algorithm at both simulation and real-world datasets and demonstrate that our proposed algorithm outperforms both conventional indirect and direct methods in the environment where illumination changes.

2. Preliminaries

In this paper, the 3D pose is described at the current IMU-affixed frame, $\{B_k\}$, at time k with respect to a global frame, $\{G\}$. The global frame is the initial body frame aligned with gravity. Unlike EKF, MSCKF considers multiple images and utilizes the geometric constraint to estimate the ego-motion of the vehicle. Therefore, MSCKF includes the previous camera poses in the state. $\{C_i\}$ is a camera frame of the ith element in the sliding window of MSCKF.

The mathematical expression is described as follows. For example, $p_{C_l f_i}^{C_l}$ is the position of camera frame described as the translation from the lth camera frame, C_l to the ith 3D feature position, f_i with respect to C_l.

3. State Representation

The MSCKF state, X_{MSCKF} is formulated as a combination vector of the IMU state, X_{IMU}, and the previous camera state, X_{cam}, in the sliding window.

$$X_{MSCKF} = \begin{bmatrix} X_{IMU}{}^T & X_{camera}{}^T \end{bmatrix}^T \in \mathbb{R}^{(16+7N)\times 1} \tag{1}$$

$$X_{IMU} = \begin{bmatrix} q_{GB}{}^T & p_{GB}^{G}{}^T & v_{GB}^{G}{}^T & b_a{}^T & b_g{}^T \end{bmatrix}^T \in \mathbb{R}^{16\times 1} \tag{2}$$

$$X_{camera} = \begin{bmatrix} q_{GC_1}{}^T & p_{GC_1}^{G}{}^T & \dots & q_{GC_n}{}^T & p_{GC_n}^{G}{}^T \end{bmatrix}^T \in \mathbb{R}^{7N\times 1} \tag{3}$$

q_{GB} is the unit quaternion describing the rotation from body frame $\{B\}$ to the global frame $\{G\}$ (or the body attitude with respect to $\{G\}$, p_{GB}^{G} and v_{GB}^{G} are the body position and velocity with respect to $\{G\}$, respectively, b_a and b_g are accelerometer and gyroscope bias, respectively, and q_{GC_l} and $p_{GC_l}^{G}$ are the l th camera attitude and position, respectively.

True position, velocity, accelerometer and gyroscope bias are expressed as $X = \hat{X} + \tilde{X}$, where $\hat{X}$ and $\tilde{X}$ are estimated and error state, respectively, and true attitude as $q = \delta q \otimes \hat{q}$, where $\otimes$ denotes quaternion multiplication. Then, the quaternion error is derived as follows.

$$\delta q = q \otimes \hat{q}^{-1} \approx \begin{bmatrix} 1 \\ \frac{1}{2}\delta\theta \end{bmatrix} \tag{4}$$

Therefore, the error state is defined as below.

$$\tilde{X}_{MSCKF} = \begin{bmatrix} \tilde{X}_{IMU}^T & \tilde{X}_{cam}^T \end{bmatrix}^T \in \mathbb{R}^{(15+6N)\times 1} \tag{5}$$

$$\tilde{X}_{IMU} = \begin{bmatrix} \delta\theta_B^{G}{}^T & \tilde{p}_{GB}^{G}{}^T & \tilde{v}_{GB}^{G}{}^T & \tilde{b}_a{}^T & \tilde{b}_g{}^T \end{bmatrix} \in \mathbb{R}^{15\times 1} \tag{6}$$

$$\tilde{X}_{cam} = \begin{bmatrix} \delta\theta_{C_1}^{G}{}^T & \tilde{p}_{GC_1}^{G}{}^T & \dots & \delta\theta_{C_N}^{G}{}^T & \tilde{p}_{GC_N}^{G}{}^T \end{bmatrix} \in \mathbb{R}^{6N\times 1} \tag{7}$$

4. Measurement Model

In our proposed algorithm, the measurement of the conventional MSCKF, which is the reprojected feature location on the image coordinate, is extended to the image gradients along the horizontal and vertical direction of the image, $z_{gradient}$,

$$z_{gradient,i,l} = \begin{bmatrix} \nabla_x I_{i,l}(\pi(p_{C_l f_i}^{C_l})) \\ \nabla_y I_{i,l}(\pi(p_{C_l f_i}^{C_l})) \end{bmatrix} + n_{gradient,i,l} \tag{8}$$

where $p_{C_l f_i}^{C_l} = h(p_{Gf_i}^{G}, \theta_{C_l}^{G}, p_{GC_l}^{G})$. $z_{gradient,i,l}$ is the measurement of the ith feature on the lth image. $\pi(\cdot)$ is a reprojected feature location, $I_{i,l}(\pi(\cdot))$ is an intensity at the reprojected feature location, $\nabla_x I_{i,l}(\pi(\cdot))$ and $\nabla_y I_{i,l}(\pi(\cdot))$ are gradients along horizontal and vertical directions of image. $n_{gradient,i,l}$ is the noise of the ith feature on the lth image.

5. Measurement Update

The measurement update of our proposed algorithm proceeds when either a feature is lost from tracking or the length of the feature track exceeds the size of the sliding window, which are the same measurement update conditions of the conventional MSCKF-based VIO algorithm [6], [7]. Since the novel measurement, image gradients along the horizontal and vertical direction of the

image are utilized, the residual is expanded to the difference between the anchor and the lth image gradient along two directions as,

$$
\begin{aligned}
r_{i,l} &= z_{i,l} - \hat{z}_{i,l} \\
&= \begin{bmatrix} \nabla_x I_{i,A} - \nabla_x I_{i,l}(\pi(\hat{p}_{C_l f_i}^{C_l})) \\ \nabla_y I_{i,A} - \nabla_y I_{i,l}(\pi(\hat{p}_{C_l f_i}^{C_l})) \end{bmatrix} \\
&\approx H_{X_{i,l}} \tilde{X}_k + H_{f_{i,l}} \tilde{p}_{Gf_i}^{G} + n_{i,l}
\end{aligned}
\tag{9}
$$

where $\hat{p}_{C_l f_i}^{C_l} = h(\hat{p}_{Gf_i}^{G}, \hat{\theta}_{C_l}^{G}, \hat{p}_{GC_l}^{G})$. $\nabla_x I_{i,A}$ and $\nabla_y I_{i,A}$ are the image gradients along the horizontal and vertical direction of the anchor image. The anchor frame is defined as the camera image where the ith feature is captured in the sliding window. $r_{i,l}$, $z_{i,l}$ and $\hat{z}_{i,l}$ are the residuals, measured gradients and estimated gradients of the ith feature on the lth image, respectively. $H_{X_{i,l}}$ and H_{f_i} are state and feature position Jacobian matrix, respectively. $\tilde{X}_k$ is the error state at step k and $\tilde{p}_{Gf_i}^{G}$ is the error feature position.

The residuals of the ith feature on all image frames are accumulated to form a block vector of residuals of the ith feature. Since the measurement is extended from the image feature projection location on the image coordinates to image gradients, Jacobian matrices of state, $H_{X_{C_l}}$, and feature position, $H_{p_{Gf_i}^{G}}$, are newly derived as below.

$$
\begin{aligned}
H_{x_{C_l}} &= \frac{\nabla^2 I_l}{\partial(u_d, v_d)} \frac{\partial(u_d, v_d)}{\partial p_{C_l f_i}^{C_l}} \frac{\partial p_{C_l f_i}^{C_l}}{\partial X_{C_l}}, \\
H_{p_{Gf_i}^{G}} &= \frac{\nabla^2 I_l}{\partial(u_d, v_d)} \frac{\partial(u_d, v_d)}{\partial p_{Gf_i}^{G}}, \\
\frac{\nabla^2 I_l}{\partial(u_d, v_d)} &= \begin{bmatrix} \frac{\nabla_x(\nabla_x I_l)}{\partial(u_d)} & \frac{\nabla_x(\nabla_x I_l)}{\partial(v_d)} \\ \frac{\nabla_x(\nabla_y I_l)}{\partial(u_d)} & \frac{\nabla_y(\nabla_y I_l)}{\partial(v_d)} \end{bmatrix}
\end{aligned}
\tag{10}
$$

∇_x and ∇_y are gradients along horizontal and vertical direction of the image, respectively. u_d and v_d are undistorted image pixels along horizontal and vertical direction of image, respectively. X_{C_l} is the lth camera pose. $\frac{\nabla^2 I_l}{\partial(u_d, v_d)}$ implies the gradients of the gradient image. Then, the residual is projected to a left null-space to eliminate the terms related to the 3D feature position. The block vectors of the residuals of the ith feature are accumulated to form a block vector of all residuals and proceed QR decomposition to reduce computational complexity.

Unlike EKF, which utilizes prior estimate as a linearization point, iterated EKF iteratively computes posterior estimate, which is more accurate since the measurement is reflected. The MSCKF measurement update equation is summarized as follows.

$$
\begin{aligned}
\delta X_k^+ &= K_k(y_k - h(\hat{X}_k^-)) \\
K_k &= P_k^- T_{H_k}{}^T (T_{H_k} P_k^- T_{H_k}{}^T + Q_{1_k}{}^T R_{0_k} Q_{1_k})^{-1} \\
r_{n_k} &= y_k - h(\hat{X}_k^-) = Q_{1_k}{}^T r_{0_k}
\end{aligned}
\tag{11}
$$

δX_k^+ is a posterior estimated state, which is the correction term with respect to the error state from $\hat{X}_k^+ = \hat{X}_k^- \boxplus \delta X_k^+$. $\boxplus$ is the operator defining the error state as the estimated error state and the correction term. $h(\hat{X}_k^-)$ is the measurement equation of the system, K_k is the

Kalman gain, and P_k^- is the prior covariance of the estimated error. T_{H_k} is the upper triangular matrix computed from the QR decomposition. Q_{1_k} is the unitary matrix computed from the QR decomposition, whose columns form bases for the range of H_X. y_k is the measurement, and R_{0_k} is the covariance matrix of the measurement.

The EKF-based MSCKF uses the prior estimate state as the linearization point. Therefore, the measurement is not reflected on the linearization point. However, the iterated EKF-based MSCKF first computes the posterior estimate state using the prior estimate state to reflect the measurement on the linearization point and iteratively computes the posterior estimate state to reduce the linearization point. Therefore, the adaptation of the iterated EKF to MSCKF is made through modification of equation 11 to

$$\delta X_{k,i+1}^+ = K_{k,i}(y_k - h(\hat{X}_{k,i}^+) + T_{H_{k,i}}(\delta X_{k,i}^+))$$
$$K_{k,i} = P_k^- T_{H_{k,i}}^T (T_{H_{k,i}} P_k^- T_{H_{k,i}}^T + Q_{1_{k,i}}^T R_{0,k,i} Q_{1_{k,i}})^{-1} \quad (12)$$
$$r_{n_{k,i}} = y_k - h(\hat{X}_{k,i}^+) + T_{H_{k,i}}(\delta X_{k,i}^+) = Q_{1_k}^T r_{0_k} + T_{H_{k,i}}(\delta X_{k,i}^+)$$

$\delta X_{k,i+1}^+$ is the correction term at the $i+1$th iteration and $h(\hat{X}_{k,i}^+)$ is the measurement equation of system, where posterior is reflected. $K_{k,i}$, $T_{H_{k,i}}$, and $Q_{1_{k,i}}$ are the Kalman gain, the upper triangular matrix, and the unitary matrix, respectively, at the ith iteration. The combination of the iterated EKF and the low-pass pyramid results in a reduction of the residual, which implies the improvement of linearization error due to the high non-linearity of the image gradients.

Fig. 1. Attitude and position RMSE

6. Experimental Results

The proposed algorithm is evaluated at a real-world dataset to verify that it is more robust to the illumination change than the feature-based and intensity-based methods. EuRoC real-world dataset is collected from an on-board hex-rotor helicopter. This dataset provides stereo images, IMU data, and 6-DOF ground-truth. Illumination change due to the camera's automatic exposure time is included in the image. The performance of our proposed algorithm is analyzed on five different

sequences collected in the same indoor environment, and MAV travels 94.86 m in 134.8 s on average.

The experiment result is summarized in Fig. 1. It reports that the average 3D position RMSE of the feature-based method is less than that of the intensity-based method. This result implies that the illumination change strongly influences the image intensity, while the reprojected feature position is less influenced. The feature-based method is less influenced because the extracted feature position's accuracy depends on motion-blur, not the illumination change. Average 3D position RMSE of the intensity-based method is reduced by utilizing the image gradient

7. Conclusion

In this paper, we have proposed the utilization of image gradients as measurements in the monocular MSCKF-based VIO algorithm with an adaptation of iterated EKF with the low-pass pyramid. The novel measurement is used to tackle the illumination change environment, where the photometric-consistency assumption is violated. Unlike the conventional method, which utilizes the image feature coordinates, our proposed algorithm utilizes the image gradients along the horizontal and vertical direction of the image with the adaptation of iterated EKF and low-pass pyramid. The performance of the proposed algorithm is analyzed by comparing it to that of feature-based and intensity-based methods at the real-world dataset. Our experimental result reports that our proposed algorithm's accuracy of both 3D attitude and position estimation outperforms both feature-based and intensity-based algorithms.

Abstract

A method has been proposed for embedding another photographic image (image B) in a photographic image (image A). An image (image A') is generated by embedding information of image B in image A, and then an image (image B') is restored by extracting information from image A'. The conventional methods can only embed one photographic image in one photographic image. Therefore, we extend the conventional method and propose a method for embedding multiple photographic images in one photographic image. In our method, as more images B are embedding in image A, the image quality of image A' deteriorates, but the image quality of images B' dose not deteriorate. To verify the effectiveness of our method, experiments using various photographic images were performed. As a result of the experiments, the relationship between the number of images B and the image quality of image A' was clarified.

Keywords: Multiple photographic images, Embedding, Restoring, Digital watermark

1. Introduction

Digital watermarking [1] methods have been proposed that uses two photographic images of the same size with 256 gradations and embed another photographic image in one of the photographic images [2], [3]. The conventional methods [2], [3] embed one photographic image (image B) in one photographic image (image A). An image (image A') is generated by embedding information of image B in image A, and then an image (image B') is restored by extracting information from image A'. Images A and A' are similar, and images B and B' are similar. To make people unaware that image B is embedded in image A', the difference between images A and A' must be visually unrecognizable. In the conventional method [2], each pixel value of pixels in image B whose horizontal and vertical positions are odd numbers is embedded in 4 pixels in image A. At that time, the pixel values in image A are changed within ± 2, and then image A' is generated. In the conventional method [3], each pixel value of pixels in image B whose horizontal and vertical positions are the values of the tolerance sequence with first term 2 and tolerance 3 is embedded in 8 pixels in image A. At that time, the pixel values in image A are changed within ± 1, and then image A' is generated. It is known through experiments that the conventional method [3] reduces the difference between images A and A' about 60% compared to the conventional method [2]. On the other hand, the conventional method [3] is known to have a larger difference between images B and B' than the conventional method [2]. In the conventional methods [2], [3], it is important not to be aware that image B is embedded in image A', so we focus on the conventional method [3].

Since the conventional method [3] can only embed one photographic image in one photographic image, we extend the conventional method [3] and propose a method for embedding multiple photographic images in one photographic image. In our method, as more images B are embedding in image A, the image quality of image A' deteriorates, but the image quality of images B' dose not deteriorate. To verify the effectiveness of our method, experiments using various photographic images were performed. As a result of the experiments, the relationship between the number of images B and the image quality of image A' was clarified.

2. Our Method

Our method generates image A' by embedding images B_o ($o = 1, 2, \cdots, O$) in image A, where O is the number of images B_o to be embedded in image A, and then images B'_o are restored from image A'. A conceptual diagram of our method is shown in Fig. 1. The pixel values for spatial coordinates (i, j) ($i = 1, 2, \cdots, I; j = 1, 2, \cdots, J$) of images A, B, A' and B' are defined as $f_{A,i,j}$, $f_{B_o,i,j}$, $f_{A',i,j}$ and $f_{B'_o,i,j}$, respectively. Images A, B_o, A' and B'_o are the

Naoki Kouno, Kanya Goto, Toru Hiraoka

same size and have 256 gradations from 0 to 255. The methods for embedding images B_o in image A and restoring images B'_o from image A' are described below.

Fig. 1. Conceptual diagram of our method

2.1. *Embedding method*

Let the binary representations of $f_{B_o,k,l}$ be $b_{B_o,p,k,l}$ ($p = 1,2,\cdots,8$), and the following relationship (Eq. (1)) is established, where k ($= 2,5,8,\cdots$) and l ($= 2,5,8,\cdots$) are the values of the tolerance sequence with first term 2 and tolerance 3.

$$f_{B_o,k,l} = \sum_{p=1}^{8} 2^{8-p} b_{B_o,p,k,l} \tag{1}$$

Information is respectively embedded in $f_{A,k-1,l-1}$, $f_{A,k,l-1}$, $f_{A,k+1,l-1}$, $f_{A,k-1,l}$, $f_{A,k+1,l}$, $f_{A,k-1,l+1}$, $f_{A,k,l+1}$ and $f_{A,k+1,l+1}$ using the values $b_{B_o,1,k,l}$, $b_{B_o,2,k,l}$, $b_{B_o,3,k,l}$, $b_{B_o,4,k,l}$, $b_{B_o,5,k,l}$, $b_{B_o,6,k,l}$, $b_{B_o,7,k,l}$ and $b_{B_o,8,k,l}$, and then $f_{A',k-1,l-1}$, $f_{A',k,l-1}$, $f_{A',k+1,l-1}$, $f_{A',k-1,l}$, $f_{A',k+1,l}$, $f_{A',k-1,l+1}$, $f_{A',k,l+1}$ and $f_{A',k+1,l+1}$ are generated. Note that $f_{A',k,l}$ is the same value as $f_{A,k,l}$. Since $f_{A',k-1,l-1}$, $f_{A',k,l-1}$, $f_{A',k+1,l-1}$, $f_{A',k-1,l}$, $f_{A',k+1,l}$, $f_{A',k-1,l+1}$, $f_{A',k,l+1}$ and $f_{A',k+1,l+1}$ are calculated in the same procedure, only the case of $f_{A',k-1,l-1}$ is described below. The values $c_{A,k-1,l-1}$, which are integers greater than or equal to 0 and less than 2^O, are calculated from the pixel values $f_{A,k-1,l-1}$ by the following Eq. (2).

$$c_{A,k-1,l-1} = f_{A,k-1,l-1} \% 2^O \tag{2}$$

where % represents a remainder operation. The values $c_{B,k-1,l-1}$, which are integers greater than or equal to 0 and less than 2^O, are calculated from the values $b_{B_o,1,k,l}$ by the following Eq. (3).

$$c_{B,k-1,l-1} = \sum_{o=1}^{O} 2^{O-o} b_{B_o,1,k,l} \tag{3}$$

The values $f_{A',k-1,l-1}$ are calculated by the following Eq. (4).

$$f_{A',k-1,l-1} = f_{A,k-1,l-1} - c_{A,k-1,l-1} + c_{B,k-1,l-1} \tag{4}$$

If $f_{A',k-1,l-1}$ is smaller than 0, we must add 2^O to $f_{A',k-1,l-1}$. If $f_{A',k-1,l-1}$ is greater than 255, we must subtract 2^O from $f_{A',k-1,l-1}$.

When embedding images B_o in image A, our method changes the pixel values of image A within plus or minus $2^O - 1$, and then generates image A'. As more images B_o are embedding in image A, the image quality of image A' deteriorates.

2.2. *Restoring method*

Let the binary representations of $f_{A',i,j} \% 2^O$ be $b_{A',o,i,j}$, and the following relationship (Eq. (5)) is established.

$$f_{A',i,j} \% 2^O = \sum_{o=1}^{O} 2^{O-o} b_{A',o,i,j} \tag{5}$$

The pixel values $f_{B'_o,k,l}$ for spatial coordinates (k,l) are restored by the following Eq. (6).

$$\begin{aligned}
f_{B'_o,k,l} = \ &128 b_{A',o,k-1,l-1} + 64 b_{A',o,k,l-1} + \\
&32 b_{A',o,k+1,l-1} + 16 b_{A',o,k-1,l} + 8 b_{A',o,k+1,l} + \\
&4 b_{A',o,k-1,l+1} + 2 b_{A',o,k,l+1} + b_{A',o,k+1,l+1}
\end{aligned} \tag{6}$$

The pixel values $f_{B'_o,k',l'}$ for spatial coordinates (k',l') other than (k,l) are restored by the following Eq. (7) and Eq. (8).

$$f_{B'_o,k',l'} = \frac{\sum_{m=-2}^{2}\sum_{n=-2}^{2} f_{B'_o,k'+m,l'+n} d_{m,n}}{d_{m,n}} \tag{7}$$

$$d_{m,n} = \frac{1}{\sqrt{m^2+n^2}} \tag{8}$$

where m and n are the relative positions from the target pixel. Note that Eq. (7) is calculated using only the pixel values $f_{B'_o,k,l}$ obtained in Eq. (6).

3. Experiments

In this experiment, Lena image shown in Fig. 2 was used as image A, and 4 photographic images shown in Fig. 3 were used as images B_o. The size of all image A and images B_o was 256 * 256 pixels. Visual and quantitative evaluations were performed to verify the effectiveness of our method.

Fig. 2. Lena image (image A)

Fig. 3. Various photographic images (images B_o)

3.1. *Evaluation of embedded images*

Averages of absolute values of the differences between the pixel values of image A and images A' were calculated. Hereinafter, the averages are referred to as difference averages. The difference averages for 4 cases of embedding one image B_o are shown in Table 1. The difference averages for 6 cases of embedding 2 images B_o are shown in Table 2. For example, "(a)+(b)" in Table 1 means that 2 images B_o (a) and (b) of Fig. 3 are embedded. The difference averages for 4 cases of embedding 3 images B_o are shown in Table 3. The difference average for one case of embedding 4 images B_o is shown in Table 4. From Table 1 to 4, it was found that the larger the number of images B_o to be embedded in image A, the larger the difference averFiage.

Table 1. Difference averages between image A and images A' for 4 cases of embedding one image B_o

Symbols of images B_o	Difference averages
(a)	0.443
(b)	0.442
(c)	0.443
(d)	0.442

Table 2. Difference averages between image A and images A' for 6 cases of embedding 2 images B_o

Symbols of images B_o	Difference averages
(a) + (b)	1.093
(a) + (c)	1.100
(a) + (d)	1.092
(b) + (c)	1.099
(b) + (d)	1.096
(c) + (d)	1.127

Table 3. Difference averages between image A and images A' for 4 cases of embedding 3 images B_o

Symbols of images B_o	Difference averages
(a) + (b) + (c)	2.302
(a) + (b) + (d)	2.291
(a) + (c) + (d)	2.320
(b) + (c) + (d)	2.316

Table 4. Difference averages between image A and images A' for one case of embedding 4 images B_o

Symbols of images B_o	Difference averages
(a) + (b) + (c) + (d)	4.711

Next, the differences between image A and images A' were visually evaluated. Images A' for 4 cases of embedding one image B_o are shown in Fig. 4, Images A' for 6 cases of embedding 2 images B_o are shown in Fig. 5. Images A' for 4 cases of embedding 3 images B_o are shown in Fig. 6. Image A' for one case of embedding 4 images B_o is shown in Fig. 7. From Fig. 2 and 4 to 7, it was found that images A', in which one and 2 images B_o were embedded, were visually unrecognizable as different from image A. It was also found that images A',

in which one or 3 images B_o were embedded, were slightly recognizable as different from image A, and image A', in which one or 4 images B_o were embedded, were clearly recognizable as different from image A.

3.2. *Evaluation of restored images*

Difference averages between images B_o and images B'_o restored from images A' were calculated. The difference averages in this case are the same value no matter how many images B_o are embedded. The difference averages are shown in Table 5. Additionally, images B'_o are shown in Fig. 8. Images B'_o do not change no matter how many images B_o are embedded. From Table 5, it was found that the difference averages were somewhat larger, ranging from 6 to 13 values. However, from Fig. 3 and 8, it was found that images B'_o are fully recognizable as same as images B_o, although images B'_o were disturbed at the edges.

Fig. 8. Images B'_o

4. Conclusion

We proposed a method for embedding multiple photographic images (images B_o) in one photographic image (image A). An image (image A') was generated by embedding information of images B_o in image A, and then an image (images B'_o) was restored by extracting information from image A'. In our method, as more images B were embedding in image A, the image quality of image A' deteriorated, but the image quality of images images B'_o did not deteriorate. To verify the effectiveness of our method, experiments using various photographic images were performed. As a result of the experiments, it was found that images A', in which one and 2 images B_o were embedded, were visually unrecognizable as different from image A. Additionally, it was found that images A', in which one or 3 images B_o were embedded, were slightly recognizable as different from image A, and image A', in which one or 4 images B_o were embedded, were clearly recognizable as different from image A.

A future task is to be able to apply our method to photographic images of different sizes.

Abstract

We propose a non-photorealistic rendering method for automatically generating flowing-line images from photographic images. Flowing-line images consist of unidirectional lines with smooth curves. Our method is executed by an iterative calculation using vertical and horizontal smoothing filters. To verify the effectiveness of our method, we conducted an experiment using various photographic images to confirm that flowing-line patterns can be generated on the entire image. Additionally, we conducted an experiment to visually examine how flowing-line patterns generated by changing the values of the parameters in our method change.

Keywords: Non-photorealistic rendering, Flowing line, Vertical smoothing filter, Horizontal smoothing filter, Automatic generation

1. Introduction

Many studies [1],[2] have been conducted on non-photorealistic rendering using computer technology. Since non-photorealistic rendering targets all expressions other than realistic expressions by photorealistic rendering, there are various methods for dealing with various styles and uses. We focus on non-photorealistic rendering methods that use image processing to generate non-photorealistic images that are different from conventional art expressions such as oil paintings and watercolors. As non-photorealistic rendering methods of the unprecedented art expressions, many methods for generating labyrinth images [3], cell-like images [4], and moire-like images [5] from photographic images have been proposed. Labyrinth images are composed of equally spaced lines like a maze and are generated using minimum spanning trees, cell-like images are composed of cell-like patterns with cell membranes and cell nuclei and are generated using inverse iris filter, and moire-like images are a kind of op art and are generated using bilateral filter and unsharp musk.

We propose a non-photorealistic rendering method for automatically generating flowing-line images from photographic images. Flowing-line images are composed of unidirectional (here vertical) lines with smooth curves. The black lines are thickly represented at the edges and black areas of photographic images, and are represented along the edges in the nearly vertical direction. Our method is executed by an iterative calculation using vertical and horizontal smoothing filters. As images similar to flowing-line images, non-photorealistic rendering methods for generating ripple images has been proposed [6],[7]. Ripple images are composed of continuous lines with fluctuations and are generated using inverse Sobel filter [6] or intensity gradients [7]. Flowing-line images are represented by the lines closer to the binary value of black and white than ripple images, and flowing-line images and ripple images have different impressions. The conventional method [8] is executed by an iterative calculation using circular-sector-type smoothing filter and inverse filter [9]. Ripple images [8] are more similar to flowing-line images than ripple images [6],[7], but flowing-line patterns are slightly more linear than ripple patterns. In the conventional methods [6],[7],[8], ripple patterns cannot be generated in white and black areas. On the other hand, our method can generate flowing-line patterns in the white and black areas. Through an experiment using various photographic images, our method examines that flowing-line patterns can be generated on the entire image. Additionally, through an experiment that changes the values of the parameters in our method, how the generated flowing-line patterns change is examined.

2. Our method

Our method is largely executed in three steps. First, since flowing-line patterns are unlikely to occur in the white and black areas, gray scale transformation is performed on a photographic image. The gray scale transformation eliminates pixel values close to white and black, and eliminates areas where flowing-line patterns cannot be generated. Second, processing is performed

Karin Kuroki, Toru Hiraoka

using horizontal smoothing filter and inverse filter. Third, processing is performed using vertical smoothing filter. A flowing-line image is generated by iterating through the second and third steps. A flow chart of our method is shown in Fig. 1.

Fig. 1. Flow chart of our method

Details of the steps in Fig. 1. are explained below.

Step 0: Let the input pixel values on coordinates (i, j) of a gray-scale photographic image be $o_{i,j}$. The pixel values $o_{i,j}$ have value of U gradation from 0 to $U - 1$.

Step 1: Let the pixel values that have undergone gray scale transformation as shown in the following equation be $f_{i,j}$.

$$f_{i,j} = o_{i,j} \frac{U - 2D - 1}{U - 1} + D \qquad (1)$$

where D is a natural number. The larger the value of D, the fewer pixels that are close to white or black. When the value of D is 0, the pixel values $f_{i,j}$ have the same pixel values as the original photographic image.

Step 2: Let the pixel values of the image at the t-th iteration number be $f_{i,j}^{(t)}$, where $f_{i,j}^{(0)} = f_{i,j}$. Let the pixel values that horizontal smoothing filter is applied as shown in the following equation be $s_{1,i,j}^{(t)}$.

$$s_{1,i,j}^{(t)} = \frac{\sum_{k=-W_1}^{W_1} f_{i+k,j}^{(t-1)}}{2W_1 + 1} \qquad (2)$$

where W_1 is the window size and k is the positions in the window. Let the pixel values that inverse filter is applied as shown in the following equation be $g_{i,j}^{(t)}$.

$$g_{i,j}^{(t)} = f_{i,j}^{(t-1)} - s_{1,i,j}^{(t)} + f_{i,j} \qquad (3)$$

If $g_{i,j}^{(t)}$ is smaller than 0, then $g_{i,j}^{(t)}$ must be set to 0, and if $g_{i,j}^{(t)}$ is greater than $U - 1$, then $g_{i,j}^{(t)}$ must be set to $U - 1$.

Step 3: Let the pixel values that vertical smoothing filter is applied as shown in the following equation be $f_{i,j}^{(t)}$.

$$f_{i,j}^{(t)} = \frac{\sum_{l=-W_2}^{W_2} g_{i,j+l}^{(t)}}{2W_2 + 1} \qquad (4)$$

where W_2 is the window size and l is the positions in the window.

A flowing-line image is obtained after T times iteration of Steps 2 and 3.

3. Experiments

We conducted two experiments. First, we visually confirmed flowing-line patterns by changing the values of the parameters in our method using Lighthouse image shown in Fig. 2. Second, we applied our method to eight photographic images shown in Fig. 3. All photographic images used in the experiments were 512 * 512 pixels and 256 gradations.

Fig. 2. Lighthouse image

Fig. 3. Photographic images

3.1. *Experiment with changing parameter values*

Flowing-line images generated by changing the iteration number T were visually confirmed using Lighthouse image. The value of T was set to 5, 10, 20, and 40. The values of the other parameters D, W_1, and W_2 were set to 10, 6, and 3, respectively. The results of the experiment are shown in Fig. 4. As the value of T was larger, flowing-line patterns became clearer and were expressed finely.

Flowing-line images generated by changing the value of the parameter D were visually confirmed using Lighthouse image. The value of D was set to 0, 10, 20, and 30. The values of the other parameters T, W_1, and W_2 were set to 40, 6, and 3, respectively. The results of the experiment are shown in Fig. 5. As the value of D was larger, flowing-line patterns became clearer in the white area at the bottom of Lighthouse image. On the other hand, as the value of D was larger, it became more difficult to recall Lighthouse image.

Flowing-line images generated by changing the window size W_1 were visually confirmed using

Lighthouse image. The window size W_1 was set to 2, 4, 6, and 8. The values of the other parameters T, D, and W_2 were set to 40, 10, and 3, respectively. The results of the experiment are shown in Fig. 6. As the value of W_1 was larger, the interval of flowing-line patterns became wider.

Flowing-line images generated by changing the window size W_2 were visually confirmed using Lighthouse image. The window size W_2 was set to 1, 2, 3, and 4. The values of the other parameters T, D, and W_1

were set to 40, 10, and 6, respectively. The results of the experiment are shown in Fig. 7. As the value of W_2 was larger, flowing-line patterns became smoother. Furthermore, in Figs. 4 to 7, it was also found that flowing-line patterns can be generate in the white area at the bottom of Lighthouse image.

Karin Kuroki, Toru Hiraoka

3.2. *Experiment using eight photographic images*

Our method was applied to eight photographic images shown in Fig. 3. The values of the parameters T, D, W_1, and W_2 were set to 40, 10, 6, and 3, respectively. The results of the experiment are shown in Fig. 8. For all flowing-line images, flowing-line patterns were composed of unidirectional (here vertical) lines with smooth curves, and could be automatically generated on the entire image. Looking at more details, the black lines were thickly represented at the edges and black areas (clothes, hair, etc. in the lower left image) of photographic images, and were represented along the edges in the nearly vertical direction.

Fig. 8. Flowing-line images

4. Conclusion

We proposed a non-photorealistic rendering method for generating flowing-line images from gray-scale photographic images using vertical and horizontal smoothing filters. Through an experiment using nine photographic images, it was found that our method can automatically generate flowing-line patterns on the entire images. Additionally, through an experiment that the values of the parameters in our method were changed, it was found that the interval and smoothness of flowing-line patterns can be changed.

A subject for future study is to expand our method for application to color photographic images, videos, and three-dimensional data.

Abstract

It is crucial for individuals to keep walking and stay healthy to prevent receiving nursing care. This paper proposes a method of recognizing walk motions and analyzing the gait cycle of a human focusing on his/her posture. We use 43 structural features defined from human joint coordinates obtained using OpenPose and 18 figural features from human domain images and their difference images. The feature vector containing these 61 features is used for the recognition of walk motion by Random Forest. In the experiment, we applied the method to recognizing six types of motions and analyzed the walk gait cycles of five persons, and obtained satisfactory results.

Keywords: OpenPose, images of human area, human walk motion, structural feature, figural feature, gait cycle

1. Introduction

According to the Ministry of Health, Labour and Welfare's 'Physical Activity Standards for Health Promotion' [1], increasing the amount of daily physical activity can reduce the risk of deterioration of life functions and other problems. Therefore, it is recommended to maintain a certain intensity of physical activity (walking or equivalent movements). The purpose of this research is to recognize human daily motions and analyze the information obtained from them.

Previous studies include posture and motion recognition methods that use a chest-mounted camera by the first person viewpoint called MY VISION [2][3], gait recognition by integrating the gait silhouette input into a CNN [4], and a method that evaluates movement based on the skeletal trajectory of the whole body using depth data [5]. There is a motion recognition method [6] using an extension of Motion History Image (MHI) called Triplet Motion Representation Images, with Histograms of Oriented Optical Flow. However, attaching a measurement device to a person may cause unnatural movements. It is necessary to consider an actual living environment.

In this paper, we propose a method of recognizing human posture and gait motion based on human joint positions and image features, as well as a method of analyzing gait motion based on the gait cycle, using a random forest classifier [7] based on a 61-dimensional feature vector.

Fig. 1. Figural and structural features. (a) Human domain image, (b) joint coordinates

2. Foreground Extraction

To recognize a motion from the shape features of a human domain image, the human domain is extracted from the image as the foreground. In this paper, the sequential background estimation method based on the Gaussian mixture model [8][9] is used to extract a human domain corresponding to background change. Then, the noise on the extracted human domain is removed by expansion and contraction processing and it is trimmed to a rectangle of a specified scale. Figural features are extracted from the human domain using the binary and frame difference images shown in Fig. 1(a). After having the foreground, figural features are extracted by the step in 3.1

3. Feature Extraction

We use figural features and structural features to recognize human motion and its gait cycles.

3.1 Figural Features

Our aim is to extract effective features from human posture images. Eight kinds of figural features used in the proposed method can be categorized as follows.

1) Image aspect ratio: The ratio of the height to the width of the human domain image.

2) Percentage of a white pixel area in a rectangle: The percentage of a white pixel area in the human domain image.

3) Hand swing (upper body width): The difference between the rightmost and the leftmost points at 60% of the height of the upper body of the human domain image.

4) Shoulder height: The *y* coordinate at which the number of white pixels per line exceeds a threshold when the image is scanned from the upper left to the lower right. The threshold was experimentally set at 40 pixels to distinguish between a stretch out the back posture and others.

5) Length of the contour line at the bottom of the human region image: The length of the contour line at the bottom 40% of the height of the person area image.

6) Body asymmetry: The center of gravity of the lower 40% portion of the person area, and the percentage of the area to the left of the center of gravity in the white pixel area.

7) Position of the center of gravity: The distance of the center of gravity of the head from the centerline of the image.

8) Number of white pixels of the difference image: The number of white pixels in the 25% height area from the bottom of the difference image.

Since features 2), 3) and 5) take periodic values, their minimum and maximum values are also extracted and used as features. In this way, 18-dimensional figural features are obtained from the image of the human domain.

3.2 Structural Features

We extract the following six structural features (43 dimensions) using human joint coordinates provided from OpenPose [10].

1) Knee, ankle, and elbow angles: The knee angle θ_{knee}[deg] is calculated using the inner product of the hip and knee vectors as follows;

$$\boldsymbol{a} = (x_{hip} - x_{knee}, y_{hip} - y_{knee}) \tag{1}$$

$$\boldsymbol{b} = (x_{ankle} - x_{knee}, y_{ankle} - y_{knee}) \tag{2}$$

$$\theta_{knee} = \frac{180}{\pi} \cos^{-1} \frac{\boldsymbol{a} \cdot \boldsymbol{b}}{\|\boldsymbol{a}\|\|\boldsymbol{b}\|} \tag{3}$$

where (x_{hip}, y_{hip}), (x_{knee}, y_{knee}), (x_{ankle}, y_{ankle}) are the coordinates of the hip, knee and ankle, respectively. Using the same method, the ankle angles θ_{ankle} (the inner product of toe and knee)and elbow angle θ_{elbow} (the inner product of wrist and shoulder) are also obtained.

2) Ankle-toe, Hip-ankle angle, and Body tilt: The angle between the ankle and toe relative to the horizontal line is defined as the ankle-toe angle θ_{instep} [deg] and is given by;

$$\theta_{instep} = \frac{180}{\pi} \tan^{-1} \frac{y_{ankle} - y_{toe}}{x_{ankle} - x_{toe}} \tag{4}$$

where (x_{toe}, y_{toe}) is the coordinates of the toe as shown in Fig. 1(b). Similarly, we determine the hip-ankle angle $\theta_{hip-ankle}$ (The angle between the vertical line of the hip-ankle and the horizontal line of the left and the right hip) and the body inclination $\theta_{bodytilt}$ (The angle between the neck and the vertical line of the waist center).

3) Steps, Hip-ankle distance, and Wrist-shoulder distance

(a) Scale transformation: Using the length of a person's *thighs* [cm], the parameter *scale* [cm/pixel], which indicates how many centimeters one pixel corresponds to in the current frame, is calculated by the following;

$$scale = \frac{thighs}{\sqrt{(x_{hip} - x_{knee})^2 + (y_{hip} - y_{knee})^2}} \tag{5}$$

(b) Step width, Hip-ankle distance, Wrist-shoulder distance: The step width is calculated using the Euclidean distance between the left heel and the right heel as follows;

$$\begin{aligned} step\_width &= scale \\ &\times \sqrt{(x_{Rheel} - x_{Lheel})^2 + (y_{Rheel} - y_{Lheel})^2} \end{aligned} \tag{6a}$$

where (x_{Rheel}, y_{Rheel}) and (x_{Lheel}, y_{Lheel}) are the coordinates of the right and the left heel, respectively. Concurrently, the Euclidean distance between hip-ankle and wrist-shoulder is calculated as follows;

$$*\_\# = scale \times \sqrt{(x_* - x_\#)^2 + (y_* - y_\#)^2} \tag{6b}$$

where * indicates hip (or wrist), and # indicates ankle (or shoulder). (x_*, y_*) and $(x_\#, y_\#)$ are the coordinates of hip and ankle or wrist and shoulder, respectively.

4) Walk speed: The feature $walk\_speed$ [cm/s] indicates how long the coordinates of the waist center (x_{c0}, y_{c0}) in the current frame have moved from (x_{cn}, y_{cn}) in the previous n frames, and is given by the following equation;

$$\begin{aligned} walk\_speed &= scale \\ &\times \frac{\sqrt{(x_{c0} - x_{cn})^2 + (y_{c0} - y_{cn})^2} \times frame\_rate}{n} \end{aligned} \quad (7)$$

where (x_{c0}, y_{c0}), (x_{cn}, y_{cn}) are the coordinates of the center of the waist between the current frame and previous n frames, whereas the *frame_rate* is a unit that indicates the number of the images makeup in one second in a video.

5) Direction of motion: The direction of motion in the horizontal (*x*-axis) and in the vertical (y-axis) is obtained by vectorizing the displacement of the coordinates of the waist center during n frames and multiplying it by *scale*.

$$\begin{aligned} x &= (x_{c0} - x_{cn}) \times scale \\ y &= (y_{c0} - y_{cn}) \times scale \end{aligned} \quad (8)$$

6) Difference of the foot joint heights and wrist height: The height of the knee, and heel $height_*$ [cm] is calculated by the difference between the heights of the right and the left $height_{-*}$, as follows;

$$height_{-*} = |(y_{R*} - y_{L*})| \times scale \quad (9)$$

where * indicates knee, or heel, (x_{R*}, y_{R*}) and (x_{L*}, y_{L*}) are the coordinates of the right and the left knee, or heel, respectively. Moreover, the height from floor to toe and the height from floor to wrist are calculated in the same way.

Features such as knee and ankle angles are calculated with the left and the right foot, respectively. The feature values 1), 3), and 6) are then repeated for similar values in each gait cycle (e.g., in the walking motion, a person repeatedly bends and extends his/her knees). Therefore, in addition to the features 1) to 6) above in the current frame, the minimum and maximum values of these features in the past n frames are included as features. This results in 43 dimensional features.

Finally, from the figural and structural features, we represent a human posture using a 18+43=61-dimensional feature vector.

4. Learning and Identification

The proposed method uses Random Forest [7] as a discriminator.

Table 1. The number of frames in the video.

Motion	The number of frames				
	A	B	C	D	E
Normal	2351	2101	1878	2124	2192

Total	9185	7416	7335	6624	7256

(a) walk   (b) fall and sleep
Fig. 2. Direction of the motion

5. Experiment

5.1. Experimental Method

One fixed camera is set up at a height of 90 cm from an indoor floor to simulate a real-life situation. A person appears in the video, and the whole body is taken a video. The experiment was conducted on five subjects (22-23 years old). They are referred to as A, B, C, D, and E. Table 1 shows the number of frames contained in each video.

Six types of motions: Normal walking, forward leaning walk, falling, asking for help (beckoning to the camera), sitting, and sleeping are captured on video. Fig. 2 shows the direction.

Gait cycle [11]: Gait cycle (seven periods) recognition is performed for normal walking, i.e. when walking from the right to the left, the target of the gait cycle is left foot, whereas when walking from the left to the right, the target of the gait cycle is right foot. So we simply call it left-right foot. We manually select seven periods of the normal walk and put the selected periods into seven classes for training. The seven classes (periods) are Loading Response (LR), Mid Stance (MSt), Terminal Stance (TSt), Pre swing (PSw), Initial Swing (ISw), Mid Swing (MSw), Terminal Swing (TSw). In the gait cycle, 58 of the 61-dimensional features mentioned in section 3 are used for training. However, posture Initial Contact at the start of the cycle is omitted.

5.2. Method of Evaluation

Leave-one-out cross-validation was applied to the experimental data. The percentage of correct frames to all frames is used for evaluation. In the gait cycle analysis, left-right balance is evaluated by determining the left-right difference in the percentage of each period to the full video.

Table 2. Result of motion recognition

Motion	Precision [%]					
	A	B	C	D	E	**Ave**
Normal walk	97.0	99.4	93.8	99.6	98.8	97.8
Forward leaning	91.5	98.4	89.6	98.9	95.6	94.7
Fall	81.3	75.2	87.7	87.7	78.4	82.0
Help	79.7	82.0	95.1	99.2	99.3	92.1
Sit	100	100	92.5	100	100	98.2
Sleep	92.3	96.1	99.0	93.1	90.6	94.2

Table 3. Result of gait cycle recognition

Phases	Periods (class)	Precision [%]					
		A	B	C	D	E	**Ave**
Stance phase	LR	45.0	61.4	63.9	76.8	67.4	62.4
	MSt	88.7	90.7	90.8	94.5	85.3	89.9
	TSt	97.4	93.6	79.0	98.0	81.2	89.6
	PSw	55.8	77.6	77.3	68.5	67.8	67.8
Swing phase	ISw	87.9	90.4	86.8	87.4	75.2	85.4
	MSw	84.7	83.0	81.6	80.4	82.5	82.6
	TSw	91.8	81.0	66.1	90.9	78.5	81.9

6. Results and Discussion

6.1. Results

Tables 2 and 3 show the motion and gait cycle recognition results, respectively. Note that, help and sit motion are recognized without considering the direction. Fig. 3 shows some of the images of the recognition results. The upper left of the image shows the motion and gait cycle recognition results. Table 4 shows the different ratios of each period of the gait cycle of walking from the right to the left (the gait cycle of left foot) and the left to the right (the gait cycle of right foot) of each subject.

6.2. Discussion

Motion Recognition: The overall average accuracy was 95.2%. As shown in Table 2, Fall was less accurate than other motions, and the variation among subjects was greater than others. In fact, there are individual differences in the way the subject falls and shifts diagonally. Collecting more training data is needed.

Gait cycle: The overall average accuracy was 82.4%. In many cases, the gait cycle class was recognized as the class before or after the class. This is because walking is a continuous motion and the before and after postures are similar. From Table 4, it is expected that subject A's Mst is shorter than that of the left, indicating a slight decrease in the muscle strength of the right leg. Since analysis of a subject gait cycle is dependent on the recognition rate, the recognition accuracy in each class needs to be improved.

7. Conclusion

In this paper, we proposed a motion recognition and gait cycle analysis method using 61 features representing human posture and Random Forest as a discriminator. It was applied to the recognition of 6 motions and the analysis of 7 periods of gait cycles. Further study is needed to obtain more accurate values, such as step width,

Fig. 3. Normal walk and the result of recognition

Table 4. The difference of left-right foot.

Phases	Periods (class)	left-right foot differences [%]				
		A	B	C	D	E
Stance phase	LR	0.3	-5.4	-2.4	2.0	2.5
	MSt	4.4	-0.3	0.3	0.8	-1.3
	TSt	-1.9	1.4	0.7	0.9	0.8
	PSw	-2.1	2.3	1.0	-1.1	1.1
Swing phase	ISw	0.6	-4.3	1.0	-3.7	0.4
	MSw	-0.4	1.4	0.1	2.7	0.7
	TSw	-0.8	4.8	-0.7	-1.7	-4.2

for human health, and to identify the cases where multiple movements and directions are mixed. If we can provide accurate and appropriate advices to individuals, we will be able to offer better health services.

Abstract

Visually impaired people face several difficulties in indoor activities, such as spending excessive time in locating objects. This paper proposes a method for assisting object acquisition by detecting desired objects and guiding users to them. The method requests a user to express the object he/she wants to acquire verbally and utilizes speech recognition to detect the specified object. Subsequently, the system guides in voice the user's hand to the location of the desired object. The performance of the method is experimentally shown. The method contributes to enhancing the comfort of indoor activities of visually impaired and, in this way, improves their quality of life.

Keywords: MY VISION, Visually impaired, QOL, Object acquisition, Network diagram

1. Introduction

Many people around the world suffer from visually impaired vision, a condition that interferes with their daily lives due to persistent vision loss. According to a report [1] published by the World Health Organization (WHO) in 2019, the number of people with visual difficulties worldwide is estimated to be at least 2.2 billion, and there are concerns that the number of people affected will increase further due to population growth and aging.

In response to this worldwide social problem of visibility difficulties, a great deal of research and development has been conducted to support the daily lives of people with visibility difficulties. For example, there has been the development of a pedestrian crossing navigation system using smart glasses to enable people with vision difficulties to safely walk across pedestrian crossings alone [2][3][4][5], and the development of a system to assist people in getting on and off public transportation [6][7].

As in the above studies, much of the research on assisting people with vision difficulties tends to focus on supporting outdoor activities. However, there are many problems that occur during indoor activities, such as spending excessive time for acquiring an object when looking for it at home. Therefore, the purpose of this study is to improve the quality of life (QOL) of people with visual acuity difficulties by focusing on a proposal for an object acquisition support method, which plays a part in supporting indoor activities for people with visual acuity difficulties.

Currently, an application has been released that uses a smartphone to capture a registered object with a camera and read it aloud to the user[8]. This application is very useful for identifying objects that are similar in shape, but since it assumes that the object's location can be accurately identified and captured by the camera, it does not work unless the visually impaired person knows the object's location. In addition, as a study that addresses the guidance of object acquisition paths, a system has been proposed by J.P. Docto *et al.* [9], in which a smart glove is worn by a visually impaired person and guides him or her to the object utilizing the built-in camera and sensors. This system does not require text input or touch operation and is easy for visually impaired people to handle. However, in practical use, there are issues related to practicality, such as the time and effort required to put on and take off the gloves, the weight of the gloves when they are worn, and the resistance caused by the wiring.

In this study, we propose a system that provides voice guidance on a route to the object requested based on MY VISION (a Magic eYe of a Visually Impaired for Safety and Independent actiON), thereby reducing the burden of visually impaired people and making the system more intuitive and practical. Specifically, the system can provide real-time guidance using a notebook PC and a webcam, regardless of location, and enables it by voice without text input or button operation. This is expected to solve the practical limitations of smartphone applications and smart gloves that have been pointed out in previous research. Therefore, the system proposed in this study can

Shun Kitazumi, Yui Tanjo

be an important step toward improving the quality of life of people with vision difficulties during indoor activities by supporting smooth acquisition of the target object when they are looking for something at home.

2. Methodology

2.1. Voice recognition

In this study, when a user has an object that he/she wants to acquire, the user is asked to tell the object loud (speech transmission) to the proposed system, and the target object's name is recognized by analyzing the speech. By asking the user to say the trigger word before the object name, the noun that follows the trigger word is known as the target object's name. In the system, "MY VISION" is used as the trigger word. For example, if the user wants to acquire a cell phone, he/she just say, "MY VISION, find a cell phone". The system then guides the user's hand to the location of the desired object using voice guidance.

2.2. *Object detection*

In the proposed system, we use YOLOv7 (You Only Look Once version 7) [10] to detect a target object in real time. Note that in the system, objects that are present on the desk and easily portable (e.g., remote controls, cell phones, cups) are considered as a class of objects to be detected. In addition, by combining YOLOv7 and DeepSORT (Deep Learning Simple Online and Realtime Tracking) [11], object features are extracted on each frame, and each object is assigned a unique ID for tracking. Fig. 1 shows the object detection results.

2.3. *Route guidance to a target object*

If a target object is detected, the direction of the object location (referred to as a route hereafter) is guided by voice guidance according to the clock position. We use MediaPipe Hands [12] to estimate the user's hand area and align the user's hand with the target object. When the target object is in the 9 o'clock direction (left direction), the system announces "move to 9 o'clock direction" with voice.

The proposed method not only focuses on the hand and the target object, but also employs proposed a network diagram to represent the positional relationship among the surrounding objects based on the object detection results. In the network diagram, nodes are defined as the center coordinates of the object, and the edges are the distances in pixel between objects. The network diagram is introduced because the system can find the target object position smoothly, and also can find the position of the target object more precisely, when the target is very close to the other objects.

Fig. 1 Object detection results. (The target object is drawn in a blue bounding box and the user's hand is in a green box.)

Moreover, if an object to be detected is not detected in the current frame, then the system estimates the undetected position by referring to the previous network diagram.

The first condition for selecting the network diagram to be referred to is when the number of detected objects is three or more and the number of detected objects is the largest (Eq. (1)), and the second condition is when the network diagram consists of the same type of objects for a certain period (Eq. (2)).

$$\begin{cases} obj\_cnt_{F(t)} \geq 3 \\ obj\_cnt_{F(t)} \geq max\_obj\_cnt \end{cases} \quad (1)$$

Here, $F(t)$, $obj\_cnt_{F(t)}$ and max_object_cnt are current frame, the number of objects detected in the current frame and the maximum number of objects detected in each frame, respectively.

$$S = \begin{cases} S + 1 & \text{if } \forall E(F(t)) = \forall E(F(t-1)) \\ 0 & \text{otherwise} \end{cases} \quad (2)$$

$$S \geq Th \Longrightarrow \text{SetReferenceModel}(\forall E(F(t)))$$

Here, S, $E(F(t))$, and Th are the variable for state continuity, node in $F(t)$ and threshold, respectively.

The object location estimation method first calculates the amount of object movement common to the current frame and the reference network diagram, respectively, and derives the average amount of movement (Eq. (3)). The position of the undetected object is then estimated based on the coordinates of the model and the average displacement (Eq. (4)). The meanings of the letters in the equations are shown in Table 2.

$$\begin{cases} \bar{x} = \dfrac{1}{n} \sum_{i=1}^{n} (x_{t,i} - x_{model,i}) \\ \bar{y} = \dfrac{1}{n} \sum_{i=1}^{n} (y_{t,i} - y_{model,i}) \\ (i = 1, \cdots, n) \end{cases} \quad (3)$$

$$\begin{cases} x_{est,k} = x_{model,k} + \bar{x} \\ y_{est,k} = y_{model,k} + \bar{y} \end{cases} \quad (4)$$

Table 2. The meanings of Eq. (3) and Eq. (4)

$\bar{x}, \bar{y}$	Average displacement in the x or y-axis direction
n	Number of common nodes between current frame and reference model
$x_{t,i}, y_{t,i}$	x or y coordinates of the common node in the current frame
$x_{model,i}, y_{model,i}$	x or y coordinate of the common node in the model
$x_{est,k}, y_{est,k}$	x or y coordinate estimates for missing nodes
$x_{model,k}, y_{model,k}$	x or y coordinates of the node in the model corresponding to $x_{est,k}$ or $y_{est,k}$

The first condition for starting object location estimation is when a reference network diagram exists, and the second condition is when the number of detected objects is two or more and there are two or more objects in common with the reference network diagram. Fig. 2 shows the results of object location estimation using the above condition.

In the proposed system, a monocular RGB camera is used to align the hand with the target object without using a depth camera. The condition for determining object acquisition is achieved by employing the bounding box positional relationship between the target object and the hand region, and by judging the change in hand orientation that occurs when the hand gestures come closer to the camera after grasping the object. By adding the latter condition, it is expected to prevent the error judgment of acquisition as successful simply because the bounding boxes of the two objects overlap, even when the depths are different, and the objects are not touched. Furthermore, the system also incorporates a process that checks whether or not the object closest to the hand matches the target object by referring to the network diagram and announces when the subject has acquired the wrong object. When the above three conditions are satisfied, the target object is judged to have been acquired, and the acquisition is communicated by voice as completed. Fig. 3 shows an example that the object acquisition decision was fulfilled.

Fig. 4 Arrangement where other objects are present in the guidance path to the target object (target object: remote controller)

3. Experimental Result

Five objects were selected as candidate objects for acquisition: a book, a cell phone, a cup, a plastic bottle, and a remote controller. An experiment was conducted to select an acquisition target from these objects and to make a robot guide a blindfolded user along a path to the target object. As shown in Fig. 4, we placed other objects on the guided path to the target object to verify if it is possible to approach the target object again after announcing that the wrong object has been grabbed. The target object position was changed in the directions of 9, 10, 12, 2, and 3 o'clock with respect to the hand position to ensure that there was no dependence on the object placement. The evaluation index was *Accuracy* which represents the percentage of correct answers acquired. A total of 25 acquisition experiments were conducted with 5 choices among 5 objects times 5 object positions, resulting in an Accuracy of 92%.

4. Conclusion

In this paper, we proposed a system that provides voice guidance on the path to object acquisition based on MY VISION and contributes to improving the quality of life during indoor activities of the people with vision difficulties. In addition, by utilizing the information obtained from Mediapipe Hands and network diagrams, we developed a practical and intuitive system that provides all information and guidance by voice, as well as countermeasures in case that object tracking is interrupted.

Abstract

In recent years, elderly people living alone account for a large proportion of the elderly population, and the issue of safety has also been a matter of great concern for the public. Considering the importance of monitoring the behavior and activities of the elderly and detecting abnormal movements, this paper proposes a method that can segment human behavior into each action and identify the action from the videos taken by a single camera. It uses features that can represent the shape of the human area in the depth direction, as well as the features such as motion direction and speed. The performance and effectiveness of the method are verified by experiments.

Keywords: Behavior segmentation, Motion recognition, Optical flows, TMRIs, Ex-HOOF, MHI

1. Introduction

Nowadays, the world's population is aging. The number and proportion of older people in the population is growing in every country in the world. Population aging will become one of the most significant social changes in the 21st century. By 2030, 1 in 6 people in the world will be 60 years or older (16%), and the share of people aged 60 and above will increase from 1 billion in 2020 to 1.4 billion. By 2050, the number of people aged 80 and over is expected to triple between 2020 and 2050, to 426 million [1]. Especially in Japan, 30% of the population is over 60 years old. Some social problems, such as solitary death which more than 50% of people worry about, are also intensifying [2]. Moreover, 67.1% of the respondents felt that the domestic security situation in Japan has deteriorated in the past 10 years [3]. Considering these problems, it is necessary to develop a system that can detect the behavior of the elderly and detect abnormal behaviors such as crime and theft, so as to realize a safe and secure society.

In related research on behavior recognition, X. Yang et al. [4] proposed a behavior segmentation and recognition method based on CSI, but it is not aimed at the segmentation of continuous human behavior. W. Xing et al. [5] proposed a behavior segmentation method based on posture histograms and adjusted sliding windows. This method requires learning the features of various postures. In related research on action recognition using computer vision, the conventional methods include the Flow Vectors method [6] and the MHI (Motion History Image) method [7]. However, these methods using a

single camera are only suitable for the motion on the plane perpendicular to the optical axis of a camera, and the motion in the direction of the camera optical axis (toward or away from the camera) is not dealt with. Therefore, an extended 3D-MHI [8] and a reverse MHI method [9] have been proposed. However, [8] has the problem of high computational cost of creating 3D images, and, with [9], the recognition rate needs to be improved.

In this study, we propose a new method to describe the motion in the depth direction, making it possible to realize the segmentation and recognition of behaviors containing these motions. We segment human behavior by extracting features from the human area and then select key frames of the segmented actions. The key frames can be described through TMRIs (Triplet Motion Representation Images) [10]. The shape features of TMRIs, the features of optical flow and the changes of motion are also extracted to analyze and identify the motion of the frame. Finally, the recognition results of these frames are counted, and the final result of behavior recognition is obtained.

2. Methodology
2.1. *Behavior segmentation*

When human behavior consists of several types of motions, it is necessary to separate the behavior into respective motions to analyze the behavior. In this paper, we propose an automatic behavior segmentation method that does not require prior learning or training. The feature points are set at equal distances on the contour

line of the human area. Then feature points are tracked through the LK method [11] to obtain the optical flow, and RANSAC [12] is applied to find the true value by removing the influence of outliers. Changes in the direction of human movement can be distinguished from changes in the trajectory of the center of gravity coordinates and the average value of optical flow. Therefore, we calculate the point where a sudden change in trajectory occurs in the *x*-axis direction of the center of gravity coordinates and the boundary point between plus and minus of the average value of optical flow separately.

In Equation (1) and (2), if the change of the current frame exceeds a certain threshold, division is performed from the current frame and the number of the previous frame is used as the division point.

$$num_{tmp} = \begin{cases} num_{tmp} + 1 & if\ th1 < \frac{X\_dif_{sum}}{num_{tmp}} < th2 \\ 1 & otherwise \end{cases} \quad (1)$$

$$X\_dif_{sum} = \frac{\sum_{n=new}^{new-num_{tmp}}(x_n - x_{n-1})}{num_{tmp}} \quad (2)$$

where, *th1* and *th2* are thresholds. num_{tmp} is a parameter that determines whether or not to divide from the current frame. X_dif_{sum} is the average rate of change of the center of gravity's *x*-axis coordinate, and *new* is the number of the current frames.

When the direction of human motion changes, it can also respond to the average of optical flow. The intersection of the average optical flow m_{ave} and the *x*-axis is determined to be the division point. m_{ave} is defined by the following formula.

$$m_{ave} = \frac{\sum_{k=1}^{N} m_k}{N} \quad (3)$$

where, m_k represents the value of the *k*-th optical flow, and *N* denotes the total number of optical flows.

Then the division points are determined by matching the points of the two features after performing data smoothing within the threshold. The video can be divided using the obtained division points. After that, key frames are selected in each divided video, as shown in Fig. 1. In the figure, the orange points are the division points detected by features, which separate the behavior into several motions. The green points are the points that divide the motion into four equal parts, are also extracted as key frames.

In the end, by identifying key frames and determining the classification of the actions they represent through majority voting, the analysis of behavior composition is completed.

Fig.1 The definition of the ground truth.

2.2. *Motion recognition*

To capture the motion in the depth dimension, we employ TMRIs to represent actions. We identify and classify actions by leveraging their shape features, extracting directional velocities from the movements, and observing changes in the human region.

TMRIs is an extension of the conventional MHI. It is designed to express human motion, including motion along the camera optical axis, using three types of motion history images: *newness*, *density*, and *depth*. Among them, *newness* represents the MHI, *density* illustrates the appearance frequency of the foreground in the past τ frames, and *depth* indicates the depth information obtained from the FoE detection results. The shape features of TMRIs, is defined as V^{TMRIs}. Ex-HOOF (Extended Histogram of Oriented Optical Flow) [10] is used to extract the speed and directional information of motions that are not readily visible in TMRIs features. The feature of Ex-HOOF is denoted as $V^{Ex-HOOF}$.

Additionally, to represent more complex and detailed motion features, we incorporate changes in the centroid and area (AC) of the human region. The feature can be defined as $V^{AC} = (F_A, F_C)$. Among them, the area feature $F_A = (Area_\tau^{ave}, Area_\tau^{sd})$, where $Area_\tau^{ave}$ is the average value, and $Area_\tau^{sd}$ denotes the standard deviation of the change of the foreground area. The formulas are as follows;

$$Area_\tau^{ave} = \frac{1}{\tau}\sum_{i=0}^{\tau} Area_{comp}^{t-i} \quad (4)$$

$$Area_\tau^{sd} = \sqrt{\frac{1}{\tau}\sum_{i=0}^{\tau}(Area_{comp}^{t-i} - Area_\tau^{ave})^2} \quad (5)$$

Here, $Area_{comp}^t$ is the changes of areas between the frames, given by

$$Area_{comp}^t = \frac{(Area_t - Area_{t-p})}{Area_t} \quad (6)$$

a. Change in the trajectory of the center of gravity coordinate in the *x*-axis

b. Average change in optical flow in the *x*-axis direction

c. Average change in optical flow in the *y*-axis direction

Fig.2. Features used for behavior segmentation.

Fig.3 The definition of the ground truth.

The centroid feature $F_C = (Cx_\tau^{ave}, Cy_\tau^{ave}, Cx_\tau^{sd}, Cy_\tau^{sd})$. C_τ^{ave} means the average value and C_τ^{sd} indicates the standard deviation of the change in the coordinate of the center of gravity. They are defined by

$$Cx_\tau^{ave} = \frac{1}{\tau} \sum_{i=0}^{\tau} (Cx_t - Cx_{(t-i-p)}) \qquad (7)$$

$$Cy_\tau^{ave} = \frac{1}{\tau} \sum_{i=0}^{\tau} (Cy_t - Cy_{(t-i-p)}) \qquad (8)$$

$$Cx_\tau^{sd} = \sqrt{\frac{1}{\tau} \sum_{i=0}^{\tau} ((Cx_t - Cx_{(t-i-p)}) - Cx_\tau^{ave})^2} \qquad (9)$$

$$Cy_\tau^{sd} = \sqrt{\frac{1}{\tau} \sum_{i=0}^{\tau} ((Cy_t - Cy_{(t-i-p)}) - Cy_\tau^{ave})^2} \qquad (10)$$

Finally, by integrating the above features, we get a feature vector V, as shown below.

$$V = (V^{TMRIs}, V^{Ex-HOOF}, V^{AC}) \qquad (11)$$

Action recognition is conducted using the *k*-nearest neighbors (*k*-NN) method in the proposed method.

3. Results and Discussion

3.1. *Accuracy of behavior segmentation*

In the behavior segmentation experiment, three people (labelled as 1,2,3) perform behavior A, B, C and D. The specific motion sequences are as follows: A: Walking left rear → Walking right → Walking front, B: Walking right rear → Walking left → Walking front, C: Walking rear → Walking left → Walking right front, D: Walking rear → Walking right → Walking left front. In the segmentation experiments, we verify the accuracy and recall of segmentation point selection based on the trajectory of the centroid in the *x*-axis and the average direction of optical flow. The example of the features of behavior A is shown in Fig. 2. The recall rate (*Recall*) is defined by

$$Recall = \frac{P_T}{P_{GT}} \times 100[\%] \qquad (12)$$

Here, P_{ALL} is the total number of calculated segmentation points, P_T is the number of segmentation points that were accurately segmented, and P_{GT} is the number of ground truth segmentation points.

In the experiment, a motion between two motions, such as turning around or standing, is called a transition action. If the division point is within a transition action, this point is considered a correct division point. If one behavior consists of four consecutive motions, the definition of the ground truth division points is shown in Fig. 3.

Table 1 shows the results of behavior segmentation, yielding an average recall of 91.7%.

3.2. *Recognition rate of the motions*

In the motion recognition experiment, four people performed 12 kinds of motions, and features were created for these motions. In the experiment, we use leave-one-out cross-validation to evaluate the accuracy of motion recognition. The recognition rate R is defined by

$$R = \frac{N_T}{N_{ALL}} \times 100[\%] \qquad (13)$$

Jing Cao, Yui Tanjo

Here, N_T is the total number of correctly recognized features and N_{ALL} represents the total number of features.

The recognition rates obtained using TMRIs, EX-HOOF, TMRIs + EX-HOOF, and the proposed method (TMRIs + EX-HOOF + AC) are shown in Table 2.

As shown in the table, the proposed method achieved an average recognition rate of 97.25%. This is because TMRIs represent depth information determined by FoE detection results. In addition, Ex-HOOF includes movement speed and direction information, and the detailed feature AC expresses changes in the area of the motion region and the center of gravity. Therefore, in the final proposed method, the average recognition rate for daily activities is 99.1%, and the average recognition rate for falling activities is 89.84%. Furthermore, the average recognition accuracy for motions that include movement in the depth direction is 96.60%, and the average recognition accuracy for other motions is 94.85%. The average recognition accuracy of the proposed method using TMRIs + EX-HOOF + AC is about 17.41% higher than the method using only TMRIs.

4. Conclusion

In this paper, we proposed a human behavior segmentation and recognition method, which can handle the behavior including movements in the depth direction. For each behavior, the segmentation method proposed in the paper effectively identifies division points, enabling the recognition of segmented actions. The average recall rate for behavior segmentation has reached 91.69%. Furthermore, in action recognition, the proposed method achieved an average recognition rate of 97.25%. This strongly validates the effectiveness of the proposed approach.

In the future, our focus will be on achieving a high-speed and fully automated process of behavior segmentation through recognition. Additionally, despite the current good recall rate, there is still a need to enhance the accuracy of the automatic segmentation method to reduce the subsequent workload of recognition and segmentation adjustments.

Table 1. The result of behavior segmentation

Per-son	Beha-vior	Trajectory	Optical flow	Integration	Positive number	Recall [%]
1	A	23	9	6	3	100.0
	B	33	20	9	4	100.0

Abstract

The surge in online education has underscored the pressing issue of cyberbullying in virtual classrooms. This paper introduces an inventive method for early cyberbullying detection by analyzing students' engagement and emotional responses in online classrooms. The proposed *SFER-YOLOv5* model, integrating Student Facial Expression Recognition with an enhanced YOLOv5 object detection model, incorporates transformative optimizations. These include Soft NMS for Non-Maximum Suppression, the integration of a Channel Attention (CA) module within the YOLOv5 architecture, and the use of Enhanced Intersection over Union (EIOU) as the bounding box regression loss function. This approach identifies diminished engagement and emotional irregularities, offering a proactive framework for mitigating cyberbullying in online classrooms.

Keywords: Cyberbullying Mitigation, Emotional Analysis, Facial Expression Recognition, Online Classroom.

1. Introduction

With the rapid advancement of information technology and the global rise of online education, online teaching platforms have become an integral part of modern education. The sudden outbreak of the COVID-19 pandemic in 2020 has had a significant impact on our learning, work, and daily lives. Traditional face-to-face teaching and communication between students and teachers have become a major challenge. Many universities have chosen online teaching as an alternative. However, accompanying this advancement are a host of challenges, one of which is the issue of cyberbullying in the digital realm. Cyberbullying, also known as online harassment or cyber aggression, refers to the malicious use of digital technology to target others with acts of aggression, insults, threats, and more. Particularly in online classroom environments, both students and educators may find themselves vulnerable to cyberbullying, which can severely impact their emotional well-being, psychological state, and overall learning experience.

In the online classroom environment, students and teachers communicate through screens, and teachers can only judge students' listening status based on their facial expressions. Analyzing changes in students' facial expressions can help teachers better understand their listening status and make timely adjustments to the

Shuai Wang, Abdul Samad Shibghatullah, Javid Iqbal Thirupattur, Kay Hooi Keoy

teaching mode [1]. In 1971, American scholar Ekman et al. [2] conducted extensive experiments on facial expressions, categorizing them into six primary emotions: happiness, surprise, fear, sadness, disgust, and anger. Students' emotions in class can be categorized as positive, negative, or neutral. Positive emotions include happiness and surprise. When students show positive emotions, it indicates their willingness to accept the knowledge taught in class, and they are actively engaged in listening and thinking. Negative emotions include sadness, anger, fear, and disgust, which indicate that students have a dislike or lack of attentiveness towards the knowledge taught by the teacher. This can be an indication of their lack of concentration in class. Neutral emotions suggest an average level of student engagement in listening during class. Therefore, analyzing students' facial expressions in online classrooms holds great significance.

Faced with this challenge, many educational institutions and online teaching platforms are turning their attention to how to effectively detect and address cyberbullying in virtual classrooms. Facial expression recognition technology has garnered significant attention due to its potential applications in emotion analysis and affective state monitoring. Currently, there is limited research on facial expression recognition based on YOLOv5. This paper proposes a facial expression recognition method based on an improved YOLOv5 model, aiming to achieve timely detection and intervention of cyberbullying incidents in online classrooms. The original YOLOv5 algorithm achieved an overall recognition accuracy of 73.1% and 83.4% on the Fer2013 dataset and a self-constructed dataset for the three expressions involved in the study: happiness, sadness, and neutral. Through improvements in NMS, and the addition of an attention mechanism module, the improved YOLOv5 algorithm further enhances the recognition accuracy on the Fer2013 dataset and the self-constructed dataset.

2. Related work

2.1. *Online classroom cyberbullying*

Online education has become increasingly prevalent in recent years, especially due to the COVID-19 pandemic, which has posed new challenges and opportunities for educators and students. One of the major challenges is cyberbullying [3], [4], which refers to various forms of

online harassment, such as verbal abuse, threats, spreading false information, and exclusion from online discussions, that occur within virtual classroom environments. Cyberbullying can have detrimental effects on students' learning outcomes, psychological well-being, and social relationships [5]. Therefore, it is imperative to develop effective strategies and mechanisms to detect and prevent cyberbullying incidents in online classrooms. Previous research on this topic has adopted various techniques and perspectives, such as behavior analysis, natural language processing, social network analysis, machine learning, and emotion recognition, to identify and intervene in potential bullying situations that students may face in virtual classrooms. Moreover, some studies have highlighted the role of educational interventions and awareness-raising among educators and students about cyberbullying, aiming to foster a safer and more positive online learning environment [6].

2.2. *YOLOv5 and object detection*

In May 2020, UltralyticsLLC released YOLOv5 [7], a lightweight model with an image inference speed of up to 0.007 second, developed using python. It can process 140 FPS and can meet the real-time requirement for video sequences. The four network structures Yolov5s\5m\5l\5x are basically same in principle and content, controlled respectively by the parameters of width_multiple and depth_multiple in width and depth. The size and accuracy of the four versions of the model increase sequentially. In practical applications, the appropriate size of the model can be selected based on different scenarios. The YOLOv5s model has small depth and fewer parameters, making it more applicable to real-time tasks in facial expression recognition due to its faster inference speed compared to the other three versions. Since the release of YOLOv5, its versions have been updated and iterated, and this paper is based on the version 6.0 for improvement.

In summary, prior research has highlighted the urgency of addressing online classroom cyberbullying and the potential of facial expression recognition technology for emotion analysis. Additionally, the advancements in object detection methods, particularly YOLOv5, provide a solid foundation for integrating object detection into cyberbullying detection frameworks. This study builds upon these foundations to propose a novel model *SFER-YOLOv5* for detecting cyberbullying incidents in online

classrooms using an enhanced YOLOv5 model for facial expression recognition.

3. Methodology

Currently, there is limited research on facial expression recognition based on YOLOv5, and this method presents a unique opportunity for enhancing online classroom engagement and security. The original YOLOv5 algorithm achieved an overall recognition accuracy of 72% and 83.1% for the three facial expressions of happiness, sadness, and neutrality on the Fer2013 dataset and the self-built dataset. Through improvements in the non-maximum suppression (NMS) algorithm, loss function, and the addition of an attention mechanism module, the improved YOLOv5 algorithm achieved further improvement in recognition accuracy on the Fer2013 dataset and the self-built dataset.

3.1. *Data collection and processing*

As students' understanding of knowledge can be broadly categorized into three levels: mastery, confusion, and non-mastery, in order to gain a more accurate understanding of the facial expression feedback corresponding to these three levels, we conducted a survey in the form of a questionnaire to investigate the relationship between mastery levels and facial expression feedback. The survey involved higher vocational schools, and undergraduate institutions, with a total of 520 questionnaires collected (male: 287, female: 233). Seven basic expressions were selected, including anger, surprise, disgust, happiness, fear, sadness, and neutral.

This study used the Fer2013 dataset and a self-constructed dataset of student facial expressions in the classroom. The Fer2013 dataset contains some non-facial images and mislabeled images. To improve the experimental accuracy, the dataset was carefully selected, cleaned, and filtered, resulting in a total of 11,000 images. The self-constructed dataset of student facial expressions in the classroom was collected through video monitoring, and it consists of 668 images. The images were annotated by extracting frames from the video footage.

3.2. *Enhanced YOLOv5*

3.2.1. *Improved Non-Maximum Suppression (NMS)*

Both NMS and Soft NMS utilize predicted classification confidence as a measure, where higher confidence indicates more accurate localization. In this

study, the improved Soft NMS is used instead of the original NMS, effectively improving the performance of the detection.

3.2.2. *Coordinate attention module*

In this study, we introduce the Coordinate Attention (CA) mechanism, which incorporates positional information into channel attention. Experimental results reveal that incorporating the CA attention mechanism module into the network backbone improves detection accuracy to some extent, particularly in classroom settings with numerous students or when students in the back rows are at a considerable distance from the camera. This enhancement is attributed to the CA module (Fig. 1), which reinforces channel features in the feature map, enabling the network to acquire more detailed and effective information.

Fig. 1 The improved network structure.

3.2.3. *Improved Loss function*

We have improved the initial loss function by incorporating the Efficient-IOU (EIOU) to compute width and height losses, replacing the aspect ratio calculation based on the CIOU foundation. Furthermore, Focal Loss has been introduced concurrently to mitigate the challenge posed by sample imbalance.

4. Experiments and results

The experimental platform in this study was a 64-bit Windows 10 operating system with a Gen Intel Core i5-11400H CPU and NVIDIA RTX 3050 graphics card. The deep learning framework used was PyTorch, with a development environment consisting of PyTorch 1.8 and Python 3.7. The number of training epochs was set to 300, and the dataset was divided into training, validation, and

Shuai Wang, Abdul Samad Shibghatullah, Javid Iqbal Thirupattur, Kay Hooi Keoy

testing sets following a 6:2:2 ratio. To effectively evaluate the experimental results, a comparative experiment was conducted on the self-constructed dataset and the Fer2013 dataset before and after algorithm improvement. The evaluation criteria were detection accuracy (P) and mean average precision (mAP@0.5).

Table 1 presents the experimental outcomes on our self-constructed dataset. Fig.2 illustrates the detection accuracy (*P*) curve of the self-constructed dataset, comparing YOLOv5 with SFER-YOLOv5.

Table 1. Experimental results on self-constructed dataset.

Expression	YOLOv5		SFER-YOLOv5

5. Conclusion

This study addresses the challenges of low real-time detection rates and poor timeliness in recognizing students' facial expressions in complex classroom environments while simultaneously focusing on mitigating and preventing cyberbullying incidents. Our *SFER-YOLOv5* model improves the non-maximum suppression (NMS) by replacing it with Soft NMS, enhances the feature extraction capability by adding the Coordinate Attention (CA) mechanism module, and improves the representation ability of target boxes by using EIoU instead of CIoU. Our experimental results are highly encouraging, demonstrating a 3.9% increase in detection accuracy (P) and a 3.0% increase in mAP@0.5 on the self-constructed dataset. Beyond facial expressions, future research will integrate poses and gestures for a comprehensive analysis of online classroom dynamics. This enhances our cyberbullying prevention by understanding students' engagement and emotions more comprehensively.

Abstract

The most critical human sensory function resides in vision. This paper focuses on utilizing visual information, specifically self-perspective footage, to identify individual movements. Existing researches require third-party filming to recognize human body movements and states. The proposed method, on the other hand, simply attaches a camera to the human head and enables the recognition of the subject's actions. Consequently, it becomes easier to monitor daily movements of a human and gather his/her data on body kinetics. This approach would be beneficial in scenarios involving individuals engaging in risky behavior or, during a certain emergency, providing valuable assistance.

Keywords: My VISION, Posture estimation, Optical flow, HSV conversion

1. Introduction

Vision is the most crucial function among human sensory organs. Human intakes a vast amount of information through vision. Therefore, self-perspective footage can potentially serve as the primary source of information from an individual. In fact, it has been evident that visual information is more potent in perceiving human posture and bodily movements compared to non-visual information [1]. Therefore, it was considered possible to recognize the filmmaker's physical state by analyzing self-perspective footage.

Maintaining physical health has become more commonplace, exemplified by the widespread use of smartwatches. Smartwatches offer various functions such as recording heart rate, blood oxygen levels, and sleep patterns. By utilizing these features to log daily physical conditions, it becomes possible to promptly recognize deviations from normal bodily states.

Hence, this study aims to develop a method for analyzing and recording an individual's activities from a self-perspective video. Similar research includes studies on self-posture estimation [2], methods utilizing single-eye images based on HOG features [3], and methods employing deep learning [4]. However, these methods focus on action estimation or recognition rather than understanding a person's activity. Additionally, the techniques using HOG-based single-eye images or employing deep learning require capturing individuals externally, which is entirely different from the self-perspective video approach in this paper.

2. Methodology

This section describes feature extraction methods. The features to be extracted are the values of the hue and the norm of the optical flow on an image.

2.1. Detection of area similarity

This subsection describes the method for detecting area similarity. By dividing the image into multiple blocks and comparing the H (Hue) histogram features of specific blocks, area similarity is determined.

2.1.1 HSV Conversion

First, the RGB color image, which serves as the input image, is converted from the RGB color space to the HSV color space. The RGB color space represents a color space with red, green, and blue as coordinate axes, while the HSV color space represents a color space with hue, saturation, and value as coordinate axes.

2.1.2 Creation of H(Hue) histogram

In the proposed method, a histogram based on the Hue (H) is constructed. The values of S (Saturation) and V (Value) are not taken into account. The H histogram, as depicted in Fig. 1, represents the hue values on the horizontal axis and the frequency count on the vertical

Iichirou Moribe, Yui Tanjo

axis. Although the original range of hue values is 1 to 360, for expedited processing, it is scaled to 1 to 180.

Fig. 1. H (Hue) Histogram

2.1.3 *Calculation of similarity*

The H histogram is used to determine the similarity between two images. Here, the similarity is calculated using the following formula. The meanings of the characters in Eq. (1) are given in Table 1.

$$S(A, B) = \frac{\sum_{i=0}^{N} \min(h_i^A, \ h_i^B)}{\sum_{i=0}^{N} h_i^A} \qquad (1)$$

Table 1. Meanings of the characters in Eq. (1)

N	Number of pixels in the image
h_i^x	The ith element of histogram x
$\min(x_A, x_B)$	Minimum value of x_A and x_B

2.2 *Derivation of optical flow*

This subsection describes the derivation of optical flow. The optical flow is the movement vector of the camera, or the subject obtained by mapping feature points in two consecutive frame images extracted from the video.

2.2.1 *Feature point extraction and description*

With respect to two consecutive frame images, the feature points in the first frame image are focused on. After extracting the feature points, the feature values of each feature point are described, and the feature points are matched in the two frame images. The Shi-Tomasi corner detection method is used for feature point extraction and feature point description [5]. The image from which the feature points were extracted is shown in Fig. 2.

Fig. 2. Input image with feature point extraction

2.2.2 *Feature point matching*

The Lucas-Kanade method is used for matching feature points [6]. The Lucas-Kanade method is one of the leading methods for deriving optical flow and is computationally less expensive than the method that finds all pixels in the image by searching for them.

2.2.3 *Removal of outliers*

The optical flow is obtained by the feature point matching, but the optical flow obtained from the actual video contains many outliers. Outliers are false flows obtained by matching different feature points and need to be removed for accurate analysis. Outliers are removed by applying RANSAC to modelling with homography matrices.

An example of the optical flow obtained by the above process is shown in Fig. 3. Note that the green points in the figure represent the end points of the optical flow.

Fig. 3. Derived optical flow.

2.3 *Normal state recognition*

In this subsection, the method of normal state recognition is first described. Next, the methods for classifying states are described.

2.3.1 *Feature extraction methods*

The input image is separated into nine blocks and each block image is assigned a number as shown in Fig. 4. Focusing on blocks 2, 5 and 8, the three block images are HSV-transformed and H histograms are created. The H histograms are compared to obtain the similarity between block 8 and block 2, and between block 8 and block 5, respectively. The similarity between block 8 and block 2 and between block 8 and block 5 is calculated by comparing the H histograms.

Block 1	Block 2	Block 3
Block 4	Block 5	Block 6
Block 7	Block 8	Block 9

Fig. 4. Separated input image

Furthermore, in the method, the number and norm of optical flows are the key features. First, the average value of the norm of the optical flow is calculated with each frame, and then the maximum value of the norm in the whole video is calculated. This value is used to evaluate the intensity of the motion of the entire video. The average value of the norm of the optical flow is calculated by the following equation. The meanings of the characters in Eq. (2) are shown in Table 2.

$$V_f = \frac{1}{N_f} \sum_{i=1}^{N_f} V_i \qquad (2)$$

Table 2. Meanings of the characters in Eq. (2)

N_f	Total number of optical flows obtained between the fth frame and the f+1th frame
V_i	Norm of each optical flow

2.3.2 *Prior statistics*

Since the estimation of each state is done by comparison with the normal state, it is necessary to know in advance what properties each state has in relation to the normal state. For the three states, feature extraction is carried out using the above procedure with the three videos.

The results of the validation of the properties of the normal state are presented in Table 3. The results of the validation of the properties of the 'looking down' state are presented in Table 4. The results of the validation of the properties of the 'stumble' state are presented in Table 5.

Table 3. Results of the validation of the properties of the normal state

Scene	$\bar{S}$	V_{max}
Video 1	0.53	118
Video 2	0.40	109
Video 3	0.51	124

Table 4. Results of the validation of the properties of the 'looking down' state

Scene	$\bar{S}$	V_{max}
Video 1	1.29	113
Video 2	1.19	110
Video 3	1.06	75.6

Table 5. Results of the validation of the properties of the 'stumble' state

Scene	$\bar{S}$	V_{max}
Video 1	0.61	271
Video 2	0.54	181
Video 3	0.45	194

From these results, it can be read that $\bar{S}$ is greater in the 'looking down' state among the three states. This means that in the 'looking down' state, the similarity of block 2, block 5 and block 8 is greater. It can also be seen that V_{max} in the 'stumble' state is the largest among the three states. This indicates that the motion in the 'stumble' state is the most intense.

2.3.3 *State analysis*

In the proposed method, the motion states are classified into three states. Classification 1: If the value of S satisfies Eq. (3), the image is classified as a 'looking down' image. If the value of S does not satisfy Eq. (3), the image is classified as 'other' image. 'other' can be either 'normal' or 'stumble'. The state of Classification 1 is determined using the following formula.

$$S - \bar{S} \geq TH1 \qquad (3)$$

Here S is the similarity in the current state and $\bar{S}$ is the average of the similarity in the normal state. $TH1$ is the threshold value in Classification 1.

Sr is the proportion of the images in the image group that are classified as 'looking down' in Classification 1, and if the value of Sr satisfies Eq. (4), the image is classified as "looking down". If the value does not satisfy Eq. (4), it is assumed to be in the 'other' state and proceeds to the next state estimation. If the value of $Vmax$ is satisfies Eq. (5), the state is judged as the 'stumble' state. If none of the above conditions is satisfied, the state is judged as normal. Eq. (4) and Eq. (5) are shown below.

$$Sr - \bar{S_r} \geq TH2 \qquad (4)$$

$$Vmax - \overline{V_{max}} \geq TH3 \qquad (5)$$

Here Sr and $Vmax$ are the evaluated values of similarity and intensity of motion in the current condition, respectively. $\bar{S_r}$ and $\overline{V_{max}}$ are the average values of similarity and intensity of motion, respectively, in the normal condition. $TH2$ and $TH3$ are the threshold values for each condition.

3. Experimental Result

3.1. *Experimental methods*

An experiment is conducted with a camera worn on the head. Fig. 5 shows an image of the camera worn by a subject during the experiment.

Iichirou Moribe, Yui Tanjo

(a)   (b)

Fig. 5. Image of a worn camera. (a) side view,(b) rear view.

The details of the experimental method are as follows:

1. Feature extraction was carried out from five videos in the 'normal' state, and a database was created by averaging the feature values in each video.
2. Eight videos containing each of the three states - 'normal', 'looking down' and 'stumbling' - taken at different locations and at different dates and times were used as input videos to estimate each of the states.

The parameters during the experiment are shown in Table 6.

Table 6. Parameters' values

	Value	
Threshold 1	0.35	$TH1$ in Eq. (2-2)
Threshold 2	0.65	$TH2$ in Eq. (2-3)
Threshold 3	55	$TH3$ in Eq. (2-4)

3.2. *Result*

The results of the experiment are shown in Table 7. For each of the eight videos, the number of correct responses for the 'normal', 'looking down' and 'stumble' states were 6, 7 and 7 respectively.

Table 7. Results of the experiment.

state	normal	looking down	stumble
normal	6	0	2
looking down	1	7	0
stumble	1	0	7

4. Conclusion

In this paper, we proposed a method for estimating the activity state of the camera wearer from the self-viewpoint video obtained using a self-viewpoint camera. Three human walk states were detected by comparing H (Hue) histograms and using features calculated from the optical flow. In the experiment, three states were detected: 'normal', 'looking down' and 'stumble' states. The results showed that estimation was successful in more than 75% of all states. However, in the estimation of all states, misrecognition occurred in which a different state was estimated. Future issues include the estimation of states in case of sudden changes in vision and estimating more precise states corresponding to the angle of looking down.

Abstract

When individuals with visual impairment go out, public transportation such as trains and buses is commonly used. However, many of them experience accidents, such as falling from train platforms or tripping due to unexpected contact with other passengers. To solve this problem, we propose a method using the MY VISION system which detects obstacles that may pose risks to individuals with visual impairment. The proposed method detects obstacles such as passengers' pillars and platform edges at train stations. We employ an RGB-D camera for capturing frontal views of a user, use depth images to detect the edge of obstacles and level differences, and give warning to the visually impaired user based on the distance between him/her and the detected obstacle. Experimental results show satisfactory performance of the method.

Keywords: Visually impaired, Safety, Train station platform, Obstacles detection, MY VISION

1. Introduction

Public transportation is often used as a means of mobility for individuals with visual impairments, and more than half of them frequently utilize railways [1]. However, approximately 30% of visually impaired individuals have experienced falls from station platforms, resulting in an average of 76 fall incidents annually [2].

There are methods for detecting steps and obstacles to assist visually impaired individuals in walking [3], [4]. However, the methods that use depth images to acquire the walking plane and to detect steps and obstacles are affected by noise, as the distance from the camera increases, it results in a narrow and less accurate detection range. Additionally, some methods use color information, but they are often designed for indoor use and are influenced by the factors such as time of day and weather when used outdoors.

In this paper, we propose a method that detects step edges directly using depth images and determines the distance from the pedestrian to the step. The proposed method, designed to assist visually impaired individuals on station platforms, involves region segmentation using Graph Based Segmentation on depth images and the detection of step lines using Line Segment Detector.

2. Method

2.1 Obstacles detection

Initially, the coordinates conversion is performed from the image coordinate system to the camera image coordinate system. The transformation formula is given as follows.

$$X(x,y) = \frac{(x - c_x) \times Z(x,y)}{f_x} \quad (1)$$

$$Y(x,y) = \frac{(y - c_x) \times Z(x,y)}{f_y} \quad (2)$$

$$Z(x,y) = d \quad (3)$$

Here c_x is the optical center in the *x*-axis direction, c_y is the optical center in the *y*-axis direction, f_x is the focal length in the *x*-axis direction, and f_y is the focal length in the *y*-axis direction.

Changes in $Y(x,y)$ and $Z(x,y)$ with respect to the change in the *y*-coordinate, as well as the changes in $X(x,y)$ and $Z(x,y)$ with respect to the change in the *x*-coordinate, are expressed by the following equations.

Shintoro Yamada, Yui Tanjo, Seiji Ishikawa

$$\frac{dY(x,y)}{dy} = Y(x,y) - Y(x,y+k) \qquad (4)$$

$$\frac{dZ(x,y)}{dy} = Z(x,y) - Z(x,y+k) \qquad (5)$$

$$\frac{dX(x,y)}{dx} = X(x,y) - X(x+k,y) \qquad (6)$$

$$\frac{dZ(x,y)}{dx} = Z(x,y) - Z(x+k,y) \qquad (7)$$

The method computes the change in angle of the gradient of the Z coordinate with respect to the gradient of the Y coordinate at the point (x,y), as well as the change in angle of the gradient of the Z coordinate with respect to the gradient of the X coordinate. If these angles exceed a certain threshold, the method judges it as an obstacle region. The formula and conditional statement are shown as follows.

$$d\_YZ(x,y) = \arctan\left(\frac{\frac{dY(x,y)}{dy}}{\frac{dZ(x,y)}{dy}}\right) \qquad (8)$$

$$d\_XZ(x,y) = \arctan\left(\frac{\frac{dX(x,y)}{dx}}{\frac{dZ(x,y)}{dx}}\right) \qquad (9)$$

$$d\_YX(x,y) = \arctan\left(\frac{\frac{dX(x,y)}{dx}}{\frac{dY(x,y)}{dy}}\right) \qquad (10)$$

$$object = \begin{cases} 1 & if\, d_{YZ} > t\ and\ d_{XZ} > th\ and\ d_{YX} = 0 \\ 0 & otherwise \end{cases} \qquad (11)$$

2.2 *Step detection at a station platform*

The method designates the regions at both ends of the area, excluding the obstacle region as candidate regions where steps are present. Graph Based Segmentation (GBS) is applied to these candidate regions. By applying GBS, it is possible to segment and merge regions with similar features in the image. This allows for the detection of steps by dividing regions according to different planes of varying height.

2.3 *Line detection at a step edge*

Line Segment Detector (LSD) is then applied to the candidate regions which contain the steps detected through region segmentation. LSD detects candidate line segments at the edges of planes with different heights. Linear approximation is performed using RANSAC on the endpoints of the line segments detected by LSD to detect the edges of the train platform. The detected lines are represented by the equation $y = ax + b$ using the coordinates (x, y), and the gradient a helps determine the direction of the platform edge from the perspective of the observer. The conditional statements are as follows.

$$Dir = \begin{cases} Right & if\ a > th_1 \\ Left & if\ a < th_2 \\ Front & else \end{cases} \qquad (12)$$

2.4 *Distance from a step edge*

Let g_c be the point where the user of the proposed method is standing. It is defined as g_c = (width/2, *height*). Let g_p be a point on the detected line segment. Referring to the depth information on the left and the right of the point g_p which is the nearest point from g_c, the distance D_{min}^H is defined as the distance from the platform edge to the user. It is formulated as follows.

$$D = \min_{p=1,2,\dots,p}(|g_c - g_p|) \qquad (13)$$

$$d(x, y, d_e) = D \qquad (14)$$

$$D_{min}^H = \min_{d_{e^*}}(d(x+1, y, d_{e^*}), \\ d(x-1, y, d_{e^*})) \qquad (15)$$

3. Experimental result

In the performed experiment, an RGB-D camera was mounted on the chest of a subject, and video taking was conducted at a train platform. The proposed method was applied to the captured depth images, and comparison with ground truth was performed to assess the accuracy of the method. Experimental videos were captured in four situations involving obstacles such as people and luggage. Each video consists of 95 frames. Accuracy evaluation is done using the following formula.

$$overlap = \frac{GT \cap OA}{OA} > T \qquad (16)$$

$$angular\ error = |a_{GT} - a_d| < T_{q_a} \qquad (17)$$

$$distance\ error = |b_{GT} - b_d| < T_{q_b} \qquad (18)$$

(a)   (b)   (c)   (d)   (e)

Fig.1. Experimental result : (a) Original color image, (b) depth image, (c) ground truth, (d) obstacle detection, (e) result of platform edge detection（in blue color）

Table 1. Experimental result

Location	Obstacle	Percentage of correct line segment location [%]	Percentage of correct angles [%]	Percentage of correct distance [%]
The left platform edge	Person	100	94.5	98.6
The right platform edge	Person	100	91.0	98.0
The left platform edge	Person & luggage	100	88.0	97.0
The right platform edge	Person & luggage	98.1	92.7	89.0

Here GT represents the area of the ground truth line segment, OA represents the area of the line segment detected by the proposed method, and T is the threshold. In this experiment, T is set to 0.5. The success of the detection is determined when the ratio of overlapping line segment areas exceeds the threshold. a_{GT} represents the distance on the image between the midpoint of the ground truth line segment and g_c, whereas a_d represents the distance on the image between the midpoint of the detected line segment and g_c. T_{q_a} is the threshold. In this experiment, T_{q_a} is set to 15 pixels. The success of the detection is declared when the error between a_{GT} and a_d is below the threshold. b_{GT} represents the angle between the ground truth line segment and the *x*-axis, and b_d represents the angle between the detected line segment and the *x*-axis. T_{q_b} is the threshold. In this experiment, T_{q_b} is set to 5 degrees. The success of the detection is declared when the error between b_{GT} and b_d is below the threshold. An example of experimental results is shown in Fig. 1.

The overall experimental results are presented in Table 1. The average accuracy for line segment position, line segment angle, and line segment distance were 99.5%, 91.6%, and 95.6%, respectively.

4. Conclusion

This paper proposed a method of detecting the edges of steps on a train platform automatically using a chest-mounted RGB-D camera. This camera captures frontal scenes of a user with visual impairment, when he/she is walking. By detecting platform edges, the proposed method is able to contribute to the safety of a user with visual impairment who takes a train. Future work includes improving the proposed method for real-time processing and conducting validation experiments.

Abstract

Vectors studied in high school are a new concept that differs from those studied in previous scalars. Therefore, it has been pointed out that difficulties arise in the conceptual formation of vectors. This study aims to develop a learning support robot that can visualize vector information by robot movements, and to acquire vector concepts for students through classroom practice using the robot. The robot operates on a piece of imitation paper, marking the start and end points and connecting them with arrows to visualize the vectors. In a class using the robot, the student predicts the sum of the vectors, and the robot confirms it. A questionnaire was administered before and after the class. The results revealed significantly higher mean values when comparing the pre- and post-assessments.

Keywords: Educational Support, Robot, Omni-wheel, Omnidirectional movement, High school mathematics

1. Introduction

Recent large-scale surveys such as OECD-PISA and TIMMS have shown that "while there has been some improvement in the percentage of students who responded positively to the enjoyment of learning mathematics and its relationship to the real world, there are still issues in terms of motivation to learn, such as the fact that the percentage is still low compared to other countries" and in upper secondary schools, "the motivation to learn mathematics is not high. [1] Therefore, in the Guidelines for the Course of Study for Senior High Schools announced in 2018, it is stated that in senior high school mathematics "problems that reflect the real world are handled, students who are not highly motivated to study mathematics are made aware of the significance of studying mathematics, and this will lead to increased motivation and the development of mathematical ability. This will lead to the development of mathematical skills.

"Vectors" are "quantities that have magnitude and direction," a new concept that is different from the "quantities that express only magnitude" that students have learned in the past. Therefore, various difficulties have been pointed out in the concept formation of vectors. One reason for this is that vector learning is conducted only at the level of abstraction on the blackboard, making it difficult to formulate concepts. In addition, lack of understanding of the phases of vectors has also been pointed out [2], which may be caused by a lack of understanding of the concept of vectors themselves.

It has been noted that the use of robots in schools can have a positive impact on students. The use of robots, as part of STEM education, has been noted to have a positive impact on students' understanding of science, technology, engineering, and mathematics; students acquire a broader range of knowledge because robots are associated with technological applications that span multiple disciplines; and the use of robots can increase students' motivation and engagement in the classroom. The use of robots can have a positive impact on students by increasing their motivation and engagement in the classroom. [3], [4], [5], [6]

Therefore, the purpose of this study is to develop a learning support robot for learning vectors and to propose a class in which students can acquire the concept of vectors in addition to numerical calculations. By using the robot, students can learn vectors not only on the blackboard but also through concrete objects, which is expected to enhance their conceptual understanding. Through the proposed class, we expect to achieve the learning effects of understanding the concept of vectors and improving the motivation to learn.

2. Robots to be developed.
2.1. Definition of robot requirements

The robot is used to consider the problem of two vectors with respect to the sum of the vectors, and to develop a robot that represents the motion of the vectors in terms of the robot's motion. The angle between the two vectors shall be limited to 0-180°. The robot should be easy to operate for high school students to acquire the concept of

vectors. To visualize the vectors (trajectory of the robot), the robot is placed on a piece of imitation paper.

2.2. Robot Functions

The speed of the robot's motor is defined as the vector magnitude, the direction of the tires is defined as the vector direction, and the trajectory of the robot's progress is defined as the vector motion. When studying vector sums, the robot's trajectory can be defined as the sum of vectors by simultaneously performing the motions of the two vectors before combining the vectors.

2.3. Robot Design

This Robot will be developed using Artec Robo from Artec, Inc. The robot to be developed uses Artec blocks, DC motors, servo motors, and a battery box Studuino: bit. The omni wheel is an omni-directional moving mechanism. [7] The omni wheel is an omni-directional moving mechanism, and the wheels using the omni wheel can move in any direction. [8] Studuino: bit is used as the microcontroller. Artec blocks are used to assemble the robot. The servo motors are used to change the direction of the tires. DC motors are used to rotate the wheels, which allow the robot to move on a flat surface. Servo motors are used to change the direction of the tires. Electric power is supplied from a battery box. The size of the robot is about the same as the size of the classroom. The size of the robot should be large enough for students to hold in their hands and manipulate on a desk.

2.4. Correspondence between robot motion and vectors

Fig. 1 shows the appearance of this teaching material. Hereafter, the two wheels at the bottom of the robot will be referred to as Wheel A and the two wheels at the top of the robot in Fig. 1 as Wheel B. In Fig. 1, the direction of rotation and speed of the tires are specified for Wheel A and Wheel B, respectively, and the trajectory of the robot's motion is referred to as vector motion. The motion of the omni wheels is shown in Fig. 2. As shown in Fig. 2, the velocity in the x-direction is V_x and the velocity in the y-direction is V_y. Let the rotational velocities of the omniwheel be V_1 and V_2, respectively. considering the x-axis as the axis horizontal to V_1, the x-axis as 0 rad, counterclockwise as positive, and the angle between the two wheels as θ, the calculation of the velocity components can be expressed by the Eq. (1). With V_x and V_y known, the direction of movement is determined, and the direction of rotation and rotation speed of V_1 and V_2 are controlled.

$$V = \begin{bmatrix} V_1 \\ V_2 \end{bmatrix} = \begin{bmatrix} 1 & 0 \\ \cos(\theta) & \sin(\theta) \end{bmatrix} \begin{bmatrix} V_x \\ V_y \end{bmatrix} \quad (1)$$

Fig.1 Robots to be developed.

Fig.2 Omni wheel movement

However, V_1 is assumed to move in the direction V_x. If $V_1 = V_2$, the body moves straight ahead. The use of an omniwheel allows the robot to move without turning, so the sum of vectors can be moved in a direction different from the direction in which the wheels rotate. The wheels can be changed to any position by using servo motors in the upper positions where the wheels are mounted. This allows the direction of the wheel to be changed.

2.5. Image Analysis

Image analysis is performed to check whether the sum of vectors can be represented by the robot's motion. For the image analysis, we use a camera stand and a video shot from the top of the robot with an iPhone13. The frame rate of the video is 30 fps. PV Studio 2D PRO is used as the image analysis software [9]. Place a marker at the center of the robot and record the axis of the robot's movement. The x-axis and y-axis are set so that the center becomes the origin. The frame when the robot starts moving is used as the reference frame. Because of the blurring of the axis, the frame when the axis increases or decrease in a certain direction without any increase or decrease in the axis is the frame of the start of the movement. Similarly, the last frame in which the axis increases or decrease in a constant direction without increasing or decreasing back and forth is the frame at the end of the motion. Image analysis is performed by combining the two motions when the sum of vectors is decomposed. The analyzed data is quantified, theoretical values are derived, and a comparison of the motion and

the theoretical values is made to confirm that the sum of vectors can be expressed.

2.5.1. Image Analysis Theoretical Value

Define the first values of x-axis and y-axis (axis of the initial position) x_1 and y_1. Thus, the x-axis and y-axis values in frame n can be defined as x_n and y_n. The general forms of the x - and y-axis are x_n and y_n, respectively, where x_1 and y_1 are first term values.

The robot is assumed to move in the minus direction of the x -axis. Therefore, if the robot stops moving at frame m, the total number of frames can be represented by m. If the range of frames in the x -axis and y-axis directions is defined as a and b, respectively, then a and b can be expressed by Eq. (2) and Eq. (3), respectively.

$$a = |x_m - x_1| \qquad (2)$$
$$b = |y_m - y_1| \qquad (3)$$

If the values advancing in the x-axis and y-axis directions per frame are defined as g and h, respectively, then g and h can be represented by Eq. (4) and Eq. (5), respectively.

$$g = \frac{a}{m} \qquad (4)$$
$$h = \frac{b}{\frac{m}{2}} \qquad (5)$$

In the case of h, the vector shows two directions, so the number of frames is $m/2$, since the direction changes after half the time. Therefore, the values x_n and y_n of the x and y-axis in the nth frame can be expressed by Eq. (6), Eq. (7) and Eq. (8). However, when $n = 1$, $x_1 = g$ and $y_1 = h$.

$$x_n = x_{n-1} - g \ (n \geqq 2) \qquad (6)$$
$$y_n = y_{n-1} - h \quad (1 < n \leq m/2) \qquad (7)$$
$$y_n = y_{n-1} + h \quad (m/2 < n \leq m) \qquad (8)$$

When the number of frames is half, y_n can be expressed in two equations for $n/2$, since the sum of the vector's changes direction after half the number of frames has elapsed, since the vectors indicate two directions.

2.5.2. Results and Discussion of Image Analysis

In PV Studio 2D PRO, each displacement of one axis results in a movement of one meter. Based on this, comparing the results of image analysis with the theoretical values, the motion when the left and right wheels are moved simultaneously is shown in Fig. 3.

Fig.3 Results of Image Analysis.

When the number of frames is half, that is, when the direction of the vector sum changes, there is a difference of several frames between the measured and theoretical values. This may be due to the motor. We believe that the individual differences in the motors caused the slight discrepancies.

In addition, there was a discrepancy in the y-axis between the initial value and the final value of the measured value. This can be attributed to friction. Friction is considered to have shifted the y-axis by approximately 0.05 meter compared to the initial position.

The results show that the approximate shape of the sum of the vectors can be represented, although there is an error of a few centimeters from the theoretical value. In order to improve these deviations, we believe that the problem can be solved by making the arrows connecting the trajectories thicker. We also believe that the learning about the robot mechanism can be expanded by having the students consider the reasons for the deviations from the theoretical values.

3. Classroom Practice

3.1. Class Structure

In the class, the sum of vectors is represented by moving a robot on paper, attaching points to the starting and ending points of the robot, and connecting these points with arrows. The goal of the class is "to be able to consider the sum of vectors by transforming the decomposed vectors. The structure of the class is shown in Table 1. A questionnaire will be administered before and after the class.

※In the post-survey, add "Through the use of the robot in the class" at the beginning of the survey item. $*p < .05 ; **p < .01$

3.2. Survey Summary

On October 11, 2023, 17 high school sophomores (16 pre-survey, 17 post-survey) will be surveyed. The subjects are students who have not studied vector sums. The questionnaire will be administered using a five-item method with reference to the literature [10]. In order to measure knowledge, survey questions were administered before and after the survey. The pre-survey was conducted before the class, and the post-survey was conducted after the class. A *t*-test (with correspondence) was used to analyze the differences in attitudes toward independent.

3.3. Result

The results of the survey are shown in Table 2; significant differences were found in three items. For the knowledge question, the response rate for Question 1 was 62.4% before and 93.8% after the response. For question 2, the pre-response rate was 18.8% and the post-response rate was 50.0%.

4. Conclusion

In this study, we developed a learning support robot that represents vector sums. The robot was also used in a class. A questionnaire survey was conducted, and significant differences were found. In addition, the percentage of correct answers in the test was higher than before and after the class. In the future, we plan to further analyze the questionnaires and modify the robot and the classes.

Abstract

This paper investigates the effective methods of measuring the burden on the infant's body. Initially, the "the burden on the body and the lumbar spine burden are the same" was defined. The calculations and comparisons were carried out based on the two methods: the AnyBody Modeling System and the smartphone application Yo-bukun (a lumbar spine burden measurement application). The lumbar burden was calculated using the AnyBody Modelling System. In addition, an iPhone running the Yo-bukun lumbar burden measurement application was placed close to the heart position in order to simulate the lumbar burden. The results were compared with the respective average values and validated.

Keywords: Infants, Physical activity, Lunbar burden,

1. Introduction

In contemporary Japan, where the decline in children's physical fitness has emerged as a prominent concern [1], a comprehensive analysis of children's physical activity, particularly among young children, holds significant relevance. Various methodologies are employed to measure physical activity, encompassing continuous heart rate recording, electromyography, pedometers, calorie counters, and accelerometers [2], [3], [4]. Notably, smartwatches like the Apple Watch have gained popularity in recent years. However, the majority of these methods are tailored for adult use. Even among smartwatches, those designed for children are geared towards elementary school students and older, lacking compatibility with younger children. Accelerometers, pedometers, and behavior analysis are frequently employed for measuring physical activity in young children, yet a prevailing challenge in research utilizing these methods is their inadequacy for accommodating the needs of this demographic. Hence, there is an immediate necessity to investigate measurement methods that align with the body size of infants when assessing their physical activity.

The AnyBody Modeling System, developed at Aalborg University in Denmark, is a widely utilized musculoskeletal mechanics analysis software globally. The AnyBody Modeling System [5] employs inverse dynamics analysis to calculate forces acting on each part of the human body, including muscle activity, muscle and antagonist muscle forces, elastic energy of tendons, joint forces, and joint moments, during motion. While extensively used for simulating joint movements and analyzing motion capture data from video, research using this system has predominantly focused on adults, with limited exploration in the context of infants.

The Yo-bukun application [6], [7], a collaborative effort between the Faculty of Engineering at Miyazaki University and Densan Corporation in 2022, is an iPhone application quantifying and displaying lower back burden. This application is calibrated when the user stands upright, and calculates the amount of lumbar burden based on the tilt of the iPhone. This iPhone application facilitates the easy measurement of lower back burden and has not been previously applied to infants.

This paper investigates the effective methods of measuring the burden on the infant's body. The calculations and comparisons were carried out based on the two methods: the AnyBody Modeling System and the smartphone application Yo-bukun (a lumbar spine burden measurement application).

2. Methodology

In this paper, we will compare the results of the anybody modeling system and the "Yo-bukun" analysis application, which are set to the height and weight of infants. As a measurement system, the AnyBody

Sachiko Kido, Praveen Nuwantha Gunaratne, Hiroki Tamura

Modeling System is accurate if the movement is measured correctly. However, the AnyBody Modeling System is not realistic to accurately measure the burden of a moving infant. The "Yo-bukun" analysis application, who wears a smartphone, has fewer restrictions and can take measurements over a long period of time.

The value of the "Yo-bukun" analysis application is unclear how accurate for infants. Therefore, in order to confirm the accuracy of the "Yo-bukun" analysis application for infants, we conduct the comparative verification using the parameter settings as those for infants.

2.1. *The AnyBody Modeling System's analysis procedure*

In this paper, we use the AnyBody Modeling System to analyze the sample basic motion. Set the analysis settings in the AnyBody Modeling System to the height and weight of a typical infant, and calculate the amount of lumbar strain during movement in a pseudo manner.

2.2. *The Yo-bukun's analysis procedure*

Set the settings in the "Yo-bukun" analysis application to the same height and weight as in Chapter 2.1. We move by hand the smartphone according to the sample basic motion. In this way, we can simulate the basic motion on our smartphone.

3. Results and Discussion

3.1. *Analysis results with the AnyBody Modeling system*

Fig. 1 shows a series of balancing movements viewed from behind. The color of the muscles used changes, indicating areas of high strain. The fact that the lower back is colored in addition to the leg on which the body weight is placed indicates that the burden is placed mainly on the lower back. The posture with the maximum burden on the lower back is considered to be posture 5, in which the subject is off-balance. In the "balance" posture, the average value was 231[N] for approximately 8 seconds, and the maximum value was 283[N] (Fig. 1).

Fig. 2 shows a series of squatting movements, viewed from behind. In this movement, too, the color of the lumbar region changes, and it can be said that the lumbar region is burdened. The posture with the maximum lumbar load is posture 5 in the standing up motion. In the crouching movement, the average value for approximately 10 seconds was 322[N], and the maximum value was 484[N].

Fig. 1. Sequence of balance movements from behind with the AnyBody Modeling System analysis

Fig. 2. Sequence of squat movements from behind with the AnyBody Modeling System analysis

According to the AnyBody Modeling System analysis, two of the movements put the burden primarily on the lumbar region, thus meeting the definition of the "the burden on the body and the lumbar spine burden are the same".

3.2. *Analysis results with the Yo-bukun*

In the context of balance movements, the approximate average load over a duration of 8 seconds was 164[N], with a maximum load reaching 204[N].

In the squatting movement, the approximate average load over a duration of 10 seconds was 228[N], with a maximum load of 320[N].

3.3. *Comparison of Analytical Results between Two Software Applications*

In the Squatting movement, the average load was 322[N] in the AnyBody Modeling System and 228[N] in the Yo-bukun, resulting in AnyBody Modeling System exhibiting a slightly higher value of approximately 90[N]. The average value for balance movements was also 231 [N] for the AnyBody Modeling System and 164[N] for Yo-bukun, with the AnyBody Modeling System being about 70[N] higher. Although there was a slight discrepancy in the average values for both "Squatting" and "Balance," the fact that similar numerical values were obtained with both software applications. The burden on the body of infants during these two movements is approximately 200[N] to 350[N]. Although we predict that the difference between the two results is due to differences in the standards of the skeletal models used.

4. Conclusion

In this paper, the physical burden on infants was measured using two different software applications. A comparison of the average values obtained from the two software applications revealed no significant differences, suggesting that the burden on infants during the two movements can be considered to range from approximately 200[N] to 350[N]. The analysis time capability of the AnyBody Modeling System is approximately ten seconds. In contrast, the Yo-bukun enables prolonged analyses. The absence of significant differences between the AnyBody Modeling System and Yo-bukun in this study suggests the potential for measuring the physical load during infant body activities using Yo-bukun. In our future work, the validations are necessary by increasing the number of infant subjects.

Authors Introduction

Ms. Sachiko Kido

She received her M.S. from Nakamura Gakuen University, Graduate School of Human Development in 2015. Currently enrolled in the doctoral program at the Graduate School of Agriculture and Engineering, University of Miyazaki. Assistant Professor, Department of Early Childhood Education, Higashikyushu Junior College, 2010. Lecturer, Faculty of Education, Miyazaki International University, since 2019. Her main research interest is the development of motor skills in young children.

Mr. Praveen Nuwantha Gunaratne

He received his Bachelor's degree in Engineering in 2018 from the Faculty of Engineering, University of Moratuwa, Sri Lanka. He is currently a Doctoral student in University of Miyazaki, Japan

Prof. Hiroki Tamura

He received the B.E. and M.E. degree from Miyazaki University in 1998 and 2000, respectively. From 2000 to 2001, he was an Engineer in Asahi Kasei Corporation, Japan. In 2001, he joined Toyama University, Toyama, Japan, where he was a Technical Official in the Department of Intellectual Information Systems. In 2006, he joined Miyazaki University, Miyazaki, Japan, where he was an Assistant Professor in the Department of Electrical and Electronic Engineering. Since 2015, he is currently a Professor in the Department of Environmental Robotics. His main research interests are Neural Networks and Optimization Problems. In recent years, he has had interest in Biomedical Signal Processing using Soft Computing.

An Integration of Contact Force Models with Multibody Dynamics Analyses for Human Joint Mechanisms and Effects of Viscoelastic Ground Contact

Abstract

In human movement and rehabilitation analyses, human joint dynamics is a key to consider the incorporation of spring-damper components, flexible bodies and contact forces analytically. In the present study, an analytical method for human gaits were introduced to integrate those essential elements, and viscoelastic properties of musculoskeletal system were modeled with the absolute nodal coordination formula (ANCF) method representing flexible body motions. A contact force model simulates interactions between different body segments and the environment. The proposed system is applied to a slider crank mechanism, demonstrating its capabilities in human joint motion analysis using integrated dynamic model within the framework of multibody dynamics (MBD), which realizes dynamic/inverse dynamics for human biomechanics.

Keywords: Multibody dynamics (MBD), Contact force model, Absolute nodal coordinate formula (ANCF), human biomechanics

1. Introduction

Joint disorders progress irreversibly due to exercise and aging, and the number of patients who have joint disorders is increasing. These joint disorders affect gait and daily life [1] and they are one of the major issues in the current aging society. Physical therapy treatments for joint disorders include step-by-step treatment that restricts extension by restraining joints using joint orthosis, and rehabilitation that applies appropriate joint loads. From the viewpoint of prevention of the disease by joint load reduction, patient-specific order-made assistive devices using 3D printers and flexible materials [2] are also developing. However, the formulation of rehabilitation programs and the design of orthotics and assist devices are performed through subjective evaluations based on the experience of physical therapists and prosthetists. Therefore, the standard numerical evaluation index is needed, and modeling human joint mechanisms and analyzing their movements plays an important role in the formulation of the programs and design for the devices.

The dynamic and inverse dynamic analysis of human motion is possible with multibody dynamics (MBD) [3], [4], [5], [6], [7]. In order to reproduce the movement of a joint and analyze in detail the increase/decrease in the load that occurs on its components, it is necessary to construct and analyze models in which the muscles and ligaments are replaced with spring damper components or flexible bodies. The absolute nodal coordinate formula (ANCF) [8], [9], [10] has been proposed as an analysis method that incorporates finite element methods for systems composed of flexible bodies in MBD. The ANCF allows the analysis of systems that include large deformation of flexible bodies by dividing the body into multiple elements. Furthermore, by considering the effects of viscoelastic ground contact [11], [12], it becomes possible to analyze human motion such as human gait.

In this study, for the implementation of an analytical system for the joint load reduction analysis based on MBD, we demonstrate an integrated dynamic model by applying a flexible body, spring-damper components and ground contact force to the crank model and analyzing it dynamically.

2. Methodology
2.1. *Integrated dynamic analysis based on MBD*

Shintaro Kasai, Dondogjamts Batbaatar, Hiroaki Wagatsuma

The motion of a multibody system (MBS) composed of rigid bodies is described by a differential algebraic equation (DAE) such as Eq. (1) based on MBD theory using Lagrange multiplier λ and acceleration equation γ. Here, M_R, Φ_R and Q_R^A mean the mass matrix of rigid bodies, constraint matrix and external force vector respectively. Subscript q means the Jacobian matrix obtained by partially differentiating the constraint matrix with respect to the generalized coordinate matrix q.

$$\begin{bmatrix} M_R & \Phi_{Rq}^T \\ \Phi_{Rq} & 0 \end{bmatrix} \begin{bmatrix} \ddot{q}_R \\ \lambda \end{bmatrix} = \begin{bmatrix} Q_R^A \\ \gamma \end{bmatrix} \qquad (1)$$

Considering incorporating a flexible body into MBS, the generalized coordinate matrix of the flexible body is defined and its motion is described based on ANCF. According to Fig. 1, the generalized coordinate matrix of the flexible body i is described as Eq. (2) with *x-y* coordinates at each node and their slope [13].

$$q_F^i = \left[e_1^i, e_2^i, e_3^i, e_4^i, \cdots e_{4N_n-3}^i, e_{4N_n-2}^i, e_{4N_n-1}^i, e_{4N_n}^i \right]^T \qquad (2)$$

The DAE of flexible multibody dynamics (fMBD) which incorporates flexible bodies based on ANCF can be expressed as Eq. (3) by expanding Eq. (1).

$$\begin{bmatrix} M_R & 0 & \Phi_{Rq}^T \\ 0 & M_F & \Phi_{Fq}^T \\ \Phi_{Fq} & \Phi_{Fq} & 0 \end{bmatrix} \begin{bmatrix} \ddot{q}_R \\ \ddot{q}_F \\ \lambda \end{bmatrix} = \begin{bmatrix} Q_R^A \\ Q_F^A \\ \gamma \end{bmatrix} \qquad (3)$$

Q_R^A and Q_F^A are external force vectors consist of gravity force and elastic force due to deformation of flexible body. When the analytical model consists of spring-damper components and the ground contact model, the total external force vector Q^A includes force vectors F_{SD} and F_c which are generated by spring-damper and viscoelastic ground contact as Eq. (4).

$$Q^A = \begin{bmatrix} Q_R^A \\ Q_F^A \end{bmatrix} + F_{SD} + F_c \qquad (4)$$

Fig. 1 The definition of the generalized coordinates of the flexible body I based on ANCF.

2.2. *Contact force in external force vector*

In the continuous contact model, the normal force F_N is expressed by Eq. (5) using the generalized stiffness parameter K and the relative penetration or indentation δ. Based on the theory of elasticity by Herts [11], the exponent n is equal to $2/3$.

$$F_N = K\delta^n \qquad (5)$$

Considering the damping term, F_N can be written as follows with hysteresis damping factor χ. Here, $c_r, \dot{\delta}$ and $\dot{\delta}^{(-)}$ mean coefficient of restitution, relative approach/departing velocity and initial approach velocity respectively.

$$F_N = K\delta^n + \chi\delta^n\dot{\delta} \qquad (6)$$

When χ is expressed as Eq. (7), substituting it into Eq. (6), F_N becomes Eq. (8).

$$\chi = \frac{3K(1 - c_r{}^2)}{4\dot{\delta}^{(-)}} \qquad (7)$$

$$F_N = K\delta^n \left[1 + \frac{3(1 - Cr^2)}{4} \cdot \frac{\dot{\delta}}{\dot{\delta}^{(-)}} \right] \qquad (8)$$

When sliding occurs in contact between the body and the ground, the dynamic friction force is described as Eq. (9) using kinetic friction coefficient μ, tangential velocity vector c_f and dynamic correction coefficient c_d based on friction velocity.

$$F_f = -\mu F_n c_f c_d \qquad (9)$$

Consider the case where body i contacts the straight line $ax + by + c = 0$ at contact point *CP* according to Fig. 2, the coordinate and velocity at point cp are as Eq. (10).

$$\begin{cases} \begin{bmatrix} x_{cp} \\ y_{cp} \end{bmatrix} = \begin{bmatrix} x_i \\ y_i \end{bmatrix} + \begin{bmatrix} r_i \\ 0 \end{bmatrix} \begin{bmatrix} \cos\theta_i & -\sin\theta_i \\ \sin\theta_i & \cos\theta_i \end{bmatrix} \\ \begin{bmatrix} \dot{x}_{cp} \\ \dot{y}_{cp} \end{bmatrix} = \begin{bmatrix} \dot{x}_i \\ \dot{y}_i \end{bmatrix} - \begin{bmatrix} r_i \\ 0 \end{bmatrix} \dot{\theta}_i \end{cases} \qquad (10)$$

The relative penetration δ can be expressed as the shortest distance between the contact point and the straight line as Eq. (11).

$$\delta = \frac{|ax_{cp} + by_{cp} + c|}{\sqrt{a^2 + b^2}} \qquad (11)$$

Fig. 2 Viscoelastic contact with the tilted ground
described as $ax + by + c = 0$

Fig. 3 Integrated dynamic model of slider crank

The driving constraint Φ^D is given to L_1 as Eq. (14) and angular velocity ω is equal to $2\pi/5\ [rad/s]$.

$$\Phi^D = \theta_1 - \omega t - \theta_1^{(0)} = 0 \qquad (14)$$

In this slider-crank model, the endpoint at L_2 collides with L_3 and the effect of viscoelastic contact occurs without sliding. The contact force between these links is described as Eq. (15).

$$F_N = K(x_3 - x_2)^{\frac{2}{3}}\left[1 + \frac{3(1 - c_r^2)}{4} \cdot \frac{\dot{x}_3 - \dot{x}_2}{\dot{\delta}^{(-)}}\right]$$
$$F_f = 0 \qquad (15)$$

Since the relative approach velocity $\dot{\delta}$ in Eq. (8) and tangential velocity c_r in Eq. (9) are perpendicular and parallel to the straight line, they can be written as Eq. (12) when the ground line moves as $[\dot{x}_G, \dot{y}_G]^T$. Here the angle between x-axis and the straight line is as $\varphi = tan^{-1}(-a/b)$.

$$\dot{\delta} = (\dot{x}_G - \dot{x}_{cp})\sin\varphi - (\dot{y}_G - \dot{y}_{cp})\cos\varphi$$
$$c_r = (\dot{x}_G - \dot{x}_{cp})\cos\varphi + (\dot{y}_G - \dot{y}_{cp})\sin\varphi \qquad (12)$$

3. Results and Discussion

3.1. *Dynamic analysis of the integrated slider-crank model based on MBD*

Numerical analysis of the dynamic analysis based on MBD was performed by solving the DAE of the analytical system with MATLAB. In numerical computation, the fourth-order Runge-Kutta Gill's method [14] was used as the numerical integration method. The time step width is $h = 1.0 \times 10^{-5}[s]$. The parameters of spring-damper components are $k = 50, c = 0.1$ and the parameters of viscoelastic contact are $K = 4.0 \times 10^5, c_r = 0.1$ and $\mu = 0.45$. The results of the dynamic analysis for each element of the integrated slider-crank model are shown in Fig. 4. The x-coordinates of link L2 with and without flexible material are compared as shown in Fig. 5. The right graph in Fig. 5 shows the difference between each movement at first contact. When the model consists of a flexible body, the viscoelastic contact causes the deformation of it.

2.3. *Slider-crank model for validation of integrated analysis*

In order to validate the MBD integrated analysis, a flexible body, a spring-damper component and the viscoelastic contact model are applied to the slider-crank model as shown in Fig. 3 to compare the changes in the behavior of the mechanism with and without these components. When N_e which is the number of division elements of the elastic beam F_1 based on ANCF is equal to 8, the kinematic constraint equation between F_1 and rigid links L_1 and L_2 of the slider-crank in Fig. 4 is described by Eq. (13).

$$\begin{bmatrix}\Phi_{L_1F_1}^K \\ \Phi_{L_2F_1}^K\end{bmatrix} = \begin{bmatrix}e_1 - x_1 - \frac{l_1}{2}\cos\theta_1 \\ e_2 - y_1 - \frac{l_1}{2}\sin\theta_1 \\ e_{33} - x_2 + \frac{l_2}{2}\cos\theta_2 \\ e_{34} - y_2 + \frac{l_2}{2}\sin\theta_2\end{bmatrix} = 0 \qquad (13)$$

Fig. 4 The result of the dynamic analysis of the integrated slider-crank model.

Fig. 5 The transition of x-coordinate at CP. The right graph is looking at the point in time when the effect of viscoelastic contact occurres.

3.2. *Constraint force by adopting viscoelastic contact model*

MBD-based dynamic analysis was performed for three models with different components in Fig. 6 to analyze the changes in contact force on the body of the analytical system. Fig. 7 shows the result of the dynamic analysis, and the deflection of the flexible body and the contraction of the spring-damper component reduces the relative penetration of the contact point, resulting in smaller contact forces compared to the rigid slider-crank model. It is possible to analyze the force by the viscoelastic contact which changes according to the components applied to the MBS.

4. Conclusion

Through this research, the integrated dynamic analysis of models which has contacts between objects or objects and ground was shown to be possible by expanding the

Fig. 6 Integrated dynamic models of slider crank. The model a) consists of rigid linkages, b) is replaced and has a flexible body and c) is applied with a flexible body and a spring-damper component.

Fig. 7 The difference of contact force at contact point between the slider-crank models

analysis system to incorporate flexible bodies and a viscoelastic contact model. The use of flexible materials and spring-damper components in the joint mechanism enables gait analysis of walking robot legs that utilize nonlinear elastic properties and dynamic analysis of the effect of joint assistive devices on human walking motion, and is effective for the design and development of such robot legs and support devices. In further analysis, it is necessary to apply this integrated dynamic analysis to joint drive control for the robot leg models and the combination models of human gaits and assistive devices.

Abstract

In this paper, we propose a highly realistic haptic feedback method for myoelectric prosthetic hands. Although several haptic feedback methods have been studied, this study attempts to create realistic sensory feedback through prosthetic hands by not only using feedback methods but also by improving the haptic sensation based on the stochastic resonance effect. In the experiment, contact information obtained from a microphone attached to the fingertip of a prosthetic hand was transferred through a vibrotactile stimulator near the elbow fossa, and white noise vibration was also applied near the elbow fossa to verify the improvement of tactile sensitivity of the fingertips. The results demonstrated the possibility of transmitting tactile information for myoelectric prostheses through sensory enhancement of the user.

Keywords: Myoelectric Prosthetic Hand, Haptic Sensation, Stochastic Resonance, Haptic Feedback

1. Introduction

To realize a prosthetic hand that resembles a human hand, it is necessary not only to consider the mechanism of the prosthetic hand but also to establish a sensory feedback method, such as tactile sensation. Sensory information has a vital function in daily activities because the sense of touch conveys various properties or information of objects [1]. However, it is said that when prosthetic users touch objects with their prosthetic hands, they feel vibrations through the socket, making it difficult to accurately acquire tactile information through the prosthetic hand. Although myoelectric prosthetic hands have evolved to imitate motor functions of human hands [2], many current devices are deemed insufficient given their inability to deliver relevant sensory information.

The senses are broadly classified as cutaneous and deep senses, and restoration of these senses shows its improvement for the daily life of forearm amputees [3]. Various methods of cutaneous sensation feedback such as touch, pressure, pain, warmth and cold have been investigated. In the past, a simple transducer attached to a small speaker [4] was proposed, and in recent years, Ueda et al. have transmitted the warmth or coldness of an object by transmitting the temperature detected by a temperature sensor at the fingertip to a device on the upper arm [5], Osborn et al. developed electronic skin, which can transmit pain to the user by detecting differences in the shape and texture of objects at the fingertips and sending signals to peripheral nerves [6], and various other skin sensations can now be transmitted. Alessia et al. measured the acceleration of the fingertip and controlled the oscillator of a socket to enable discrimination of roughness [7], Christian et al. detected pressure from a silicon bulb and confirmed that the magnitude of pressure could be discriminated by inflating the silicon pad at the cut using a monofilament [8].

These various sensory feedback methods provide only pseudo feedback, and it is difficult to reproduce actual sensation. This is due to practical issues such as the danger of direct sensory feedback, including pain, and the fact that the cutaneous sensation near the amputation site is different from that at the fingertip, where feedback is provided in the noninvasive approach. Therefore, we consider improving the user's sensation.

Minamizawa et al. have made it possible to reproduce tactile sensations through vibration stimulation by recording and playing back tactile data [9]. Jianyao et al. measure the acceleration of the fingertip and transmit the vibration as an audio signal to enable roughness discrimination [10]. Research has also been conducted to enhance the sensory perception on the human side of receiving feedback, enhancing the ability to detect signals by applying noisy vibrations to the human hand or foot [11], [12]. This phenomenon is called stochastic resonance, and looking at the case of vibration to the upper limb, it has been reported that applying noise to the wrist and fingers improves tactile sensitivity at the fingertips [13],

Yoshitaka Mizumoto, Taro Shibanoki

[14]. However, the application of these sensory enhancements using audio feedback and stochastic resonance to prosthetic hands has not been fully investigated.

This study applies these methods to a prosthetic hand and provides tactile feedback near the elbow fossa using voice. In addition, by focusing on the phenomenon of probability resonance, we attempt to enhance the sensation obtained by the sensory feedback method of the prosthetic hand, thereby increasing the realism of the sensation through the prosthetic hand.

2. Sensory feedback and enhancement

The proposed myoelectric prosthetic hand sensory feedback method is based on the TECHTILE toolkit [9] and consists of a microphone (AT9904, audio-technica), an audio amplifier (LP-2024A+, Lepy), and vibration actuators (AFT14A903A, Alps Alpine). In this paper, a microphone is attached to the fingertip of a prosthetic hand to record friction and vibration sounds when touching an object as an input signal for vibration stimulus generation. The signal is output as vibration through an audio amplifier using an actuator attached near the elbow fossa.

In this study, we further focused on the stochastic resonance effect to improve sensory function. The vibration used is low-pass filtered white noise with a cutoff frequency of 300 Hz and is output from a PC via an audio amplifier with another actuator. These processes generate tactile sensations and simultaneously enhance the sensation near the elbow fossa, resulting reproduction of human fingertip sensation.

3. Verification of differences in fingertip sensation

In this section, we first discuss the difference between the cutaneous sensation at the fingertips of a person and the sensation when using a prosthetic hand. In this section, we first describe the difference between the cutaneous sensation at the fingertips of a person and the sensation when using a prosthetic hand. We compared and verified the sensitivity of the skin sensation at the fingertips when touching an object and the sensation of the prosthetic hand near the elbow through the socket.

The participant was a healthy university student seated on a chair wearing an eye mask and earplugs (Fig. 1) In the experiment, the participant was given a piece of paper with five pieces of sandpaper of different roughness (#400, #600, #800, #1000, and #1200.) on the front side and one randomly selected piece of sandpaper from the five pieces on the front side on the back side, and asked to touch all the sandpapers on the front and back sides. The sandpaper with the same coarseness as the one on the reverse side was selected from the sandpaper on the front side, and the percentage of correct responses was recorded. The test consisted of one trial in which each roughness was presented twice at random (10 in total). One trial was performed with the human hand and one trial with the prosthetic hand.

The discrimination rate of the human hand was 70%, and that of the prosthetic hand was 10%. These results

(a) Human hand   (b) Myoelectric prosthetic hand
Fig. 1. Scenes from the verification experiment.

indicate that fingertip sensation cannot be obtained through the socket of the prosthetic hand. From a questionnaire survey after the experiment, the participant answered that when they touched the sandpaper with their prosthetic hands, they felt almost no vibration through the sockets, suggesting that discrimination was impossible.

4. Sensory enhancement experiment

4.1 Determination of vibration perception threshold

To determine the vibration perception threshold (the maximum vibration that the participant cannot feel) before the experiment, the participant was asked to wear an eye mask, relax with hands on a desk, and present the vibration. The intensity of noise was increased and decreased until the participant was unable to distinguish between it being on or off. The average value was obtained by repeating each trial three times. The threshold is referred to as 1T.

4.2 Verification of the effect of stochastic resonance

We tested whether the tactile sensitivity was affected by applying white noise near the elbow fossa to one healthy university student. The participant was asked to touch a piece of sandpaper with his hand and a prosthetic hand (Fig. 2), and the percentage of correct responses for each was recorded. Five vibration intensity conditions (0.5 T, 0.75 T, 1 T, 1.25 T, and 1.5 T) were applied randomly. One trial was conducted for each vibration condition with a 30-second rest between trials. The hand and prosthetic hand were tested separately.

Fig. 3 shows the experimental results. The result for the no-vibration condition (no-vib) was obtained from the experiment in Section 3. In both cases, the correct response rate tended to be higher than that of the no-vibration. A questionnaire survey of the participant after the experiment showed that there was no significant difference in the perception of the vibration caused by the white noise.

Fig. 4 shows signals recorded from the microphone while touching sandpapers with the prosthetic hand and their FFT results. The threshold value was set to -30 dB, and the range from the first detection of a signal above the threshold value to the last detection of a signal above the threshold value was clipped. The extreme values of the absolute values of the signals were extracted and averaged to obtain the amplitude. The results show that the roughness of #400 tends to be easily discernible, with an

(b) FFT

Fig. 4. Recorded signals and their FFT results.

amplitude of approximately 0.021, which is larger than the others. In addition, #1000 tended to be misidentified as #800. This may be because the amplitude of #800 was about 0.012, close to the amplitude of #1000 of about 0.009, and the frequency band peaks were similar at around 900 Hz. The amplitude of #600 and #1200 were approximately 0.017 and 0.014, respectively. However, #600 had a peak near 2500 Hz and #1200 had a peak near 400 Hz, which may have affected the discriminability of the two samples. The identification rate through the socket of the myoelectric prosthetic hand was 30%.

(a) Experimental scene   (b) Experimental result

Fig. 5. Tactile feedback experiment.

5. Simulation of tactile generation near the elbow fossa

Although we were able to improve the tactile sensitivity of the fingertips by adding white noise near the elbow fossa in Section 4, the result of the prosthetic hand was low (30%). Therefore, we conducted an experiment in which vibration stimuli were applied near the elbow fossa based on the measured audio signals.

The participants were two healthy university students. White noise vibration was added simultaneously with feedback from the vibratory stimulation of the audio signal using two vibrotactile stimulators attached near the elbow fossa. The same procedure as in Section 3 was used to record the percentage of correct responses by touching the sandpaper with the prosthetic hand in five vibration intensity conditions.

The results of the experiment are shown in Fig. 5(b), which compares the cases without voice feedback (No-FB, the result shown as No-vib in Section 4), with tactile feedback only (No-vib), and with tactile feedback and white noise vibrations. The results show the average of two participants. Except for 0.75T, the result was higher than that without vibration, and the highest response rate was obtained when the vibration intensity was 1T. A questionnaire survey of the participants after the experiment suggested that the correct rate increased because the participants were able to feel strong vibrations due to the tactile feedback. These results indicate that some fingertip sensation can be obtained by vibration stimulation based on audio signals near the elbow fossa and tactile sensitivity enhancement by white noise vibration.

6. Verification of tactile sensation generation with a prosthetic hand

Based on the results obtained in Section 5, an experiment was conducted with a healthy university student as a participant to verify whether tactile feedback and white noise vibration could provide a realistic sensation when touching objects with a prosthetic hand. In the experiment, three different textures of cloth (nylon, polyester, and cotton) were traced with the prosthetic hand to test whether it could reproduce the sense of touch.

From the experimental results, when the participant touched the cloth with the prosthetic hand, the participant could not feel much difference in texture and could not reproduce the tactile sensation. Fig. 6 shows the sound waveforms and FFT results of touching the cloth with the

Yoshitaka Mizumoto, Taro Shibanoki

Fig. 6. Recorded signals and their FFT results.

prosthetic hand. The amplitudes of both results were almost the same (0.006) and the peak frequency bandwidths were similar at around 100 Hz, suggesting that the feedback vibration stimuli were similar and therefore could not be determined.

7. Conclusion

This paper showed that vibrotactile feedback and stochastic resonance effects near the elbow fossa can provide some fingertip sensation when touching an object through a prosthetic hand. However, it is difficult to distinguish objects with small amplitude or similar frequency bands. In the future, we plan to improve the feedback method to detect slight differences in vibration.

Abstract

Precise control of DC motors is vital for robotics, industrial automation, and mechatronics. Traditional PID (Proportional-Integral-Derivative) control methods, while widely used, often require offline parameter tuning, which can be time-consuming and suboptimal for real-time applications. This paper proposes a GUI (Graphical User Interface) based approach for PID tuning of a DC motor model. The proposed method utilizes a MATLAB-based parameter estimation model with GUI to continuously monitor and update PID controller parameters based on real-time data from the Arduino-controlled DC motor setup.

Keywords: PID parameter tuning, Graphical user interface (GUI), DC motor control

1. Introduction

Despite its simplicity, Proportional-Integral-Derivative (PID) control remains remarkably efficient, offering a three-term solution to address both transient and steady-state responses in numerous real-world problems. Since its invention in 1910, largely attributed to Elmer Sperry's ship autopilot, and the development of straightforward tuning methods by Ziegler and Nichols in 1942 [1], [2]. PID control has witnessed widespread adoption [3]. DC motors are widely employed as actuators for wheeled mobile robots, robots controlled by programmed microcontrollers, or computers that navigate autonomously based on sensor information. These robots typically have two, three, or four wheels, each driven by a DC motor for smooth maneuverability [4], [5], [6]. Two primary control applications for DC motors are speed and position control. Speed controllers regulate robot movement speed, while position controllers ensure accurate movement to predetermined positions. [7], [8]. Recent research on DC motor speed control focuses on stabilization, with many works combining PID controllers with other methods like fuzzy logic control, genetic algorithms [1],

and particle swarm optimization. Similarly, PID-based position controllers have been combined with artificial intelligence techniques like fuzzy logic and genetic algorithms to enhance accuracy [9], [10], [11]. While PID control exhibits remarkable effectiveness, optimal tuning remains a challenge, particularly in dynamic environments encountered by wheeled mobile robots. However, these approaches often lack user-friendliness and adaptivity.

This study utilizes one of the DC motors from a two-wheeled mobile robot as the plant. The DC motor's mathematical model is developed by acquiring input and output signals from an open-loop experiment [10]. The applied working voltage serves as the input signal, and the electronically measured speed is the output signal. The resulting model's step response is compared to the original motors to validate its accuracy. A PID-based speed controller is proposed, with initial parameters obtained from the relay feedback experiment and MATLAB based PID

Munkh-Erdene Ayurzana, Erkhembayar Gankhuyag, Dondogjamts Batbaatar, Naranbaatar Erdenersuren

tuning integrated with GUI. These parameters are then manually fine-tuned based on practical PID tuning knowledge to achieve optimal performance without overshoot or steady-state error. The paper is structured as follows: Section 1 presents the background and related work, Section 2 outlines the proposed approach and methodology, Section 3 details the implementation and results, and Section 4 concludes the study and highlights its potential impact.

2. Methodology

2.1. *Mathematical model of DC motor*

Before we create a GUI interface, we need to start off with a Simulink model of the DC motor system with PI controller. The DC motor has to be modeled first, in Simulink and the mathematical equations behind the functioning of the motor has to be understood before advancing   further

Fig.1 DC Motor model

In order to model a DC Motor in Simulink, we have to define the mathematical equations on which it functions, The DC Motor functioning diagram is given in Fig.1.

2.2. *Electrical Characteristics*

By using Kirchoff's voltage law in the DC-motor model according to Fig. 1 DC motor model following equation is derived

$$V_{in} - V_{Ra} - V_{La} - V_{emf} = 0 \qquad (1)$$

Where, V_{in}, V_{Ra}, V_{La} and V_{emf} is the input-voltage, voltage over the armature resistance, voltage drop over the armature inductance and voltage induced by the coil respectively. The equations for the voltage parts in the DC-motor are,

$$V_{Ra} = i_a \cdot R_a \qquad (2)$$

$$V_{La} = L_a \frac{d}{dt} i_a \qquad (3)$$

$$V_{emf} = K_e \cdot \dot{\theta}_a \qquad (4)$$

2.3. *Mechanical Characteristics* [2]

By torque balance (energy balance) in the system the mechanical equations can be stated.

$$T_e - T_{\ddot{\theta}a} - T_b - T_L = 0 \qquad (5)$$

Where T_e is the electromagnetic torque, $T_{\ddot{\theta}_a}$, is torque generated from the rotational acceleration of rotor. T_b, is the torque due to the friction and angular velocity in the motor. T_L is the torque of mechanical load (external load), equations for the first three parts are

$$T_e = K_t \cdot i_a \qquad (6)$$

$$T_{\ddot{\theta}_a} = J_m \cdot \frac{d}{dt} \dot{\theta}_a \qquad (7)$$

$$T_b = b_m \cdot \dot{\theta}_a \qquad (8)$$

Substituting equation (5) with (6), (7) and (8) yields following differential equation,

$$V_{in} - i_a \cdot R_a - L_a \cdot \frac{d}{dt} i_a - K_e \cdot \dot{\theta}_a = 0 \qquad (9)$$

$$\frac{d}{dt} i_a = \frac{1}{L_a} \cdot (i_a \cdot R_a + K_e \cdot \dot{\theta}_a - V_{in})$$

(10)

3. Results and Discussion

The experiment's foundation lay in meticulous data collection, enabling the analysis of the intricate interplay between voltage and RPM. A 140 second data acquisition process captured the voltage profile, characterized by a 20-second ramp-up to 24V followed by a 20-second minimum, and this pattern mirrored the observed RPM variations with relay feedback experiment was shown in Fig. 2.

Fig.2 Relay output

From the relay feedback experiment, the following result was obtained.

Fig.3 System without PID tuning

The open-loop experiment Fig. 3 revealed significant overshoot and sustained oscillations in the DC motor speed due to suboptimal PID settings. Manually configuring the parameters or using the time-consuming Ziegler-Nichols method might not be ideal for real-time applications.

3.1 *Parameter estimation and tuning*

From the mathematical model of DC motor following initial parameters are to be known such as moment of inertia of the rotor J_m, damping ratio of the mechanical system b_m, electric resistance R_m, electric inductance L_m, armature constant K_t, before being tuned with a PID controller. While manufacturers may provide values for some of these DC motor parameters, they are only approximate. Its necessary to estimate these parameters as precisely as possible for our model to ascertain whether it is an accurate representation of the actual DC motor system.

Fig.4 Parameter estimation plot

Again, these values are of important for designing and tuning a PID controller for the DC motor. The PID controller will use these parameters to calculate the motor's input voltage in order to achieve the desired speed. Furthermore, without knowing the specific values of the parameters, it is difficult to say much about the specific performance of the DC motor. However, the fact that these are estimated parameters (Fig. 5) suggests that the motor has not been precisely modeled or

characterized [12], [13]. This could lead to difficulties in tuning the PID controller effectively.

Fig. 5 Iteration for finding motor parameters

As shown in Fig. 4 the measured data overlaid with the simulated data. The simulated data comes from the model with the estimated parameters listed in Table 1. Comparing the response of the system before and after the estimation process clearly shows that the estimation successfully identified the model parameters and the simulated response accurately matches the experimental data.

Table 1. DC Motor parameters

Constants	Value	Unit
K_t	0.0035401	$[N \cdot m/A]$
R_m	0.0065388	$[Ohm]$
L_m	8.758e-05	$[H]$
b_m	0.0001263	$[-]$
J_m	4.3114e-05	$[kg \cdot m^2]$

While from PID tuning result following initial PID parameters are determined in Table 2.

Table 2. Parameters used in the numerical simulation.

Controller	PID Parameters		
	K_p	K_i	K_d
PID	0.01	0.061	0

After the fine-tuning process in MATLAB, it was found that the final $K_p = 0.01$, $K_i = 0.061$ and $K_d = 0$. The initial value of Kp = 0.9 gives big oscillation output. The fine tuning is performed to adjust the K_p, such that the P controller output results in only one overshoot and no oscillation, although steady state error is still not zero. This final value of Kp is 0.01.

Fig.6 System with PID tuning

The Fig. 6 illustrates the response of a DC motor speed control performance after it has been tuned with PID controller. The blue line shows the reference input, the red line shows the actual output speed of the motor, which initially lags behind the reference input and then abruptly rise to meet it. There are some oscillations in the motor speed, which indicates that the system is damped due external disturbances or externally given mechanical load. The system is returned to stable state approximately after 1 second under the varying operating conditions.

3.2. GUI for motor control

In order to simplify the dc motor control process, a GUI is developed that allows a user to quickly identify model, tune controller coefficients and send reference data was created. Two types of GUIs were created.

   a)   GUI for identification

Fig.7 Identification GUI MATLAB

This GUI (presented on Fig. 7) allows user to control motor speed manually, send identification data, identify model, tune PID, set object constants and deploy model with new coefficients and constants to Arduino. After uploading a model to Arduino, user can check the quality of tuned controller by reconnecting to Arduino, setting reference velocity manually and checking the response. The quality of controlling depends on several factors.

First of all, getting a proper data is one of the most important steps. Based on the collected data, picking the correct model is directly affects the PID tuning response and therefore directly affects the possibilities of tuning. At last, figuring the optimal response through MATLAB PID tuner directly affects the quality of controlling.

   b)   GUI for standalone application

Once identification and tests are complete, user can shut down MATLAB and use a standalone application as shown in Fig. 8 to control the DC motor. Standalone application requires less resources to run compared to multistep manual identification.

Fig.8 Speed controller performance at final stage with standalone application

In Fig. 8 graph depicts the reference tracking response of the DC motor after it has been tuned with the PID controller. The blue line shows the reference input, which is direction of motor changes with time. The red line shows the actual output of a motor, which closely tracks the reference input with minimal overshoot, and settling time, and there is no steady-state error. Finally, an analysis was performed to ensure that the controller was well-tuned with GUI of standalone application.

4.   Conclusion

This project developed an interactive GUI to optimize PID controller parameters for a DC motor SIMULINK model in real-time. This approach enables continuous adaptation to varying operating conditions, achieving significant improvements compared to traditional offline or manual tuning methods. Experimental results demonstrate enhanced control accuracy and system stability, confirming the effectiveness of the proposed method. The PID controller, adjusted through the GUI, optimizes the motor's input voltage to minimize the error between the desired and actual output. This is achieved by utilizing a parameter estimation tool based on the DC motor's mathematical model. Careful tuning of the PID gains ensures a system that is both responsive and stable. The developed GUI serves as a valuable tool for robot designers and researchers, enabling real-time control optimization and hands-on learning of control systems concepts. It offers undergraduate students a practical learning experience in the classroom, fostering their understanding of PID control and its applications.

Abstract

When using wheeled walker robots to help individuals with limited walking ability improve their mobility, the stability of the robot's motion control and trajectory tracking accuracy are critical. In this paper, a new trajectory tracking method for wheeled walking robots is proposed by combining the Deep Deterministic Policy Gradient (DDPG) algorithm in reinforcement learning with a Proportional Integral Differential (PID) controller. The article first analyzes the kinematic model of the chassis of the wheeled walking robot, and then introduces the design principle and structure of the adaptive PID controller that combines the DDPG algorithm and the PID controller. Finally, the effectiveness of the research scheme and control strategy is verified by joint simulation experiments, and the results show that this DDPG-based PID controller can automatically adjust the parameters when tracking the trajectory to ensure the accuracy of the trajectory, and it has a strong anti-interference capability.

Keywords: Wheeled helper robot, trajectory tracking, DDPG algorithm, PID controller.

1. Introduction

In recent years, with increasing aging, the elderly show significant physiological decline, limb flexibility and other basic abilities, increasing the risk of falls. Meanwhile, as people's lifestyles change, there are more and more lower limb motor dysfunctions caused by sports injuries, traffic accidents, or diseases, making there a huge demand for intelligent assistive devices [1]. Walking robots for the elderly and patients with lower limb motor dysfunction can be categorized into two types: exoskeleton robots [2] and wheeled assisted walking robots [3]. However, the center of gravity control of most exoskeleton rehabilitation robots is not satisfactory, and the safety of the rehabilitation process cannot meet the requirements [4]. Wheeled walking robot itself has a stable chassis, not only can well avoid the patient in the training process due to the center of gravity is not stable and caused by the fall and other secondary injuries, but also in a narrow space to achieve any direction of movement, to give the patient a good sense of spatial movement and real walking experience, wheeled walking robot with its stable chassis and flexible spatial movement ability, in terms of safety and practicality with the Advantages.

When using wheeled walking robots for rehabilitation training, due to the complexity of the external environment, the wheeled walking robots are required to follow the desired trajectory as much as possible, which requires the robots to be able to track an ideal trajectory with a time function according to the actual position and motion state, and complete the tracking of each point in the trajectory according to the time requirements Therefore, this paper applies the reinforcement learning algorithm to the traditional proportional-integral-derivative (PID) controller to realize adaptive PID

parameter tuning in order to adjust the robot position more accurately so that the robot can complete trajectory tracking.

Although the traditional PID control has the advantages of simplicity of use, easy to implement, no static error, etc., its disadvantage is that it cannot realize the online adjustment of parameters, so when it encounters a strong interference, it is bound to have the phenomenon of prolonged recovery time and increased overshooting, which affects the stability of the motion of the chassis of wheeled robots. A large number of scholars have conducted research on adaptive PID, and introduced the idea of online parameter adjustment in the traditional PID, which improves the response speed of the system. At present, adaptive PID control methods mainly include: fuzzy PID controller [5], the method requires a large amount of a priori knowledge, there are parameter optimization problems; neural network-based adaptive PID control [6], the method can be achieved without identifying the complex nonlinear system to achieve effective control, but in the use of supervised learning to optimize the parameters, the acquisition of the teacher's signals is relatively difficult; evolutionary algorithm adaptive PID controller [7], the method, although the acquisition of a priori knowledge of the lower requirements, but the computation time is longer, it is difficult to achieve real-time control in practical applications; reinforcement learning adaptive PID controller [8], proposed the Actor-Critic algorithm to achieve adaptive tuning of PID parameters, which makes use of AC algorithms of model-free online learning The algorithm utilizes the model-free online learning capability of AC algorithm, but the convergence speed of AC algorithm is slow and the training time is long.

In this paper, we adopts the deep deterministic policy gradient (DDPG) algorithm, which is based on the Actor-Critic (AC) framework, to enhance the performance of the PID controller and the deep Q-network (DQN) algorithm is added on the basis of the deterministic policy gradient (DPG) algorithm. This algorithm can not only update in a single step like DQN, but also has the advantages of high data utilization and fast convergence of DPG. In order to realize the adaptive adjustment of PID parameters, a PID controller based on DDPG algorithm is proposed. In the simulation experiments, the kinematic model of the omnidirectional chassis of the wheeled walking robot in our laboratory is used to verify the superiority and generality of the proposed method.

2. Proposed Method

This section will introduce the kinematic model of the wheeled walking robot chassis. Then, it will describe the design principles and structure of the adaptive PID controller that combines the DDPG algorithm and the PID controller.

2.1. *Kinematic modeling of assistive robots*

The schematic and kinematic model of the robot's omnidirectional wheel chassis is shown in Fig. 1. Taking the world coordinate system $x_w o_w y_w$ as a reference, the robot moves in the motion coordinate system xoy with a velocity of magnitude v toward an angle α from the Y_w axis. V_x, V_y denote the horizontal and vertical travel speeds of the robot relative to the motion coordinate system, respectively [9].

Fig. 1 Kinematic modeling of assistive robots

When the robot is moving in any direction, e.g., at an angle α from the y -direction with velocity v , the magnitudes of the horizontal and vertical velocities of the robot respectively:

$$
\begin{aligned}
V_x &= v sin\alpha \\
V_y &= v cos\alpha
\end{aligned}
\tag{1}
$$

Let the angle between the omnidirectional wheels and the x-axis, measured from the center of the robot chassis, be θ ,and the distance from the center of the chassis to the four wheels be a , then the wheel speed of each omnidirectional wheel is degree is:

$$
\begin{aligned}
V_1 &= -sin\theta V_x + cos\theta V_y + \dot{\theta}a \\
V_2 &= \ \ sin\theta V_x + cos\theta V_y - \dot{\theta}a \\
V_3 &= \ \ sin\theta V_x + cos\theta V_y - \dot{\theta}a \\
V_4 &= -sin\theta V_x + cos\theta V_y + \dot{\theta}a
\end{aligned}
\tag{2}
$$

Where V_1, V_2, V_3, V_4 denote the linear velocities of the four omni-directional wheels respectively and $\dot{\theta}$ denotes the angular velocity of the robot writing Eq. (1) in matrix form gives:

$$\begin{bmatrix} V_1 \\ V_2 \\ V_3 \\ V_4 \end{bmatrix} = \begin{bmatrix} -sin\theta & cos\theta & a \\ cos\theta & sin\theta & a \\ -sin\theta & cos\theta & a \\ cos\theta & sin\theta & a \end{bmatrix} \qquad (3)$$

Let the transformation matrix R be:

$$R = \begin{bmatrix} -sin\theta & cos\theta & a \\ cos\theta & sin\theta & a \\ -sin\theta & cos\theta & a \\ cos\theta & sin\theta & a \end{bmatrix} \qquad (4)$$

Let the positional attitude of the robot at $Y_w O_w X_w$ be $P = [x, y, \theta]^T$, and the differential of this positional attitude be $\dot{P}$, and the velocities of each of the robot's wheels $V_b = [V_1, V_2, V_3, V_4,]$, then the equations of kinematics of the robot's differential omnidirectional wheels are:

$$\dot{P} = R^{-1} \cdot V_b \qquad (5)$$

2.2. Incremental PID Control Principle

Digital PID control can be categorized into two types: positional PID and incremental PID. incremental PID does not require the use of the accumulated value of past deviations, which effectively reduces the system's computational error. Incremental PID is an algorithm that realizes PID control by controlling the increment. The formula is as follows:

$$u(t) = u(t-1) + K_i(t)e(t) + K_p\Delta e(t) + K_d(t)\Delta^2 e(t) \quad (6)$$

$$\begin{aligned} e(t) &= y_d(t) - y(t) \\ \Delta e(t) &= e(t) - e(t-1) \\ \Delta^2 e(t) &= e(t) - 2e(t-1) + e(t-2) \end{aligned} \qquad (7)$$

In these equations, $y_d(t)$ denotes the current actual signal value, $y(t)$ denotes the current system output value of the current system, $e(t)$ denotes the output error of the system, $\Delta e(t)$ denotes the first difference of the error, and $\Delta^2 e(t)$ denotes the second difference of the error.

The use of incremental PID controllers in control system design can optimize the use of computational resources. The method relies only on the last three sampling points to determine the control increments, thus reducing the computational burden and storage requirements. This facilitates fast training of the DDPG algorithm and storage of sample data. In addition, the incremental PID controller ensures stable operation in the event of a system failure, and since its output is the changing value of the control quantity, it makes the rewards obtained in a reinforcement learning

environment more stable, which in turn accelerates the convergence of the algorithm.

In summary, the incremental PID algorithm is used to realize the trajectory tracking control of the wheeled robot, which requires the design of two PID controllers, i.e., the transverse position X controller and the longitudinal position Y controller, and the block diagram of the control system is shown in Fig. 2. The input of the transverse PID controller is x_e, i.e., the transverse deviation of the wheeled robot system; the output is v_x, the transverse speed of the wheeled robot system. the output of the PID controller goes to the speed distribution controller, which calculates the speeds of the four omnidirectional wheels according to Eq. (2) to correct the transverse deviation of the wheeled robot. The principle of longitudinal position Y control is the same as the principle of transverse position X control, i.e., y_e is the longitudinal error, v_y is the longitudinal velocity.

Fig.2 Block diagram of two PID controller systems

2.3. DDPG algorithm

Reinforcement learning is a machine learning method that learns behavioral strategies through trial and error, while deep learning is a machine learning method that performs high-level abstraction and feature extraction through multi-layer neural networks. Deep Reinforcement Learning combines the feature extraction capability of Deep Learning with the decision-making capability of Reinforcement Learning to autonomously learn and improve the performance of decision-making strategies. DDPG (Deep Deterministic Policy Gradient) algorithm is an optimization algorithm based on the Actor-Critic algorithm [5] framework, which is able to better select the optimal policy in continuous actions such as robot movement. The DDPG algorithm is based on deterministic policy gradient and refers to the experience pool replay mechanism and Double-Depth Q-Network (DDQN) objective network method to update the network parameters and realize the self-tuning of PID parameters, and its algorithm structure is shown in Fig. 3.

Fig.3. Block diagram of DDPG algorithm structure

Actor gives a new parameter μ according to the strategy network, denoted as $a_t = \mu(S_t|\theta^\mu) + N_t$, where θ^μ denotes the parameter of the neural network, G_k denotes the noise.After one update iteration, the state changes from S_t to S_{t+1} , and obtains the reward R_t. (S_t, A_t, S_{t+1}, R_t) is stored in the experience pool. Finally, samples are drawn from the experience pool to train the strategy network and evaluation network.

The strategy network and evaluation network are updated as shown in Fig. 4. The actor and the Critic consist of two identical networks, denoted as: actor evaluation network $\mu(s|\theta^\mu)$, actor estimation network $\mu' = (s_t|\theta^{\mu'})$, Critic evaluation network $Q(s, a|\theta^Q)$, Critic estimation network $Q'(s, a|\theta^{Q'})$.

Fig.4. updating network parameters

The actor evaluation network updates the parameters according to the following objective function:

$$\mu = \frac{1}{N} \sum_t \left(\nabla_a Q(s, a|\theta^Q)|_{S=s_t, A=\mu(S_t)} \cdot \nabla_{\theta^\mu} \mu(s|\theta^\mu)|_{S=s_t} \right) \quad (8)$$

where $\nabla_a Q(s, a|\theta^Q)$ is the gradient of the Critic evaluation network, and the gradient is updated by computing the loss function. The loss function is computed as follows:

$$L = \frac{1}{N} \sum_t \left(y_t - Q(s_t, a_t|\theta^Q) \right)^2 \quad (9)$$

where y_t is referred to as the TD target, which consists of an immediate reward and an estimated discounted reward. The formula is as follows:

$$y_t = r_t + \gamma Q'(s_{t+1}, \mu'(s_{t+1}|\theta^{\mu'})|\theta^{Q'}) \quad (10)$$

Then update the Critic evaluation network according to $\nabla_a Q(s, a|\theta^Q)$, and at the same time pass $\nabla_a Q(s, a|\theta^Q)$ to the actor, update the actor evaluation network according to Eq. (9), and finally update the parameters of the target network as follows:

$$\begin{cases} \theta^{Q'} \leftarrow \tau\theta^Q + (1-\tau)\theta^{Q'} \\ \theta^{\mu'} \leftarrow \tau\theta^\mu + (1-\tau)\theta^{\mu'} \end{cases} \quad (11)$$

2.4. *General Structure of Adaptive PID Controller Based on DDPG Algorithm*

The design idea is to combine the DDPG algorithm on the basis of incremental PID controller, so the structure design is shown in Fig. 5.

Fig.5. adaptive PID controller based on DDPG algorithm

The system block diagram is based on the traditional PID with the addition of closed-loop control by the DDPG algorithm. The speed allocation module allocates the speeds of the four wheels according to Eq. (2), and the scores are obtained through a self-designed reward function, and output to the DDPG algorithm. According

to the state obtained by the system output, the DDPG algorithm continuously carries out trial and error training until it selects the action group with the highest score, which is the optimal PID parameter, and outputs it to the two PID controllers, adaptively adjusts the parameter, and the error under the parameter is minimized, and the parameter outputs it to the speed allocation module, and then outputs the speeds of the four wheels to the wheeled walking robots' chassis system, which realizes the trajectory tracking control. The controller uses the parameter vector of the PID controllers, i.e. the 6 parameters to be tuned by the two PID controllers, as the action space.

Critics rate each reinforcement learning cycle using the system's state variables and the defined reward function R_t to generate the TD error $\delta_{TD}(t)$ and evaluate the value function Q_t, where $\delta_{TD}(t)$ is provided directly to the actor and Critic, and the reward R_t is used to evaluate the quality of the current behavior.

$$\begin{cases} R_1 = -0.00001 \\ R_2 = -10, e(t) \geq 1 \times 10^{-5} \\ R_3 = 0, e(t) < 1 \times 10^{-5} \\ R_4 = -200, e(t) > 0.5 \\ R_t = R_1 + R_2 + R_3 + R_4 \end{cases} \quad (12)$$

R_1 is the reward for the speed of the four wheels, which is set to a score that has less impact on the system since the main reward comes from the error rather than the amount of control. R_2 and R_3 denote the scores when the error is lower or higher than the error tolerance interval, respectively, and R_4 denotes the score of -200 when the system error is more than 0.5. Finally, the four scores are summed up to form the final reward function. Based on the continuous trial-and-error training, the maximum reward value is obtained, and thus the optimal PID parameter values are obtained.

3. Simulation experiment

In this paper, trajectory tracking control simulation experiments are carried out in python environment. Based on the chassis modeling of the wheeled walking robot, the system simulation model was established in Simulink. In the simulation process, the initial position of the controlled object is set as [0,1], the desired trajectory is set as a cosine curve along the x-axis, and the sampling time is set as 1ms. The parameters of the adaptive PID control based on the DDPG algorithm are listed in Table 1 and Table 2.

Table 1. DDPG Algorithm Parameters

Parameter	Value
Actor learning rate	0.005
Critic learning rate	0.001
Discount rate	0.99
Soft update parameter	0.001
Total training steps	50000
Experience pool capacity	1000000

Table 2. PID controller Parameters

Parameter	Value
K_{p1}	5.0
K_{p2}	5.0
K_{i1}	2.0
K_{i2}	2.0
K_{d1}	0.2
K_{d2}	0.2

4. Result

Experiment shows the simulation results of trajectory tracking realized by traditional PID controller in the Fig. 6. The solid line shows the desired trajectory and the dashed line shows the tracked trajectory. It can be seen that the method can also realize the trajectory tracking, the overshoot is 4.5%, and the tracking trajectory is far away from the target trajectory, and the error is large. Fig. 7 shows the simulation results of trajectory tracking control using the PID controller based on DDPG algorithm proposed in this paper. The overshoot of this method is 2.7%, and the trajectory is closer to the target trajectory with less error than the traditional PID control.

Fig.6 Traditional PID for trajectory tracking

Junkai Li, Mohd Rizon Mohamad Juhari, Tiang Sew Sun

Fig.7 PID control for trajectory tracking based on DDPG algorithm

Compared with the traditional PID controller, the maximum error of this controller is reduced by 48.12%, as listed in Table 3. In addition, the controller's overshoot is reduced by 40% compared to a traditional PID controller, which improves user safety during assisted walking and training.

Table 3. Comparison of results

Controller	Maximum error	Overshoot
Traditional PID	0.2097	4.5%
DDPG+PID	0.1088	2.7%

Comparative results show that the controller is able to track the desired trajectory more accurately when the user uses the wheeled mobility aid robot for rehabilitation training. It also has a strong anti-interference ability due to the trial-and-error mechanism of reinforcement learning, which increases the safety and comfort of training.

5. Conclusion

In order to ensure that the elderly and patients with lower limb dysfunction can move accurately according to the pre-set desired trajectory when they use wheeled walking robots for rehabilitation training in complex environments, this paper proposes a reinforcement learning method that combines the DDPG algorithm with a PID controller. This method not only solves the problem that the traditional PID cannot adjust the parameters online, but also reduces the storage space requirement of the controlled system, thus reducing the computation time of the system. Simulation results show that the PID control based on the DDPG algorithm has the advantages of high tracking accuracy, small overshooting amount and strong adaptability, which enables the wheeled walking robot to realize accurate

trajectory tracking control. The method has good generality and generalization.

Abstract

Metastatic tumors are frequently identified through follow-up surveillance using computed tomography (CT) scans. However, CT scans produce more than 100 images in an examination, which imposes a significant burden on radiologists and entails a potential risk of misdiagnosis. Temporal subtraction is utilized in Computer-Aided Diagnosis (CAD) and proves to be an effective technique in aiding image interpretation process for the radiologists. In this study, we focus on the preliminary stage of CAD development specialized in bone metastasis extraction, with a particular emphasis on rigid registration. We propose a novel rigid registration technique by augmenting DRMINE, which estimates mutual information using neural networks, with skip connections and normalization. From the three datasets, ten images were selected randomly from the cervical, thoracic, and lumbar regions. These images were then augmented with rotation as well as horizontal and vertical translations to create modified versions. The registration accuracy was assessed based on the Full Width at Half Maximum (FWHM) of the difference images. In the proposed method, FWHM values for the thoracic and lumbar regions of the spine exhibited a maximum reduction rate of 2.8% and a minimum reduction rate of 0.533%. However, the cervical spine region exhibited superior FWHM results with DRMINE compared to the proposed methodology. The proposed method was influenced by the capture area, but it indicated the potential to provide stable registration as the standard deviation decreased for all FWHM values.

Keywords: Computed Tomography, Rigid registration, Unsupervised learning, MINE, DRMINE

1. Introduction

As per the estimates of the World Health Organization (WHO) in 2019, cancer is the first or second leading cause of death in 112 of 183 countries [1]. Furthermore, there exists the possibility of cancer metastasizing to distant locations through the vascular and lymphatic systems, with the spine, in particular, being the most susceptible site for skeletal metastasis [2], [3]. Metastatic bone tumors necessitate prompt identification and timely intervention. However, as metastatic bone tumors commonly lack discernible symptoms, they are often detected through Computed Tomography(CT) examinations during follow-up observations. Therefore, the assessment of osseous structures harboring metastases and the early detection thereof predominantly rely upon CT scanning as the most efficacious modality. However, in CT examinations, where 100 to several hundred cross-sectional images can be obtained in an examination, the burden on the diagnosing radiologist increases significantly, and the results vary due to differences in interpretation experience, which poses a significant challenge.

The Temporal Subtraction technique (TS) [4] is a method that involves performing calculations between two images taken at different times to extract lesions that appeared during a specific period. This technique is applied in computer-aided diagnosis (CAD) systems for supporting radiographic interpretation. However, the mere subtraction of a simple current image and a past image results in the occurrence of differential artifacts due to positional discrepancies between the images. Therefore, it becomes crucial to perform registration processing as a preprocessing step. In typical image registration frameworks, prior to performing non-rigid registration, the target image pairs are often pre-aligned based on rigid registration or affine transformations. However, unless there is a significant improvement in the accuracy of affine deformations, the performance of alignment will be greatly diminished [5], [6].

In recent years, numerous studies have been conducted on registration techniques, particularly in the domain of deep learning. However, deep learning requires a substantial amount of annotated data for training, which hampers the practical application of deep learning methods in medical research. Consequently, unsupervised learning, which does not rely on annotated data, has garnered significant attention as a potential solution to this limitation. Differentiable registration with mutual information and matrix exponential (DRMINE) [7] is an unsupervised learning-based rigid registration model that utilizes Mutual Information Neural Estimation (MINE) [8] to estimate mutual information using a neural network, instead of relying on conventional approximations of mutual information.

Shogo Baba, Tohru Kamiya, Takashi Terasawa, Takatoshi Aoki

In this study, we focused on rigid registration and proposed a model incorporated with skip connections and normalization in the MINEnet framework within the DRMINE model.

2. Materials and methods
2.1. Dataset

We conducted experiments employing TOSHIBA Aquilion PRIME and TOSHIBA Aquilion ONE, utilizing data from three datasets encompassing imaging ranges spanning from the cervical to lumbar spine levels. The image size was set at 512×512, with a slice thickness of 1.0 mm and pixel size ranging from 0.625 to 0.820 mm. We conducted experiments by randomly selecting ten images each from the cervical, thoracic, and lumbar regions based on the data of these three datasets cases.

Furthermore, in order to replicate the displacement in positioning, an image was created with horizontal and vertical movements of 15 pixels each along the x-axis and y-axis, along with a 10° rotation (Bicubic interpolation). Fig. 1 illustrates the image transformation, depicting the image before and after the conversion.

Our computing system consisted of an Intel Core i7-7500U CPU and an NVIDIA Tesla V100 GPU with 16GB of memory.

Fig. 1 The image transformation
Left: Original image, Right: transformed image

2.2. DRMINE registration algorithm

MINE utilizes the principle of Donsker-Varadhan (DV) duality to compute mutual information (MI),

$$MI = \sup_{f} J(f) \tag{1}$$

where $J(f)$ is the DV lower bound.

$$J(f) = \int f(x,z)P_{XZ}(x,z)dxdz$$
$$- \log(\int exp(f(x,z))P_X(x)P_Z(z)dxdz) \tag{2}$$

MINE uses a neural network to compute $f(x,z)$ and uses Monte Carlo technique to approximate the right hand side of (2). MINE claims that computation of (1) scales much better than histogram-based computation of MI.

The optimization of DRMINE is as follows.

$$\max_{\substack{v_1,\cdots,v_6 \\ v_1^1,\cdots v_6^1 \\ \theta}} \{ \sum_{l=2}^{L} MINE(T_l, Warp(M_l, M_{exp}(\sum_{i=1}^{6} v_i B_i)))$$
$$+ MINE(T_1, Warp(M_1, M_{exp}(\sum_{i=1}^{6}(v_i + v_i^1)B_i)))\} \tag{3}$$

B_i is an affine transformation on a two-dimensional plane. This group comprises six generators, where $Mexp$ denotes the matrix exponential operation.

$$B_1 = \begin{bmatrix} 0 & 0 & 1 \\ 0 & 0 & 0 \\ 0 & 0 & 0 \end{bmatrix} B_2 = \begin{bmatrix} 0 & 0 & 0 \\ 0 & 0 & 1 \\ 0 & 0 & 0 \end{bmatrix} B_3 = \begin{bmatrix} 0 & -1 & 0 \\ 1 & 0 & 0 \\ 0 & 0 & 0 \end{bmatrix}$$

$$B_4 = \begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 0 \end{bmatrix} B_5 = \begin{bmatrix} 1 & 0 & 0 \\ 0 & -1 & 0 \\ 0 & 0 & 0 \end{bmatrix} B_6 = \begin{bmatrix} 0 & 1 & 0 \\ 1 & 0 & 0 \\ 0 & 0 & 0 \end{bmatrix}$$

Using the multi-resolution pyramid technique [9], [10], [11], the fix image pyramid $:T_l$ and the moving image pyramid $:M_l$ $(l = 1, \dots, L)$. L is the maximum level in the image pyramid.

MINE is a method for estimating mutual information utilizing neural network architectures. MINE learns using the error backpropagation method, similar to conventional neural networks, in order to maximize the mutual information between the fixed image and the distorted moving image. θ denotes the parameters of the neural network utilized to accomplish MINE. MINEnet is constructed with two hidden layers composed of 100 neurons each, and utilizes the non-linear activation function ReLu between the hidden layers.

However, note also that image structures are slightly shifted through multi-resolution image pyramids. So, a transformation matrix suitable for a coarse resolution may need a slight correction when used for a finer resolution. To alleviate this issue, in the second item, we employ the parameterization of matrix exponential functions and introduce a dedicated additional parameter vector $v^1 = [v_1^1, \cdots, v_6^1]$ for the finest level of resolution, optimizing the multiresolution approach. Fig. 2 illustrates DRMINE registration algorithm.

Fig. 2 DRMINE algorithm

2.3. Our method

In order to enhance the registration technique utilizing DRMINE, it is of paramount importance to precisely estimate mutual information. MINEnet is a method that utilizes neural networks for the estimate mutual information, and thus, we postulated that the effective propagation of differentials plays a pivotal role in the estimate mutual information. The conventional approach comprises a simplistic two-layer structure, whereas the proposed methodology constructs a three-layer architecture by incorporating additional layers into MINEnet. Furthermore, we introduced skip connections

[12] between each layer. Additionally, we believed that the normalization of the hidden layers also influences the precision of the neural network. Hence, we incorporated layer normalization [13] into the model, as depicted in Fig. 3. Moreover, we set the number of neurons in each layer to 100, similar to DRMINE.

To demonstrate the enhancement in accuracy attributed to the incorporation of normalization, this study conducted a comparative analysis of precision among three methodologies: the conventional approach, a model enriched solely with skip connections in the DRMINE framework (Method [a]), and the proposed technique (Method [b]).

2.4. Evaluation methods

The evaluation of image registration accuracy involved the computation of the Full Width at Half Maximum (FWHM) from the histogram of the difference image. This difference image was aligned using a reference image and registered with the moving image (Fig. 4). FWHM represents the width at which the distribution encompasses half of its maximum value. A smaller FWHM indicates a reduction in the presence of artifacts attributed to residuals.

3. Experiments and results
3.1. Results

From Table 1, the method[b] yielded the lowest average FWHM for both thoracic and lumbar regions of all data of datasets. The mean reduction rate was found to be 1.389%, with a maximum reduction rate of 2.8% and a minimum reduction rate of 0.294%. However, in the cervical spine region, DRMINE yielded superior precision results across all data of datasets. The model constructed solely with skip connections without normalization did not show a clear improvement in accuracy compared to DRMINE. Therefore, the enhancement of accuracy cannot be achieved solely through the addition of skip connections. By combining Layer Normalization, we have achieved an enhancement in the accuracy of estimations.

Fig. 5, Fig. 6, Fig. 7 depict the results obtained from algorithms applied to the cervical, thoracic, and lumbar regions. The proposed methodology led to the observable reduction of residuals in the contour region.

Fig. 3 Proposed network

4. Discussion and conclusion

From Table 1, it can be inferred that the contour's shape exerts an influence on the FWHM. However, it is posited that the stratification of the proposed methodology was rather shallow, resulting in an insufficient learning efficacy. Therefore, we contemplate that further deepening the layers and establishing interconnections between them through skip connections may lead to an improvement in precision. Furthermore, the mere addition of skip connections did not exert any influence on the enhancement of accuracy and stabilization of estimation precision. This demonstrates the contribution of adding layer normalization not only to the improvement of accuracy but also to the stabilization of estimate mutual information.

The proposed methodology has demonstrated further enhancement and stabilization of precision in rigid registration. Additionally, it has suggested its utility in rigid registration of medical images from an unsupervised learning perspective.

Abstract

This study aims to develop a smart belt that can be used to monitor elderly activities at home by integrating Multi-Modal Sensors (MMS) and the Internet of Things (IoT). The MMS used in this study to collect elderly information is the IMU sensor, vibration sensor, push button, and ESP32 to process IoT data. Furthermore, the IoT platform used to transmit elderly information data from the smart belt to the family smartphone is Blynk. In this study, the smart belt can monitor the activities of the elderly when walking, sitting, lying down, and sleeping. After that, the smart belt can provide warning alerts when the elderly carry out abnormal activities at home. The results of this study show that the smart belt can monitor the activities of the elderly when walking, sitting, lying down, sleeping, and warning alerts on the family smartphone based on the integration of MMS and IoT.

Keywords: Smart Belt, Elderly, Multi-Modal Sensor, Internet of Things.

1. Introduction

The elderly is a person who has reached the age of 60 years or older [1]. During this phase, the elderly will have a reduced ability to perform activities, which means that their family will need to provide them with special assistance. In addition to monitoring the condition of the elderly at home, the busy activities of family members outside the home can pose an additional problem when caring for an elderly relative who is alone at home. Therefore, the urgency of this research is to build a smart belt device that can help family members monitor their elderly activities based on the integration of Multi-Modal Sensors (MMS) and the Internet of Things (IoT).

Some researchers have conducted studies on the development of devices to monitor elderly activities based on IoT technology. Hua et al. have developed a device that can be used to monitor elderly activities using ICE (IoT Cares for the Elderly) [2]. In that study, the researchers used a heartbeat sensor, a body temperature sensor, and an Intel Edison platform to monitor elderly activities based on the Internet of Things. Narasinghe et al. have conducted a study to monitor and detect activities of elderly care by integrating various technologies of wearable and non-wearable devices connected to the wireless network [3]. The researchers in that study used the heart rate sensor and the PIR sensor to detect elderly activities and the cloud system to store elderly information using an internet connection. Cheng et al. have presented an application to monitor elderly care with IoT [4]. In that study, the researchers used the ThingSpeak IoT platform and the ADXL345 accelerometer to monitor the elderly while doing activities at home. Rupasinghe et al. conducted the design and development of an IoT-based device to track the physical activities of the elderly using an accelerometer sensor [5]. Firebase IoT platform was used to transmit elderly information from the device to the smartphone of the elderly family. Furthermore, Naeim et al. have developed a device for monitoring elderly activities for safety based on mobile IoT [6]. In that study, the researchers used a low-cost prototype device to measure heart pulse, detect falls, and determine the location of the elderly, then used Blynk, Firebase, and Google Assistant for the IoT platform.

According to the results of the study shown previously, it can be seen that some researchers have developed devices to monitor elderly activities using IoT. Therefore, the contribution of this study is to develop a smart belt that can be used to monitor elderly activities based on the integration of MMS and IoT. In this study, we used the IMU sensor, vibration sensor, and push-button for MMS, and Blynk as an IoT platform to transmit elderly information from the smart belt to elderly activities when the elderly is walking, sitting, lying down, and sleeping.

This paper consists of a fourth chapter to elaborate on our study results. In the second chapter, we explain the method used in our study to develop a smart belt to monitor elderly activities. The third chapter presents the results of our study. Then in the last chapter, we show the conclusion and future work of our study.

2. Methodology

Figure 1 shows the architecture design developed in our study to build the smart belt based on the integration of MMS and IoT to monitor elderly activities.

Fig.1. Architecture design

According to the information in Fig. 1, it can be seen that the sensor devices used to develop MMS in our study consist of the IMU sensor, vibration sensor, and push button. The function of the IMU sensor in this study is to detect the activities of the elderly when they walk, sit, lie down, and sleep. We detected it when the degree of motion of the IMU sensor was observed following the activities of the elderly. IMU sensor is a sensor device that can be used to detect the degree of motion of an object according to acceleration and gyroscope [7]. The vibration sensor function in the smart belt is to confirm that the elderly is moving when the IMU sensor detects that the elderly walk, sit, and lie down. Then after that, when the IMU sensor detected the elderly in a sleep position and the vibration sensor did not detect the elderly moving, the system confirmed that the elderly was in a sleep state. The vibration sensor is a sensor device that can detect the vibration of an object based on the mechanical quantity received by the sensor and then convert it into electrical current [8]. Furthermore, the push button function is a security button that sends elderly information when the elderly need helps or are in an abnormal condition.

In this study, the microcontroller used to read and process MMS and IoT data is ESP32. ESP32 is a microcontroller that can be used to process sensor data for the controller, is low-cost and low-power, and is integrated with the Wi-Fi and Bluetooth module on a board [9]. The IoT platform used to transmit IoT data between the smart belt and the smartphone in this study is Blynk. Blynk is an IoT platform that can be used to communicate IoT data between devices to an iOS or Android smartphone over an Internet connection [10]. Furthermore, Fig. 2 shows the flowchart system developed in our study to operate the smart belt based on IoT.

Fig.2. Flowchart systems

Based on the information in Fig. 2, it can be seen that, in the first step, the smart belt reads the data input received from the IMU sensor, vibration sensor, and push button, then processes the IMU and vibration sensor data to detect elderly activities. When the system detects that the elderly is walking, the system then sends the information from the smart belt to the family's smartphone to inform the elderly that they are walking using Blynk IoT, connected over the Internet connection.

Furthermore, when the elderly is sitting, lying down, and sleeping, the system sends the information data to the family's smartphone based on the information from the IMU and vibration sensor, respectively. When the system detects that the push button is pressed, the Blynk IoT then sends the warning information to the family that the elderly need helps or are in an abnormal condition. The systems then run repeatedly until the power on the smart belt is turned off.

3. Results and Discussion

We have developed a smart belt that can be used to monitor the activities of the elderly based on the integration of MMS and IoT. Figure 3 shows the smart belt developed in our study.

Fig.3 The smart belt developed in this study.

Based on the information in Fig. 3, to implement the experiment, we used an IMU sensor (KKHMF, MPU-6050) to detect elderly activities when walking, sitting, lying down, and sleeping according to the degree of movement of the IMU sensor (acceleration and gyroscope), a vibration sensor (DKARDU, Piezoelectric) to confirm elderly activities when walking, sitting, lying down, and sleeping according to the vibration of elderly moving, then push button as trigger for the smart belt to send a warning to the family when the elderly is an abnormal condition. The microcontroller used in our study to process MMS data and IoT is ESP32 (ESP32 DEVKIT V1) and then used the Blynk platform to transmit IoT data between the smart belt and the family smartphone. Furthermore, Table 1 shows the DATASTREAM ID and data type used to transmit the elderly information from the smart belt to the family smartphone using Blynk.

Table 1. The DATASTREAM ID and data type are used to transmit elderly information.

Elderly Information	DATASTREAM	Data Type
Walking	V1	INT, 0/1
Sitting	V2	INT, 0/1
Lying Down	V3	INT, 0/1
Sleeping	V4	INT, 0/1
Warning	V5	INT, 0/1

According to the information in Table 1, we use INT data type 1 or 0 to confirm the activities of the elderly when they walk, sit, lie down, sleep, and have abnormal conditions. When the system detected that the elderly was doing activities (walking, sitting, lying down, sleeping, and abnormal conditions), the system then sent the INT data of 1 to confirm that the elderly was doing the activities. If not, the system sends 0 data information to the family smartphone. Furthermore, Fig. 4 shows the

activities of the elderly when walking, standing up, sitting, and lying down, respectively. Fig. 5 shows the elderly information on the family smartphone using the Blynk application based on the Android OS when the elderly walk.

Fig.4. Activities of the elderly when (a) walking, (b) standing, (c) sitting, and (d) lying down.

Fig.5. Information of elderly when walking.

4. Conclusion

In this study, the development of a smart belt based on the integration of MMS and IoT that can be used to monitor elderly activities when walking, sitting, lying down, sleeping, and under abnormal conditions was carried out. We used an IMU sensor, vibration sensor, and push button for MMS and ESP32 as a microcontroller to process MMS and IoT data, then Blynk for the IoT platform. In our study result, the smart belt can detect the elderly walking, sitting, lying down, and sleeping on the family smartphone.

Abstract

Measuring the altitude distribution of electron density in the upper atmosphere, known as the ionosphere, using High-Frequency radio wave reflections often causes the low signal-to-noise ratio of ionospheric echoes due to radio frequency interference. We propose a model for converting low-signal-to-noise-ratio ionospheric echo video images (Ionogram) into noise-reduced images using image processing techniques, for tracing the ionospheric echoes from Ionogram. The proposed method consists of three processing parts: noise removal optimized for individual Ionogram images, extraction of ionospheric echoes by penalized background subtraction technique, and fine-tuning of ionospheric echo signals using a minimum spanning tree algorithm. The proposed model successfully reproduces fine Ionograms with 98% recall and 99% precision.

Keywords: Ionospheric Observation, Computer Vision, Motion Detection, Time-series data

1. Introduction

The ionosphere is a part of Earth's upper atmosphere from about 100km to high altitudes and is very closely related to our modern life. The ionosphere has a significant impact on the radio propagation for communications, satellite positioning system, etc. The structure of ionosphere is not stable and variable in the time of day, season, latitude, and solar activity, because of the differences of the energetic photo-ionization process. The irregularities and disturbances in the ionosphere cause various severe problems, for example, lower accuracy of the radio navigation due to the global positioning system/Global Navigation Satellite System scintillation, disruptions in High Frequency (HF) radio wave bands or interferences due to anomalous propagation, etc. In order to utilize radio propagation safely and securely in modern society, it is essential to measure and analyze the fluctuating ionospheric environment at high speed and with high accuracy.

The fluctuating ionospheric environment is characterized by electron density variations in this region. The fluctuating ionospheric environment is characterized by electron density variations in this region. Ionosonde, a vertical ionospheric sounder, has been widely used to detect the ionospheric electron density as a function of height, using HF radio wave reflections. Ionosonde emits radio impulses with increasing frequency, measuring the time delay of radio signals received back from the different ionospheric layers. Fig. 1a shows an ionogram, which is a visualization of the output of an ionosonde measurement. The ionogram represents the received echo intensities in a virtual height (time-of-flight) against transmitted frequency. To analyze the fluctuating ionospheric environment, it is important of the interpretation of the ionogram, the so-called "scaling" of

Yuu Hiroshige, Akiko Fujimoto, Akihiro Ikeda, Shuji Abe, Akimasa Yoshikawa

ionograms. In other words, the scaling is the detection of the ionospheric echo on the ionograms and the extraction of characteristics of E and F layers (virtual heights: h'E, h'F, h'F2, etc. or critical frequencies: foE, foF1, foF2, etc.) from ionograms [1].

Classical manual scaling by professional researchers has been used, but several methods of automatic scaling have been proposed in recent decades. There are two main approaches to automatic scaling: image processing (computer vision) approaches [2], [3] and deep-learning image generation approaches [4], [5]. The both methods perform the scaling of ionograms with higher accuracy, but the expected ionogram for scaling is high signal-to-noise ratio (SNR) image. Here, the signal is the ionospheric echo, and the noise is the background noise, such as radio frequency interference (RFI) from other emissions. In Fig. 1a, the noise appears as the vertical strip. The ionogram visualization process also generates noise [6]. Ionogram images are visualized using spectral analysis techniques such as the Fast Fourier Transform (FFT) algorithms on original data obtained by the ionosonde. Artificial noises are generated by this process. The noise due to RFI and FFT complicates automatic information extraction from ionogram through scaling [7].

Ionosonde transmitting power by a typical HF radar is high power, several tens of kW. In ionogram images acquired by such high-power ionosondes, the signal strength of the ionospheric echo and the background noise are distinctly different, and the ionospheric echo is sufficiently strong. This means that scaling can be performed from ionogram images with high SNR. On the other hand, our ionosonde observations with Frequency Modulated Continuous Wave (FM-CW) type radar, operated by the joint research with Kyushu Institute of Technology and Kyushu University, have a maximum peak power of 20 watts. Although the advantage of FM-CW radar is its high gain even at low power, the reflected echo strength from the ionosphere is relatively weak compared to a typical HF radar. Therefore, the signal strength of the ionospheric echoes is often comparable to the background noise, and it is difficult to separate from each other. Since the scaling process is performed from ionogram images with low SNR, a simple noise elimination processing is not sufficient.

There are two challenges in automatic ionogram scaling for FM-CW ionogram. First, as described above, scaling accuracy is poor when the input image is an ionogram with low SNR. Second, in terms of the quasi-real-time monitoring of the ionospheric condition, the processing time on scaling is required within few seconds. We sequentially operate the FM-CW ionosonde with every 3 minutes. A low-cost computer, which is usually expected to perform with no high processing speed, is required on the observation site. The deep learning approaches have a processing time of 2-3 minutes, and real-time scaling requires a computer with high processing speed. We try to propose a new algorithm without deep-learning

approach for scaling which includes the elimination process of background noises.

a. Original Ionogram   b. Full denoised Ionogram

c. Histogram of signal intensity for Fig .1a

d. Histogram for signal intensity of Fig. 1b

Fig. 1. Comparison of the signal intensities of original and full denoised ionograms recorded at 00:06:00 UT, January 1, 2019.

In this paper, we provide a new method to scaling of FM-CW ionogram with low SNR. The new scaling method can be applied to ionograms containing any ionospheric echo class (E and F layers) for quasi-real-time detection. The shape and position of the ionogram echoes vary with time, due to daily and seasonal changes in the ionospheric electron density structure and its solar activity dependence. Therefore, our study focuses on time-variant scaling based on time-series analysis. The proposed method consists of three parts. First, we remove the noise from the ionogram with low SNR, optimizing the noise elimination threshold value for individual ionogram image. Second, we extract the ionospheric echoes based-on penalized background subtraction technique. Finally, the ionogram with high SNR are regenerated by fine-tuning of ionospheric echo signals using a minimum spanning tree algorithm.

2. Dataset

The dataset used in this study consists of 960 ionogram data observed every 90 seconds on January 1, 2019, at the FM-CW radar ionosonde located at Sasaguri (130.34° E, 33.37° N). Fig. 1a shows a sample of the ionogram image data obtained on January 1, 2019, at 00:06:00 UT (Universal Time). Ionogram image shows the signals with frequency values from 2 MHz to 9 MHz and altitude values from 0 km to 700 km. In order to treat the ionograms as a two-dimensional array, we consider the class width as an array with 278 x 238 bins with a frequency of 0.25 MHz and an altitude of 2.9296875 km.

As mentioned above, the ionogram is usually contaminated with RFI noise appearing as vertical strips,

shown in Fig. 1a. As shown in Fig. 1, the signal intensity distribution in histograms is significantly different between the original ionogram (Fig. 1c) and the full denoised ionogram (Fig. 1d). Fig. 1b was produced by manual removal of the background noise from Fig. 1a. The signal distribution in Fig. 1d only corresponds to the ionospheric echoes. Comparing between Fig. 1c and Fig. 1d, it is obvious that ionospheric echoes are highly intense relative to noises. In other words, the almost background noises are in lower value of signal intensity.

3. Methodology

The proposed method consists of three processing parts: (1) Weak Signal Reduction, (2) Penalized Background Subtraction, and (3) Fine-tuning Ionogram. In the processing part on Weak Signal Reduction, the divided value between the ionospheric echoes and the background noises is automatically estimated based-on Ridge Regression [8]. After this process, almost background noises are eliminated, and we get the denoised ionogram remaining enough ionospheric echoes. The processing part of Penalized Background Subtraction enables the extraction of ionospheric echoes with motion detection algorithms. Finally, the processing part of Fine-tuning Ionogram provides the regenerated ionogram, removing the remained noises and interpolating the ionospheric echoes from the detection region using the minimum spanning tree in the graph structure. The following subsections describe the detail algorithm of each part.

3.1. *Weak Signal Reduction*

As pre-processing, the weaker RFI noises are eliminated by aligning the average signal strength in the altitude direction to a constant value, which is the mode of histogram of signal intensity. We define the elimination function of RFI noises as below:

$$\boldsymbol{R}_{f,h} = \boldsymbol{I}_{f,h} + MO - \mu_f \tag{1}$$

where $\boldsymbol{R}_{f,h}$ and $\boldsymbol{I}_{f,h}$ represent the power of the original ionogram as input and the eliminated ionogram as output, respectively. The subscript f and h indicate the positions of the frequency and altitude values on the ionogram. MO represents the mode value of signal intensity histogram. μ_f is the average of signal intensity at each frequency bin.

As shown in Fig. 1, it is possible to separate the ionospheric echoes and the background noise by estimating the boundary value between them. However, the distribution of signal intensity is different each ionogram. This suggests that it is necessary to estimate the threshold value according to the signal distribution of each ionogram. We estimate this threshold of boundary between the ionospheric echoes and the background noise by ridge regression [8].

Ridge regression is a method which further improves generalization performance by adding an L2 regularization term to multiple regression analysis. For each raw ionogram, Ridge regression estimates the coefficients, w, of multiple regression models for the boundary threshold value as the objective variable, y, and when you give the frequency, mean and variance of the mode of the signal intensity as the explanatory variable, X. The loss function of the ridge regression, L, is shown in Eq. (2), where the weight of the L2 regularization term is $\alpha = 0.7$.

$$L = (y - Xw)^T(y - Xw) + \alpha\|w\|_2^2 \tag{2}$$

$$\hat{y} = X^T w \tag{3}$$

The equation for the objective variable is given by Eq. (3). The above equation yields a model for estimating the threshold for removing an appropriate low-intensity signal. The ionogram after applying this algorithm is shown in Fig. 2.

Fig. 2. Ionogram with Weak Signal Reduction applied to Fig. 1a

3.2. *Penalized Background Subtraction*

As shown in Fig. 2, it is still impossible to completely remove the noise from the ionogram, even after removing the low intensity signal. This is because the noise signal is more intense than the ionospheric echoes. We use Background Subtraction method [9] to extract of the ionospheric echoes from the ionogram and to ignore the remained intense background noise. The Background Subtraction method is one of the motion detection techniques to detect moving objects in a video frame. A moving object is detected by comparing a frame of video with its corresponding background image. It is important to generate a background image without moving objects. In this study, we consider an ionospheric echo as the moving object and an ionogram image with only noise present as the background image. The processing part of Penalized Background Subtraction is divided into four steps and the following subsections describe the detail algorithms.

Yuu Hiroshige, Akiko Fujimoto, Akihiro Ikeda, Shuji Abe, Akimasa Yoshikawa

3.2.1. *Penalty based on ionospheric echo shape*

As shown in Fig. 1b, ionospheric echoes in the ionogram are observed mainly as line shapes extending in the frequency direction. This suggests that the signal intensity of ionospheric echoes is higher at specific altitudes than at other altitudes in each frequency band bin. In fact, as shown in Fig. 3b, the distribution of signal intensity against the altitude in interest frequency bin, 4.0 MHz, shows two significant peaks corresponding to the ionospheric echoes.

a.   Original Ionogram data and the interest frequency, 4.0 MHz, in red vertical line

b.   Signal intensity as a function of the altitude for the interest frequency, 4.0 MHz

Fig. 3. Signal distribution in altitude direction, recorded at 06:01:30 UT, January 1, 2019

For generating the background image from the input ionogram image including the ionospheric echoes, we only penalize the corresponded frequency into the significant ionospheric echoes in each ionogram, to reduce the amplitude of signal power. The detail operating flow is as shown in Fig. 4. First, a vector of the signal intensity is extracted for each frequency bin from the two-dimensional matrix of the ionogram. Next, the components that penalize the extracted vectors are selected according to the flowchart shown in the Fig. 4.

Fig. 4. Determination flow of penalization for the generation of background image

The penalty, $f_{f,h}^p$, is given as Eq. (4), where $I[t]_{f,h}$ is the signal intensity of the unprocessed ionogram array at time t. We use anomaly detection in deciding whether to penalize. This is designed based on the Hotelling's theory

[10]. In the present work, a normal distribution is assumed for each signal with the same frequency value after removing weak intensity signals, and signals that deviate from the 95% confidence interval are penalized by detecting them as anomalies. By penalizing with these procedures, we ideally aim to get the background image contains only noise.

$$f_{f,h}^p(I[t]_{f,h}) = \begin{cases} \dfrac{1}{I[t]_{f,h}} & (penalized) \\ I[t]_{f,h} & (\text{else}) \end{cases} \quad (4)$$

3.2.2. *Penalty based on one previous detection frame image*

The background subtraction method can efficiently detect moving objects under the constraint that the background scene is stationary. However, the accuracy decreases under dynamically changing background image. Ionograms are no exception to this problem, as the position and shape of background noise as well as ionospheric echoes change from moment to moment. Therefore, the ionospheric echoes detected from the previous ionogram are used to estimate the background image.

This method assumes a two-dimensional Gaussian distribution centered on the detected component. Here, the frequency value is f and the height value is h, from which the mean μ_f, μ_h, and standard deviations σ_f and σ_h are calculated, respectively. The covariance ρ is given by Eq. (5), considering the characteristic that the ionospheric echoes vary in the frequency direction. Eq. (6) and (7) show the weight Gaussian. The generated background image is penalized by considering the previous ionospheric echo detection region.

$$\rho = \begin{pmatrix} 8 & 0 \\ 0 & 4 \end{pmatrix} \quad (5)$$

$$f_{f,h}^g = \frac{1}{2\pi\sigma_f\sigma_h\sqrt{1-\rho^2}}e^\alpha \quad (6)$$

$$\alpha = -\frac{1}{2(1-\rho^2)}\left\{\frac{(f-\mu_f)^2}{\sigma_f{}^2} - \frac{2\rho(f-\mu_f)(h-\mu_h)}{\sigma_f\sigma_h} + \frac{(h-\mu_h)^2}{\sigma_h{}^2}\right\} \quad (7)$$

3.2.3. *Penalized background image generation algorithm*

In addition to the background image update algorithm for the Background Subtraction method [9], the background image, $B[t]$, is updated by adding the weight terms of Eq. (4) and Eq. (6) as follows.

$$\boldsymbol{B}[t] = \alpha \cdot \boldsymbol{B}[t-1] + (1-\alpha) \cdot f^p_{f,h}(\boldsymbol{I}[t])$$
$$-\beta \cdot f^g_{f,h}(\boldsymbol{F}[t-1]) \quad (8)$$

where α and β are weights for $f^p_{f,h}$ and $f^g_{f,h}$. In this study, we set $\alpha = 0.5$ and $\beta = 8.0$, which are assumed the same level of influence of each term.

3.2.4. *Detection region determination*

The positions where the result of subtracting the background image obtained by Eq. (8) from the input image is a positive value is detected as ionospheric echoes, $\boldsymbol{D}[t]_{f,h}$, as shown in Eq. (9). It is assumed that background regions are distributed where the difference values are small. Thus, *thresh* in Eq. (9) is set to the class value of the mode in the histogram of difference values between the input and background images.

$$\boldsymbol{D}[t]_{f,h} = \begin{cases} 1 & (\boldsymbol{I}[t]_{f,h} - \boldsymbol{B}[t]_{f,h} \geq thresh) \\ 0 & (else) \end{cases} \quad (9)$$

Fig. 5 shows that our method can detect ionospheric echoes. This indicates that our method is also effective for ionograms with high signal-to-noise ratios.

a.   Original Ionogram   b.   Ionogram detection data after processing for Fig. 2

Fig. 5. Ionospheric echo detection by Penalized Background Subtraction, original ionogram data recorded at 00:06:00UT, January 1, 2019

3.3. *Fine-tuning Ionogram*

As shown in Fig. 6a, the background subtraction method can be used to detect ionospheric echoes, but it can also leave isolated noises. In addition, the signal should be detected might have missing or incorrectly detected as the ionospheric echo. For solving these problems, we propose two post-processing methods: the convolution operation to remove noise that appears as isolated echoes, and the optimization for interpolating and denoising of the detection region using an algorithm based on a minimum spanning tree.

3.3.1. *Denoise impulse noise*

The convolution is, an algorithm of image processing, used to reduce of impulse noises in the present work. The multiplication a two-dimensional square matrix composed of odd-numbered widths several times is applied to the detected ionogram with two-dimensional array. If there are many signals around the element of interest that have been labeled as ionospheric echoes by the background subtraction method, then they should be ionospheric echoes, otherwise they should be considered as noise.

The filter $H_{i,j}$ consists of an $n \times n$ square matrix, with all elements 1. It is also scanned with stride 1 to maintain the size of the two-dimensional array of the ionogram. The convolution equation using this filter is shown in Eq. (9). Let D^{bs} be the array output by the algorithm in the processing part of Penalized Background Subtraction and D be the array after impulse noise removal.

$$D_{f,h} = \begin{cases} 1 & \left(\sum_{i=-n}^{n} \sum_{j=-n}^{n} D^{bs}_{f+i,h+j} \cdot H_{i,j} \geq 2+n\right) \\ 0 & (else) \end{cases} \quad (10)$$

In this study, impulse noises are removed by performing the convolution operation, changing the filter width n in the order of 5, 7, 9, and 11. Ionograms before and after the removal of impulse noises are shown in Fig. 6. It is obvious that this process reduces extracted excess noises and does not disappear the detected signal of ionospheric echoes (Fig. 6b).

a.   Ionospheric echo detection results before processing   b.   Ionospheric echo detection results after processing

Fig. 6. Comparison of ionograms with and without Impulse noise reduction processing

3.3.2. *Optimization by a minimum spanning tree*

First, for all points detected as ionospheric echoes, these detection points are connected for each E and F layer. The points are connected so that they form a minimum spanning tree, considering the linear shape of the ionospheric echoes. Next, edges with large distances between vertices are removed. The graph to which the removed vertices belong is judged to be noise and removed. For the remained edges after the above processes, the detection area is interpolated between the two vertices that compose the edge. The result is shown in Fig. 7.

4. Result and discussion

To evaluate the accuracy of our automatic scaling method, we compared the accuracy of ionograms obtained by our algorithm with that of manually scaled ionograms. The evaluation is based on the absolute error of the critical frequencies' foE and foF of each layer of the ionogram and the percentage of absolute error within 0.5 MHz indicating that sufficient accuracy was achieved. The accuracy of the proposed method is compared with that of the Weighted Background Subtraction without each weight term (Table 1). The average processing time of the proposed algorithm was 7.1 seconds per ionogram. The proposed model successfully reproduces fine ionograms with 98% recall and 99% precision.

Table 1 shows that the detection results were satisfactory despite the low SNR of the ionograms. From Table 1 and the detection result shown in Fig. 7b, it is clearly found that the addition of a weight term to the background subtraction algorithm was effective. The processing time with few of seconds indicates that the proposed method is useful to generate quasi-real-time ionograms with high SNR.

Table 1. Performance Comparison with different weight terms in this study

Model		Main result	Base+ $f_{penalty}$	Base+ f_{gauss}	Base
Absolute error (MHz)	foE	0.47	0.93	0.92	0.99
	foF	0.26	0.44	0.42	2.6
Rate of accuracy (%)	foE	67%	50%	50%	47%
	foF	83%	49%	61%	15%

On the other hand, the continuity of ionospheric echoes remains an issue. Some ionospheric echoes are missing from the detection results of our method. This is due to the altitudinally banded intermodulation noise in the ionograms. This is a factor that reduces the signal strength, and thus causes the background subtraction method to fail to detect the ionospheric echoes. Also, although not present in this study's data set, scattered

signals such as those seen in equatorial spread F are not expected to give meaningful results.

5. Conclusion

Automatic scaling of ionograms presents various challenges for the ionogram image contaminated with noises. In this study, we proposed an algorithm to automatically extract ionospheric echoes from ionograms with low signal-to-noise ratio.

Our algorithm is based on statistical thresholding according to the signal intensity distribution of each ionogram, image processing techniques focusing on time variability and ionospheric echo characteristics, noise reduction filtering, and graph theory. Although it is necessary to define some parameters, it is possible to extract ionospheric echoes from ionograms in quasi-real-time without the huge amount of teacher data as in deep learning.

On the other hand, for frequent noise and special ionospheric echo classes, the algorithm may not guarantee accuracy. The algorithm should be improved to be robust in these cases as well for the future work.

Abstract

One of the measures to prevent back pain is the use of appropriate posture corrections. In generally, the Squat method (method of keeping the knees bent and the waist as straight as possible) is recommended over the Stoop method (method of keeping the knees straight and the waist bent). The results of previous studies using acceleration and muscle potentials have shown that the lifting with knees in a kneeling position reduces the amount of load born by the lower back. However, few studies discuss the case where there is an obstacle between the subject and the object to be lifted and further, the scenarios where the object is away from the body's center of gravity. Therefore, this research focus on analyzing three types of movements using the AnyBody musculoskeletal mechanics analysis software, the Yo-bukun back pain prevention application, and the Delsys surface EMG and verifying the amount of lower back burden when there is an obstacle between the lifting object and the subject. This paper presents the verification results.

Keywords: Lower back burden, Posture correction, EMG, The body's center of gravity

1. Introduction

Frequent lifting activities in the construction and nursing care industries place a heavy burden on the lower back and can easily lead to lower back pain. One of the measures that can be taken by individuals to prevent back pain is to improve posture. There are two main types of lifting movements: the Stoop method (keeping the knees straight and the hips flexed) and the Squat method (keeping the knees flexed and the hips as straight as possible). The Japanese Ministry of Health, Labour and Welfare's "Guidelines for Prevention of Back Pain in the Workplace" recommends the knee-bend lifting method. The results of the previous study and the analysis using the "Yo-bukun" application for measuring back strain showed that the lifting method with the knees bent reduced the amount of back strain compared to the lifting method without knees bent [1], [2], [3]. In addition, the previous study showed that the lifting method with the knees bent was associated with a lower EMG burden

Tomoka Kimura, Yutaro Fujino, Sachiko Kido, Hiroki Tamura

when the lifting object was located close to the body's center of gravity [4], [5].

However, few previous studies have discussed the case where there is an obstacle between the lifting object and the subject and also when the object is far from the body's center of gravity. Therefore, the purpose of this paper is to analyze three types of movements using the AnyBody musculoskeletal mechanics analysis software, Yo-bukun back pain prevention application, and the Delsys surface electromyograph, in order to verify the amount of back burden when there is an obstacle between the lifting object and the subject.

2. Methodology

In this paper, lumbar burden was measured using AnyBody, Yo-bukun applications, and Delsys EMG.

2.1. Measuring equipments

AnyBody is a musculoskeletal mechanics analysis software from Terrabyte Co. Basically, it calculates the forces acting on each part of the human body, such as muscle activity, muscle force, and joint moments, when a movement is applied to a musculoskeletal model using inverse dynamics analysis.

Yo-bukun is an application developed by the University of Miyazaki in collaboration with DENSAN Corporation for the prevention of back pain for the iPhone. It is calibrated when the user stands upright, and calculates the amount of lumbar burden based on the tilt of the iPhone.

Delsys is the generic name for Trigno EMG system incorporated with some additional sensors developed by Delsys. In addition to EMG, IMU sensors (accelerometer, gyroscope, and magnetometer) are built in to collect kinematic data (angles) at the same time.

2.2. Measurement method

A video camera footage was used as the method of measurement for the analysis by AnyBody application. Under Yo-bukun approach, subjects were asked to keep their iPhones installed with Yo-bukun application, in their chest pockets for the measurement. EMG based approach employs two EMG sensors placed on the subject's erector spinae. The positioning of the lumbar EMG sensors is shown in the Fig. 1. The left side sensor is considered as the first channel and the right side sensor is the second channel.

The subjects were all healthy adult males, 174±3 cm tall and 22±1 years old. Subject identifiers are A, B, and C respectively. The movement to be measured was the lifting and lowering of an object while kneeling on one knee. The dimensions of the object (a box), are 35(W)× 23.5(D)×31(H)cm and the weight is 1 kg. Three types of movements were measured to examine the effects of

the presence of an obstacle and the distance between the centers of gravity. The size of the obstacle was 51(W)×10(D)×51(H)cm. The subject's center of gravity was set at the pelvis. The experimental apparatus is shown in the Fig. 2.

The initial measurement was a subject lifting the object as close as possible to its body's center of gravity without placing any obstacles. The step wise process involves a subject lifting the object and remaining for 5 seconds, before lowering it. The distance between the center of gravity of the object and the subject's center of gravity was 10 cm. In the second measurement, the obstacle is in place, and the subject lowers the object to behind the obstacle starting from an apparatus configuration as in Fig. 2, subsequently returns it to the top of the obstacle. Upon lowering the object behind the obstacle, the subject stood upright and maintained the position for a duration of 5 seconds.

Fig.1 . EMG sensor placements

Fig.2 . Experimental apparatus (includes the lifting object and the obstacle)

Fig.3 Posture in which the center of gravity of both the subject and the object 10 cm

Fig.4 . Posture in which the center of gravity of both the subject and the object 30 cm

Then, the subject knelt down once more and raised the object back over the obstacle. The distance between the object's center of gravity and the subject's center of gravity was 30 cm. The third measurement closely resembled the second, with the distance between the center of gravity of the object and that of the subject being 45 cm. The postures observed during such measurements at the distance between the center of gravity of the object and that of the subject being 10 cm and 30 cm are depicted in Fig 3 and Fig. 4.

After that the transition of the amount of burden applied on the lower back during such movements were calculated using AnyBody and Yo-bukun. Later, the analysis incorporates the maximum and average values of the amount of burden observed here. The Delsys measured the EMG potentials of the lower back during movements. To reduce the influence of noise, the rate of increase was calculated by dividing the difference between the mean value of the EMG during movement and the mean value of the EMG at rest by the mean value of the EMG at rest. The resting EMG potentials refer to the potentials recorded when the subject is at rest for a 5-second interval between lifting and lowering movements.

3. Results

This chapter outlines the measurement outcomes for the three equipment types and provides a comparison between them. The movements are individually analyzed for lifting and lowering at center-of-gravity distances of 10 cm, 30 cm, and 45 cm, respectively.

3.1. Similarity between AnyBody and Yo-bukun

To validate the reliability of Yo-bukun, the similarity between AnyBody and Yo-bukun was assessed. Verification utilized the measurement data of subject B, analyzable with A. The coefficients of determination for each center-of-gravity distance are presented in Table 1. A somewhat stronger correlation was evident in the data at a center-of-gravity distance of 10 cm, while robust correlations were observed at center-of-gravity distances of 30 cm and 45 cm.

Table 1. Correlation between AnyBody and Yo-bukun (Subject B)

Center of gravity distance (cm)	R^2
10	0.5582
30	0.9289
45	0.9812

Table 2. The rates of increase in Yo-bukun measurements

Subject Identity	Center of gravity distance (cm)	Raising movement (Up) %	Lowering movement (Down) %
A	10	97.39	107.02
	30	110.71	104.21
	45	120.70	105.34
B	10	90.68	108.78
	30	140.64	132.38
	45	172.14	163.56
C	10	137.98	157.31
	30	197.84	193.90
	45	196.63	162.03

3.2. Analysis results using Yo-bukun

The rate of increase was also determined for the Yo-bukun in comparison with myoelectric potentials. The rate of increase in the Yo-bukun measurements for the three movements is shown in Table 2. The comparisons

Tomoka Kimura, Yutaro Fujino, Sachiko Kido, Hiroki Tamura

for the raising and lowering movements are shown in Fig. 5 and 6, respectively. The average rate of increase was obtained by excluding the rate of increase at 10 cm. The average rate of increase was 156.44% for the lifting motion and 143.57% for the lowering motion.

Fig.5. Yo-bukun Increase rate (up)

Fig.6. Yo-bukun Increase rate (down)

3.3. Analysis results using Delsys device

The rates of increase in lumbar EMG potentials during the three movements are shown in Table 3, and comparisons for raising (up) and lowering (down) movements are shown in Fig. 7 and Fig. 8, respectively. In all cases, the rate of increase was lowest when the center of gravity distance was 10 cm for each subject. For Subjects A and C, the rate of increase was higher when the center of gravity was 45 cm than when the center of gravity was 30 cm, for both lifting and lowering. For subject B, the rate of increase was higher when the center of gravity was 30 cm than when the center of gravity was 45 cm. The average rate of increase was obtained by excluding the rate of increase at 10 cm. The average rate of increase was 404.43% for the lifting motion and 394.71% for the lowering motion. The average increase was 2.59 and 2.75 times that of Yo-bukun for each operation.

Table 2. The rates of increase in lumbar EMG potentials

Subject Identity	Center of gravity distance (cm)	Raising movement (Up) %	Lowering movement (Down) %
A	10	30.43	5.73
	30	230.24	239.78
	45	339.78	296.69
B	10	59.08	68.08
	30	352.31	357.99
	45	247.76	284.30
C	10	16.20	16.48
	30	518.76	534.77
	45	737.72	654.72

Fig.7. EMG Increase rate (up)

Fig.8. EMG Increase rate (down)

Fig.9 . Posture (Left: Subject B, Right: Subject C)

4. Conclusion

The rate of increase of EMG potentials during the movement was different in Subject B than in the other subjects. The possible reason for this is the difference in posture. The most notable difference is the curvature of the back. A comparison of the posture of Subject B and Subject C at a center of gravity distance of 45 cm is shown in the Fig. 9. The yellow circle at the pelvis position is the center of gravity. The white line is a simplified representation of the back. It can be seen that subject B has a straighter back than subject C. This indicates that subject B has a straighter back than subject C. This suggests that Subject B had less muscle stretch than Subject C, and that the rate of increase in myopotential was less pronounced in Subject B than in the other subjects.

In this paper, we analyzed movements using three types of measurement devices and verified the amount of lumbar burden in a situation where there is an obstacle between the subject and the lifting object. The analysis results shows that the change in the amount of lumbar burden due to the difference in the center of gravity distances was more pronounced in the electromyograms than in the measurements from the posture-based devices, such as the Anybody and the Yo-bukun. Therefore, it is possible that even in the one-kneeling lifting method, a significant distance between the object and the operator's center of gravity might not result in a reduction of electromyographic back burden.

Abstract

This study primarily relies on a smartphone application, developed within our research institute known as Yo-bukun, for the real-time estimation of lumbar burden. The Yo-bukun is capable of estimating the lumbar burden of a subject (the user) by placing an app. installed smartphone in the subject's chest pocket, while the subject is lifting/ relocating an object. The subject's movements are assessed through sensors embedded in the smartphone and certain aspects of their physical information initially fed into the app. are used in the estimation formula for determining lumbar burden. In the current scenario, Yo-bukun lacks the capability to ascertain whether the user is holding an object or not; consequently, it can only estimate the lumbar burden for limited cases of a subject holding an object. To address such limitations, the proposed system integrates voice recognition to facilitate lumbar burden estimation, considering the presence or absence of an object. Further, it was incorporated with the capability to recalculate lumbar burden after measurements, enabling prospective studies.

Keywords: Lumbar burden estimation, smartphone application, voice recognition.

1. Introduction

The smartphone application called Yo-bukun allows you to estimate the lumbar burden when holding an object in real time by placing a smartphone in the chest pocket [1], [2]. The estimation method of the Yo-bukun involves utilizing smartphone sensors such as the acceleration sensor and gyro sensor to assess the user's state (standing, sitting, turning, crouching, walking). Subsequently, the user's physical information is incorporated, and the estimation formula used in MIYADAI Pro developed by Professor Mitarai [3] is applied to perform the estimation. Here, the user needs to set the user's physical information and the weight of the object being held by the user before taking measurements. During measurement, the lumbar burden is estimated at every second in real-time.

However, few constraints have been identified in its functionality. The initial challenge is the inability to determine whether the user is actively holding an object during measurement or not. Therefore, throughout the measurement the lumbar burden is approximated under the assumption that the user is consistently holding an object. As a result, the Yo-bukun can't estimate the lumbar burden regarding movements occurring before the user holds an object or after putting an object down.

The second issue arises upon the completion of measurement, in which the user has not been given the capability to modify the set information and reevaluate the lumbar burden. In that case, if a measurement has already been conducted with incorrect information, it demands repeating the same measurement. Therefore, this paper outlines the functionalities introduced to address and resolve these identified challenges.

2. Methodology

This paper describes the proposed method that can be resolved only using a smartphone, emphasizing user-friendly ease of operation.

2.1. First problem-solving method

To address the problem of measurement being possible only in the limited situation where the user holds an object, a voice recognition function has been introduced to the Yo-bukun. The user articulates speech, while initially holding an object and when releasing it, and this voice information is utilized to determine the object possession status. The judgment method can be described as follows: upon detecting the initiation of object holding, the system assumes continuous possession until the

Seigo Imura, Praveen Nuwantha Gunaratne, Hiroki Tamura

moment of object release is identified. Conversely, if the system detects the timing when the user puts down an object, it assumes that the user does not hold an object until the point of object holding initiation is recognized. In this way, the status of object possession can be determined using voice recognition.

2.2. Second problem-solving method

The limitation was explained wherein, the post-measurement, user is unable to modify pre-measurement information and recalculate lumbar burden again. Utilizing the estimation formula utilized in Yo-bukun, the key parameters for lumbar burden estimation, extending beyond the pre-measurement information provided by the user were identified. These additional parameters are recorded for each lumbar burden estimation. Consequently, even if the user modifies the pre-measurement information after the completion of measurement, the proposed system facilitates the use of recorded parameter data for any recalculations of lumbar burden.

3. Implementation Procedure
3.1. First problem-solving Procedure

With the use of Apple's speech recognition framework [4], a voice recognition feature was incorporated with the Yo-bukun and developed a system that assesses the lumbar burden based on the user's object possession status. This advancement enables the estimation of lumbar burden solely through a smartphone, considering the user's object possession status. The proposed system estimates lumbar burden based on a user-selected preset weight if an object is held. In instances where the user is not holding an object, the system assumes an object weight of 0 kg. Furthermore, this approach replaces traditional button operations as the commencement (Start) and cessation (End) of measurement have been automated through voice recognition.

3.2. Second problem-solving Procedure

A review was conducted on the fundamental parameters crucial for lumbar burden estimation and the system development was carried forward for their systematic recording during measurements. Moreover, the system was facilitated with the use of recorded parameters to reassess lumbar burden subsequent to the measurement. As a result, users possess the capability to modify pre-measurement information, enabling recalculation of lumbar burden based on these alterations.

4. Experiment

Two experiments were conducted to validate the functionality of the introduced system.

4.1. First experiment

In the first experiment, Yo-bukun was employed for lumbar burden assessment, using specific verbal cues during both the Start and End of the object handling process. The weight of the object was set at 2 kg. To ensure the optimal accuracy in estimation result, the smartphone was securely affixed to a vest, positioned in close proximity to chest area. Initially, the configuration was set for the subject to commence the measurement without holding an object as the Yo-bukun also offers configurability to specify the status of holding an object or not, at the initialization. The Fig. 1 depicts the following operational sequence proceeded during the experiment:

a) Start the measurement without any object.
b) Uttered a specific word and lifted an object after 11 seconds.
c) Raised the upper half of the body.
d) Safely place the object on the floor by uttering a word after 21 seconds.
e) End the measurement by raising the upper half of the body.

Fig. 1. Operation sequence of the first experiment

Fig. 2. Graph illustrating lumbar burden estimation during the first experiment.

Fig. 3. Graph showing the change in lumbar burden estimation during the second experiment; graph for the object weight 2kg (blue), 5kg object (orange)

4.2. Second experiment

The second experiment was conducted to reassess the estimation results obtained from the initial trial by modifying user-input information. In this subsequent trial, an examination was made to determine the impact on estimation results by altering the weight of an object to 5 kg.

5. Experiment result
5.1. First experiment result

The experimental results are illustrated in Fig. 2. The first experiment result outlines the procedure for determining whether the presence or absence of an object can be considered. During the measurement, the Yo-bukun is modified to enable the recording of user-predefined information and the other parameters essential for estimating lumbar burden. Consequently, the recorded parameters included the weight of an object, with the weight being logged every second. From this, it is evident that the Yo-bukun assesses lumbar burden based on the criteria that a weight of 0 kg indicates the person is not holding an object, whereas a weight of 2 kg implies the person is holding an object. The first experiment result revealed that the weight was 0 kg for the initial 10 seconds, 2 kg from seconds 11 to 20 Sec., and returned to 0 kg thereafter until the end of the

measurement. Therefore, it was deduced that lumbar burden could be estimated through voice recognition, considering the presence or absence of an object.

5.2. Second experiment result

The reevaluated results, depicting changes on object weight from 2 kg to 5 kg, are illustrated in Fig. 3. During different measurements when no object is held, the recorded weight is maintained at 0 kg, yielding consistent measurements. Subsequently, the object's weight is adjusted to 5 kg, and recalculation is executed during object holding. As a result, no variations were observed during the intervals from 0 to 11 seconds and from 21 Seconds until the conclusion of the measurement when the person was not holding an object. The fluctuations in results were only evident from the 12 to 20 seconds time interval when the person was holding an object. Therefore, the results of the second experiment illustrate the possibility of parameter adjustments and post-measurement recalculations.

6. Conclusion

Through the integration of voice recognition into Yo-bukun, the system is now capable of estimating lumbar burden, considering whether the user is holding an object or not. The start and end of measurements which were previously reliant on manual button press within the application, can now be automated via voice recognition. By recording the parameters essential for lumbar burden estimation during the measurement, users have the flexibility to modify pre-set information even after completing the measurement, allowing the re-calculation of lumbar burden. The implementation of this system has also simplified the prospective studies of how changes in object weight or physical information during the same movement influence lumbar burden.

Abstract

In the Global Trade Analysis Project (GTAP), GDP and economic statistical indices can be analyzed for forecasting future trends in multiple countries by using the GTAP database and GEMPACK utilities, which realize the numerical calculation based on the concept of Computable General Equilibrium (CGE) models. Even with such well-prepared tools with the official database, appropriate forecasting is still difficult due to the sensitivity of the Free Trade Agreement (FTA) circumstances. FTA scenarios with a uniform tariff reduction can be assumed in general, while an abrupt and unreasonable change may occur in the simulation depending on the network structure of trading countries and the upper and lower bounds of tariffs in the time course. In the present study, we focused on the Great Mekong subregion (GMS) and explored possible methods to calculate substantially.

Keywords: computable general equilibrium (CGE), General Equilibrium Modelling PACKage (GEMPACK), Global Trade Analysis Project (GTAP), Free trade agreements (FTA).

1. Introduction

Computable General Equilibrium (CGE) analysis has emerged as a competitive tool for policy evaluation. Its widespread application includes research on trade policy, regional infrastructure development, and environmental protection. However, challenges in the technical implementations explained in [1], [2], [3], data preparation, and interpreting the simulation results pose significant burdens in the current state of CGE modeling.

To lower this technical barrier involved, this research investigates the roadmap to handle the implementation of the GTAP model. It discusses preparing data and measures the effect of altering the growth rates and reduction in the tariff value. Moreover, it forecasts the changes in the real GDP among the countries in the Great Mekong subregion (China, Lao-PDR, Myanmar, Vietnam, Thailand, and Cambodia).

2. Methodology

Ahmad Altaweel, Bo-Young Lee, Masayuki Fujiwara, Jang-Sok Yoon, Hiroaki Wagatsuma

2.1. *Simulation environment*

2.1.1. *General Equilibrium Modelling PACKage (GEMPACK)*

One of the fundamental characteristics of the CGE models is their computational capability, specifically, they can generate numerical solutions to shocks (changes) using the provided database and parameters. GEMPACK short for General Equilibrium Modelling Package is a set of software created for solving applied general equilibrium models. This package comprises various tools for managing economic models, databases, and simulations. In GEMPACK, data is typically presented in the format of HAR files, which are header-array files capable of storing multiple numeric and string arrays with dimension labels, accommodating up to seven dimensions. The outcome of the simulation is also multiple HAR files or solution files (e.g., .slc, .sl4) can be saved in header files.

2.1.2. *Modifying header files*

It is often required to adjust the input parameters, shock files, and process the model's outputs, and that involves modifying the data within header files. The conventional approach for handling HAR files has been to employ executable programs provided by GEMPACK (e.g., seehar.exe or modhar.exe). However, utilizing these programs may pose a challenge. Manual transfer of data between HAR files and data editing software (e.g., Excel) using a basic clipboard method is also a common practice. However, this process is highly manual, time-consuming, and prone to errors. Another approach for modifying HAR files is to create a data manipulation TABLO Input file using ViewHAR. That can be done by exporting the header file as a TABLO Code from the Export menu within the ViewHAR program. This process automatically generates the foundational code, which can be further edited using the Tablo language to include specific filenames, formulas, updates, assertions, and other adjustments tailored to the model's requirements. In addition, this approach requires creating a Command file (CMF) to define the input, output, and auxiliary file. This can also be generated automatically through the menu (view/Create CMF) within the Tablo file (.tab file).

2.1.3. *Executing a model in GEMPACK*

GEMPACK compiles a model by interpreting a model written in the TABLO language into a system of equations and generating an executable file (e.g., 'gtapv7.exe'). Users must specify the endogenous and exogenous variables, along with the chosen solution method (e.g. Gragg, Johansen, Euler, 1,3,5 steps) in the CMF file. Subsequently, the model is executed, and the coefficients of the model are filled with the actual data. The simulation generates a set of files (.tab, .cmf, .exe, .sl4, .slc, .har) associated with the model. To retrieve the solution, users can utilize ViewSol, AnalyzeGE, or ViewHAR to access data in '.slc' and '.sl4' files.

2.2. *Data and Model Preparation*

2.2.1. *GTAP Database*

The GTAP-RD model is calibrated to the most recent database produced by the Global Trade Analysis Project GTAP database version 11 [2]. The database GTAP 11 reconciles different data sources at a global scale and offers a time series of 5 reference years (2004, 2007, 2011, 2014, and 2017), distinguishing 65 sectors in each of 141 countries and 19 aggregate regions [4]. The GTAP database is typically supplied in the default format of the HAR file (flows file, parameters, sets,..etc). This database has been precisely adjusted to achieve equilibrium in the world's initial state [5].

2.2.2. *The GTAP-RD model*

This study uses GTAP-RD, a dynamic multi-region model that is described in detail in [6]. GTAP-RD model was built on the latest GTAP 7 framework [7] and offers features including, capital accumulation, and international capital and investment mobility. In addition, GTAP-RD offers flexibility in terms of closures as well as a more convenient way to perform a modification to the model due to consistent variables, coefficients, and equation-naming conventions.

2.3. *Forecasting Process*

Quantitative policy analysis is typically framed within the confines of a specific scenario (numerical projection). This scenario assumes that the economy will be affected by future adjustments in the macroeconomic forecasts of each country and the expected policy changes. The baseline scenario provides a reference point for evaluating the impact of policy changes [3] and should reflect as closely as possible the changes expected to occur in the world economy. For example, FTAs that are already in effect [8]. In most baselines, external information about certain future trends of the macroeconomic drivers, for example, population, labor force growth, and other drivers are taken from external projections, such as the United Nations Population Division, World Bank, IMF, OECD, CEPII…, etc.). The forecasts gathered from the mentioned sources may lack

5	vnm	Vietnam	18	sas	Oceania
6	mmr	Myanmar, East Timor	19	eas	East Asia
7	phl	Philippines	20	nwa	North America
8	idn	Indonesia	21	lam	Latin America
9	mys	Malaysia	22	wer	Western Europ

11	sgp	Singapore	24	ssa	Sub-Saharan and North Africa
12	jpn	Japan	25	row	Rest of World
13	kor	South Korea			

The analysis begins with the 2017 GTAP database serving as the base year (Fig. 1). It shifts forward by three years to establish 2020 as the benchmark year. Subsequently, for each period, there is a five-year increment until reaching the year 2050 in all scenarios.

Fig. 1. Forecasting Process and sequence of years

We utilized the GTAP-RD aggregation utility database [10] by making the necessary adjustments to align it with GTAP database version 11. This involved modifying the region mapping from the original 230 countries to fit the 160 countries of the GTAP database and aggregate years to match the relevant years in the study.

Scenario 1 (High Case): The SSP5 scenario percent change for each of real GDP (qgdp), Population (pop), skilled and unskilled labor qe(ENDWL,REG) is applied as target shocks to the years from 2025~2050. In addition, import tariff within the six regions in the GMS area was reduced gradually in the S1 Scenario but maintained between the rest of the world and GMS regions. The reduction periods are as follows (Table 2):

Table 2. Tariff Reduction Schedule between the GMS countries.

Period	Percent change
(2020~2025)→	-20%
(2025~2030)→	-20%

information and may not align. This necessitates some processing to guarantee the availability of data for all countries and relevant years. Shaping a baseline is important for long-term economic issues, such as climate change, the Intergovernmental Panel on Climate Change (IPCC) has created standard scenarios for future greenhouse gas (GHG) emissions so-called Shared Socioeconomic Pathways (SSPs). The SSPs are five scenarios that form a consistent set of socioeconomic drivers widely used in the climate modeling community, and also in the broader global modeling community [3].

2.3.1.   *Simulation design and policy scenarios*

The baseline projection runs from 2017 to 2050 and includes past data and projections for growth in real GDP, population, and the skilled and unskilled labor supply for all regions. The baseline projection data comes from the Shared Social-Economic Pathways (SSP) database macro forecasts for 230 countries for the period of 2007-2100. This paper uses the SSP2 projections for the baseline (business-as-usual scenario). In the baseline scenario, we did not incorporate policy changes caused by existing and ongoing FTAs. Absence of the policy changes in the baseline may affect the simulation results of the policy scenarios [9]. The baseline projection is run under the default GTAP-RD closure for all regions and to make the GTAP model follow a chosen growth path, real GDP (qgdp) is swapped with the region-wide technological change (afereg) to be calculated endogenously. In subsequent model runs, technological change are then maintained at those estimated levels, while GDP is endogenously computed in the base rerun.

The study focuses on global logistics in Southeast Asia and the Great Mekong subregion, and therefore, countries in this area are the targets of the analysis and are treated as individual countries. Countries in other regions are consolidated into regional units, with each treated as a hypothetical country in the GTAP Model.
We aggregated the GTAP database to 25 countries/regions and 10 sectors (Table 1) The region of the rest of Southeast Asia contains Myanmar and East Timor after making all the other countries in this region as individual countries.

Table 1. Regional aggregation of the GTAP Data Base.

NO	ID	COUNTRY/REGION	NO.	ID	COUNTRY/REGION
1	lao	Lao-PDR	14	ind	INDIA
2	chn	China	15	aus	India
3	tha	Thailand	16	nzl	Australia
4	khm	Cambodia	17	xoc	New Zealand

Ahmad Altaweel, Bo-Young Lee, Masayuki Fujiwara, Jang-Sok Yoon, Hiroaki Wagatsuma

(2030~2035)→	-20%
(2035~2040)→	-40%

It is improbable that an agreement would lead to the complete removal of all import barriers, and therefore, this experiment provides an upper bound for the benefits of a free trade agreement that can be captured by the model.

To control the change in the tariff, we used the "rate%" function in the CMF file of the shocks as a policy file after associating the new levels variable TMS_L (power of import tariff) Eq. (1) with the previously declared linear variable tms in the GTAP model [2].

$$TMS\_L(c,s,d) = VMSB(c,s,d)/VCIF(c,s,d) \quad (1)$$

VMSB: the value of imports of commodity c from s to d at domestic (basic) prices.
VCIF: the value of imports of c from s to d at CIF prices (tradeable only).

After adding the level variable TMS_L, it is possible to model the removal of all import taxes by utilizing the "final_level" function Eq. (2) from GEMPACK as follows:

$$Final\_level \ TMS\_L(COMM,GREG,GREG) = uniform \ 1 ; \quad (2)$$

This function will remove the import taxes; thereby ad valorem (tariff rate) is equal to zero and the power level of the tariff is equal to one from the year 2040 in the S1 scenario. The uniform reduction in the tariff rate is applied to all commodities within the six countries and regions in the Great Mekong subregion by making a new region set GREG in the model to contain the GMS countries.

Scenario 2 (Low Case): The SSP4 scenario for the percent changes in the real GDP, population, and labor force are implemented for the years 2025~2050. This scenario takes a pessimistic stance on the advancement of a trade agreement, envisioning no reduction, and predicts a modest growth rate.

3. Results and Discussion

3.1. *Estimated Gross domestic product growth*

The estimated values of real GDP are displayed in Fig 2. As described in Section 2.3.1, It is exogenously given in the baseline scenario. Looking at the high case the increments in the value of GDP come from the benefit of changes in the tariff reduction and the increase in the total

factor of production growth rate in the remarkable countries.

Fig.2. GDP value change in GMS countries

4. Conclusion

In this study, the authors employed the GTAP model to estimate the future GDP value in the Great Mekong subregion area. The study delves into the technical intricacy of implementing modifications in the growth rate and reduction of the tariff rate. It simulates a free trade agreement among the involved countries.

Subsequently, the authors intend to expand the range of Free trade agreements, encompassing the agreements currently in force in the baseline scenario. Additionally, they plan to refine the calibration to the growth rate in the GMS area.

Abstract

Simultaneous measurement of EEG, motion, and gaze in humans has the potential to lead to the discovery of new scientific insights. In order to achieve these simultaneous measurements, it is necessary to manage triggers and time information between measurement devices, as well as to correct time offsets. However, the management of accurate triggers and time information requires the design of a dedicated circuit board and the integration of Transistor-Transistor Logic signal voltage information. In this study, we report on the building of a trigger circuit and an experimental system using it to solve these problems. We created a home-made trigger circuit board for voltage integration and combined it with a commercially available microcomputer to realize an integrated trigger circuit and measurement system.

Keywords: Trigger circuit design, Electroencephalography (EEG), Motion, Gaze

1. Introduction

Simultaneous recording of physiological and behavioral data in standard data formats and analysis of these data in combination may lead to new scientific discoveries. So, in recent years, multimodal measurement methods and data formats have been attracting attention. In response to this situation, data acquisition through the Lab Streaming Layer (LSL) [1], new standard data formats, such as Brain Imaging Data Structure (BIDS) [2], [3], Neuroscience Information eXchange [4] and Open metaData Markup Language [5] (NIX-odML) [6], have been proposed to integrate and handle multimodal data and meta information.

For these simultaneous recordings, an experimenter is faced with the necessity to manage the trigger and time information between measuring instruments and to compensate for time offsets. In fact, while there are paid software and hardware types of equipment that manage the trigger and time information, it is so challenging to handle between measuring instruments that do not support such information.

The simultaneous measurement of various types of information, such as movement and gaze, in conjunction with human electroencephalography (EEG), holds particular significance due to their intimate involvement with neural activities. As introduced by Iturrate et al. [7], in the case of humans, the information derived from the gaze is directed to the V1 area within a span of 60-90 ms, reaches the motor cortex in approximately 220 ms, and the expression of fingertip movements is processed with a latency roughly between 280-400 ms (it is noteworthy that the process is expedited in monkeys [8]). Measuring and analyzing brain activities during this process is beneficial to understanding human cognitive functions.

In the previous work, we have proposed a methodological design [9] to reveal human-robot interactions in the real world by managing Transistor-Transistor Logic (TTL) signals. This proposal provided a specific event analysis based on data from multiple instruments and contributed to a reproducible experimental scheme in which each element could be interchangeable in the future.

However, to achieve accurate trigger and time information to be managed, a dedicated and versatile circuit board and its system must be designed to integrate

Masayuki Fujiwara, Phan Hoang Huu Duc, Laurent Bougrain, Patrick Hénaff, Hiroaki Wagatsuma

Fig. 1 Recording System Integration for human EEG, motion, and gaze data synchronization.

the voltage information of the TTL signal.

Therefore, this study reports on the fabrication of a trigger circuit and an experimental system using it to solve the problems mentioned above. We built a trigger circuit board for voltage integration and combined it with a commercially available microcontroller to integrate the trigger circuit and the measurement system.

2. Proposed Trigger circuit design and system integration s

2.1. *Recording System Integration*

The integrated measurement system of our recording instruments is shown in Fig. 1. The system uses a home-made trigger circuit and a microcomputer for integrated management of the voltage and time information output from each measurement instrument with and without trigger output function. The following is a description of the actual measurement instruments that were used:

- g.tec USBamp and g.tec GAMMAbox for EEG recording;
- Perception Neuron 2.0 for Motion Capturing;
- Tobii Pro Glasses 2 for Eye Tracking.

Perception Neuron 2.0 does not have a trigger output function. Nevertheless, the trigger and time information can be obtained by combining a trigger circuit and a microcomputer, as described in the next section. Note that the timing of the first output of the trigger signal

depends on detecting the pressing of the Axis Neuron's recording button using software for the perception neuron with a global hook function on Windows.

2.2. *Home-made Trigger Circuit and Microcomputer*

Fig. 2 shows the fabrication and design of the trigger circuit board. We used Autodesk Fusion 360 [10] to unify circuit design (Fig. 2a) and board design (Fig. 2b). The designed circuit was fabricated to be integrated with the microcomputer (Fig. 3). Moreover, this circuit has two input ports (blue and yellow cables), but multiple input ports can be managed by increasing the number of level-shift circuits. For measurement instruments that do not have a trigger output, a timer function in the microcomputer is used to output a square wave (e.g., 5.00 [V]) with accuracy in the order of microseconds. The trigger and synchronization are managed by adding/subtracting the above-mentioned multiple trigger inputs to/from this voltage. If other measurement equipment has a trigger output, it can be integrated after checking the output voltage.

2.3. *Testing Equipment information*

We observed the trigger signals using a digital oscilloscope to test the integrated trigger circuit board and its recording system. Actually, we connected multiple measurement instruments to the input ports of the trigger circuit to capture the changes in the trigger

signal. The settings used for observation were an amplitude of 2.00 [V]/scale and a period of 100 ms/scale.

3. Results and Discussion

We measured the trigger signal from the integrated trigger circuit board (Fig. 4). Fig. 4a shows the case in which only the trigger circuit was used, and a square wave (5.00 [V]) was measured. Fig. 4b shows a simultaneous measurement, including trigger signals from other measurement devices and the timing of multiple trigger inputs. These recorded trigger signals showed the management we expected.

As a limitation, if the measurement start time of the measurement device depends on the recording software, the accuracy of the trigger may be affected by the system clock of the Operating System (OS), leaving room for further study. Currently, in this case, a dedicated application is developed and used to output the trigger from the Universal Serial Bus port to detect the measurement start time, which may cause an accuracy problem.

4. Conclusion

We designed a custom trigger circuit board to measure EEG, motion, and eye movement simultaneously. This trigger circuit board and its system integrate the voltage information of multiple TTL signals, allowing for accurate triggering and time synchronization between different measurement instruments. It also may suggest a potential way to provide data from measurement instruments that do not have trigger output functions with respect to existing measurement methods for integrating multimodal data.

Future work is to investigate the accuracy of triggering at system time, etc., when relying on measurement software., i.e., the management of time information between the OS and the trigger circuit.

Authors Introduction

Dr. Masayuki Fujiwara

He graduated from Fukuoka Institute of Technology (FIT) in 2015. He then went on to earned his Master and Ph.D (Knowledge Science) degrees from Japan Advanced Institute of Science and Technology (JAIST) in 2017 and 2023. Until 2020, he was a Research Fellow of the Japan Society for the Promotion of Science (JSPS) (DC1) and is now a researcher at Kyushu Institute of Technology (Kyutech). His research focuses on the EEG studies and neural modeling of (non-)symbolic communication from the perspective of cognitive neurodynamics.

Mr. Phan Hoang Huu Duc

He received Bachelor degree in Biomedical Engineering, from Department of Biomedical Engineering, Faculty of Applied Science, Ho Chi Minh City University of Technology (HCMUT) in 2021. He is currently studying Neuroscience in Kyushu Institute of Technology from 2022.

Dr. Laurent Bougrain

He earned his MSc in artificial intelligence from université Paris 6, his BS in psychology from université Nancy 2 and his Ph.D in Computer Science from Université de Nancy 1 in 2000. He is leading the Neurosys/Neurorhythms team since 2015 at LORIA. His research focuses on brain-computer interfaces, motor systems, machine learning, feature extraction and selection, post-stroke rehabilitation, artificial intelligence, and monitoring of general anesthesia. He is currently an Associate Professor of Computer Science at the University of Lorraine.

Dr. Patrick Hénaff

He earned his M.Sc and Ph.D in Robotics from Université Pierre et Marie Curie in 1989 and 1994. He worked as a lecturer at the University of Cergy-Pontoise and a researcher at LISV (Systems Engineering Laboratory at the University of Versailles) and the University of Cergy-Pontoise. Since 2013, he has been a Professor at the Ecole des Mines de Nancy, University of Lorraine, and worked in the LORIA laboratory. He led the Complex Systems, AI, and Robotics department at LORIA from 2015 to 2022, and the Computer Science department at Mines Nancy from 2018 to 2023.

Dr. Hiroaki Wagatsuma

He received his M.S., and Ph.D. degrees from Tokyo Denki University, Japan, in 1997 and 2005, respectively. In 2009, he joined Kyushu Institute of Technology, where he is currently an Associate Professor of the Department of Human Intelligence Systems. His research interests include non-linear dynamics and robotics. He is a member of the IEEE society.

Terminal Synergetic Controller for Car's Active Suspension System Using Dragonfly Algorithm

Abstract

This research introduces a terminal synergetic controller (TSC) designed for the active suspension system of automobiles through the implementation of the dragonfly algorithm (DA). The proposed controller aims to enhance the dynamic performance of a car's suspension using the DA in tuning the system parameters. The stability of the designed controller is proved through the application of Lyapunov stability theory. Through iterative optimization processes, the TSC approach seeks to achieve an optimal balance between ride comfort and vehicle handling. The simulation results demonstrate that the proposed controller enhances convergence properties and alleviates the presence of chattering. The results indicate that the proposed approach with the optimal parameters provided insights into its potential application in improving the overall suspension system.

Keywords: Active suspension, Synergetic control, Feedback control, Metaheuristic; Swarm-based optimization

1. Introduction

Since the primary objective of controlling active suspension systems is disturbance rejection, in this control application, it is imperative to select a potential feedback control method that can effectively counteract disturbances. Even though the robustness and enhancement of the convergence of the control system can be achieved by using the concept of sliding mode control (SMC), the method has a key drawback from the chattering phenomenon. This drawback can be avoided by using the synergetic control (SC) which was proposed by Kolesikov et al. [1], [2]. The SC method allows the designer to achieve the desired characteristics of the control system including parameter insensitivity and robustness if the macro variables are selected properly. Sliding surfaces in sliding mode control can be utilized as macro variables in the SC method. Consequently, the convergence time of the control system under the SC method can be improved by choosing macro variables and/or dynamic evolutions with terminal attractors [3]. Swarm-based optimization algorithms, including the dragonfly algorithm (DA) [4], enable the optimal selection of controller parameters. The benefit of achieving an improved convergence rate is obtained when a feedback controller is combined with the DA [5].

In this study, we present the TSC method specifically designed for the active suspension system of automobiles. Based on the quarter-car model, the primary objective of

the proposed controller is to improve the stability of the car by utilizing the DA for the precision tuning of system parameters.

2. Methodology

Lemma 1: Consider a nonlinear system in Eq. (1):

$$\dot{\mathbf{x}}(t) = \mathbf{f}(\mathbf{x}(t)), \qquad (1)$$

where $\mathbf{x}(t)$ denotes a state vector and $\mathbf{x}(\cdot): \square \to \square^n$,. $\mathbf{f}(\cdot): \square^n \to \square^n$ is sufficiently smooth nonlinear mapping. If there exists a positive-definite and continuous Lyapunov function $V(\cdot,\cdot): \square^n \times \square \to [0,\infty)$ satisfied with Eq. (2)

$$\dot{V}(\mathbf{x}(t),t) \le -\lambda V^{\eta}(\mathbf{x}(t),t), \ \forall t \ge t_0, \ V(t_0) \ge 0, \quad (2)$$

where $\lambda > 0$, η is a constant exponent such that $0 < \eta < 1$, and $t_0 > 0$ is the initial time. Then,

$$V(\mathbf{x}(t),t) = 0, \ \forall t \ge T_s, \qquad (3)$$

where T_s is so call the settling time and determined as

$$T_s = t_0 + \frac{V^{1-\eta}(\mathbf{x}(t_0),t_0)}{\lambda(1-\eta)} \qquad (4)$$

2.1. Mathematical model

In this study, the model of the suspension system derived from Newton's law presented in [6], [7] was used. Fig. 1 shows a quarter-car model of an active suspension which includes the hydraulic actuator in the suspension system. The model can be extended by considering the hydraulic dynamics can be found in [6]. However, in this study, the model views the hydraulic actuator in the suspension system as the control input u_a and ignores the hydraulic dynamics as shown in Eq. (5):

$$M_b \ddot{x}_s + K_a(x_s - x_w) + C_a(\dot{x}_s - \dot{x}_w) - u_a = 0$$

$$M_{us}\ddot{x}_w + K_a(x_w - x_s) + C_a(\dot{x}_w - \dot{x}_s) + K_t(x_w - r) + u_a = 0 \tag{5}$$

where M_b represents the car body mass and M_{us} the wheel. The displacement of car body and wheel are denoted by x_s and x_w. The stiffness of the active suspension system are defined by K_a and K_t. The damping coefficient is represented by C_a. The force u_a is the actuator force from the hydraulic system. The road disturbance is defined by r and it is assumed to be bounded.

According to [6], [7] by letting $x_1 = x_s$ $x_2 = \dot{x}_s$ $x_3 = x_w$ and $x_4 = \dot{x}_w$, the corresponding state space representation is shown in Eq. (6):

$$\dot{x}_1 = x_2$$
$$\dot{x}_2 = -\frac{1}{M_b}\left[K_a(x_1 - x_3) + C_a(x_2 - x_4) - u_a\right]$$
$$\dot{x}_3 = x_4 \tag{6}$$
$$\dot{x}_4 = \frac{1}{M_{us}}\left[K_a(x_1 - x_3) + C_a(x_2 - x_4) - K_t(x_3 - r) + u_a\right]$$

The control objective is to control the error in Eq. (7) to converge to zero:

$$e = x_1 - \bar{x}_3, \tag{7}$$

where $\bar{x}_3$ is the filtered signal of the wheel displacement, x_3. The filter is defined as:

$$\dot{\bar{x}}_3 = \varepsilon(x_3 - \bar{x}_3). \tag{8}$$

where $\varepsilon > 0$ is the parameter to be determined later. The output is defined as:

$$y \,\square\, e = x_1 - \bar{x}_3. \tag{9}$$

It is worth noting that the reasons for introducing ε and additional dynamics of Eq. (8) were elaborated in detail in [6]. To summarize, introducing ε can provide us the degree of freedom to guarantee the stability of the zero dynamics corresponding to the chosen output in Eq. (9) as we will further discuss at the end of section 2.3. In addition, it will play an important role in the tradeoff between ride quality and rattle space usage.

Fig. 1. A quarter-car model with active suspension system

2.2. Controller design

According to [1], [2], [3], the terminal synergetic controller design procedure can be presented as follows: Firstly, define the macro variable of the controller.

$$\psi = e + \frac{(\dot{e})^{\frac{p}{q}}}{\alpha}. \tag{10}$$

where p and q are positive odd numbers such that $p > q$ Second, define the dynamic evolution of the macro variable as Eq. (11):

$$(\beta\dot{\psi})^{\frac{m}{n}} + \psi = 0 \tag{11}$$

where $1 < \frac{m}{n} < 2$, m and n are positive odd numbers, $\beta > 0$ is parameters to be determined by the designer and affect the convergence time of the macro variable to converge to zero. Finally, determine the control input as follows. By Eq. (10), the derivative of the macro variable is,

$$\dot{\psi} = \dot{e} + \frac{p(\dot{e})^{\frac{p}{q}-1}\ddot{e}}{q\alpha} \tag{12}$$

Recall that $e = x_1 - \bar{x}_3$, then.

$$\dot{e} = \dot{x}_1 - \dot{\bar{x}}_3 = x_2 + \varepsilon(\bar{x}_3 - x_3) \qquad (13)$$

And,

$$\ddot{e} = -\frac{\left[K_a(x_1 - x_3) + C_a(x_2 - x_4)\right]}{M_b} - \varepsilon^2(\bar{x}_3 - x_3) - \varepsilon x_4 + \frac{u_a}{M_b} \qquad (14)$$

By using the Eq. (11) – Eq. (12) and Eq. (14), we can determine the controller u_a as

$$u_a = M_b \left(\left(\frac{(-\psi)^{\frac{n}{m}}}{\beta} - \dot{e} \right) \frac{q\alpha}{p(\dot{e})^{\frac{p}{q}-1}} + \varepsilon^2(\bar{x}_3 - x_3) + \varepsilon x_4 \right) \\ + \left[K_a(x_1 - x_3) + C_a(x_2 - x_4) \right] \qquad (15)$$

Note that to guarantee that the term $(\dot{e})^{\frac{p}{q}-1}$ will not cause the singularity, the additional condition must be imposed on the parameters p, q, m, n, which the following

i) $\dfrac{pn + m(q-p)}{qn} > 0$ and ii) $\dfrac{m(p-q)}{pn} < 1$.

2.3. Proof of stability

The Lyapunov function is defined in terms of the macro variable as

$$V(\psi) = \frac{1}{2}\psi^2 \qquad (16)$$

By Eq. (12), the derivative of Eq. (16) is determined as

$$\dot{V}(\psi) = \psi\dot{\psi} = \psi \left(\dot{e} + \frac{p(\dot{e})^{\frac{p}{q}-1}\ddot{e}}{q\alpha} \right) \qquad (17)$$

By substituting the controller in Eq. (15) into Eq. (17), we yield,

$$\dot{V}(\psi) = \psi \frac{(-\psi)^{\frac{n}{m}}}{\beta}$$

Recall that m and n are positive odd number such that $0.5 < {n}/{m} < 1$ and let define $\eta = \dfrac{n+m}{2m}$ and $\lambda = \dfrac{2^\eta}{\beta}$.

Note that $0.75 < \eta < 1$ and $\lambda > 0$ by construction, then,

$$\dot{V}(\psi) = -\psi\frac{(\psi)^{\frac{n}{m}}}{\beta} = -\frac{1}{\beta}\left(2\frac{\psi^2}{2}\right)^\eta = -\lambda V^\eta \qquad (18)$$

Based on Lemma 1, the settling time T_1 is determined as

$$T_1 = t_0 + \frac{(\psi(t_0))^{2-2\eta}}{2^{1-\eta}\lambda(1-\eta)}. \qquad (19)$$

Then, this implies that the manifold $\psi = 0$, $\forall t > T_1$. From Eq. (10),

$$\dot{e} = -\bar{\alpha}e^{\bar{\eta}} \qquad (20)$$

whenever the manifold $\psi = 0$, where $\bar{\alpha} \triangleq \alpha^{\frac{q}{p}}$ and $\bar{\eta} \triangleq {q}/{p}$. Furthermore, notice that $\alpha > 0$ and both of p, q are positive odd numbers such that $p > q$, then $\bar{\alpha} > 0$ and $0 < \bar{\eta} < 1$ by construction. Again, by Lemma 1, the error $e(t)$ converges to zero within the time:

$$T_2 = T_1 + \frac{(e(T_1))^{2-2\bar{\eta}}}{2^{1-\bar{\eta}}\bar{\alpha}(1-\bar{\eta})} \qquad (21)$$

Hence, $x_1(t)$ converges to $\bar{x}_3(t)$ within $T = t_0 + T_1 + T_2$ which is a finite real number. Note that, since we choose the output $y \triangleq x_1 - \bar{x}_3$, we can obtain the zero dynamics in the matrix form as Eq. (22) [6] by setting the output identically equal to zero.

$$\dot{z} = A_z z + B_z r \qquad (22)$$

where $z \triangleq \begin{bmatrix} \bar{x}_3 & x_3 & x_4 \end{bmatrix}^T$

$$A_z \triangleq \begin{bmatrix} -\varepsilon & \varepsilon & 0 \\ 0 & 0 & 1 \\ -\varepsilon^2\dfrac{M_b}{M_{us}} & \left(\dfrac{\varepsilon^2 M_b - K_t}{M_{us}}\right) & -\varepsilon\dfrac{M_b}{M_{us}} \end{bmatrix} \text{ and}$$

$$B_z \triangleq \begin{bmatrix} 0 & 0 & {K_t}/{M_{us}} \end{bmatrix}^T.$$

and r is assumed to be a bounded road disturbance i.e., $|r| \le M_r$ where M_r is a positive constant.

One can easily realize that the matrix A_z is Hurwitz if and only if $\varepsilon > 0$ by using the Ruth-Hurwitz criterion. It is also worth noting that there is no finite escape time phenomenon that occurs no matter how large the magnitude of road disturbance $|r|$ is since the zero dynamics Eq. (22) is a linear system with z is the state vector of the system and r is the disturbance. From the design perspective, one can choose a parameter ε such that the matrix A_z is sufficiently robust enough to dominate the bounded road disturbance r to guarantee the convergence of the state z to zero. Then, the state x_1 and x_2 converge to zero for the following reasons. Since x_1 converges to $\bar{x}_3$ in finite time by Eq. (18) and the argument from Eq. (20) i.e., $\dot{e} = -\bar{\alpha}e^{\bar{\eta}}$ when the manifold $\psi = 0$. Then, whenever $z \square \begin{bmatrix} \bar{x}_3 & x_3 & x_4 \end{bmatrix}^T$ is identically equal to zero, it implies that x_1 is identically equal to zero and then it also implies that $x_2 = 0$ i.e., $x_2 \square \dot{x}_1$. Hence, the proof of locally terminal time stability is completed $\square$

2.4. *Controller parameter tuning*

By using the algorithm of DA, the controller parameters of the design control input as shown in Eq. (15) are selected optimally to minimize the cost function or performance index which is defined as

$$J = \sqrt{u_a^{\ T} u_a}$$

3. Simulation Results and Discussions

To show the capability of the designed controller, the model in Eq. (6) with the system parameters from [8], [9] are used as the simulation example. The system parameters are defined as follows: $M_b = 290$ kg, $M_{us} = 59$ kg, $K_a = 16{,}812$ N/m, $K_t = 190{,}000$ N/m, $C_a = 1000$ Ns/m. The controller parameters are given by DA with 40 search agents and 20 iterations. The controller parameters before tuning are arbitrarily defined as $\alpha_1 = 0.228$, $\beta_1 = 0.9431$, $\varepsilon_1 = 1.3356$, and the controller parameters after tuning are $\alpha_2 = 3.9648$ $\beta_2 = 0.10942$, $\varepsilon_2 = 3.7505$. Both cases are using $p = 5$, $q = 3$, $m = 7$, $n = 5$. We formulate the road disturbance based on the principles outlined in [6]. This disturbance is mathematically described as a single bump with a height of 5 cm ($a = 0.025$), defined as:

$$r = \begin{cases} a(1 - \cos 8\pi t), & 3.5 \leq t \leq 3.75 \\ 0, & otherwise \end{cases}$$

Fig. 2 and Fig. 3 illustrate that the proposed TSC method can effectively guide all state responses to the desired levels of displacement and velocity. Nevertheless, upon comparing the controller with and without optimal parameters obtained from DA, it is evident that the TSC with optimal parameters exhibits a superior convergence rate performance. Fig. 4 demonstrates that the TSC with optimal parameters can alleviate the presence of chattering.

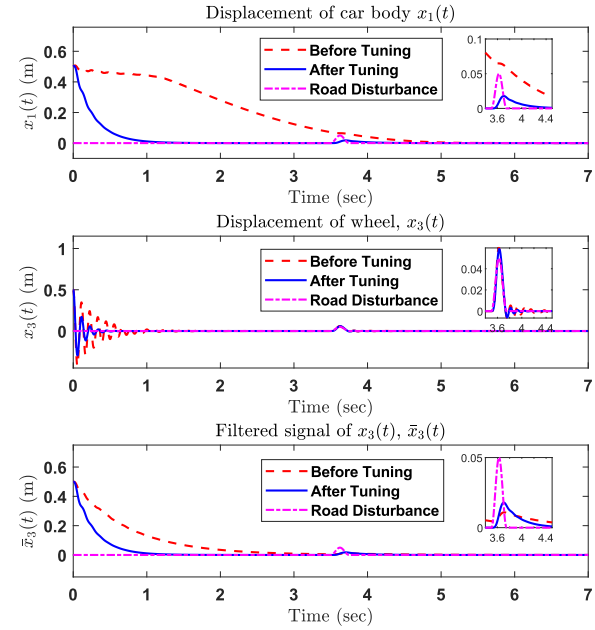

Fig. 2. Comparison of state response x_1, x_3, and $\bar{x}_3$ of the control system before and after DA tuning

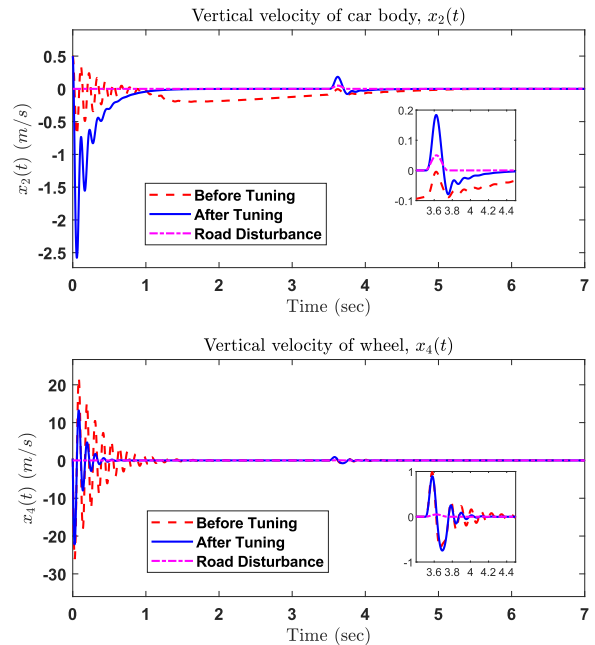

Fig. 3. Comparison of state response x_2 and x_4 of the control system before and after DA tuning
Fig. 4. Comparison of state response of the control input before and after DA tuning

4. Conclusion

In this study the TSC method was applied for controlling of the active suspension system. The controller parameters are selected optimally based on the algorithm of DA. The proposed controller effectively stabilizes the active suspension system by Lyapunov stability analysis. Simulation of the control system was carried out to validate the efficacy of the proposed controller. The simulation results demonstrate that the proposed controller enhances convergence properties. Additionally, the observed decrease in chattering in the control input signals, a significant issue in sliding mode control, further supports the potential application of the proposed TSC method in enhancing the overall performance of the suspension system.

Abstract

Reusing flood-damaged cars gives a unique opportunity in the car rental market in today's fast-paced world, where sustainable solutions are crucial. This study represents the result of efforts to design and construct a web-based car rental system that utilizes flood-damaged cars. The system will be developed using Rapid Application Development (RAD) methodology. Surveys and interviews are conducted to collect potential users' feedback. The results show that due to global economic recession and the increased awareness of global warming, citizens will prefer transportation that is eco-friendly and cost effective if the vehicle is in good condition and properly fixed. This project intends to transform the car rental environment by leveraging a strong technological stack and a user-centric design. With a strong emphasis on user experience and system efficiency, the web-based platform promises not only to ease seamless vehicle rentals but also to promote sustainability in the automotive sector. The favorable results of user acceptability testing confirm the system's success in reaching its objectives. GPS features and transparent vehicle history disclosure will be included for future enhancements.

Keywords: Car Rental System, Eco-Friendly, Flood

1. Introduction

The car industry has long struggled with the issues of sustainability and environmental friendliness. Simultaneously, natural calamities such as floods have resulted in many flood-damaged cars that, despite being salvageable, are frequently underutilized. Recognizing the potential of combining these two factors, this project will create a web-based automobile rental system that will reuse flood-damaged vehicles. This system solves the environmental challenges connected with underutilized cars while also catering to the increasing demands of modern consumers seeking economical and sustainable transportation alternatives by providing a digital platform for vehicle renters.

2. Methodology

2.1 Latest Statistic on Website Usage

In 2023, there are approximately 1.13 billion websites on the internet. Only a small portion of the world's 1.13 billion websites are regularly updated and used. Only 200,121,724 of the 1.13 billion websites are regularly maintained and viewed, a startling 82% of which are inactive. Each three seconds, a brand-new website is created.

In 2023, 71% of companies will have websites. This is a rise over prior years, owing primarily to the influence of the Covid-19 epidemic. Companies have realized the value of having a web site to reach a bigger audience and stay competitive in today's digital market because of the move to online commerce and remote employment. The trend of companies creating a website has been hastened by the Covid-19 pandemic, and it is probable that this trend will continue.

The latest research shows that 28% of all company activity is now done online. This transition to online shopping reflects the internet's growing significance in today's business environment and the expanding trend of e-commerce.

Recent studies show that 43% of small firms intend to spend money in 2023 to improve the functionality of their websites. This phenomenon highlights the growing significance of having a strong online presence for companies of all sizes. A business' success in today's digital environment depends on having a well-designed and optimized website, as consumers are increasingly turning to the internet to make purchasing decisions [1].

Moreover, 5.18 billion people used the internet at the start of the second quarter of 2023. The number of

Pon Xiao Qi, Abdul Samad bin Shibghatullah, Kasthuri Subaramaniam

individuals using the internet is increasing; according to the latest recent data, there were 147 million more users globally connected in the year before April 2023. Due to growing internet availability globally, the number of people who are "unconnected" to the internet has fallen to 2.85 billion, with the majority of these people living in Southern and Eastern Asia as well as Africa.

Mobile phones now account for approximately 60% of all web traffic and are used by 95% of internet users globally to access the internet at least periodically as shown in Fig 1. People spend more than 57 percent of their online time on mobile devices. However, in the world's major economies, more than 6 in 10 internet users still utilize laptops and desktop computers for at least some of their online activity [2].

Fig 1. Statistics of internet usage

2.2 History of Flood in Malaysia

According to studies conducted specifically in Malaysia, the fast-rising number of flood events in recent decades are the result of unregulated human activity in rivers, the cutting down of forests, and extreme weather events brought on by climate change [3]. Since 2001, there have been 143 floods on average annually, more than 90% of which have been flash floods. Such often recurrent floods pose a serious risk to the lives and property of Malaysian inhabitants, severely damaging the nation's infrastructure [4].

According to information from the Country Disaster and Risk Profile of the United Nations Office for Disaster Risk Reduction (UNDRR), floods in Malaysia account for 98% of average yearly damage between 1990 and 2014. According to a report from the Malaysian Department of Irrigation and Drainage published in 2003, flooding affects an average of 29 000 km2, or 9 percent of the nation's total land area, and more than 4.82 million people (22 percent of the population) per year [5].

Two different forms of rainfall generate floods. The first kind of rainfall is of a moderate intensity and lasts for a long time over a large region. The second kind is localized heavy rain that lasts for a short time. Floods in Malaysia are predictable to happen. While the west coast of Peninsular is primarily plagued by thunderstorms from September to November because of the inter-monsoon

season, the east coast and eastern Malaysia are typically affected by floods during December to January when the northeast monsoon sweeps. Most floods in Malaysia typically originate from persistent, heavy rains that cause runoff because of surplus water supplies that exceed the capacity of streams and rivers. Many states in Peninsular Malaysia, including Kelantan, Johor, Pahang, Perak, Kuala Lumpur, and Selangor, as well as east Malaysia's Sabah and Sarawak, are home to the majority of flood-prone areas [6].

2.3 Overview of Car Rental System

The development of technology caused fierce competition among businesses to win over more clients [7]. Technology aids in decision-making by allowing the owner of the car rental to concentrate on the usage of IT to gain a competitive edge [8]. Car rental companies frequently struggle with transactions that are inefficient. The tenant must make individual calls to the rental provider to inquire on the car's availability [9]. Distance is a problem for communication and information technologies, yet a website allows us to access a wide range of information from around the globe. Online transactions are those when the buyer and seller conduct their business over the Internet. Web-based Information Systems were created because of the quick advancement of information technology. Research on general models for the study and design of web-based information systems has been done in numerous papers [10]. Due to the current rapid growth of information technology, it is essential to access information quickly and accurately to facilitate decision-making. Due to the accessibility of information and the effective and efficient processing of order data, using web design as a tool to promote the rental of vehicles is highly beneficial in attracting more consumers and making transactions easier.

2.4 Problem Statement

Natural calamities, such as floods, have caused severe damage to automobiles in Malaysia in recent years, bringing huge financial damages to individuals. Depending on the type and level of damage, it might cost the automobile owner between RM20,000 and RM40,000. Repair costs will be higher for luxury vehicles such as BMW, Porsche, Range Rover, Peugeot, Mini Cooper, and so on. Due to the amount of damage in the car, some car owners may be unable to afford the repair costs or may opt to sell it and acquire a new car. These cars will almost certainly wind up in landfills, contributing to pollution. This is because not all vehicles have flood insurance. Driving a flood-damaged car that has not been adequately repaired might be hazardous to the driver's health and threaten the safety of other vehicles on the road. Mold can form in flood-damaged cars if wet conditions are not handled, causing respiratory difficulties for the driver and passengers. A web-based car rental system for flood-damaged vehicles can provide a convenient option for

these car owners to sell their flood-damaged vehicles through a reputable platform. The owner can utilize the money from selling the flood-damaged car to our platform to buy a new car. Our platform will then repair these flood-damaged vehicles and rent them out at a low cost.

Without a web-based car rental system, flood-affected car owners must either continue to use the vehicle, dispose it in landfills, or spend time contacting secondhand car dealers who are prepared to acquire their flood-damaged vehicle, which is a time-consuming process. The goal of this project is to reduce the number of vehicles that wind up in landfills, hence reducing environmental effect. Furthermore, reusing flood-damaged vehicles through rental businesses is a more sustainable option than scrapping them. Furthermore, an affordable automobile rental system including flood-damaged vehicles would provide transportation options for people who might not be able to purchase a car otherwise. This accessibility would allow people to commute to job, education, or other important places, making their lives easier. Furthermore, these flood-damaged vehicles might be used in the film business. Our platform ensures that vehicles are thoroughly inspected and repaired prior to rental, ensuring renters' safety.

3. Implementation

3.1 Method

The proposed car rental website is built using the Rapid Application Development (RAD) methodology. The RAD methodology is divided into four phases: user requirements, user design, prototype, and implementation. During the user requirements phase, system requirements will be gathered through surveys and questionnaires. Once the requirements are defined, we will move into the user design phase. The emphasis here was on creating the high-level structure of the web-based car rental system. We envisioned the system's components, their interrelationships, and the general architecture that would support its functionality.

The prototyping step marked the move from concept to actual representation. At this point, we'll start working on a workable model of the system. This prototype served as proof of concept as well as a visual depiction of the system's primary functions. It enabled my supervisors and potential customers the opportunity to interact with a simplified version of the system and obtain a hands-on grasp of how it would work. This phase included continuous testing and validation to ensure that the system remained reliable and of high quality throughout development.

The final phase, implementation, marked the web-based automobile rental system's preparedness for deployment. To ensure a successful launch, several critical procedures will be followed. Extensive testing will be carried out to ensure that the system's performance, usability, and functionality are satisfactory.

3.2 User Functionality

Users should be able to quickly register on the suggested website. Important information such as their name and contact information will need to be obtained throughout the registration process. Users must be able to securely log in using their selected credentials (username and password) once registered, allowing them to tailor their interactions with the system and log in or out as needed.

Access to a comprehensive list of available cars is an important component of the user experience. This list should include specific information about each car, such as its model, year, rental fee, and a brief description. A search option should be included to improve user ease, allowing consumers to filter available cars based on particular parameters such as location and rental term. This enables users to quickly select the appropriate car that suits their individual requirements.

Furthermore, reserving a car for a specific time should be a simple process. Users should be able to enter their preferred pick-up and return dates, allowing for smooth booking procedures. Users should also be able to alter or cancel previous bookings to accommodate changes in plans if the request is made at least three days before the scheduled pick-up date.

The Touch & Go payment system, which was recommended by 96% of poll respondents, will be included in the system. This strategy offers quick and easy payment processing, which improves the entire customer experience.

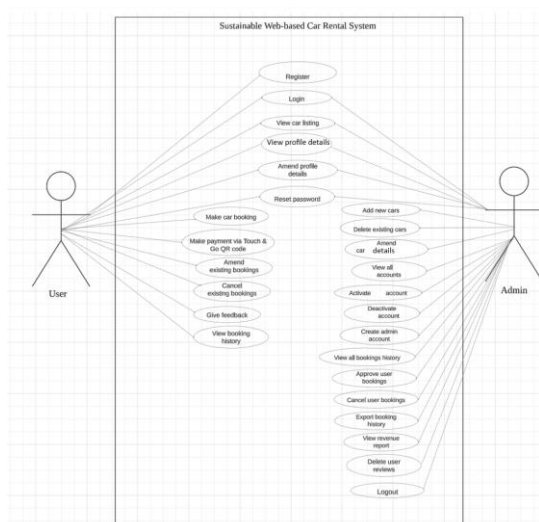
Additionally, the system will highlight how important user feedback is. Users should be able to provide ratings and comments about their rental experience after completing a booking. Future users can benefit greatly from these user reviews, which offer insights and support well-informed decision-making. A thorough booking history that provides a summary of prior reservations for simple access and tracking of rental activity should also be available to users. To safeguard our clients, our business will offer a warranty on every vehicle. However, GPS features and transparent vehicle history disclosure will be included for future enhancements (Fig 2).


Fig 2. Use Case Diagram

4. Conclusion

Administrators should be equipped with powerful tools to efficiently manage automobile listings. This involves having the power to update current listings, remove out-of-date ones, and add new cars to the inventory. This guarantees the accuracy and currentness of the vehicle inventory.

Besides this, administrators need to be able to supervise and manage every user account. This includes having the power to activate and deactivate admin and user accounts as necessary. Admins also can make new admin accounts, which will improve platform integrity and security.

All bookings must be managed efficiently. Administrators should be able to approve or cancel reservations based on availability and particular criteria. Admin should be able to manage user reviews as well. The administration of user reviews is equally important in maintaining the platform's positive and trustworthy reputation.

Moreover, admins should be able to export booking history records to aid in record-keeping and analysis. This information is crucial in accounting and auditing. Admins should also be able to track the platform's financial performance over time by viewing revenue data, which will help them assess the platform's viability and growth.

Lastly, both users and administrators should have access to a visual booking calendar that displays all bookings made on certain days. This calendar tool aids in efficient planning and management, improving the system's overall functionality.

Abstract

In the dynamic landscape of Southeast Asia's digital economy, Malaysia is gearing up for a transformative shift with the mandatory rollout of electronic invoicing (e-Invoicing) beginning June 2024. Recognizing the critical need for a structured approach to this transition, this study presents the design and evaluation of an Adaptive E-Invoicing Rollout (AER) Framework, which is aimed at facilitating a successful e-Invoicing implementation across Malaysia's diverse business sectors. The framework is developed through a qualitative methodology that synthesizes insights from an extensive literature review, expert interviews, case studies, and the Delphi technique. The AER Framework stands out for its comprehensive approach, incorporating a theoretical predictive model that assesses various variables influencing e-Invoicing success. By employing the correlation coefficient, the model quantifies the relationships between key variables, providing a structured mechanism to predict and enhance the successful adoption of e-Invoicing. This model is particularly designed to be adaptable and dynamic, evolving with ongoing insights and changes in the e-Invoicing landscape. The study's findings offer a significant contribution to the digital economic literature and practice, providing policymakers, businesses, and stakeholders with a robust tool for strategic planning and effective decision-making. As Malaysia navigates its digital transformation, the AER Framework serves as a critical guide, ensuring that the e-Invoicing rollout is not only compliant with regulations but also conducive to enhancing fiscal transparency, economic efficiency, and business operations. Furthermore, the framework's adaptability and predictive nature make it a relevant model for other countries considering similar digital transitions, marking it as an asset in the broader context of digital finance evolution.

Keywords: Electronic Invoicing, Digital Transformation, Adaptive Framework, Predictive Model, Qualitative Methodology, Malaysia, Correlation Coefficient, Stakeholder Strategy, Fiscal Transparency

1. Introduction

In the burgeoning digital economy of Southeast Asia, Malaysia stands on the precipice of a significant transformation with the impending mandatory rollout of e-Invoicing beginning June 2024. The introduction of e-Invoicing is not merely a technological shift, but a strategic maneuver poised to streamline tax compliance, bolster fiscal transparency, and catalyze economic efficiency. However, despite the clear benefits and the comprehensive guidelines issued by the Inland Revenue Board (IRB), the successful adoption and implementation of e-Invoicing across diverse business ecosystems presents a complex challenge.

The significance of this study lies in its potential to bridge the gap in understanding the multifaceted dimensions of e-Invoicing adoption, from the perspective of compliance [1],[2] to the readiness of technological infrastructure [3],[4]. As noted by Chan [5], the digital economy collaboration and the integration of digital payment systems are crucial areas of development in ASEAN, with Malaysia being no exception. Yet, a comprehensive framework that encompasses all aspects of the transition to e-Invoicing is absent, underscoring the necessity for

this research. This study aims to contribute to the body of knowledge by providing an empirical evaluation of the factors influencing e-Invoicing success in Malaysia, thereby guiding policymakers and businesses in their decision-making processes. Moreover, it will offer a novel predictive model to anticipate the trajectory of e-Invoicing adoption and its ripple effects on the digital economy, drawing on the insights from the ASEAN Digital Economy framework [6].

The novelty element of this study is encapsulated in its comparative analysis approach, juxtaposing the Malaysian e-Invoicing rollout with global best practices [7], [8] and its predictive nature, which seeks to forecast the long-term implications of e-Invoicing on the digital transformation of the Malaysian economy [9], [10]. By examining the intersection of digital payments, data regulations, and e-Invoicing [5], [11], along with the critical factors for cloud-based e-invoice service adoption [12] and the effects of e-government measures on 2. taxpayer compliance [13], this research will carve out a novel paradigm in the digital economic literature, specifically tailored to the Malaysian context. The proposed research is poised to offer a robust, scalable, and adaptive framework for e-Invoicing implementation in Malaysia, contributing significantly to the literature

and providing practical implications for stakeholders across the board.

3. Methodology

The methodology for the research study, " Optimizing E-Invoicing Rollout: Adaptive E-Invoicing Rollout (AER) Framework for Navigating Malaysia's Digital Transformation" will be composed of a qualitative approach, given the pre-implementation state of e-invoicing in Malaysia.

3.1. *Literature Review*

A comprehensive literature review was conducted to synthesize global and local e-invoicing practices, identifying critical themes and practices that inform a predictive model for e-invoicing success. The key findings are summarized in Table 1.0: Key Findings from Literature Review.

3.2. *Expert Interviews*

Insights were gathered from industry experts to understand the operational, technical, and compliance aspects of e-invoicing implementation. The synthesized perspectives are documented in Table 2: Table 2.0: Theoretical Predictive Model Variables for E-Invoicing Success.

3.3. *Case Study Analysis*

An analysis of various regional e-invoicing implementations provided criteria for success, highlighting parallels and distinctions across ASEAN countries. Findings are presented in a comparative format.

3.4. *Delphi Technique*

A Delphi study established consensus on predictive parameters for e-invoicing success, integrating expert opinions into the AER Framework's development criteria. Parameters such as system integration readiness, compliance rates, and user adoption were discussed, echoing the approach suggested by Wagiman et al. [14] in applying the Delone & McLean Information Systems Success Model to assess net benefits.

3.5. *Theoretical Predictive Analysis*

The theoretical predictive model was developed from an integration of literature reviews, expert interviews, and case study findings. It evaluated various variables impacting the success of e-invoicing, each assigned a rating from 1 to 5 for its predictive importance.

Application of the Correlation Coefficient:

The correlation coefficient, a crucial metric in this model, was calculated to measure the relationship between pairs of variables, such as regulatory compliance and e-invoicing success rate. It indicated both the strength and direction of their relationship.

Pearson's Correlation Formula Simplified:

$$r = \frac{n\sum xy - (\sum x)(\sum y)}{\sqrt{[n\sum x^2 - (\sum x)^2][n\sum y^2 - (\sum y)^2]}}$$

Where:

- **r (correlation coefficient):** This was the desired outcome of the analysis. It is a value between -1 and 1 that indicated how strongly two variables were related.
- **n (number of pairs):** This represented the total number of observations or data points available. Each pair represented a set of two variables, such as a particular e-invoicing feature's implementation and its observed impact on overall success.
- **Σxy (sum of the product of paired scores):** For each pair of variables, they were multiplied together and then all these products were summed up. This sum helped understand the joint variability of the two variables.
- **Σx and Σy (sum of x scores and y scores):** These were simply the totals of all the first and second variables in the pairs respectively.
- **Σx² and Σy² (sum of the squares of x scores and y scores):** Similar to Σx and Σy, but each variable was squared before they were summed up. This component helped in understanding the spread or distribution of each variable.

The results of this predictive analysis, including correlation coefficients and predictive importance ratings, were summarized in Table 2.0: Theoretical Predictive Model Variables for E-Invoicing Success. This table served as an essential tool for stakeholders, offering insights into the influential factors of e-invoicing success. It enabled stakeholders to anticipate potential outcomes more effectively and align strategies accordingly.

3.6. *Documentation and Reporting*

The meticulous documentation and reporting of findings throughout the research process ensured that the framework would be dynamic and subject to continuous improvement. This living document approach allows the framework to evolve as new insights emerge, maintaining its relevance and effectiveness.

4. Result/Discussion

4.1. *Development of the AER Framework*

The "Adaptive E-Invoicing Rollout (AER) Framework" is the outcome of a methodical approach that amalgamates a comprehensive literature review, expert interviews, comparative case studies, Delphi consensus,

and theoretical predictive analysis. This blend has formulated a detailed and adaptable guide suitable for the nuanced needs of Malaysia's e-invoicing initiative.

4.2. *Literature Review Outcome*

The outcome of the literature review of e-invoicing related journal papers were consolidated in the Table 1 below:

Table 1 Key Findings from Literature Review

Theme	Key Findings	Predictive Model Relevance	Reference
Digital Economy & E-Invoicing	Studies note the rapid growth of e-invoicing and regulations in ASEAN	Highlights the significance of Cintegration and Aadoption in the predictive model.	[5], [6]
Implementation & Adoption Challenges	Identifies technology, operational, and compliance barriers to e-invoicing adoption	Reinforces the importance of Rreadiness and Ccompliance	[1], [9], [5], [16], [18], [20]
Benefits & Outlook	Discusses the potential benefits of e-invoicing and forecasts its adoption trajectory	Suggests Uusage as a critical outcome measure in the model.	[7], [8], [14], [17]
Regulatory Aspects & Compliance	Focuses on the role of regulations and legal frameworks in facilitating or hindering e-invoicing	Underscores Ccompliance as a vital predictor in the model.	[3], [11], [13], [19]

4.3. *Predictive Analysis for E-Invoicing Success*

The critical component of the AER Framework is the theoretical predictive model, which was designed to forecast and evaluate the success of the e-invoicing rollout. Drawing insights from the comprehensive literature review, this model incorporates various variables identified as significant predictors of e-invoicing success. Each variable, substantiated by the literature, is accompanied by a correlation coefficient indicating its impact and relevance in forecasting the successful implementation of e-invoicing, as consolidated in Table 2 below.

Table 2 Theoretical Predictive Model Variables for E-Invoicing Success

Variable (Factor)	Predictive Importance (Scale: 1-5)	Correlation Coefficient	Description
Cintegration (System & Data Integration Capability)	4	0.85	Technical integration capability [10]
Aadoption (Rate of Adoption Among Users)	3	0.65	User acceptance rate [9]
Rreadiness (Organizational & Technological Readiness)	4	0.75	Business and infrastructure preparedness [16]
Ccompliance (Compliance with Legal & Tax Requirements)	5	0.90	Regulatory adherence [13]
Uusage (Actual Usage & Utilization Rates Post-Implementation)	4	0.80	Utilization post-implementation [1]

In this table:

- **Predictive Importance** is quantified on a scale of 1-5, where 1 is the lowest and 5 is the highest level of importance. This allows a more objective comparison of factors.
- **Correlation Coefficient** remains a numeric value indicating the strength and direction of the relationship between each variable and the success of e-invoicing implementation.
- **Description** is a concise statement of what each variable represents.
- **References** are provided for each variable, offering direct access to the underlying studies or sources.

The predictive model is a robust, theoretical construct based on identified variables derived from qualitative insights and empirical evidence from similar initiatives. Each variable is assigned a predictive importance and a correlation coefficient, indicating how strongly it's expected to influence the success of the e-invoicing rollout. This model not only aids in forecasting outcomes but also assists in identifying areas requiring strategic focus and resource allocation, making it a grounded and practical tool for stakeholders. A conceptual model was defined to guide future quantitative studies. The variables identified for the predictive model are enumerated in Table 5: Predictive Model Variables for E-Invoicing Success. Informed by Hernandez-Ortega's work [10] and other seminal studies, this model was conceptualized to guide stakeholders in anticipating and preparing for the

potential outcomes of the e-invoicing rollout. The formula for the theoretical predictive model is as follows:

$$Psuccess=$$
$$f(Cintegration, Aadoption, Rreadiness, Ccompliance, Uusage)$$

Where:

- *Psuccess* is the probability of successful e-invoicing rollout.
- *Cintegration* represents system and data integration capability.
- *Aadoption* indicates the rate of adoption
- *Rreadiness* reflects organizational and technological readiness.
- *Ccompliance* is the degree of compliance with legal and tax requirements.
- *Uusage* measures actual usage and utilization rates post-implementation.

This model, as illustrated in Fig. 1, is significantly grounded in empirical evidence and industry insights, making it a novel and practical contribution to the field of e-invoicing and digital economy strategies.

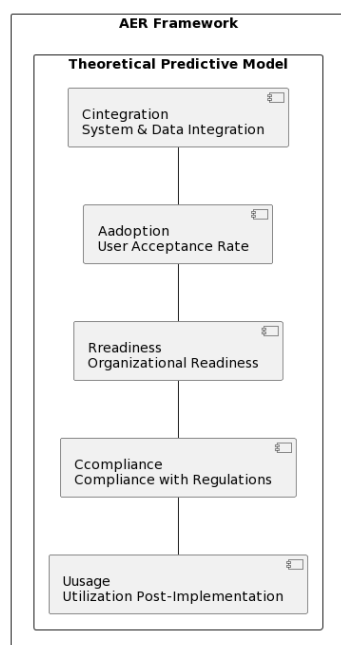

Fig.1 AER Framework - Theoretical Predictive Model

4.4. *Conclusion and Strategic Implications*

The AER Framework emerges as a strategic, comprehensive guide for e-invoicing adoption in Malaysia. It is not just a theoretical construct but a practical, dynamic tool reflecting the complexities and requirements of real-world implementation. The framework's adaptability, combined with its predictive capability, positions it as a model for digital transformation, not only for Malaysia but potentially for other countries embarking on a similar journey. As the landscape of digital finance continues to evolve, the AER Framework is poised to remain a relevant, effective tool for navigating the future of e-invoicing.

5. Conclusion

Malaysia's transition to mandatory e-Invoicing reflects a crucial shift in its digital economy. This study developed an adaptive framework, utilizing a qualitative methodology to integrate insights from various sources, culminating in a theoretical predictive model. This model offers stakeholders a robust tool for strategic e-Invoicing implementation. The AER emerges as a practical guide, significant for Malaysia's digital transformation and relevant for similar global contexts, ensuring continued efficacy in evolving digital finance landscapes.

Abstract

In this project the researcher chosen area is the development of an App for forgetful users to take their phones from their cars it functions as a medium to take their phones from their cars. the target users will be senior adults who may be careless or may have memory deteriorating diseases such as dementia or Alzheimer. The researcher used surveys to gather information and used various online resources. The research methodology used by the researcher is modified waterfall model for its simplicity and ability to reverse to different phases. The research methodology used by the researcher is modified waterfall model for its simplicity and ability to reverse to different phases. Overall, the project can be deemed as success as the researcher has successfully developed an App for users to remind them to take their phone before exiting their personal vehicle.

Keywords: Development of an App, Senior Adults, Surveys, Modified Waterfall Model

1. Introduction

Since the introduction of the first smartphone, made by IBM, it was called the IBM Simon it had a calendar, address book, clock, notepad, keyboard, touchscreen and email capability. Since then, humans have been using this device to benefit themselves in daily tasks such as navigating, working and using it as a form of entertainment [3]. But with good the bad always come. Below are the problem that users are facing:

- Elderly users who have dementia may forget to take their smartphones.
- The underground basement parking is too dark and did not notice their smartphones in the holder.
- Buying a new smartphone is affordable but repairing or buying a new car is a liability.

With the problems identified, we propose to build a notification App for forgetful users when the car engine has been shut off. The app will notify the user when the ignition has been turned off. The App will be user friendly and simple. he objectives of the research include:

- To identify why users always forget to take their phones from their cars.
- To design a notifying system
- To develop a prototype Notifying App
- To evaluate the system

2. Methodology
2.1 *Impact of Smartphones in Malaysia*

According to Malaysian Communications and Multimedia Commission (MCMC) the use of smartphones and their apps has dramatically increased since the introduction of affordable 5G smartphones in 2021. According to the survey conducted by MCMC

the number of smartphone users in 2021 is 94.8% compared to a mere 78.0% in 2018 [1], [2]. The higher usage of smartphones indicates people are much more digitally connected. As shown in (Fig.1) below.

2.2 What kind of Apps are used in Malaysia

According to the HPUS 2021, MCMC has found out that communication remained the top activity among smartphone users [1]. The survey has found out that 82.9% of the respondents use text messaging. On which it found that 97.3% of users performed at least once a day. Not only that, 78.9% of users communicated via social media and statistics showed 94.4% users performing it at least once in a day [4].

While in the realm of voice communication, the survey has found that 78.6% of respondents use
smartphones for voice calls and 80.2% benefit from it once a day.

2.3 Methodology that had been used in app development

For the researcher's case it is developing an App for forgetful users to take their smartphones from their cars. As for this the researcher have discussed with his/her supervisor the choices the researcher has for developing the App. The researcher may have some factors to consider such as suitability of the methodology, the confidence of the researcher using that methodology, and factoring the time constraint [5] [6]. After considering all the factors, the researcher has decided to go with the modified waterfall model as can see in (Fig.2).

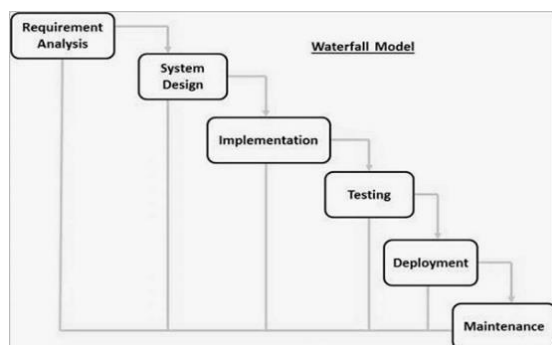
According to the survey created by the researcher titled "FYP Survey: Forgetfulness, Phones & Cars" has received a total of 40 respondents. This is all possible without the use of various distribution channels such as Facebook, Word of Mouth, Instagram and family members.

3.1 Survey Results

In the first question the researcher has asked what age is the respondent. According to the survey, 18 respondents are in between 31-60 years old while 15 are young adults in between 18-30 years of age and another 7 which are seniors in the golden years. According to the survey conducted by the researcher. The number of respondents that currently possessed diseases that deteriorates memory are as follow. Respondent that has dementia are 10 respondents while 6 have Alzheimer disease.

3.2 Use Case Diagram

Shown below in (Fig.3) is the Use Case Diagram which represents the methodology used during the development of the App. The Use Case Diagram is used to organize and identify the requirements required for the Forgetful Alarm App.



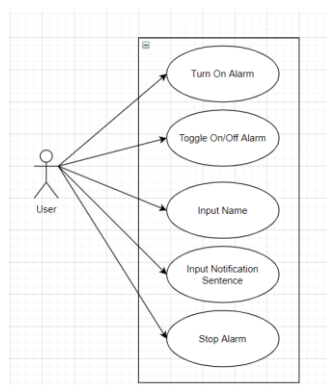


Fig.1. Percentage distribution of Smartphone and feature phone users, 2017 to 2021.

Fig.2. Modified Waterfall model

3. Results and Discussion

Fig.3.Use Case Diagram

Fig.4. Usefulness of the App.

3.3 Implementation

In this section, the implementation of the App is discussed. To develop the App the researcher used Java as the backend programming language and use Extensible Markup Language (XML) to develop the frontend of the App. Android Studio was also used in developing the App [7].

3.4 Evaluation

After successfully developed the App. The researcher will conduct testing to determine whether the App satisfy the requirements that had been identified [8], [9]. To ensure the apps functionality, the researcher has conducted various ways of testing to test the App. The various ways are Unit Testing and User Acceptance Testing.

3.5 User Acceptance Testing

Before the user acceptance test, the researcher would ask the participants which would be selected from the previous survey to download the App and use the app in their daily routine. Participants are asked to commute to work as usual but with a twist of putting their phones in their phone holders and charging it using the cars cigar lighter that can be function as a charging port. In (Fig.4) majority of the participants has agreed that the app is useful.

4. Conclusion

In conclusion all the objectives of the App development had been met and users who used the app had shown interest and can see the potential of this app. Based on the results of this researcher it can be concluded that this app can benefit users in helping them to remember to take their phones from their car. Some recommendations had been elevated from the users during their time using the app. One of the recommendations received during the evaluation is to have reminders to take medication or take an insulin jab. To improve the overall usability of the app the researcher has found some ways to improve the app.

Abstract

Hand gestures of sign language is a form of non-verbal communication which have been used by most people in their daily life. Sign language is not only used by people with speaking issues but it is also unconsciously used by normal people during their daily interaction with others. This is because it is a way to express their current feelings or the meaning they wanted to convey to others. On other hand, sign language is an important alternative used by people with hearing impairment or speaking obstacles so they can communicate with others. However, not everyone from all walks of life has learned sign language so there will be problems of interaction between them and people with speaking issues. Thus, this research focuses on developing a hand gesture recognition system for accurately interpreting American Sign Language (ASL) so that it can deliver a message that can be understood by others and enable efficient communication. In our system, it will utilize computer vision techniques to analyze hand postures and movements which will include hand sign recognition, finger tracking, and motion estimation. With the pre-developed libraries like OpenCV and MediaPipe are employed in the system so it can recognize and classify ASL gestures based on extracted features. Extensive datasets of ASL hand gestures are collected and annotated to enhance the system's accuracy and robustness. The developed system aims to improve human-computer interaction, enabling seamless communication between deaf individuals and technology. The potential applications include real-time interpretation of ASL gestures for enhanced accessibility and inclusivity.

Keywords: Human-Computer Interaction, American Sign Language, Hand Gesture Recognition System.

1. Introduction

In this age of technology, there are many IT related tools or systems that provide various benefits to all walks of life which include Hand Gesture Recognition System (HGRs). The Hand Gesture Recognition System is a type of technology that uses computer vision and machine learning to interpret the motion and sign of individuals [1]. Therefore, this technology can contribute a significant transformation to society nowadays by providing a particular group of people huge benefits who are born with hearing impairment or muted. This is because people with hearing impairment or mute usually rely on sign language, and it is an important tool of communication for them. There is a specific meaning from each gesture in sign language which can construct a complex meaning with the combination of various gestures. In American sign language, where each hand sign will represent different alphabets from A to Z which then can form a specific word. As a result, this project purpose is about developing a Hand Gesture Recognition System that can help in reading sign language. With this system, it can help people with hearing impairment or speaking disabilities to communicate with others more efficiently as well as allow non-signers to get know more about what actually a sign language is [7], [8].

Hand gestures are something that are typically used in daily communication including communicating with people having hearing problems. According to the research, hand gestures can be defined as a type of body language that can be expressed through the center of the palm, finger position and the shape constructed by the hand [9]. There are two classifications of hand gestures which will be the static and dynamic. The static

gestures mostly have to do with the shape of the hand whereas the dynamic gestures deal with a variety of hand movements [9]. For instance, we can find static gestures from the American Sign Language (ASL) at the figure (Fig. 1) in which most of its hand gestures are in a particular shape or pattern that represent an alphabet excluding j and z. Dynamic gestures are mostly related to body language or hand gestures that require movement such as waving, shaking other hands, or even showing the J and Z letter in ASL [11]. It is hard to track the dynamic gestures so in our project we will be focusing more on the ASL static gestures and think of future improvement for the dynamic hand gestures recognition system.

Fig. 1 American Sign Language [10].

2. Methodology

2.1 Comparison Of Different Methodology in Hand Gestures Recognition System

A comparison of methodology is shown in the table below (Table 1).

Table 1 Comparison Table of methodology
in Hand Gesture Recognition System

Sr. No	Paper Name	Year of Public	Techniques	Advantages
1	Hand Gesture Recognition via Lightweight VGG16 and Ensemble Classifier [4]	2022	1.CNN 2.Random Forest Classifier	• Random forest is great in handling large input variables. • Having the highest classification rate.
2	Indian Sign Language Recognition Using Random Forest Classifier [2]	2021	1.Random Forest Classifier	• High accuracy even on complex datasets. • Robust to missing data as users may not always perform gestures perfectly.
3	A Vision-based System for Recognition of Words used in Indian Sign Language Using MediaPipe [6]	2022	1.Random Forest Classifier 2.MediaPipe	• Able to learn complex relationships between the features of the sign language gestures. • Achieving high accuracy in 97.4%.
4	Communicating with the Deaf and Hard of Hearing through Automatic Arabic Sign Language Translator [5]	2021	1.Feature Extraction 2.Random Forest Classifier	• Achieving best recognition accuracy out of all other classification algorithms.
5	Smart Communication System Using Sign Language Interpretation [3]	2022	1.MediaPipe 2.Light Weight Random Forest Classifier	• Achieving good accuracy on recognition about 94.69% • Ability in adapting to different sign language datasets by using different feature extraction techniques and hyperparameter tuning

Fig. 2 Proposed concept of Hand Gesture Recognition System
2.2 Analysis

We will be revealing the outcomes and analyzing the information about the Hand Gesture Recognition System in interpreting ASL from the survey organized that was distributed on the network through emailing and messaging (Fig. 2). Based on the outcomes of the survey, we will know about whatever this project can provide a system in interpreting ASL for

communication between normal people and deaf or people with hearing problems.

2.3 Methodology

In this report, we have employed a quantitative method to gather information regarding the Hand Gesture Recognition System in interpreting ASL. The chosen approach for data collection was a survey form created using Google Forms. The survey form consisted of 2 parts, the first part is about the demographics of the respondents and the second part is about the system inquiries. There are a total of 16 questions that focus on which the 12 questions from the total are mostly asking about the Hand Gesture Recognition System and ASL. The questions included in the survey form were carefully selected to extract essential information required for our research. We aimed to understand more about the Hand Gesture Recognition system so that we can successfully develop the system in interpreting ASL.

The survey form consisted of multiple-choice questions that allowed respondents to select multiple answers from a given list of options. This format enabled us to capture a range of basic understanding of the respondents in the Hand Gesture Recognition System. In addition to multiple-choice questions, we also included rating questions in the survey form. These questions employed a scaling approach to measure respondents' agreement or disagreement with specific statements related to the Hand Gesture Recognition System. This format allowed us to assess the level of agreement towards certain measures or opinions about the Hand Gesture Recognition System in interpreting ASL.

By utilizing the survey form with these question formats and employing various distribution methods, we intended to gather comprehensive insights into the Hand Gesture Recognition System. For reference, the appendix of this report contains 15 survey questions pertaining to the Hand Gesture Recognition System in interpreting ASL.

3. Results and Discussion

In this section, it will be discovering all the validation and testing that are done after the development of the Hand Gesture Recognition system. This chapter is a very significant part that needs to be taken in the entire process of the project development as it will be the sources to know what are the weaknesses and limitations of the current system and the improvement that it needs to enhance in the future. The results are shown in Table 2 and Table 3.

Table 2. Results of Unit Testing

Procedure Description	Expected Result	Actual Result	Test Result
Click Start Camera Button	The camera is started after button was clicked	Worked as expected	Pass
Click Stop Camera Button	The camera frame is stopped after the button was clicked	Worked as expected	Pass
Recognizing the ASL hand gesture	All the static ASL hand gesture is recognized successfully on both right and left hand	Worked as expected	Pass
Click Exit Button	Close the entire program	Worked as expected	Pass
Click Save Character Button	Able to save the recognized ASL hand gesture to text file	Worked as expected	Pass
Click Clear Texts Button	Able to clear the textbox with the recognized ASL hand gesture	Worked as expected	Pass
Enable to save message as history	Click the Save Messages button to store it as history at history message page	Worked as expected	Pass
Click History Message Button	Open up a new frame that redirect to the History Message page	Worked as expected	Pass
Click ASL Display Button	Allow users to view on the ASL gestures information on new frame	Worked as expected	Pass
Click Testing Page Button	Open up a new frame that redirect to the testing page	Worked as expected	Pass
On History Message page, double click on message	Allow long message to be view in full on the label of "Full Message:"	Worked as expected	Pass
On History Message page, click clear button	Able to clear the full shown messages on the below the label of "Full Message:"	Worked as expected	Pass
On History Message page, click clear history button	All the history on the page will be able to clear	Worked as expected	Pass
Click Text to Speech	Able to hear the voice of messages to speech	Worked as expected	Pass
Inside message box of History Message page	Information of saved message will be recorded such as Date, Time and Message contents	Worked as expected	Pass
On testing page, click start camera button	It will activate the camera frame for hand gesture recognition process	Worked as expected	Pass
On testing page, click stop camera button	It will stop the operation of camera frame	Worked as expected	Pass
On testing page, information box display	After camera operated, it will show different information such as recognized alphabets, hands, interpretation and FPS	Worked as expected	Pass

Table 3. Results of System Testing

Procedure Description	Expected Result	Actual Result	Test Result
Recognizing ASL hand gestures through webcam	To ensure the users were able to recognize the ASL hand gesture through the start camera.	Worked as expected	Pass
Saving the ASL hand gestures	To ensure that the users are able to save the recognized ASL alphabets to the textbox.	Worked as expected	Pass
ASL information display	To ensure that the users are able to view types of ASL hand gestures at the page.	Worked as expected	Pass
Saving the text in Message History	To ensure that the users are able to save and view back the history of text.	Worked as expected	Pass
Testing feature for users	To ensure that the users are able to familiarize themselves with the ASL hand gesture system before directly using it.	Worked as expected	Pass
Converting Text to Speech	To ensure the messages from the deaf or people with hearing problem can be heard by the others	Worked as expected	Pass
Stop the system operation	To ensure that the users are able to quit the system by clicking the exit button.	Worked as expected	Pass

4. Conclusion

In conclusion, the project is researched and analyzed comprehensively in order to ensure that the objectives and aims that have been decided at the proposal phase are accomplished. After the development and analysis of the hand gesture recognition system, it can be stated and concluded that all objectives that were planned in the proposal phase have all been accomplished. Since the hand gesture recognition system is specially created for people with hearing problems to have an interaction with others through the gesturing and recording characters of ASL which form a text to bring the meaning they are expressing. At the same time, it may also serve as an educational tool to help people who might be interested in American Sign Language and want to learn it by using the system. This is how the research project's key goals will be accomplished. However, there are no perfect system exist in the world which include our hand gesture recognition system. For instance, one of the limitations of our hand gesture recognition system are unable to recognize in dark environment or classify dynamic gestures. Therefore, there will be future works to be accomplish in order to conquer these limitations stated in this project. Nevertheless, our hand gesture recognition system has already attained the objectives and solve some of the problems stated in the project.

Abstract

Due to the complexity and high cost of typical Enterprise Resource Planning (ERP) systems, medium-sized enterprises (SMEs) often face challenges in their implementation. To address this, the article develops a tailored, cost-effective ERP system specifically designed for SMEs, considering their unique needs and limitations. The research analyzes existing ERP systems in large organizations and conducts surveys and interviews to identify common issues faced by SMEs when adopting standard ERP systems. The paper's main goal is to create an affordable and user-friendly ERP system that empowers SMEs to overcome financial obstacles in an increasingly digital world. The system addresses key business processes such as financial accounting, employer management, and procurement. Additionally, the report highlights the interest homeowners have in using ERP systems for household tasks, indicating a substantial market and demand. Emphasizing the importance of a flexible Home Resource Planning (HRP) system, the study aims to design a cost-effective ERP solution suitable for both homes and SMEs. The proposed ERP system's impact on SME operating performance, productivity, and decision-making is thoroughly examined. The conclusion underscores the significance of customized ERP systems for homes and SMEs in the current digitized environment. The developed small-scale ERP system proves successful in helping SMEs and homes overcome financial challenges and reach their full potential.

Keywords: SMEs, Resource Planner, ERP

1. Introduction

Organizations nowadays are trying to attain optimal efficiency, get an edge over their competitors, and accomplish their objectives as quickly as possible. ERP, or enterprise resource planning, aids in achieving previous corporate goals. As a definition, ERP is a piece of software that contains all the components necessary for a corporation to be managed and operated with maximum effectiveness, avoiding the most possible issues. Enterprise resource planning works by integrating technology from many industries— including human resources, finance, manufacturing, supply chain, and more—in one environment. In other words, it automates numerous business processes with the least amount of effort while remaining in the same setting. Most large businesses globally have already embraced ERP, and more and more small and medium-sized businesses are trying to do the same to compete; they find it both cost-effective and necessary to keep pace [1]. Although the scope and close integration of ERP has only just become available, the market for ERP has been expanding quickly, with more customers and users on a daily basis.

Any firm may gain a lot from using an ERP system. For instance, it can improve and automate the majority of daily tasks an organization must do by removing the need for human data entry, saving time and money [2]. Second, ERP keeps everything organized and in a single system, which removes the need for numerous technologies. Third, ERP can quickly analyse and identify the saved data to provide managers with operational insights. Overall, enterprise resource planning provides seamless data flow between any organization's sectors while maintaining customizability so that it can follow the business needs and strategies.

It has become a must for the future of any establishment that is looking to improve and remain on the popular side of the market [3]. Throughout this proposal, a deeper analysis of the significant characteristics, challenges of implementation, and difficulties related to ERP systems will be done to ultimately gain a thorough understanding of their

function in promoting organizational success. also mentioning some issues and their solutions, using my approach to resolve them, and expanding the accessibility of ERPs to everyone, without exception.

2. Methodology

2.1 Brief History

ERP history traces back to the 1960s with material requirements planning (MRP) systems, pioneered by J.I. Case in collaboration with IBM. The increasing complexity of workplaces led to the need for cross-functional data flow in areas like decision-making, product ordering, inventory management, accounting, human resources, and distribution. This complexity gave rise to the first ERP system, aimed at consolidating diverse functions into a unified platform. ERP systems emerged commercially in the late 1980s and early 1990s, initially designed for the demands of large, complex organizations. Recognized for their complexity and high costs, ERP systems have evolved over time [4].

2.2 Existing System In The Market

SAP ERP, by SAP, a leading corporate software solutions provider, automates key business operations like accounting, sales, and human resources. SAP ECC, the main component, handles transactions, reporting, and integration. SAP S/4HANA, the latest version, offers real-time data processing and improved analytics. Known for a well-explained UI, SAP ERP is popular among giants like PayPal and NBA. Recently integrated with cloud capabilities, SAP ERP provides a customizable cloud solution for global business models and revenue growth [5].

Oracle ERP, from Oracle Corporation, optimizes finance, supply chain management, and human resources. Renowned for dependability and scalability, it suits both small and large businesses. Oracle ERP is customizable to meet industry needs and offers extensive capabilities in data analytics, reporting, and system integration. With a solid reputation and broad support services, Oracle ERP has been a market leader for over a decade.

Microsoft Dynamics 365, part of Microsoft's business application package, is a popular ERP system. It covers accounting, supply chain management, sales, and customer support. Unique for seamless integration with Microsoft products like Office 365, it provides a consistent user experience. Microsoft Dynamics 365 ERP offers advanced analytics, AI-driven insights, and cloud-based deployment options, facilitating operational growth, insights, and automation.

Odoo ERP, an adaptable open-source system, is among the fastest-growing ERP systems. It offers tools for accounting, manufacturing, and sales. Odoo's uniqueness lies in its modular approach, allowing organizations to integrate only the required modules. With an approachable UI, community-driven ecosystem, and cloud-based options, Odoo is an affordable and scalable solution for businesses of all sizes and sectors. Known for fitting SMEs, Odoo is simple and free to test for new users.

2.3 ERP Benefits

Streamlined Operations: Streamlined operations are achieved through the reduction of delivery and cycle times, strategically minimizing delays in data retrieval and reporting. By optimizing these processes, the organization enhances overall efficiency and responsiveness, contributing to a more agile and competitive operational framework.

Cost Reduction: The realization of cost reduction stems from a comprehensive, enterprise-wide review of organizational decisions. This holistic approach not only saves valuable time but also enhances control over financial aspects. Through the identification and elimination of inefficiencies, the organization not only achieves monetary savings but also establishes a more robust and cost-effective foundation for future endeavours.

Adaptability and Flexibility: The system's inherent adaptability and flexibility empower the organization to undergo simple reorganization swiftly. This adaptability extends to accommodating modifications in business processes, ensuring that the enterprise remains agile in response to evolving market dynamics. This capability becomes a cornerstone for sustained innovation and resilience in an ever-changing business landscape.

E-Commerce and E-Business Integration: The system seamlessly supports online shopping experiences and fosters a collaborative environment conducive to effective teamwork. This collaboration, in turn, enables effortless integration with e-commerce systems. By embracing and facilitating digital interactions, the organization not only capitalizes on the growing trend of online commerce but also positions itself for enhanced connectivity and synergy across various aspects of its e-business operations.

2.4 ERP Drawbacks

Time-consuming deployment, the time and resources required to accomplish an ERP deployment are frequently considerable [6]. The collecting of requirements, system configuration, data migration, testing, and user training all need resources from organizations.

Organizational disruption can result from the implementation phase, which forces staff members to become used to new procedures and systems. Employee

reluctance to change and temporary productivity declines may result from this shift.

Challenges with complexity and customization, because of their extensive nature, ERP systems may be very complicated. Adapting the system to a given organization's requirements can be difficult and may call for advanced technical knowledge.

2.5 ERP In Different Industries

Healthcare Industries: ERPs are pivotal in healthcare, streamlining processes like patient scheduling, inventory control, and invoicing. Key benefits include increased operational effectiveness and compliance with healthcare data protection laws like HIPAA.

Financial Sector: In finance, ERPs are indispensable for managing financial data, reducing data loss risks, and ensuring compliance with industry laws, emphasizing the importance of rapid and secure access to accounting information [7].

Education Sector: ERPs play a vital role in education, simplifying tasks like resource organization, grading, and student enrollment. They provide colleges and schools with seamless support for effective operations.

Manufacturing Industries: In manufacturing, ERP systems prove invaluable throughout the workday, efficiently managing logistics, invoicing, and ensuring data organization [8]. Beyond these functionalities, they also assist employees in maintaining accessible personal data, highlighting the depth of their capabilities.

2.6 Comparison Table

Table 1 shows the comparison of the ERP providers.

Table 1. ERP Comparison Table

ERP Provider	Odoo	Microsoft 365	Oracle	SAP
Deployment	On-premises, Cloud	On-premises, Cloud	On-premises, Cloud	On-premises, Cloud
Open source	Yes	No	No	No
Customization	Highly	Moderate	Moderate	Moderate
Scalability	Yes	Yes	Yes	Yes
User-Friendly	Yes	Yes	Yes	Yes
Cost-effective	Yes	Varies	Varies	Varies
Popularity	Growing	Popular	Popular	Popular
Community	open	Strong	Active	Active

2.7 ERP Implementation

When implementing an ERP system, a comprehensive plan is crucial. It begins with a detailed requirements analysis to identify organizational issues and objectives. Vendor selection follows, involving research to choose an ERP provider that aligns with the organization's

needs. Project planning outlines the implementation schedule, resource allocation, and key tasks after vendor selection. Configuration and customization of the ERP system to match unique requirements and procedures follow, including data transfer with accuracy. User training introduces the new system through sessions, workshops, and documentation. Testing and quality control ensure functionality, with various tests like user acceptability and functionality testing. Upon readiness, the system is deployed, with ongoing support to address user queries. Continuous improvement is emphasized, with regular monitoring and feedback collection for streamlined procedures.

2.8 Quantitative Methodology

Data collection involved in-depth interviews and organized surveys to gather user and stakeholder insights. Surveys targeted user groups, focusing on quantitative aspects like performance indicators, system usability, and user satisfaction. A comprehensive analysis of comparable ERP systems enriched contextual knowledge, dissecting and comparing various systems to understand ERP dynamics. The investigation explored the advantages, disadvantages, and unique features of existing ERPs for designing and developing the Home Resource Planning (HRP) system.

2.9 Survey Structure

The survey comprised two parts. The first assessed respondents' ERP knowledge, experience, and understanding of fundamental features. The second part delved into comprehensive testing methods, evaluating the system's stability, performance, and user satisfaction in challenging circumstances. Survey sections included Knowledge and Familiarity with ERP, HRP Interest, ERP Experience, Future ERP Use, and an Additional Comments section for open-ended feedback.

2.10 Qualitative Methodology

Qualitative methods, including interviews and personal comments, supplemented statistical approaches for a holistic understanding. One-on-one interviews covered participants' experiences with ERP systems, potential benefits of an HRP system for daily tasks, and desired features. Questions focused on familiarity with ERP systems, willingness to use an HRP system, valued features, anticipated impacts, and challenges faced with ERP systems in the past.

3. Implementation

3.1 Functional Requirements

User registration and authentication: Users are able to set up accounts with distinctive passwords and

Adim Khalid Aldireejah, Kasthuri Subaramaniam, Ghassan Saleh Hussein Al-Dharhani

usernames. During the login process, the system authenticates and verifies the user's credentials.

User-Specific Views: Based on their role and preferences, every user is shown a customized dashboard or view. The interface is customized by the system to provide appropriate information, including appointments, finances, people, and duties, for various users.

Service Selection: A variety of services are available for users to select from, such as appointment scheduling, money, personnel management, and chore organization.

Data Entry and Management: Within the service category they have chosen, users can enter and manage data. To ensure data accuracy, the system offers capabilities for data entry, modification, and deletion.

Notification and Reminder System: Users are able to choose how they want to be notified and reminded. Reminders and automatic notifications are sent by the system in accordance with user-specified schedules and actions.

Data Integration: Users may access and use information from several modules by means of the ERP system's smooth integration of data from the other services. Maintaining data consistency helps to guarantee accuracy and dependability.

3.2 Non-Functional Requirements

Security: To safeguard user data and preserve privacy, the ERP system complies with industry-standard security standards. Sensitive data is protected by robust encryption and authentication processes.

Scalability: Exhibits the capacity to increase with the number of users and volume of data. meets predetermined performance goals and maintains peak performance as the system grows.

Performance: Reduces downtime and guarantees quick user request responses. Supports several users concurrently and effectively handles data transfers without appreciable performance reduction.

Usability: The design of the user interface places a high value on simplicity and clarity, making it easy for users to navigate and finish activities.

Dependability: An ERP system with high dependability has fewer mistakes and interruptions.
3.3 Web-based Resource Planner

Fig 1. HRP Home-Page

The Homepage in Home Resource Planning (HRP) is an intuitive user interface that offers a smooth sign-up or log-in process for current users (Fig. 1). The design places a high value on simplicity, guaranteeing users a seamless onboarding experience. Furthermore, the platform provides a brief yet useful feature summary, enabling customers to rapidly understand the possibilities it provides. A dedicated "Learn More" page offers a thorough examination of the web application for individuals looking for more specific details. This page functions as an in-depth manual, providing information on the features, and advantages.

Fig 2. HRP Home-Page Responsiveness

It's also important to note that the majority of its pages adjust to the screen size, even on mobile devices. Whether on a laptop, tablet, or desktop, HRP will try to adjust the size to fit the screen (Fig. 2).

Fig 3. HRP Main Page

Similar to the home page, the system home page is simple to navigate; users may select the service they want to use here as shown in Fig. 3.. Additionally, the header and footer are always there and allow users to

select from the services offered on each page. At this point, it is worth noting that the purpose of HRP is to provide similar services any ERP can but with easier navigation.

Fig 4. HRP Services

One of the features offered by the web-based app is the ability for users to add individuals to the database, modify or remove their information, or even look for a specific record as shown in Fig. 4.. Each record has a unique ID to help with identification, and each user will see their data in a unique way, guaranteeing that each user's data is private and personal.

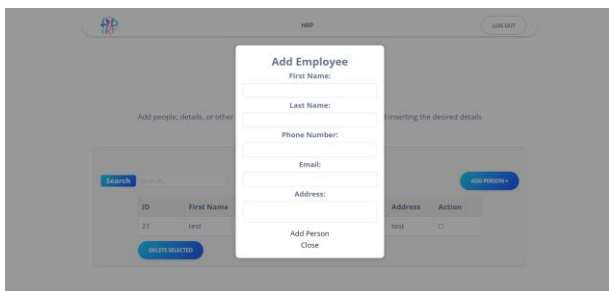

Fig 5. Pop-ups and Forms

The user will always be informed if an activity was successful or not with pop-up pages and messages that appear after any action (Fig. 5). In any online application, error management is Considered one of the most important features for a web-app/website to have.

Fig 6. Database Schema

The ERP system's database is distinguished by advanced development and maximum functionality. With a strong performance, it effectively organizes and maintains large amounts of data, which adds to the system's overall dependability and efficiency. Because the database is designed to be scalable, data can be stored and retrieved quickly, guaranteeing a flexible and responsive system. Its challenging architecture creates a safe and organized space for the archiving and retrieval

of vital corporate data while accommodating the various needs of ERP modules (Fig. 6). The smooth functioning of the database is essential to the overall effectiveness and success of any ERP system.

Fig 7. User Authentication

Since HRP uses user authentication (Fig. 7), that allows each user to have their own view which will allow data to be secure and no mix-ups can happen between users.

4. Conclusion

As a result of their ability to offer a centralized system that unifies several company processes such as supply chain management, manufacturing, finance, and human resources—resource planners are incredibly helpful to businesses. They have been becoming more popular by the day owing to their utilization in the business world. Small firms can increase their productivity and efficiency considerably by using an ERP system, but it does require careful design, sufficient funding, and good user support and training. A number of other implementation-related aspects are covered, such as small business owners' as well as homeowners' interest in utilizing such a system, their familiarity with ERP software, and their long-term goals for system adoption or upgrades. The analysis also showed that different small business owners have different long-term plans for adopting or upgrading their systems; some want to move to more simple solutions, while others would rather learn more about them in general.

Additionally, Homeowners' interest in utilizing an ERP system for household tasks is also emphasized. The research revealed a significant market and need for such systems, with over 80% of participants expressing a strong interest in an HRP system designed for duties connected to the household. In order to satisfy the needs of a diverse variety of customers with a wide range of user requirements and expectations, the research highlights the significance of having an adaptive and versatile HRP system.

Introducing HRP to the market and matching it with the current trends might have a lot of benefits for homes and company owners alike, as well as for anyone looking to improve efficiency and organization in their everyday lives. An HRP system is a promising addition to homes and small enterprises, with the potential to revolutionize resource management.

Abstract

This research is going to develop a cloud-based sportswear website that can handle high volumes of traffic during events or seasonal sales, assist customers in selecting the right size for their sportswear, the interface should have options, size charts, fitting instructions, and recommendations. A study on the existing system will be conducted, design, develop and evaluate on the sportswear website also will be carried out. The system development approach used on this website is Rapid Application Development (RAD) model. The reason to choose RAD is because this method is time efficient, flexibility and adaptability. With RAD, functional software is delivered quickly. We can quickly build prototypes, iterate on them, and gather feedback from stakeholders with a website project. There are four of the steps in Rapid Application Development (RAD) methodology life cycle, which is define the requirements, prototypes, rapid construction and feedback gathering, and cutover.

Keywords: Cloud computing, Sportswear trend, E-commerce

1. Introduction

The Internet, especially with the advent of cloud computing, has brought about significant changes in our world. Cloud computing, a highly advanced technological product, has emerged as a key player in the 21st century's era of globalization, promoting social normalization and expanding social equality [1]. This innovation relies on the World Wide Web and the rapid growth of Internet technology, offering a solid and scalable security structure crucial for its real-world applications.

Distinguishing e-commerce from traditional commerce, e-commerce conducts transactions online, allowing users to shop, trade, auction, and access various services. The advantages of e-commerce include lower costs, increased convenience, and access to a broader range of products. Cloud computing, viewed as the next revolution in the science and technology industry, is expected to significantly impact enterprise operations when combined with e-commerce. It eliminates the complexities and costs associated with traditional business applications, providing shared infrastructure and scalability.

Cloud computing provides computer resources as a service over the internet, offering dynamic scalability and virtualization. Users' information is stored remotely, allowing accessibility anytime, anywhere. The three basic cloud computing service models are Infrastructure as a Service (IaaS), Platform as a Service (PaaS), and Software as a Service (SaaS), each serving distinct purposes in the cloud ecosystem [6].

The e-commerce landscape is evolving, and cloud computing is playing a pivotal role in shaping its technical architecture. Different types of e-commerce, such as B2B, B2C, C2C, C2B, B2A, and C2A, cater to diverse business models and transactions. This project specifically adopts the B2C model, focusing on selling athletic apparel and related items directly to individual users through a sportswear website [2].

Amazon EC2 (Elastic Compute Cloud) exemplifies how cloud computing can benefit e-commerce enterprises. Instead of purchasing hardware and software, businesses can rent them, reducing system building costs. EC2, a popular cloud system, allows users to rent cloud-based applications, providing flexibility and cost-effectiveness. In this project, EC2 is

chosen as the cloud server to store website data, leveraging the benefits of Amazon Web Services (AWS).

The impact of social media on customer buying behavior is noteworthy, with 3.6 billion users across various platforms. Social media platforms enhance customer connection, broaden reach, and provide businesses with opportunities to interact with and influence customer behavior. Building brand equity through social media is recognized as a valuable asset in the contemporary market [3].

Sportswear has become a fashion trend, influenced by changes in lifestyle, the demand for functional performance clothing, and the growing interest in fitness outerwear [7]. Activewear manufacturers thrive as fitness-conscious consumers seek appropriate gear. The activewear market, particularly in the United States, is robust, with Nike and Adidas leading in revenue. Women's sportswear sales surpass those of men's and children's, and this trend is expected to continue into the 2020s [4], [5], [8].

2. Methodology

The Rapid Application Development (RAD) approach revolutionizes software application development with its iterative and user-centric methodology. Primarily designed for projects requiring ongoing user participation, RAD's strength lies in its adaptability and responsiveness to changing requirements. Contrary to the traditional waterfall development paradigm, RAD, introduced in 1991, thrives on flexibility and efficiency, making it particularly effective for managing modest and medium-sized projects.

The RAD process unfolds through distinct phases. During the Planning and Define Requirements phase, meticulous research and requirement gatherings take place to grasp the project's objectives, audience, scope, and establish measurable goals. A questionnaire sent to website clients ensures a comprehensive understanding of their needs. Prototyping follows, where the project team collaboratively creates an early working model of the website, incorporating user feedback through iterative cycles and casual interviews to refine features and eliminate design errors.

Rapid Construction and Feedback Gathering phase translates user feedback into practical development tasks, including coding and testing. Adjustments are made to application prototypes based on recommendations, and thorough testing ensures effective functionality. Once the website is launched, the Maintenance phase kicks in, focusing on regular upkeep to keep the site current, secure, and operational. This involves content updates, software and plugin maintenance, issue resolution, and adapting to evolving user input or business requirements.

3. Results and Discussion

The questionnaire results reveal key insights into consumer behavior and preferences for online sportswear shopping. Regardless of age, respondents engaged in sports are more inclined to shop for sportswear online, with those in their 20s and 30s showing the highest likelihood. Older age groups, especially those between 51 to 60 years old, show a reluctance to adopt e-commerce, possibly due to limited familiarity with technology.

Device usage for online shopping is evenly split between desktop and mobile, with respondents less likely to use tablets. JD Sports emerges as more popular than Nike and Adidas, attributed to its diverse range of brands and products. User-friendly navigation menus and simple, clean website designs are highly valued by respondents.

Product preferences highlight running shoes and activewear as top choices, driven not only by sports engagement but also as fashion items. Eco-friendly and sustainable sportswear gains significant preference, reflecting a growing awareness of environmental impact among consumers.

In terms of information, sizing guides, material details, and product reviews are considered crucial. The website's content, including blog articles, styling tips, and athlete endorsements, is appreciated by half of the respondents.

Checkout preferences are divided, with half opting for guest checkout and the other half preferring account creation before purchase. Touch ′ n Go is the favored payment method, emphasizing the importance of seamless transactions and a secure checkout process.

Email is the preferred mode of communication for customer support, chosen by half of the respondents over phone and live chat. Privacy and data security are paramount, with customers expecting companies to safeguard their information.

Overall, respondents express satisfaction with their online shopping experiences, emphasizing the importance of trust, reasonable pricing, and quality products for a successful e-commerce venture.

3.1 Implementation

This section focuses on a dynamic use case as shown in Fig. 1, emphasizing the synthesis of various diagrams to provide a comprehensive understanding of a specific system. Starting with a clever use case scenario analysis, An Entity-Relationship (ER) diagram (Fig. 2) visualizes the database structure. Concrete observations, such as screenshots of the admin and customer website sections, are integrated to bridge conceptual and practical aspects,

offering a holistic overview of the system's design and operation (Fig. 3).

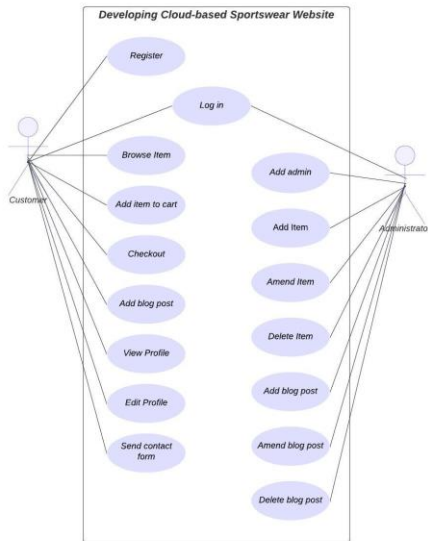

Fig. 1 Use Case Diagram

Fig. 2 Entity Relationship Diagram

Fig. 3 Class Diagram

3.2 Evaluation

Evaluation begins with three crucial testing stages: unit testing, integration testing, and system testing. Together, these stages allow us to thoroughly assess the functionality and dependability of the proposed website.

Table 1, Table 2, Table 3 and Table 4 show the summary of the testing for each of the stages.

Table 1. Login Unit Test

Procedure Description	Expected Result	Actual Result	Test Result
Username text field	Allow user to key in their username.	Working as expected	Pass
Password text field	Allow user to key in their password.	Working as expected	Pass
Login button (Admin)	Allow admin to authenticate to access the website.	Working as expected	Pass
Login button (Customer)	Allow customer to authenticate to access the website.	Working as expected	Pass
Forget Password button	Allow user to reset their password.	Working as expected	Pass

Table 2. Integration Test

Procedure Description	Expected Result	Actual Result	Test Result
Login function should connect to database to validate the user.	The system able to connect to database and authenticate the user based on their username and password.	The system connects to database and verifies the user.	Pass
Customer place order function should connect to database to record customer order.	The system able to store customer order in the database.	The system connects to database and store customer order.	Pass
Admin side function should connect to database to update product detail.	The system able to store product detail in the database.	The system connects to database and store product detail.	Pass

Table 3. Admin side System Testing

Expected Result	Actual Result
Admin able to login to the system.	Admin can login successfully by insert username and password.
Admin able to view product on website.	All product is showed on the website.
Admin can add new product.	Product can be added by insert all the product detail.
Admin can amend product detail.	Product can be amended by insert all the amend detail.
Admin can delete product.	Product can be deleted by clicking the confirm delete button.
Admin can search user list.	User list is showed when search button is clicked.
Admin can add new admin.	New admin can be added by insert all the admin detail.
Admin can inactivate or activate user.	User can inactivate or activate when button is clicked.
Admin can logout from then system.	Admin can logout successfully when logout button is clicked.

Table 4. User Perception Test

Function	Yes/No
All the button are working perfectly	Yes
Able to login	Yes
All text field allow user to enter text	Yes
Dropdown menu allow user selection	Yes
Navigation menu allow user selection	Yes
All website functions are operational and working seamlessly	Yes
Error message when username or password incorrect	Yes
Alert successful message when action is performed	Yes
Able to logout	Yes

4. Conclusion

In summary, the construction and hosting of a cloud-based sportswear website on Amazon EC2 involved careful consideration of critical factors, particularly in response to the evolving landscape of e-commerce accelerated by the COVID-19 pandemic. The adoption of Amazon EC2, a reliable and scalable cloud computing solution, underscored the importance of leveraging technology for resilience and competitiveness in the e-commerce industry. The Rapid Application Development (RAD) methodology facilitated a collaborative and iterative development approach, aligning with the dynamic nature of e-commerce. Rigorous testing, including unit tests, integration tests, system tests, and user perception tests, ensured the website's reliability, functionality, and user satisfaction. This effective combination of digital technologies, cloud computing, RAD methodology, and comprehensive testing positions the sportswear website for success in the competitive e-commerce landscape, addressing challenges posed by the pandemic and establishing a robust foundation for sustained success in the dynamic online business environment.
