Contents

SPONSERED

ALife Robotics Corporation Ltd.

ORGANIZED BY

International Steering Committee of International Conference on Artificial Life and Robotics (ICAROB)

SUPPORTED BY

IEEE Fukuoka Section (Japan)

CO-ORGANIZED BY

Chinese Association for Artificial Intelligence (CAAI, P. R. China)

ADVISORY COMMITTEE CHAIRS

Kazuo Ishii (Kyushu Institute of Technology, Japan)
Kensuke Harada (Osaka University, Japan)
Takashi Kohno (University of Tokyo, Japan)
Eiji Hayashi (Kyushu Institute of Technology, Japan)
Jeffrey Johnson (The Open University, UK)
Katia Passerini (Seton Hall University, USA)

ADVISORY COMMITTEE

Bruce Eisenstein (Drexel University, Former IEEE President, USA)
Hidenori Kimura (RIKEN & Wasada University, Japan)
Joshua M. Epstein (The Johns Hopkins University, USA)
Ken-ichi Tanaka (Executive Fellow, Mitsubishi Electric Corporation, Japan)
Masato Nakagawa (Executive Fellow, DENSO CORPORATION, Visiting Professor of Hiroshima University, Japan)
Moshe Kam (New Jersey Institute of Technology, Former IEEE President, USA)
Paul Kalata (Drexel University, USA)
Paul Oh (Drexel University, USA)
Peter Herczfeld (Drexel University, USA)

GENERAL CHAIR

Masanori Sugisaka
(Alife Robotics Corporation Ltd., Japan)

CO-GENERAL CHAIRS

Yingmin Jia (Beihang Univesty, P. R. China)
Takao Ito (Hiroshima University, Japan)
Ju-Jang Lee (Honorary professor, KAIST, Korea)

VICE GENERAL CHAIR

Ang, Chun Kit (University of UCSI, Malaysia)
Henrik. H. Lund (Technical University of Denmark, Denmark)
John. L. Casti (International Institute for Applied Systems Analysis, Austria)
Luigi Pagliarini (Technical University of Denmark, Denmark)
(Academy of Fine Arts of Macerata, Italy)
Mohd Rizon bin Juhari (University of UCSI, Malaysia)
Norrima Mokhtar (University of Malaya, Malaysia)

PROGRAM CHAIRMAN

Makoto Sakamoto (University of Miyazaki, Japan)

CO-PROGRAM CHAIR

Marion Oswald (Technische Universität Wien, Austria)

INTERNATIONAL ORGANIZING COMMITTEE

Akira Nakamura (Saitama Institute of Technology, Japan)
Akinori Abe (Chiba University, Japan)
Caoli Wang (University of Shanghai for Science and Technology, P. R. China)
Chan Gook Park (Seoul National University, Korea)
Evgeni Magid (Kazan Federal University, Russia)
Fuzhong Wang (Henan Polytechnic University, P. R. China)
Hazry Desa (University of Malaysia, Perlis, Malaysia)
Hidehiko Yamamoto (Gifu University, Japan)
Hiroki Tamura (The University of Miyazaki, Japan)
Hiroshi Kage (Mitsubishi Electric Corporation, Japan)
Hiroshi Matsuno (Yamaguchi University, Japan)
Jiwu Wang (Beijing Jiaotong University, P. R. China)
Jovana Jovic (CNRS-AIST JRL, Japan, France)
Junping Du (Beijing University of Posts and Telecommunications, P. R. China)
Katsunori Shimohara (Doshisha University, Japan)
Kazuo Ishii (Kyushu Institute of Technology, Japan)
Kenichi Tanaka (Nagasaki Institute of Applied Science, Japan)
Kenji Hashimoto (Waseda University, Japan)
Kunikazu Kobayashi (Aichi Prefectural University, Japan)
Kuo-Hsien Hsia (Far East University, Taiwan)
Kuo-Lan Su (National Yunlin University of Science and Technology, Taiwan)
Kyungho Park (U.S. ARMY, Japan and USA)
Masao Kubo (National Defense Academy of Japan, Japan)
Maxim Sokolov (Innopolis University, Russia)
Mehta Rajiv (New Jersey Institute of Technology, USA)
Minoru Kumano (University of Miyazaki, Japan)
Peter Sapaty (Ukrainian Academy of Science, Ukraine)
Pierre Parrend (University of Strasbourg, France)
Qiang Cai (Beijing Technology and Business University, P. R. China)
Qu Yanbin (Harbin Institute of Technology, P. R. China)
Singo Mabu (Yamaguchi University, Japan)
Takashi Kohno (The University of Tokyo, Japan)
Takashi Ogata (Iwate Prefectural University)
Tetsuro Hattori (Kagawa University, Japan)

Thi Thi Zin (University of Miyazaki, Japan)
Thomas S. Ray (University of Oklahoma, USA)
Toru Yamamoto (Hiroshima University, Japan)
Victor Berdonosov (Komsomolsk-on-Amur State University of Technology, Russia)
Yasunari Yoshitomi (Kyoto Prefectural University, Japan)
Yi Chai (Chongqing University, P. R. China)
Yoshifumi Morita (Nagoya Institute of Technology, Japan)
Yoshiro Imai (Kagawa University, Japan)

INTERNATIONAL PROGRAM COMMITTEE

Abdul Rahman bin Dullah (Universiti Teknikal Malaysia Melaka, Malaysia)
Akinori Abe (Chiba University, Japan)
Akihiro Yamaguchi (Fukuoka Institute of Technology, Japan)
Akihito Kanai (Hosei University, Japan)
Ali Selamat (University of Technology of Malaysia, Malaysia)
Aminurafiuddin bin Zulkifli (Multimedia University, Malaysia)
Amornphun Phunopas (King Mongkut's University of Technology, North Bankok, Thailand)
Andre Rosendo (ShanghaiTech University, P. R. China)
Anne Jeannin-Girardon (University of Strasbourg, France)
Anton Shiriaev (Norwegian University of Science and Technology, Norway)
Artur Sagitov (Kazan Federal University, Russia)
Ashi Gautam (The University of Tokyo, Japan)
Atsuya Tange (The University of Tokyo, Japan)
Ayumu Tominaga (Kitakyushu National College of Technology, Japan)
Bin Zhang (Beijing University of Posts and Telecommunications, P. R. China)
Cecilia Zanni-Merk (INSA-Rouen, France)
Chaoli Wang (University of Shanghai for Science and Technology, P. R. China)
Chia-Nan Ko (Nan kai University of Technology, Taiwan)
Chung-Wen Hung (National Yunlin University of Science & Technology, Taiwan)
Congdao Han (Shanghai Institute of Technology, P. R. China)
Cui Zhang (Beihang University, P. R. China)
Cynthia Matuszek (University of Maryland, USA)
Donglian Qi (Zhejiang University, P. R. China)
Duangiai Jitkongchuen (Dhurakij Pundit University, Thailand)
Dunwei Gong (China University of Mining and Technology, P. R. China)
Jiao Jia (Beihang University, P. R. China)
Endra Joelianto (Bandung Institute of Technology, Indonesia)
Fabio Guigou (University of Strasbourg, France)
Fei Hao (Beihang University, P. R. China)
Fuzhong Wang (Henan Polytechnic University, P. R. China)
Haibo Li (Royal Institute of Technology, Sweden)
Haisheng Li (Beijing Technology and Business University, P. R. China)

Haruhisa Okuda (Mitsubishi Electric Corporation, Japan)
Haruka Tsuboi (The University of Miyazaki, Japan)
Haruna Matsushita (Kagawa University, Japan)
Heeje Kim (Pusan National University, Korea)
Hidetsugu Suto (Muroran Institute of Technology, Japan)
Hiroyuki Iizuka (Osaka University, Japan)
Hongbo Li (Tsinghua University, P. R. China)
Hongji Ma (Shandong University of Science and Technology, P. R. China)
Hongjiu Yang (Yanshan University, P. R. China)
Hongpeng Yin (Chongqing University, P. R. China)
Hussein Abbass (University of New South Wales, and ADFA, Australia)
I-Hsien Liu (National Cheng Kung Univrsiity, Taiwan)
Ilya Afanasyev (Innopolis University, Russia)
Istvan Harmati (Budapest Institute of Technology and Economics, Hungary)
Ivan Tanev (Doshisha University, Japan)
Jiandong Zhao (Beijing Jiaotong University, P. R. China)
JJ Merelo (University of Granada, Spain)
Joono Cheong (Korea University, Korea)
Julio Navarro Lara (University of Strasbourg, France)
Jun Kobayashi (Kyushu Institute of Technology, Japan)
Jung-Shian Li (National Cheng Kung University, Taiwan)
Keiji Kamei (Nishinippon Institute of Technology, Japan)
Keisuke Watanabe (Tokai University, Japan)
Keita Honda (Gifu University, Japan)
Ke Zhang (Chongqing University, P. R. China)
Kenichi Tanaka (Nagasaki Institute of Applied Science, Japan)
Kensuke Ogata (Osaka City University Japan)
Khairul Salleh bin Mohamed Sahari (Universiti Tenaga Nasional, Malaysia)
Khoyratee Farad (The University of Tokyo, Japan)
Kouichi Takeuchi (Okayama University, Japan)
Konstantin Yakovlev (Russian Academy of Sciences, Higher School of Economics, Russia)
Kui Xiang (Wuhan University of Technology, P. R. China)
Leonid Freidovich (Umea University, Sweden)
Levi Timothée (The University of Tokyo, Japan)
Liming Chen (Beihang University, P. R. China)
Lin Li (University of Shanghai for Science and Technology, P. R. China)
Lin Zhao (Qingdao University, P. R. China)
Mamoru Yoshimura (The University of Miyazaki, Japan)
Manabu Yamada (Nagoya Institute of Technology, Japan)
Masahide Ito (Aichi Prefectural University, Japan)
Masahiro Ushio (Kyushu Institute of Technology, Japan)
Masahiro Yokomichi (The University of Miyazaki, Japan)
Masamichi Hori (The University of Miyazaki, Japan)
Masanori Takahashi (Tokai University, Japan)

Masayoshi Kano (Chukyou University, Japan)
Masayoshi Tabuse (Kyoto Prefectural University, Japan)
Masaomi Hatakeyama (university of Zurich, Switzerland)
Max Talanov (Kazan Federal University, Russia)
Meng Duan (Beihang University, P. R. China)
Moeko Tominaga (Kyushu Institute of Technology, Japan)
Mohammad Al-Shabi (University of Sharjah, United Arab Emirates)
Mohammad Biglarbegian (University of Guelph, Canada)
Mou Chen (Nanjing University of Aeronautics and Astronautics, P. R. China)
Nan Xiao (Northeastern University at Qinhuangdao, P. R. China)
Nicolas Monmarché (university of Tours, France)
Noritaka Sato (Nagoya Institute of Technology, Japan)
Norrima Mokhtar (University of Malaya, Malaysia)
Palakorn Tantrakool (King Mongkut's Institute of Technology, North Bankok, Thailand)
Ping Wang (North China Electric Power University, P. R. China)
Pierre David (University of Strasbourg, France)
Pierre Willaume (University of Strasbourg, France)
Rizauddin bin Ramli (Universiti Kebangsaan Malaysia, Malaysia)
Roman Lavrenov (Kazan Federal University, Russia)
Ruztamreen bin Jenal (Universiti Teknikal Malaysia Melaka, Malaysia)
Ryohei Anshi (Kyushu Institute of Technology, Japan)
R.K.P.S. Ranaweera (University of Moratuwa, Sri Lanka)
Satoshi Ikeda (The University of Miyazaki, Japan)
Sanjay S. Joshi (University of California, USA)
Seong-Ik Han (Pusan National University, Korea)
Shahriman Abu Bakar (Universiti Malaysia Perlis, Malaysia)
Shanbi Wei (Chongqing University, P. R. China)
Shihao Sun (Beihang University, P. R. China)
Shin-ichi Asakawa (Tokyo Woman's Christian University, Japan)
Shin Wakitani (Hiroshima University)
Shumin Fei (Southeast University, P. R. China)
Shyi-Ming Chen (National Taichung University of Education, Taiwan)
Stephen Wilkerson (York College of Pennsylvania, USA)
Takashi Kuremoto (Nippon Institute of Technology, Japan)
Takayoshi Yamada (Gifu University, Japan)
Takuya Fuginaga (Fukuoka University, Japan)
Takuya Nanami (The University of Tokyo. Japan)
Taishiro Kishimoto (Keio University, Japan)
Taisuke Akimoto (Kyushu Institute of Technology, Japan)
Tarik bin Abd Latef (Universiti Malaya, Malaysia)
Taro Shibanoki (Okayama University, Japan)
Tetsuro Katayama (The University of Miyazaki, Japan)
Thomas Noel (University of Strasbourg, France)
Thunyaseth Sethaput (Thammasat University, Thailand)

Tianping Zhang (Yangzhou University, P. R. China)
Tomohiko Takagi (Kagawa University, Japan)
Toru Hiraoka (University of Nagasaki, Japan)
Toshihiro Inukai (DENSO Wave Incorporated, Japan)
Toshinori Nawata (Kumamoto National College of Technology, Japan)
Tsunehiro Yoshinaga (Tokuyama National College of Technology, Japan)
Ussath Martin (The University of Potsdam, Germany)
Wan Khairunizam Wan Ahmad (Universiti Malaysia Perlis, Malaysia)
Weicun Zhang (University of Science and Technology Beijing, P. R. China)
Wenhao Zheng (Beihang University, P. R. China)
Wenlin Li (Beihang University, P. R. China)
Wisanu Jiviriya (King Mongkut's University of Technology North Bankok, Thailand)
Xiaocan Wang (Technical University Munich, Germany)
Xiaofeng Su (Beijing Institute of Astronautical Systems Engineering, P. R. China)
Xiaoyan Chen (Tianjin University of Science and Technology, P. R. China)
Xiaoyan Fu (Capital Normal University, P. R. China)
Xuemei Ren (Beijing Institute of Technology, P. R. China)
Xuhui Lu (Beihang University, P. R. China)
Yan Cui (Shanxi Normal University, P. R. China)
Yasunori Takemura (Nishinippon Institute of Technology, Japan)
Yo Horikawa (Kagawa University, Japan)
Yongqiang Qi (China University of Mining and Technology, P. R. China)
Yoshihiro Kita (University of Nagasaki, Japan)
Youji Kawamura (Kindai University, Japan)
Yu-an Zhang (Qinghai University, P. R. China)
Yue Lin (Beijing Institute of Control Engineering, P.R. China)
Yueqian Liang (China Academy of Elecronics and Information Technology, P. R. China)
Yuji Minami (National Institute of Technology, Ube College, Japan)
Yunju Chen ((Shiga University, Japan)
Yunzhong Song (Henan Polytechnic University, P. R. China)
Zacharie Mbaitiga National Institute of Technology, Okinawa College, Japan)
Zakri bin Ghazali (Universiti Malaysia Pahang, Malaysia)
Zengqiang Chen (Nankai University, P. R. China)
Zhao Peng (Huazhong University of Science and Technology, P. R. China)
Zhengquan Yang (Civil Aviation University of China, P. R. China)
Zhongxin Liu (Nankai University, P. R. China)
Zuradzman bin Mohamad Razlan (Universiti Malaysia Perlis, Malaysia)

LOCAL ARRANGEMENT COMMITTEE

Makoto Sakamoto (University of Miyazaki, Japan)
Masanori Sugisaka (ALife Robotics Corporation Ltd., Japan)
Takao Ito (Hiroshima University, Japan)

HISTORY

The International Conference on Artificial Life and Robotics (ICAROB) resulted from the AROB-symposium (International Symposium on Artificial Life and Robotics) whose first edition was held in 1996 and the eighteenth and last edition in 2013. The AROB symposium was annually organized by Oita University and ALife Robotics Corporation Ltd., under the sponsorship of the Science and Technology Policy Bureau, the Ministry of Education, Science, Sports, and Culture (Monbusho), presently, the Ministry of Education, Culture, Sports, Science, and Technology (Monkasho), Japanese Government, Japan Society for the Promotion of Science (JSPS), the Commemorative Organization for the Japan World Exposition ('70), Air Force Office of Scientific Research, Asian Office of Aerospace Research and Development (AFOSR/AOARD), USA. I would like to express my sincere thanks to not only Monkasho (annually fund support from 1996 to 2013) but also JSPS, the Commemorative Organization for the Japan World Exposition ('70), and various other Japanese companies for their repeated support. The old symposium (this symposium has been held every year at B-Con Plaza, Beppu, Oita, Japan except in Oita, Japan (AROB 5th '00) and in Tokyo, Japan (AROB 6th '01).) was organized by the International Organizing Committee of AROB and was co-operated by the Santa Fe Institute (USA), RSJ, IEEJ, ICASE (Now ICROS) (Korea), CAAI (P. R. China), ISCIE, IEICE, IEEE (Japan Council), JARA, and SICE. The old AROB-symposium expanded much by absorbing much new knowledge and technologies into it. This history and character of the former AROB symposiums are passed on the current ICAROB conference and to these journals, Journal of Robotics, Networking and Artificial Life (JRNAL)(vol1-8) indexed by SCOPUS & ESCI and Journal of Robotics, Networking and Artificial Life (JRNAL)(vol9-) indexed by SCOPUS & ESCI and Journal of Advances in Artificial Life Robotics (JAALR). From now on, ALife Robotics Corporation Ltd. is in charge of management of both the conference and the journals. The future of the ICAROB is brilliant from a point of view of yielding new technologies to human society in the 21st century. We also expect to establish an international research institute on Artificial Life and Robotics in the future with the help of Japanese Government and ICAROB. This conference invites you all.

AIMS AND SCOPE

The objective of this conference is the development of new technologies for artificial life and robotics which have been recently born in Japan and are expected to be applied in various fields. This conference presents original technical papers and authoritative state-of-the-art reviews on the development of new technologies concerning robotics, networking and artificial life and, especially computer-based simulation and hardware for the twenty-first century. This conference covers a broad multidisciplinary field, including areas such as:

Artificial intelligence & complexity
Artificial living
Artificial mind research
Artificial nervous systems for robots
Artificial sciences
Bipedal robot
Brain science and computing
Chaos
Cognitive science
Computational Molecular biology
Computer graphics
Data mining
Disasters robotics
DNA computing
Empirical research on network and MOT
Environment navigation and localization
Evolutionary computations
Facial expression analysis, music recommendation and augmented reality
Foundation of computation and its application
Fuzzy control
Genetic algorithms
Human-welfare robotics
Image processing
Insect-like aero vehicles
Intelligence in biological systems
Intelligent control
Management of technology
Medical surgical robot
Micro-machines
Multi-agent systems
Nano-biology
Nano-robotics
Networking
Neural circuits
Neuro-computer

Neuromorphic Systems
Neuroscience
Pattern recognition
Quantum computing
Reinforcement learning system & genetic programing
Robotics
Software development support method
System cybernetics
Unmanned underwater vehicles
Unmanned Aerial Systems Technologies
Unmanned Aerial Systems designing, controls and navigation
Unmanned Aero vehicles
Virtual reality
Visualization
Hardware-oriented submissions are particularly welcome. This conference will discuss new results in the field of artificial life and robotics

COPYRIGHTS

Accepted papers will be published in the proceeding of The 2024 International Conference on Artificial Life and Robotics (ICAROB2024) by ALife Robotics Corp. Ltd. Copyright belongs to ALife Robotics Corp. Ltd. Some of high-quality papers in the proceeding will be requested to re-submit their papers for the consideration of publication in Journal of Robotics, Networking and Artificial Life indexed by SCOPUS & ESCI (JRNAL)(vol.1-8) & Journal of Robotics, Networking and Artificial Life(vol.9-) indexed by SCOPUS & ESCI and Journal of Advances in Artificial Life Robotics under agreement of both Editor-in- Chief Dr. Masanori Sugisaka and 3 reviewers. All correspondence related to the conference should be addressed to ICAROB Office.

MESSAGES

Masanori Sugisaka
General Chair
(President, ALife Robotics Corp.,
Ltd, Japan)

Masanori Sugisaka

General Chair of ICAROB

It is my great honor to invite you all to The 2024 International Conference on Artificial Life and Robotics (ICAROB 2024) to be held at J:COM HorutoHall, Oita, Japan, 2024. This Conference is changed as the old symposium from the first (1996) to the Eighteenth (2013) annually which were organized by Oita University and ALife Robotics Corporation Ltd. under the sponsorship of the Science and Technology Policy Bureau, the Ministry of Education, Science, Sports, and Culture (Monbusho), presently, the Ministry of Education, Culture, Sports, Science, and Technology (Monkasho), Japanese Government, Japan Society for the Promotion of Science (JSPS), The Commemorative Organization for the Japan World Exposition ('70), Air Force Office of Scientific Research, Asian Office of Aerospace Research and Development (AFOSR/AOARD), USA. I would like to express my sincere thanks to not only Monkasho (annually fund support from 1996 to 2013) but also JSPS, the Commemorative Organization for the Japan World Exposition ('70), Japanese companies for their repeated support.

The old symposium was organized by International Organizing Committee of AROB and was co-operated by the Santa Fe Institute (USA), RSJ, IEEJ, ICASE (Now ICROS) (Korea), CAAI (P. R. China), ISCIE, IEICE, IEEE (Japan Council), JARA, and SICE. The old AROB symposium was growing up by absorbing many new knowledge and technologies into it. This history and character was inherited also from ICAROB2014(The 2014 International Conference on Artificial Life and Robotics, included a series of ICAROB proceedings indexed by SCOPUS and CPCI-Web of Science now. From now on, ALife Robotics Corporation Ltd. is in charge of management. This year we have The 2024 International Conference on Artificial Life and Robotics (ICAROB2024) (29th AROB Anniversary). The future of The ICAROB is brilliant from a point of view of yielding new technologies to human society in 21st century. I have founded Robot Artificial Life Society in 2017/12/07 together with Professor at Hiroshima University Takao Ito and Professor at University of Miyazaki Makoto Sakamoto. I hope that fruitful discussions and exchange of ideas between researchers during Conference (ICAROB2024) will yield new merged technologies for happiness of human beings and, hence, will facilitate the establishment of an international joint research institute on Artificial Life and Robotics in future.

Yingmin Jia

Co-General Chair of ICAROB

It is my great pleasure to invite you to The 2024 International Conference on Artificial Life and Robotics (ICAROB *2024*), will be held at J:COM Horuto Hall, Oita, JAPAN, from February 22 to 25, your understanding and support will be the strongest driving force for us to organize the meeting well.

ICAROB develops from the AROB that was created in 1996 by Prof. Masanori Sugisaka and will celebrate her 29th birthday in 2024. So far many important results have been presented at the past meetings and have a profound impact on artificial life and robotics. Doubtless, it is really one of the most famous international conferences in the field of artificial intelligence and attract wide interests among scientist, researchers, and engineers around the world.

For a successful meeting, many people have contributed their great efforts to the ICAROB. Here, I would like to express my special thanks to all authors and speakers, and the meeting organizing team for their excellent works. Looking forward to seeing you at the ICAROB2024.

Yingmin Jia
Co-General Chair
(Professor, Beihang University, P.R. China)

Takao Ito

Co-General Chair of ICAROB

It is my great honor and pleasure to invite you all to the 2024 International Conference on Artificial Life and Robotics (ICAROB 2024).

The ICAROB has its long history. First launched in 1996 as ISAROB, this former organization of ICAROB, was developed under the strong leadership and yeoman efforts of the President—the internationally famous Professor Masanori Sugisaka, who is widely acknowledged as the father of our AROB conference. Our conference has brought together many research scholars, faculty members, and graduate students from all over the world, and published numerous manuscripts in high-quality proceedings as well as highly reputed journals every year.

Over the years, dramatic improvements have been made in the field of artificial life and its applications. The ICAROB has provided a foundation for unifying the exchange of scientific information on the studies of man-made systems that exhibit the behavioral characteristics of natural living systems, including software, hardware, and wetware. Our conference shapes the development of artificial life, extending our empirical research beyond the territory circumscribed by life-as-we-know-it and into the domain of life-as-it-could–be. It will provide us a good place to present our new research results, innovative ideas, and valuable information about artificial intelligence, complex systems theories, robotics, and management of technology.

The conference site is Horuto Hall, one of the most famous international convention centers in Oita city, Japan. You can find many fantastic scenic spots and splendid historical places in Oita city. Enjoy your stay!

I eagerly look forward to personally meeting you during the ICAROB 2024 and to sharing a most pleasant, interesting, and fruitful conference with you. Do come and make this conference a fruitful, productive as well as enjoyable event!

Takao Ito
Co-General Chair
(Professor Hiroshima University, Japan)

Ju-Jang Lee

Co-General Chair of ICAROB

The First International Conference on Artificial Life and Robotics (ICAROB) was held in Oita City, Oita, Japan from Jan. 11th to 13th, 2014. This year's Conference will be held amidst the high expectation of the increasingly important role of the new interdisciplinary paradigm of science and engineering represented by the field of artificial life and robotics that continuously attracts wide interests among scientist, researchers, and engineers around the globe.

Distinguished researchers and technologists from around the world are looking forward to attending and meeting at ICAROB. ICAROB is becoming the annual excellent forum that represents a unique opportunity for the academic and industrial communities to meet and assess the latest developments in this fast-growing artificial life and robotics field. ICAROB enables them to address new challenges, share solutions, discuss research directions for the future, exchange views and ideas, view the results of applied research, present and discuss the latest development of new technologies and relevant applications.

In addition, ICAROB offers the opportunity of hearing the opinions of well-known leading experts in the field through the keynote sessions, provides the bases for regional and international collaborative research, and enables to foresee the future evolution of new scientific paradigms and theories contributed by the field of artificial life and robotics and associated research area. The twenty-first century will become the century of artificial life and intelligent machines in support of humankind and ICAROB is contributing through wide technical topics of interest that support this direction.

It is a great honor for me as a Co-General Chair of the 11th ICAROB 2024 to welcome everyone to this important event. Also, I would like to extend my special thanks to all authors and speakers for contributing their research works, the participants, and the organizing team of the 11th ICAROB.

I'm looking forward to meeting you at the 11th ICAROB in on line and wishing you all the best.

Ju-Jang Lee
Co-General Chair
(Honorary professor, KAIST)

GENERAL SESSION TOPICS

GS1 Machine Learning & Neural Network & Artificial Life (8)	GS2 Image Processing I (5)
GS3 Image Processing II (3)	GS4 Robotics (6)
GS5 Applications I (4)	GS6 Applications II (4)
GS7 Applications III (6)	

ORGANIZED SESSION TOPICS

OS1 Intelligent Life and Cybersecurity (6)	OS2 Pattern Recognition and Robotics I (5)
OS3 Pattern Recognition and Robotics II (9)	OS4 Pattern Recognition and Robotics III (10)

2/24(Sat.)	Room 303 on-site	Room 403 on-site	Room 404 on-site	Room 405 on-site, online (ZOOM ID: 851 9389 0058)	Room 406 on-site, online (ZOOM ID: 823 7614 7664)
9:40-	Registration (407)				
10:00-11:15	OS20-1 Advances in Field Robotics and Their Applications (5) Chair: Kazuo Ishii	OS17 Electronics and Kansei Engineering Based on ETT theory (5) Chair: Tetsuo Hattori	GS1-1 Machine Learning & Neural Network & Artificial Life (5) Chair: Hiroki Tamura	OS19 Natural Computing (3) Chair Marion Oswald Will be end at 10:45	OS18-1 Computer and Information Engineering (5) Chair: Norrima Mokhtar online, onsite
11:15-11:30	Coffee break				
11:30-12:00	OS20-2 Advances in Field Robotics and Their Applications (2) Chair: Kazuo Ishii		GS1-2 Machine Learning & Neural Network & Artificial Life (3) Chair: Hiroki Tamura Will be end at 12:15	OS22 Mathematical Informatics (8) from 11:00 to 13:00 Chair: Takao Ito	OS18-2 Computer and Information Engineering (2) Chair: Norrima Mokhtar online, on-site
12:00-13:00	Lunch				
13:00-14:00	Chair: Yingmin Jia (Room 302, 303) Plenary Speech PS3 Haruhisa Okuda				
14:00-14:15	Coffee break				
14:15-15:30	OS20-3 Advances in Field Robotics and Their Applications (5) Chair: Kazuo Ishii	OS27 Post-narratological Approaches to Cognition in Humans and Robots (5) Chair: Jumpei Ono (ZOOM ID: 826 8397 1634)	OS8 Intelligent Control (5) Chair: Yingmin Jia	OS5-1 Intelligent Life and Robotics (4) Chair: Kuo-Hsien Hsia on-site, online	OS18-3 Computer and Information Engineering (5) Chair: Norrima Mokhtar online, on-site
15:30-15:40	Coffee break				
15:40-16:25	OS20-4 Advances in Field Robotics and Their Applications (3) Chair: Kazuo Ishii		OS14 Robotic Manipulation (3) Chair: Kensuke Harada onsite, online (ZOOM ID: 849 1028 4955)	OS5-2 Intelligent Life and Robotics (2) Chair: Kuo-Hsien Hsia on-site, online	OS21 Human-Machine Interface (3) Chair Norrima Mokhtar online, on-site
16:25-16:40	Coffee break				
16:40-17:40	OS7 Deep Learning and its Applications (4) online Chair Mastaneh Mokayef (ZOOM ID: 824 3203 3781)	OS12 Machine Learning and its Applications (4) Chair: Masato Nagayoshi	GS5 Applications I (4) Chair: onsite, online (ZOOM ID: 849 1028 4955)	OS16 Industrial Artificial Intelligence Robotics (4) Chair Eiji Hayashi on-site	GS6 Applications II (4) Chair Masayuki Fujiwara on-site
18:30-20:30	Banquet (Tokiwa Kaikan)				

17

TIME TEBLE (2/25)

2/25(Sun.)	Room 405 online (ZOOM ID: 851 9389 0058)	Room 406 online (ZOOM ID: 823 7614 7664)	Room 407 online (ZOOM ID: 883 1147 2552)
9:40-	Registration (407)		
10:00-11:30	OS6 Intelligence and Optimization (5) Chair Mastaneh Mokayef	OS26-1 Navigating the Digital Frontier: Innovations in the Age of Industry Revolution 4.0 (6) Chair Wei Hong Lim	OS25-1 Research Towards the Sustainable Development Goals (SDG's) (5) Chair Ammar A.M. Al Talib
11:30-12:30	Lunch		
12:30-13:45	OS4-1 Pattern Recognition and Robotics III (5) Chair Huahao Li	OS26-2 Navigating the Digital Frontier: Innovations in the Age of Industry Revolution 4.0 (5) Chair Wei Hong Lim	OS25-2 Research Towards the Sustainable Development Goals (SDG's) (5) Chair Ammar A.M. Al Talib
13:45-14:00	Coffee break		
14:00-15:30	OS4-2 Pattern Recognition and Robotics III (5) Chair Huahao Li	OS11 Intelligent Life and Robotics (6) Chair: Evgeni Magid	GS7 Applications III (6) Chair: Kasthuri Subaramaniam
15:30-16:00	Farewell Party (Room 406 ZOOM ID: 823 7614 7664)		

The 2024 International Conference on
ARTIFICIAL LIFE AND ROBOTICS
(ICAROB2024)

February 22 (Thursday)

17:30-19:30   Welcome Party (Oita Century Hotel)

February 23 (Friday)

Room 302, 303
11:30-12:00 Opening Ceremony
Chair: Marion Oswald (Vienna University of Technology, Austria)

Welcome Addresses

1. General Chairman of ICAROB   Masanori Sugisaka (ALife Robotics Co., Ltd., Japan)
2. Co-General Chairman of ICAROB   Yingmin Jia (Beihang University, China)
3. Co-General Chairman of ICAROB   TaKao Ito (Hiroshima University, Japan)
4. Vice General Chair of ICAROB   Katia Passerini (Seton Hall University, USA)
5. Vice General Chair of ICAROB   Norrima Mokhtar (University of Malaya, Malaysia)

February 24 (Sunday)

Banquet: Tokiwa Kaikan
18:30-20:30
Chair: Takao Ito (Hiroshima University, Japan)
Welcome Addresses
Prof. Yingmin Jia (Beihang University, P.R. China)
Dr. Norrima Mokhtar (University of Malaya, Malaysia)

TECHNICAL PAPER INDEX

February 23 (Friday)

9:40-Registration

Room 302, 303
11:30-12:00 Opening Ceremony
Chair: Marion Oswald (Vienna University of Technology, Austria)

13:00-14:00
Plenary Speech PS1
Chair: Takao Ito (Hiroshima University, Japan)

PS1 *Developing High-Speed Working Motion of the Multi Robot in DENSO*
Tomoaki Ozaki (DENSO CORPORATION, Japan)

14:20-15:20
Plenary Speech PS2
Chair: Marion Oswald (Vienna University of Technology, Austria)

PS2 *Experimenting with Variable Arm Quadrotors: Realizing Dynamic Configurations for Enhanced Flight Performance*
Hazry Desa (Universiti Malaysia Perlis, Malaysia)

Room 403
10:00-11:15 OS24-Robotics and Intelligent Casting (5)
Chair: Jiwu Wang (Beijing Jiaotong University, China)

OS24-1   *A high-performance motion planning method based on asymptotically optimal RRT*
Tianbin Meng, Jiwu Wang (Beijing Jiaotong University, China)

OS24-2   CSM-RRT*: an improved RRT* algorithm based on constrained sampling mechanism
Hang Yang, Jiwu Wang (Beijing Jiaotong University, China)
Xueqiang Shang (Aero Engine Corporation of China, China)

OS24-3   *Small Sample Object Detection Based on Improved YOLOv5*
Yuxuan Gao (Beijing Jiaotong University, China),
Jiwu Wang (Beijing Jiaotong University, China),
Zixin Li (Aero Engine Corporation of China)

OS24-4   *Research on Gas Pore Prediction Method Based on Sand Core Characteristic Time*
Xiaolong Wang (Beijing Jiaotong University, China), Qihua Wu (Weichai Power Co., Ltd. China), Jiwu Wang (Beijing Jiaotong University, China), Jinwu Kang (Tsinghua University,China),
Na Li (Weichai Power Co., Ltd. China), Yucheng Sun(Weichai Power Co., Ltd. China)

OS24-5   *Optimization Analysis of a Deep Learning-Based Model for Predicting Temperature Fields in the Solidification Process of Castings*
Yahui Yang (Beijing Jiaotong University, China), Jiwu Wang (Beijing Jiaotong University, China),
Jinwu Kang (Tsinghua University,China)

15:40-17:10 OS1 Intelligent Life and Cybersecurity (6)
Chair: I-Hsien Liu (National Cheng Kung University, Taiwan)
Co-Chair: Chu-Fen Li (National Formosa University, Taiwan)
Co-Chair: Pang-Wei Tsai (National Cheng Kung University, Taiwan)

OS1-1   *Detecting abnormal operations in ICS using finite-state machines*
Pei-Wen Chou, Nai-Yu Chen, Jung-Shian Li, I-Hsien Liu
(National Cheng Kung University, Taiwan)

OS1-2   *Industrial Control System State Monitor Using Blockchain Technology*
Yun-Hao Chang, Tzu-En Peng, Jung-Shian Li, I-Hsien Liu
(National Cheng Kung University, Taiwan)

OS1-3   *Enhancing Dam Security and Water Level Alerting with Blockchain Technology*
YingCheng Wu, Jung-Shian Li, Chu-Fen Li, I-Hsien Liu
(National Cheng Kung University, Taiwan)

OS1-4   *MiniDAM: A Dam Cybersecurity Toolkit*
Tzu-En Peng, Meng-Wei Chang, Yun-Hao Chang, Jung-Shian Li, I-Hsien Liu
(National Cheng Kung University, Taiwan)

OS1-5   *Case Study of Network-Based Intrusion Detection System Deployment in Industrial Control Systems with Network Isolation*
Nai-Yu Chen, Pei-Wen Chou, Jung-Shian Li, I-Hsien Liu
(National Cheng Kung University, Taiwan)

OS1-6   *The AI integration service innovation model of real estate industry in Taiwan*
Li-Min Chuang, Chih-Hung Chen (Chang Jung Christian University, Taiwan)

Room 404
10:00-11:00 OS9 Software Development Support Method (4)
Chair: Tetsuro Katayama (University of Miyazaki, Japan)
Co-Chair: Tomohiko Takagi (Kagawa University, Japan)

OS9-1   *An Improved Conversion Technique from EPNAT Models to VDM++ Specifications for Simulation of Abstract Software Behavior*
Sho Matsumoto[1], Ryoichi Ishigami[1], Tetsuro Katayama[2], Tomohiko Takagi[1]
[1] Kagawa University, Japan, [2] University of Miyazaki, Japan

OS9-2   *Prototype of RAGESS Which Is a Tool for Automatically Generating SwiftDiagrams to Support iOS App Development*
Haruki Onaga*, Tetsuro Katayama*, Yoshihiro Kita†, Hisaaki Yamaba*, Kentaro Aburada*, and Naonobu Okazaki*
*University of Miyazaki, Japan, †University of Nagasaki, Japan

OS9-3   *Extension to Support Types and Operation/Function Definitions in BWDM to Generate Test Case Tool from the VDM++ Specification*
Shota Takakura*, Tetsuro Katayama*, Yoshihiro Kita†, Hisaaki Yamaba*, Kentaro Aburada*, and Naonobu Okazaki*
*University of Miyazaki, Japan, †University of Nagasaki, Japan

OS9-4   *Proposal of ASLA Which Is a Segmentation and Labeling Tool for Document Images Based on Deep Learning*
Kanta Kakinoki*, Tetsuro Katayama*, Yoshihiro Kita†, Hisaaki Yamaba*, Kentaro Aburada*, and Naonobu Okazaki*
*University of Miyazaki, Japan, †University of Nagasaki, Japan

15:40-17:10 OS15 Artificial Intelligence for Embedded Systems and Robotics (6)
Chair: Hakaru Tamukoh (Kyushu Institute of Technology, Japan)
Co-Chair Yuma Yoshimoto (National Institute of Technology, Kitakyushu College, Japan)

OS15-1   *YOLO real-time object detection on EV3-Robot using FPGA hardware Accelerator*
Dinda Pramanta[1], Ninnart Fuengfusin[2], Arie Rachmad Syulistyo[2], Hakaru Tamukoh[2]
([1]Kyushu Institute of Information Sciences, Japan) ([2]Kyushu Institute of Technology, Japan)

OS15-2   *A Low Computational Cost Hand Waving Action Recognition System with Echo State Network for Home Service Robots*
Hiromasa Yamaguchi[1], Akinobu Mizutani[1], Arie Rachmad Syulistyo[1], Yuichiro Tanaka[1], Hakaru Tamukoh[1] ([1]Kyushu Institute of Technology, Japan)

OS15-3   *A Rapidly Adjustable Object Recognition System through Language Based Prompt Engineering*
Naoki Yamaguchi[1], Tomoya Shiba[1], Kosei Isomoto[1], Hakaru Tamukoh[1]
([1]Kyushu Institute of Technology, Japan)

OS15-4   *Development of a SayCan-based task planning system capable of handling abstract nouns*
Kosei Yamao[1], Daiju Kanaoka[1], Kosei Isomoto[1], Akinobu Mizutani[1], Yuichiro Tanaka[1], Hakaru Tamukoh[1], ([1]Kyushu Institute of Technology, Japan)

OS15-5   *RoboCup@Home 2023: Stickler for the Rules Task Solutions*
Tomoya Shiba[1], Hakaru Tamukoh[1], ([1]Kyushu Institute of Technology, Japan)

OS15-6   *Offloading Intellectual Processing from Home Service Robots to Edge Devices*
Yuma Yoshimoto[1], Mizuki Kawashima[1], Shun Yonehara[1]
([1]National Institute of Technology, Kitakyushu College, Japan)

Room 405
10:00-11:15 GS2 Image Processing I (5)
Chair: Yui Tanjo (Kyushu Institute of Technology, Japan)

GS2-1   *A Method for Embedding Multiple Photographic Images in a Photographic Image*
Naoki Kouno, Kanya Goto, Toru Hiraoka (University of Nagasaki, Japan)

GS2-2   *Generation of Flowing-Line Images Using Vertical and Horizontal Smoothing Filters*
Karin Kuroki, Toru Hiraoka (University of Nagasaki, Japan)

GS2-3   *Human Motion Recognition from Multiple Directions and Its Gait Cycles Analysis*
Miki Ooba, Yui Tanjo (Kyushu Institute of Technology, Japan)

GS2-4   *A Method of Improving the QOL of the People with Visual Impairment by MY VISION*
Shun Kitazumi, Yui Tanjo (Kyushu Institute of Technology, Japan)

GS2-5   *Human Behavior Segmentation and Recognition Using a Single-camera*
Jing Cao, Yui Tanjo (Kyushu Institute of Technology, Japan)

15:40-17:10 GS4 Robotics (6)
Chair: Jiwu Wang (Beijing Jiaotong University, China)

GS4-1   *Development and evaluation of a learning support robot for vector learning*
Kosei Machida, Shinichi Imai (Tokyo Gakugei University, Japan)

GS4-2   *Feasibility Study on Methods to Measure the Strain on Young Children's Bodies*
Sachiko Kido, Praveen Nuwantha Gunaratne, Hiroki Tamura
(University of Miyazaki, Japan)

GS4-3 *An Integration of Contact Force Models with Multibody Dynamics Analyses for Human Joint Mechanisms and Effects of Viscoelastic Ground Contact*
Shintaro Kasai[1], Dondogjamts Batbaatar[2], Hiroaki Wagatsuma[1]
([1]Kyushu Institute of Technology, Japan; [2]Mongolian University of Science and Technology, Mongolia)

GS4-4 *Haptic Sensation Enhancement via the Stochastic Resonance Effect and Its Application to Haptic Feedback for Myoelectric Prosthetic Hands*
Yoshitaka Mizumoto, Taro Shibanoki (Okayama University, Japan)

GS4-5 *PID Parameter Tuning of a Low-Cost DC Motor Speed Control for Mobile Robot Application*
Munkh-Erdene Ayurzana[1], Erkhembayar Gankhuyag1, Naranbaatar Erdenesuren[1], Dondogjamts Batbaatar[1]
([1]Mongolian University of Science and Technology, Mongolia)

GS4-6 *Reinforcement Learning DDPG Algorithm Based Wheeled Mobility Aid Robot Control Methods*
Junkai Li, Mohd Rizon Mohamad Juhari, Tiang Sew Sun (UCSI University, Malaysia)

Room 406
10:00-11:15 OS23 Industrial Revolution (5)
Chair: Hazry Desa (Universiti Malaysia Perlis (UniMAP), Malaysia)

OS23-1 *Investigating the Engineering Interventions in the Conservation of Malaysia Heritage Structures: A Review on Preserving Historical Edifices Through Advance Civil Engineering Techniques*
Muhammad Azizi Azizan, Nurfadzillah Ishak, Hazry Desa (UniMAP, Malaysia)

OS23-2 *Drones and Data: A Comprehensive Exploration of UAVs in Data Mining*
Muhammad Azizi Azizan, Nurfadzillah Ishak, Hazry Desa (UniMAP, Malaysia)

OS23-3 *Development of Variable Arm to Control the Manoeuvrability of Quadrotor*
L. Y. Hong, H. Desa and M. A. Azizan (UniMAP, Malaysia)
M. H. Tanveer (Kennesaw State University, USA)

OS23-4 *Development of IOT-Enabled Smart Water Metering System*
S. D. Wen, H. Desa and M. A. Azizan (UniMAP, Malaysia)
A. -S. T. Hussain (Al-Kitab University, Iraq)
M. H. Tanveer and R. Patan (Kennesaw State University, USA)

OS23-5 *Object Detection and Instance Segmentation with YOLOV8: Progress and Limitations*
L. J. Lee, H. Desa and M. A. Azizan (UniMAP, Malaysia)
A. -S. T. Hussain (Al-Kitab University, Iraq)
M. H. Tanveer (Kennesaw State University, USA)

11:30-12:45 OS2 Pattern Recognition and Robotics I (5)
Chair: Fengzhi Dai (Tianjin University of Science and Technology, China)
Co-Chair: Yunzhong Song (Henan Polytechnic University, China)

OS2-1 *A Study on Sales Patterns for Vegetable Products in Retail Stores*
Yuhao Zhang [1], Shuangshuang Ma [1], Jiashuai Wang [1], Fengzhi Dai [1], Lijiang Zhang [2]
([1] Tianjin University of Science and Technology, China, [2] Xinjiang Shenhua Biotechnology Co., Ltd, China)

OS2-2 *Research and Implementation of Cooperative Control for ROS Mobile Robot*
Saijie Zhang, Huailin Zhao
(Shanghai Institute of Technology, China)

OS2-3 *An OpenCV-based Method for Workpiece Residue Image Processing*
Jiaxin Wang, Hao He, Fangyv Liu, Fengzhi Dai
(Tianjin University of Science and Technology, China)

OS2-4 *On Nonblockingness Verification and Enforcement of Controlled Nondeterministic Discrete-Event Systems*
Xiang Ren, Zipei Wang (Tianjin University of Science and Technology, China)

OS2-5 *Modeling and Reachability Verification of Controlled Nondeterministic Finite-State Automata*
Zipei Wang, Xiang Ren (Tianjin University of Science and Technology, China)

15:40-16:25 GS3 Image Processing II (3)
Chair: Seiji Ishikawa (Kyushu Institute of Technology, Japan)

GS3-1 *Online Classroom Student Engagement Analysis using Enhanced YOLOv5*
Shuai Wang, Abdul Samad Shibghatullah (UCSI University, Malaysia)

GS3-2 *A Method of Recognizing Body Movements Based on a Self-viewpoint Video*
Iichirou Moribe, Yui Tanjo (Kyushu Institute of Technology, Japan)

GS3-3 *Supporting Safe Walk of a Visually Impaired Person at a Station Platform based on MY VISION*
Shintaro Yamada, Yui Tanjo, Seiji Ishikawa (Kyushu Institute of Technology, Japan)

Room 407
10:00-11:15 OS13-1 Robot Control (5)
Chair: Yizhun Peng (Tianjin University of Science and Technology, China)

OS13-1   *Intelligent Logistics Handling Robot: Design, Control, and Recognition*
Yanchao Bi, Jiale Cheng, Limei Wang, Yizhun Peng
(Tianjin University of Science and Technology, China)

OS13-2   *Greenhouse Design Using Visual Recognition and IoT Technology*
Yuntian Xia, Yizhun Peng
(Tianjin University of Science and Technology, China)

OS13-3   *Design of Modular Photovoltaic Environmentally Friendly Portable Stroller*
Suqing Duan, Yizhun Peng
(Tianjin University of Science and Technology, China)

OS13-4   *"Teenage Mutant Ninja Turtles" - Design of a Bionic Quadrupedal Rescue Robot*
Hongpi Zhao, Yingfan Zhu, Zhihan Zhao, Xin Liang, Lei Lv, Yizhun Peng (Tianjin University of Science and Technology, China)

OS13-5   *Design of Grass Lattice Planter for Complex Environment Based on Adaptive Suspension Technology*
Shaokai Tian, Wenqi Fu, Yizhun Peng
(Tianjin University of Science and Technology, China)

11:30-12:45 OS13-2 Robot Control (5)

Chair: Yizhun Peng (Tianjin University of Science and Technology, China)

OS13-6   *Design of Intelligent Ecological Multifunctional Plant and Animal Breeding System*
Suqing Duan, Yuntian Xia, Siyi Wang, Yizhun Peng (Tianjin University of Science and Technology, China)

OS13-7   *Design of a Fully Automated Logistics Handling Platform*
Hongpi Zhao, Jianfeng Qin, Yizhun Peng (Tianjin University of Science and Technology, China)

OS13-8   *Design and Application of AI-based Brush Calligraphy and Painting Robot*
Haibo Li, Yizhe Sun, Shuxin Wang, Yizhun Peng (Tianjin University of Science and Technology, China)

OS13-9   *Intelligent Wheelchair System: Non-contact Heart Rate and Body Temperature Measurement*
Dongpo Ma, Junsheng Zhang, Yizhun Peng (Tianjin University of Science and Technology, China)

OS13-10   *Recognition and Localization Method for Automotive Axle Holes in Assembly Robots*
Junsheng Zhang, Dongpo Ma, Yizhun Peng (Tianjin University of Science and Technology, China)

13:00-14:15 OS3-1 Pattern Recognition and Robotics II (5)

Chair: Fangyan Li (Tianjin University of Science and Technology, China)

Co-Chair: Haozhe Sun (Tianjin University of Science and Technology, China)

OS3-1   *Detection and Identification of Daylily Maturity Based on YOLOv8*
Fangyan Li (Tianjin University of Science and Technology, China)

OS3-2   *Chaos Synchronization and Circuit Design of Chen System and Lü System with Different Structures*
Haozhe Sun (Tianjin University of Science and Technology, China)

OS3-3   *A Parking Space Recognition Method Based on Digital Image Technology*
Hao He, Fangyv Liu, Jiaxin Wang (Tianjin University of Science and Technology, China)

OS3-4   *A Design of Intelligent Handling Robot Based on AT89C52*
Fangyv Liu, Jiaxin Wang, Hao He (Tianjin University of Science and Technology, China)

OS3-5   *Application and Differences of Robotic Arms, Traditional Machines and Manual Work in Production*
Xue Yang, Ying Su, Yuping Mei, Haiquan Wang (Tianjin University of Science and Technology, China)

14:20-15:20 OS3-2 Pattern Recognition and Robotics II (4)

Chair: Fangyan Li (Tianjin University of Science and Technology, China)

Co-Chair: Haozhe Sun (Tianjin University of Science and Technology, China)

OS3-6   *A Deep Exploration of the Mounting Issues Related to Six Rotor UVA*
Yuping Mei, Ying Su, Xue Yang (Tianjin University of Science and Technology, China)

OS3-7   *The Application of Hexacopter UAV in The Field of Climbing Evasion*
Ying Su, Yuping Mei, Xue Yang (Tianjin University of Science and Technology, China)

OS3-8   *Deep Learning and Embedded Based Operational Safety System for Special Vehicles*
Haoran Gong, Yumei Huang, Jiahao Xie (Tianjin University of Science and Technology, China)

OS3-9   *"Green Fruit" - Intelligent Traceable Agricultural Product Production and Marketing Platform Based on Blockchain Technology*
Yumei Huang, Jiahao Xie, Haoran Gong, Ziyue Xiao (Tianjin University of Science and Technology, China)

15:40-17:10 OS10 Intelligent Life and Robotics (6)
Chair: Evgeni Magid (Kazan Federal University, Russia)
Co-Chair: Kuo-Hsien Hsia (National Yunlin University of Science and Technology, Taiwan)

OS10-1   *A Design of a Modular Mobile Robot for Rescue Operations*
Baris Celiker, Shifa Sulaiman, Tatyana Tsoy (Kazan Federal University, Russia)

OS10-2   *Implementation of Bug1 and Bug2 Path Planning Algorithms for TurtleBot Using ROS Noetic*
Ilya Spektor[1], Aidar Zagirov[2], Ramil Safin[2], Evgeni Magid[1,2]
([1]HSE University, Russia) ([2]Kazan Federal University, Russia)

OS10-3   *Implementation of Alg1 and Alg2 Path Planning Algorithms for Mobile Robots Using ROS Noetic*
Anastasia Yankova1, Timur Gamberov[2], Tatyana Tsoy[2]
([1]HSE University, Russia) ([2]Kazan Federal University, Russia)

OS10-4   *Implementation of VisBug-21 and VisBug-22 Path Planning Algorithms Using ROS Noetic*
Viktoriia Mirzoian[1], Maxim Mustafin[2], Evgeni Magid[1,2]
([1]HSE University, Russia) ([2]Kazan Federal University, Russia)

OS10-5   *DistBug path planning algorithm package for ROS Noetic*
Alexander Pak[1], Alexander Eremin[2], Tatyana Tsoy[2]
([1]HSE University, Russia) ([2]Kazan Federal University, Russia)

OS10-6   *On sensor modeling in Gazebo simulator*
Niez Yuldashev, Alexandra Dobrokvashina, Roman Lavrenov
(Kazan Federal University, Russia)

February 24 (Saturday)
9:40-Registration

Room 302, 303
13:00-14:00
Plenary Speech PS3
Chair: Yingmin Jia

PS3 *Artificial Intelligence and Technologies of Arm-type and Mobile Robots in Industry*

Haruhisa Okuda

(Mitsubishi Electric Corporation, Japan)

Room 303
10:00-11:15 OS20-1 Advances in Field Robotics and Their Applications (5)
Chair: Kazuo Ishii (Kyushu Institute of Technology, Japan)
Co-Chair: Keisuke Watanabe (Tokai University, Japan)

OS20-1 *Image Collection Experiments of a Handy AUV for Offshore Structure Inspection*
Keisuke Watanabe, Koki Amano, Shingen Urano, Yasutaka Taniguchi, Konosuke Watanabe (Tokai University, Japan)

OS20-2 *Design of Disassembly-reassembly Type USV for Coral Reef Research*
Keisuke Watanabe, Koki Amano, Gaku Minato, Yasutaka Taniguchi, Konosuke Watanabe (Tokai University, Japan)

OS20-3 *Optimization method to improve visual SLAM in dynamic environment*
Yufei Liu, Kazuo Ishii (Kyushu Institute of Technology, Japan)

OS20-4 *Design of flexible mechanism for flexible manipulator*
Huang Jiawei, Kazuo Ishii (Kyushu Institute of Technology, Japan)

OS20-5 *Driver Drowsiness Detection Method based on Deep Learning*
Shi Puwei, Kazuo Ishii (Kyushu Institute of Technology, Japan)

11:30-12:00 OS20-2 Advances in Field Robotics and Their Applications (2)
Chair: Kazuo Ishii (Kyushu Institute of Technology, Japan)
Co-Chair: Keisuke Watanabe (Tokai University, Japan)

OS20-6 *An Analysis of Translational Motion for a Mobile Robot with Line-Symmetric Rollers Arrangement*
[1]Kenji Kimura, [2]Kazuo Ishii
([1]National Institute of Technology, Matsue College, Japan, [2]Kyushu Institute of Technology, Japan)

OS20-7 *Development of Teaching Materials for Robot Programming for Junior High School Students: Student-Based Educational Activities*
Kenji Kimura, Youta Takano (National Institute of Technology, Matsue College, Japan)

14:15-15:30 OS20-3 Advances in Field Robotics and Their Applications (5)
Chair: Kazuo Ishii (Kyushu Institute of Technology, Japan)
Co-Chair: Keisuke Watanabe (Tokai University, Japan)

OS20-8 *Design and Software Production of Robotics Educational Design for Elementary and Junior High School Student*
Youta Takano, Kenji Kimura (National Institute of Technology, Matsue College, Japan)

OS20-9 *Development of visual inspection system for low-reflective material utilizing of a string shadow*
Keiji Kamei[1], Tomorou Kawahara[1], Yoshiyuki Daimaru[2]
([1]Nishinippon Institute of Technology, Japan) ([2]Nissan Motor Kyushu, Japan)

OS20-10 *Development of IoT-Based Remote Monitoring Module for Greenhouse Environment to Facilitate Crop Growth Data Analysis*
Moeko Tominaga, Yasunori Takemura, Junya Era, Wataru Kaishita
(Nishinippon Institute of Technology, Japan)
Eiji Mizoe, Tomoyasu Furukawa
(Kumamoto Fruit and Vegetable Shippers Association Co. Ltd., Japan)

OS20-11 *Development greenhouse environment prediction system using IoT data*
Yasunori Takemura, Naoya Nishida, Moeko Tominaga
(Nishinippon Institute of Technology, Japan)
Eiji Mizoe, Tomoyasu Furukawa
(Kumamoto Fruit and Vegetable Shippers Association Co. Ltd., Japan)

OS20-12 *The Development of SaaS for Quantifying the Amount of Drifted Debris on the Coast*
Ayumu Tominaga, Ryohei Komori
(National Institute of Technology Kitakyushu College, Japan)
Eiji Hayashi (Kyushu Institute of Technology, Japan)

15:40-16:25 OS20-4 Advances in Field Robotics and Their Applications (3)
Chair: Kazuo Ishii (Kyushu Institute of Technology, Japan)
Co-Chair: Keisuke Watanabe (Tokai University, Japan)

OS20-13   *Development of an antagonistic wire-driven joint mechanism capable of rapid motion and variable stiffness*
Katsuaki Suzuki[1], Yuya Nishida[2], Kazuo Ishii[2]
([1]Kumamoto Industrial Research Institute, Japan, [2]Kyushu Institute of Technology, Japan)

OS20-14   *Gakken Hills Interdisciplinary Ekiden Competing with Humans, Animals, and Robots*
Takuya Fujinaga[1], Moeko Tominaga[2], Daigo Katayama[3], Kazuo Ishii[3]
([1]Fukuoka University, [2]Nishinippon Institute of Technology, [3]Kyushu Institute of Technology, Japan)

OS20-15   *Development of a Low-Cost Underwater Robot for Research and Education*
Takuya Fujinaga (Fukuoka University Japan)

16:40-17:40 OS7 Deep Learning and its Applications (4)

Chair: Mastaneh Mokayef (UCSI University, Malaysia)

Co-Chair: Takao Ito (Hiroshima University, Japan)

OS7-1   *Parallel Cross Window Attention Transformer and CNN Model for Segmentation of Instrument during Surgery*
Abdul Qayyum[1], M. K. A. Ahamed Khan[3], Moona Mazher[4], Imran Razzak[5], Steven Niederer[1,2], Mastaneh Mokayef[3], C.S. Hassan[3], Ridzuan, A.[3]
([1]Imperial College, London, United Kingdom) ([2]The Alan Turning Institute, London, UK) ([3]UCSI University, Malaysia) ([4]University College London, UK) ([5]University of New South Wales, Australia)

OS7-2   *Magnetic Resonance Spectroscopy (MRS) Reconstruction using Style Transfer Deep Depth wise Framework*
Abdul Qayyum[1], M. K. A. Ahamed Khan[3], Moona Mazher[4], Imran Razzak[5], Steven Niederer[1,2], Mastaneh Mokayef[6], C.S. Hassan[6], Ridzuan, A.[6]
([1]Imperial College, London, UK) ([2]The Alan Turning Institute, UK)
([3,6] UCSI University, Malaysia) ([4]University College London, UK)
([5]University of New South Wales, Australia)

OS7-3   *Federated Learning on Brain Disease Research: Segmentation of Cerebral Small Vessel Diseases (CSVD) using Multi-scale Hybrid Spatial Deep Learning Approach*
Moona Mazher[1], Abdul Qayyum[2], M. K. A. Ahamed Khan[3], Steven Niederer[2,4], Mastaneh Mokayef[3], Ridzuan, A[3], C. S. Hassan[3] ([1]University College London, UK) ([2]National Heart & Lung Institute, Imperial College, London, UK) ([3]UCSI University, Malaysia) ([4]Alan Turning Institute, London, UK)

OS7-4 *Hybrid Classical and Quantum Deep Learning Models for Medical Image Classification*
Moona Mazher[1], Abdul Qayyum[2], M. K. A. Ahamed Khan[3], Steven Niederer[2,4], Mastaneh Mokayef[3], Ridzuan, A[3], C. S. Hassan[3] ([1]University College London, UK,) ([2]National Heart & Lung Institute, Imperial College, UK) ([3]UCSI University, Malaysia) ([4]Alan Turning Institute, UK)

Room 403
10:00-11:15 OS17 Electronics and Kansei Engineering Based on ETT theory (5)
Chair: Tetsuo Hattori (Kagawa University, Hiroshima Institute of Technology, Japan)
Co-Chair: Yusuke Kawakami (NIT (Kagawa College), Japan)

OS17-1 *A High-Speed Estimation Method of Parameters in Impulse Response*
Toshiki Tanaka, Ivan Tanev (Doshisha University, Japan), Tetsuo Hattori (Kagawa University, Japan)

OS17-2 *A Consideration on Amplification Function in BJT Evers-Moll Model and PTT (I) ---- V-I Characteristics ----*
Shimon Hattori, Osamu Matoba (Kobe University, Japan), Tetsuo Hattori (Kagawa University, Japan), Toshiki Tanaka (Kinkei System, Japan), Yusuke Kawakami (NIT (Kagawa College), Japan)

OS17-3 *A Consideration on Amplification Function in BJT Evers-Moll Model and PTT (II) ---- H Parameters in the Small Signal Amplifier Circuit----*
Shimon Hattori, Osamu Matoba (Kobe University, Japan), Tetsuo Hattori (Kagawa University, Japan), Toshiki Tanaka (Kinkei System, Japan), Yusuke Kawakami (NIT (Kagawa College), Japan)

OS17-4 *Color Image Arrangement Using Histogram Matching*
Yusuke Kawakami (NIT (Kagawa College), Japan), Tetsuo Hattori (Kagawa University, Japan), R.P.C. Janaka Rajapakse (Tainan National University of the Arts, Taiwan (R.O.C.))

OS17-5 *Methodology for Creativity Oriented STEM Education Based on ETT Theory*
Tetsuo Hattori, Toshihiro Hayashi, Mai Hattori, Yoshiro Imai (Kagawa University, Japan), Asako Ohno (Osaka Sangyo University, Japan), Takeshi Tanaka (Hiroshima Institute of Technology, Japan)

14:15-15:30 OS27 Post-narratological Approaches to Cognition in Humans and Robots (5)
Chair: Jumpei Ono (Aomori University, Japan)
Co-Chair: Hiroki Fxyma (Kobe University, Japan)

OS27-1   *A Game Framework Based on the Disinformation Warfare in Russo-Ukrainian War*
Jumpei Ono (Aomori University, Japan), Takashi Ogata (Iwate Prefectural University, Japan)

OS27-2   *Comparative Analysis of Eye Tracking between Veteran and Novice during Radiological Interpretation*
Yuka Naito (Chuo University, Japan), Jun Nakamura (Chuo University, Japan), Yoshinobu Ishiwata (Yokohama City University, Japan)

OS27-3   *Development of Notification System to Prevent Working Productivity from Declining Caused by Increased Carbon Dioxide Concentration*
KAMODA Yohei, NAKAMURA Jun (CHUO University, Japan)

OS27-4   *Visualization of the Skilled Physician's Gaze Characteristic during Diagnosis*
Taiki Sugimoto (Chuo University, Japan), Jun Nakamura (Chuo University, Japan), and Yoshinobu Ishiwata (Yokohama City University, Japan)

OS27-5   *Comparative Analysis of Methods for Visualizing the Sensory Experience of Food and Beverages*
Hiroki Fxyma (Kobe University, Japan)

16:40-17:40 OS12 Machine Learning and its Applications (4)
Chair: Masato Nagayoshi (Niigata College of Nursing, Japan)
Co-Chair Takashi Kuremoto (Nippon Institute of Technology, Japan)

OS12-1   *Restoration of Guqin Music by Deep Learning Methods*
Takashi Kuremoto*, Kazuma Fujino*, Hirokazu Takahashi*, Shun Kuremoto**, ***,
Mamiko Koshiba**, Hiroo Hieda***, Shingo Mabu**
(*Nippon Institute of Technology, **Yamaguchi University, ***Institute for Future Engineering, Japan)

OS12-2   *Constructive Nurse Scheduling Using Reinforcement Learning Considering Variations in Nurse Work Patterns*
Masato Nagayoshi (Niigata College of Nursing, Japan),
Hisashi Tamaki (Kobe University, Japan)

OS12-3   *A Basic Study on Indicator of Transfer Learning for Reinforcement Learning*
Satoshi Sugikawa, Kenta Takeoka, Naoki Kotani
(Osaka Institute of Technology, Japan)

OS12-4   *Machine Learning Approach to Predict Cooling Load for Existing Buildings*
Makoto Ohara*, Hideo Isozaki**
(*International Professional University of Technology in Osaka, Japan,
**Kobe University, Japan)

Room 404
10:00-11:15 GS1-1 Machine learning& Neural Network & Artificial Life (5)
Chair: Hiroki Tamura (University of Miyazaki, Japan)

GS1-1   *Deep Learning Based Prediction of Heat Transfer Coefficient Using Spectrogram Images from Boiling Sound*
Fuga Mitsuyama, Ren Umeno, Tomohide Yabuki, Tohru Kamiya (Kyushu Institute of Technology, Japan)

GS1-2   *A Study on Classification of Faulty Motor Sound Using Convolutional Neural Networks*
Jamil Md Shafayet, Praveen Nuwantha Gunaratne, Hiroki Tamura
(University of Miyazaki, Japan)

GS1-3   *Design and Development of a Flexible Active Ankle Joint Orthosis for Locomotion Assistance*
Praveen Nuwantha Gunaratne, Hiroki Tamura (University of Miyazaki, Japan)

GS1-4 *A study on the Real-Time Biomechanical Analysis of Lamber Burden Utilizing Stereoscope Cameras*
Taufik Hidayat Soesilo, Praveen Nuwantha Gunaratne, Hiroki Tamura
(University of Miyazaki, Japan)

GS1-5 *Verification of Determination Possibility using Convolutional Autoencoder for Machine Tool Abnormality Detection*
Yuta Sumoto, Praveen Nuwantha, Hiroki Tamura (University of Miyazaki, Japan)

11:30-12:15 GS1-2 Machine learning& Neural Network & Artificial Life (3)
Chair: Hiroki Tamura (University of Miyazaki, Japan)

GS1-6 *Basic Research for High-speed Heart Sound Determination using AI*
Riku Nakashima, Praveen Nuwantha Gunaratne, Hiroki Tamura
(University of Miyazaki, Japan)

GS1-7 *Prediction of High-Energy Electron Flux at Geosynchronous Orbit using a neural network technique*
Ami Iwabu, Kentaro Kitamura (Kyusyu Institute of Technology, Japan)

GS1-8 *Image Gradient-based Monocular Visual-Inertial Odometry*
Tae Ihn Kim (Hyundai Motor Company, Republic of Korea), Jae Hyung Jung, and Chan Gook Park (Seoul National University, Republic of Korea)

14:15-15:30 OS8 Intelligent Control (5)
Chair: Yingmin Jia (Beihang University, China)
Co-Chair: Weicun Zhang (University of Science and Technology Beijing, China)

OS8-1 *Global Stabilization of A Class of Nonholonomic Integrators via Discontinuous Control*
Lixia Yan, Yingmin Jia (Beihang University (BUAA), China)

OS8-2 *Frequency Dependence Performance Limit of Vibration Absorbers*
Jiqiang Wang[1], Xiaoyu Yin[2], Weicun Zhang[3]
([1]Chinese Academy of Sciences, China)
([2]Science & Technology Bureau of Zhenhai District, China)
([3]University of Science and Technology Beijing, China)

OS8-3 *Adaptive Concurrent Learning Algorithm Based on Pontryagin's Maximum Principle for Nonlinear System Optimal Tracking Control with State Inequality Constraints*
Yuqi Zhang, Bin Zhang (Beijing University of Posts and Telecommunications, China)

OS8-4   *Privacy preserving Mean-square consensus for discrete-time heterogeneous multi-agent systems with Communication Noises*
Tongqing Yang[1], Lipo Mo[1], Yingmin Jia[2]
([1]Beijing Technology and Business University, China)
([2]Beihang University (BUAA), China)

OS8-5   *Event-Triggered Consensus Control for Nonlinear Singular Multi-Agent Systems under Directed Topology*
Lin Li, Tong Yuan, Mei Huang
(University of Shanghai for Science and Technology, China)

15:40-16:25 OS14 Robotic Manipulation (3)
Chair: Kensuke Harada (Osaka University, Japan)
Co-Chair: Akira Nakamura (Saitama Institute of Technology, Japan)
Co-Chair: Tokuo Tsuji (Kanazawa University, Japan)

OS14-1   *Evaluation Standard of Error Recovery Planning Focused on Revival Process from Failures in Robotic Manufacturing Plants*
Akira Nakamura[1], Kensuke Harada[2]
([1]Saitama Institute of Technology, [2]Osaka University, Japan)

OS14-2   *Robotic Food Handling Utilizing Temperature Dependent Variable-Stiffness Material*
Rozilyn Marco[1], Prashant Kumar[2], Xinyi Zhang[2], Weiwei Wan[2] , Kensuke Harada[2]
([1]University of Toronto, Canada, [2]Osaka University, Japan)

OS14-3   Vegetable maturity evaluation for harvest robots
Reno Muhammad Fadilla, Tokuo Tsuji, Tatsuhiro Hiramitsu, and Hiroaki Seki
(Kanazawa University, Japan)

16:40-17:40 GS5 Applications I (4)
Chair: Chair Jiwu Wang (Beijing Jiaotong University, China)

GS5-1   *Unsupervised image registration based on Residual-connected DRMINE for diagnostic metastatic bone tumors*
Shogo Baba[1], Tohru Kamiya[1], Takashi Terasawa[2], Takatoshi Aoki[2]
([1]Kyushu Institute of Technology, Japan), ([2]University of Occupational and Environmental Health, Japan)

GS5-2   *Developing a smart Belt for Monitoring Elderly Activities Based on Multi-Modal Sensors Integration*
and Internet of Things
Abdul Jalil, Pujianti Wahyuningsih, Najirah Umar, Muhammad Risal, Suwatri Jura, A. Edeth Fuari Anatasya (Universitas Handayani Makassar, Indonesia)

GS5-3   *A penalized motion detection model for extracting ionospheric echoes from low signal-to-noise ratio Ionogram video images*
Yuu Hiroshige[1], Akiko Fujimoto[1], Akihiro Ikeda[2], Shuji Abe[3], Akimasa Yoshikawa[3]
([1]Kyushu Institute of Technology, Japan) ([2]National Institute of Technology, Kagoshima College, Japan), (3Kyushu University, Japan)

GS5-4   *Verification Experiments on the Lower Back Burden caused by Posture and Environment during Lifting Operations*
Tomoka Kimura, Yutaro Fujino, Sachiko Kido, Praveen Nuwantha Gunaratne, Hiroki Tamura
(University of Miyazaki, Japan)

Room 405
10:00-10:45 OS19 Natural Computing (3)
Chair: Marion Oswald (Vienna University of Technology, Austria)
Co-Chair: Yasuhiro Suzuki (Nagoya University, Japan)

OS19-1   *A Model of Reaction-diffusion phenomena with Multiset Processing*
Yasuhiro Suzuki (Nagoya University Japan)

OS19-2   *Extract tactile qualities from time series data*
Yasuhiro Suzuki (Nagoya University, Japan)

OS19-3   *Healthcare applications of vibrotactile stimulation developed by Tactile Score*
Yasuhiro Suzuki, Rie Taniguchi (Nagoya University, Japan)

11:00-13:00 OS22 Mathematical Informatics (8)
Chair Takao Ito (Hiroshima University, Japan)
Co-Chair Makoto Sakamoto (University of Miyazaki, Japan)

OS22-1   *Adsorption Behavior of Arsenic and Selenium using NiZn Hydroxy Double Salts with Acetate, Chloride, Nitrate, and Sulfate Anions*
Kaoru Ohe*, Ryosuke Tabuchi, Tatsuya Oshima
(University of Miyazaki, Japan)

OS22-2   *Parallel Acoustic Analysis Based on the Domain Decomposition Method with Higher-Order Element*
Amane Takei[1], Makoto Sakamoto[1], Akihiro Kudo[2]
([1]University of Miyazaki, Japan)
([2]National Institute of Technology, Tomakomai Collage, Japan)

OS22-3   *Sound Field Evaluation on Acoustical Experiment using Non-Steady State Analysis*
Akihiro Kudo[1], Makoto Sakamoto[2], Amane Takei[2]
([1]National Institute of Technology, Tomakomai College, Japan)
([2] University of Miyazaki, Japan)

OS22-4   *A DeepInsight Method with Morphological Analysis*
Toyoaki Tomioka[1], Satoshi Ikeda[1], Makoto Sakamoto[1], Takao Ito[2]
([1]University of Miyazaki, Japan), ([2]Hiroshima University, Japan)

OS22-5   *Support for Museum Exhibition of Small Fungi using AR Technology*
Kakeru Takemura[1], Ota Hamasuna[1], Fumito Hamakawa[1], Satoshi Ikeda[1], Kaoru Ohe[1],
Amane Takei[1], Makoto Sakamoto[1], Shuichi Kurogi[2]
([1]University of Miyazaki, Japan)
([2]Miyazaki Prefectural Museum of Nature and History, Japan)

OS22-6   *Automatic Selection of High-Grade Dried Shiitake Mushrooms using Machine Learning*
Ota Hamasuna[1], Kakeru Takemura[1], Kodai Hasebe[1], Fumito Hamakawa[1], Bidesh
Biswas Biki[1], Satoshi Ikeda[1], Kaoru Ohe[1], Amane Takei[1], Makoto Sakamoto[1],
Kazuhide Sugimoto[2]
([1]University of Miyazaki, Japan), ([2] SUGIMOTO Co., Ltd. Japan)

OS22-7   *Predicting High Volatility Cryptocurrency Prices using Deep Learning*
Tsutomu Ito[1], Kodai Hasebe[2], Fumito Hamakawa[2], Bidesh Biswas Biki[2], Satoshi
Ikeda[2], Amane Takei[2], Makoto Sakamoto[2], Md Riajuliislam[3], Sabrina Bari Shital[4],
Takao Ito[5]
([1]National Institute of Technology, Ube College, Japan)
([2]University of Miyazaki, Japan), ([3] TU Dortmund, Germany)
([4]Daffodil International University, Bangladesh), ([5]Hiroshima University, Japan)

OS22-8   *Simulation of Weathering Representation using Vertex and UV Information*
Tsutomu Ito[1], Fumito Hamakawa[2], Kodai Hasebe[2], Satoshi Ikeda[2], Amane Takei[2],
Makoto Sakamoto[2], Takao Ito[3]
([1]National Institute of Technology, Ube College, Japan),
([2]University of Miyazaki, Japan), ([3]Hiroshima University, Japan)

14:15-15:15 OS5-1 Intelligent Life and Robotics (4)
Chair Kuo-Hsien Hsia (National Yunlin University of Science and Technology, Taiwan)
Co-Chair Evgeni Magid (Kazan Federal University, Russia)

OS5-1   *Research on dynamic obstacle avoidance and complex path planning strategies based on ROS robots*
Yi-Wei Chen, Jr-Hung Guo
(National Yunlin University of Science and Technology, Taiwan)

OS5-2   *Research on Multi-Robot Formation on Two-Dimensional Plane*
Kuo-Hsien Hsia, Chun-Chi Lai, Yi-Ting Liu, Yu-Le Chen
(National Yunlin University of Science and Technology, Taiwan)

OS5-3   *The Development of Utilization Rate and Energy Consumption Monitoring and Networking System*
Chung-Wen HUNG, Chun-Chieh WANG, Heng-En CHANG
(National Yunlin University of Science and Technology, Taiwan)

OS5-4   *MCU Based Edge Computing Platform for Liquid Level Measurement*
Chung-Wen HUNG, Chun-Liang LIU, Tai-Hsuan WU (National Yunlin University of Science and Technology, Taiwan)

15:40-16:10 OS5-2 Intelligent Life and Robotics (2)
Chair Kuo-Hsien Hsia (National Yunlin University of Science and Technology, Taiwan)
Co-Chair Evgeni Magid (Kazan Federal University, Russian Federation)

OS5-5   *Potential of genetic algorithms in multi-UAV coverage problem*
Ramil Faizullin[1], Tatyana Tsoy[1], Edgar A. Martínez-García[2], Evgeni Magid[1,3]
([1]Kazan Federal University, Russian Federation)
([2]The Autonomous University of Ciudad Juarez, Mexico)
([3]HSE University, Russia)

OS5-6   *Construction of Anthropomorphic Grippers with Adaptive Control*
Evgeny Dudorov[1], Julia Zhdanova[2], Ivan Zhidenko[1], Vladimir Moshkin[2], Alexander Eryomin[3], Evgeni Magid[3], Alexander Permyakov[1]
([1]JSC 'SPA 'Android technics', Russia) ([2]MIREA – Russian Technological University, Russia)
([3]Kazan Federal University, Russia)

16:40-17:40 OS16 Industrial Artificial Intelligence Robotics (4)
Chair: Eiji Hayashi (Kyushu Institute of Technology, Japan)

OS16-1   *A Research on Performance Information Editing Support System for Automatic Piano*
Yoshiki Hori, Eiji Hayashi (Kyushu Institute of Technology, Japan)

OS16-2   *Development of Autonomous Mobile Field Robots – Accuracy Verification of Self-Localization through Simulation -*
Takamasa Hayashi[1], Shintaro Ogawa[1], Yuto Okawachi[1], Tan Chi Jie[1], Janthori Titan[1], Ayumu Tominaga[2], Eiji Hayashi[1], Satoko Seino[3]
([1]Kyushu Institute of Technology, Japan), ([2]National Institute of Technology (Kitakyushu College), Japan), ([3]Kyushu University, Japan)

OS16-3   *Development of AR System for Grasping String Foods on Introduction of Industrial Robot*
Yoshihiro Koyama, Eiji Hayashi (Kyushu Institute of Technology, Japan), Akira Kawaguchi (The City College of New York of The City University of New York, United States of America)

OS16-4   *An Image Analysis of Coastal Debris Detection -Detection of microplastics using deep learning*
Yuto Okawachi[1], Ayumu Tominaga[2], Shintaro Ogawa[1], Takamasa Hayashi[1], Tan Chi Jie[1],
Janthori Titan[1], Eiji Hayashi[1], Satoko Seino[3]
([1]Kyushu Institute of Technology, Japan), ([2]National Institute of Technology (Kitakyushu College),
Japan), ([3]Kyushu University, Japan)

Room 406
10:00-11:15 OS18-1 Computer and Information Engineering (5)
Chair: Norrima Mokhtar (University of Malaya, Malaysia)
Co-Chair: Heshalini Rajagopal (UCSI University, Malaysia)

OS18-1   *Efficient Campus Shuttle Tracking and Management Mobile Application for College Campus*
Andrea Tantay Gonzales[1], Kavitha Thamadharan[1], Neesha Jothi[2]
([1]INTI International College Penang, Malaysia) ([2]UCSI University, Malaysia)

OS18-2   *GCN Analysis of Task-Based fMRI Data for Diagnosis of Schizophrenia*
Tejaswini Thota[1], Reuben Stephen John[1], Dr R Dhanush[1], Dr Amutha S[1]
([1] Vellore Institute of Technology, India)

OS18-3   *AR-Based Application for Campus Navigation*
Renuka Devi Rajagopal[1], Akshay S[1], Manoj Rathinam[1], Shakthi B[1], Heshalini Rajagopal[2]
([1] Vellore Institute of Technology, India), ([2]UCSI University, Malaysia)

OS18-4   *Development of Robotic Assistant for Health Care Sector with A Special Focus to Aid the Geriartric Patients*
Narayanan Ganesh (Vellore Institute of Technology, India)

OS18-5   *Development of a Desktop Application Restaurant Management System*
Gabriela Maria Ancilla, Heshalini Rajagopal, Ismail Ahmed Al-Qasem Al-Hadi
(UCSI University, Malaysia)

11:30-12:00 OS18-2 Computer and Information Engineering (2)
Chair: Norrima Mokhtar (University of Malaya, Malaysia)
Co-Chair: Heshalini Rajagopal (UCSI University, Malaysia)

OS18-6   *Face Recognition based on Attendance System*
Koh Pei Cong[1], Heshalini Rajagopal[1], Ghassan Saleh[1], Norrima Mokthar[2]
([1]UCSI University, Malaysia), ([2]University of Malaya, Malaysia)

OS18-7   *U-Reserve: Development of a Facility Reservation System for UCSI University*
Esther Chong Jun Lynn[1], Neesha Jothi[1], Ismail Ahmed[1]
([1]UCSI University, Malaysia)

14:15-15:30 OS18-3 Computer and Information Engineering (5)
Chair: Norrima Mokhtar (University of Malaya, Malaysia)
Co-Chair: Heshalini Rajagopal (UCSI University, Malaysia)

OS18-8   *The Smart Document Processing with Artificial Intelligence*
Raenu Kolandaisamy[1], Heshalini Rajagopal[1], Indraah K[2], Glaret Shirley Sinnappan[3]
([1] UCSI University, Malaysia), ([2]University Utara Malaysia, Kedah)
  ([3]Tunku Abdul Rahman University of Management and Technology, Malaysia)

OS18-9   *Digital Security Challenges Faced by Business Organizations*
Raenu Kolandaisamy[1], Heshalini Rajagopal[1], Indraah K[2], Glaret Shirley Sinnappan[3]
([1]UCSI University, Malaysia), ([2]University Utara Malaysia, Malaysia), ([3]Tunku Abdul Rahman University of Management and Technology, Malaysia)

OS18-10   *The Study on Perception on E-Waste Among the People*
Raenu Kolandaisamy[1], Heshalini Rajagopal[1], Indraah K[2]
([1]UCSI University, Malaysia), ([2]University Utara Malaysia, Malaysia)

OS18-11   *Emergence of Cybercrimes in Online Social Networks*
Raenu Kolandaisamy[1], Heshalini Rajagopal[1], Indraah K[2]
([1]UCSI University, Malaysia) ([2]University Utara Malaysia, Malaysia)

OS18-12   *Development of a music recommendation application by using facial emotion recognition*
Shengke Xie, Raenu Kolandaisamy, Ghassan Saleh, Heshalini Rajagopal
(UCSI University, Malaysia)

15:40-16:25 OS21 Human-Machine Interface (3)
Chair: Norrima Mokhtar (University of Malaya, Malaysia)
Co-Chair: Heshalini Rajagopal (UCSI University, Malaysia)

OS21-1   *Enhancing Reconnaissance Missions Through Multiple Unmanned Systems in ROS*
Anees ul Husnain[1,2], Norrima Mokhtar[1], Takao Ito[3], Siti Sendari[4], Muhammad Farris Kyasudeen[5], Muhammad Badri M Noor[1,6], Heshalini Rajagopal[7]
([1] Universiti Malaya, Malaysia), ([2] The Islamia University of Bahawalpur, Pakistan), ([3]Hiroshima University, Japan), ([4] Universitas Negeri Malang, Indonesia), ([5] University Technology MARA (UiTM), Malaysia)
([6] Ifcon Technology Sdn Bhd, Malaysia), ([7]UCSI University, Malaysia)

OS21-2   *Illumination Effects on Facial Expression Recognition using Empirical Mode Decomposition*
Hashimah Ali[1], Wan Khairunizam Wan Ahmad[1], Hariharan Muthusamy[2], Mohamed Elshaikh[1]
([1] Universiti Malaysia Perlis, Malaysia)
([2] National Institute of Technology Uttarakhand, India)

OS21-3   *Supercontinuum Generation Pump By a Molydenum Disulfide Based Soliton Mode-Locked Fiber Laser*
Aeryn D. Ahmad[1], Norrima Mokhtar[1], Hamzah Arof[1], Sulaiman Wadi harun[1], Ahmad Haziq Aiman Rosol[2]
([1]Universiti Malaya, Malaysia), ([2]MJIIT, UTM, Malaysia)

16:40-17:40 GS6 Applications II (4)
Chair: Masayuki Fujiwara (Kyushu Institute of Technology, Japan)

GS6-1   *Development of Smartphone Application for Calculating the Low Back Pain Risk*
Seigo Imura, Praveen Nuwantha, Hiroki Tamura (University of Miyazaki, Japan)

GS6-2   *A Computational Approach for Global Trade Analysis Sensitive to Free Trade Agreement Circumstances: A Case Study Focusing on the Great Mekong Subregion*
Ahmad Altaweel[1], Bo-Young Lee[2], Masayuki Fujiwara[1], Jang-Sok Yoon[2], Hiroaki Wagatsuma[1]
([1]Kyushu Institute of Technology, Japan; [2]Logistics Revolution Korea, Korea)

GS6-3   *Trigger circuit design and system integration for simultaneous measurement of human EEG, motion, and gaze*
Masayuki Fujiwara[1], Phan Hoang Huu Duc[1], Laurent Bougrain[2], Patrick Hénaff[2], Hiroaki Wagatsuma[1] ([1]Kyushu Institute of Technology, Japan; [2]Université de Lorraine, France)

GS6-4   *Terminal Synergetic Controller for Car's Active Suspension System Using Dragonfly Algorithm*
Tinnakorn Kumsaen[1], Sorn Simatrang[2], Arsit Boonyaprapasorn[3], Thunyaseth Sethaput[4]
([1]Khon Kaen University, Thailand; [2]Nacres Co., Ltd, Thailand; [3]Chulachomklao Royal Military Academy, Thailand; [4]Thammasat University, Thailand)

February 25 (Sunday)
9:40-Registration

10:00-11:00
Room 405
10:00-11:15 OS6 Intelligence and Optimization (5)
Chair: Mastaneh Mokayef (UCSI University, Malaysia)
Co-Chair Takao Ito (Hiroshima University, Japan)

OS6-1   *Simulation-Based Enhancement of SNR in Drone Communication through Uniform Linear Array Configurations*
Gershom Phiri[1], Mastaneh Mokayef[1], MHD Amen Summakieh[1], M.K.A Ahamed Khan[1], Sew Sun Tiang[1], Wei Hong Lim[1], Abdul Qayyum[2]
([1]UCSI University Malaysia)
([2]National Heart and Lung Institute, Imperial College London, UK)

OS6-2   *Empowering Elderly Individuals through the Intelligent Shopping Trolley*
Mastaneh Mokayef[1], Muzaiyanah Binti Hidayab[1], MHD Amen Summakieh[1], M.K.A Ahamed Khan[1], Kim Soon Chong[1], Chin Hong Wong[2], Chua Huang Shen[3], Abdul Qayyum[4]
([1]UCSI University Malaysia) ([2]Fuzhou University, China) ([3]UOW Malaysia University, Malaysia) ([4]National Heart and Lung Institute, Imperial College, UK)

OS6-3   *Optimized Microstrip Slot UWB Patch Antenna for Medical Imaging*
Maxime Duvacher[1], Mastaneh Mokayef[2], MHD Amen Summakieh[2], M.K.A Ahamed Khan[2], Sew Sun Tiang[2], Wei Hong Lim[2], Abdul Qayyum[3]
([1]Polytech Nantes, France) ([2]UCSI University Malaysia) ([3]National Heart and Lung Institute, Imperial College London, UK)

OS6-4   *Development of an Innovative Undergraduate Industrial Automation and Robotics Degree Program*
M.K.A. Ahamed Khan[1], Mastaneh Mokayef[1], Ridzuan, A.[1], Irraivan Elamvazuthi, Badli Shah Yusoff[2], Abu Hassan Darusman[3] ([1]UCSI University Malaysia) ([2]University Technology Petronos, Malaysia) ([3]UNIKL Malaysia France Institute, Malaysia)

OS6-5   *Smart Assistive Trolley for Elderly Care and Independence*
Dina Ashraf[1], Mastaneh Mokayef[1], MHD Amen Summakieh[1], M.K.A Ahamed Khan[1], Abdul Qayyum[2], Sivajothi A/L Paramasivam[3] ([1]UCSI University Malaysia) ([2]National Heart and Lung Institute, Imperial College London, UK) ([3]UOW Malaysia University College, Malaysia)

12:30-13:45 OS4-1 Pattern Recognition and Robotics III (5)
Chair: Huahao Li (Tianjin University of Science and Technology, China)
Co-Chair Hongshuo Zhai (Tianjin University of Science and Technology, China)

OS4-1   *A Digital Twin Design Based on Robot Workstation*
Huahao Li (Tianjin University of Science and Technology, China)

OS4-2   *A Study of Chemical Reactor Simulation System Based on PCS7*
Hongshuo Zhai (Tianjin University of Science and Technology, China)

OS4-3   *Analysis of Learning Quality Evaluation for University Student Courses with Process Assessment*
Yuhao Zhang, Ying Gong, Xuran Wang
(Tianjin University of Science and Technology, China)

OS4-4   *Motion Analysis and Transfer Applications Based on Posture Recognition*
Yuhao Zhang, Mingyue Li, Jianhao Jiao (Tianjin University of Science and Technology, China)

OS4-5   *Functional Safety Assessment of the Safety Protection System Based on Petri Net*
Peng Wang, Mengyuan Hu
(Tianjin University of Science and Technology, China)

14:00-15:15 OS4-2 Pattern Recognition and Robotics III (5)
Chair: Huahao Li (Tianjin University of Science and Technology, China)
Co-Chair: Hongshuo Zhai (Tianjin University of Science and Technology, China)

OS4-6   *Pedestrian Attribute Recognition Based on Deep Learning*
Peng Wang, Qikun Wang, Shengfeng Wang
(Tianjin University of Science and Technology, China)

OS4-7   *Simulation of office air conditioning air supply based on COMSOL*
Peng Wang, Mengda Liu, Qikun Wang
(Tianjin University of Science and Technology, China)

OS4-8   *Solo Wheel Technology-Self-balancing Wheelbarrow*
Ziyue Xiao, Yumei Huang, Zhencheng Chang, Mingxuan Li
(Tianjin University of Science and Technology, China)

OS4-9   *Second-order self-balancing inverted pendulum*
Ziyue Xiao, Zhencheng Chang, Mingxuan Li, Yumei Huang
(Tianjin University of Science and Technology, China)

OS4-10   *Design of Nanny's Abnormal Behavior Recognition Bracelet Based on Human Activity Recognition (HAR) Deep Learning Model*
Depeng Wang, Yingfan Zhu, Yande Xiang, Ziyue Xiao
(Tianjin University of Science and Technology, China)

Room 406
10:00-11:30 OS26-1 Navigating the Digital Frontier: Innovations in the Age of Industry Revolution 4.0(6)
Chair: Wei Hong Lim (UCSI University, Malaysia)
Co-Chair: Takao Ito (Hiroshima University, Japan)

OS26-1   *An Intelligent Cargo/Warehouse Management System*
Zhongheng Sun, Zhou Yue, Xun Sun, Wenzhuo Fan, Wenxuan Zhou
(Fuzou University, China)

OS26-2   *A Comprehensive Approach to Design and Implement an IoT-Enabled Intelligent Shopping Cart System with Obstacle-Aware Navigation and Enhanced Customer Engagement for Elevated Consumer Experiences*
Yao Chen[1], Jiacheng Du[1], Bo Peng[1], Ningfei Wang[1], Zehan Huang[1], Wei Hong Lim[2], Sew Sun Tiang[2], Mastaneh Mokayef[2], Chin Hong Wong[1]
([1]Fuzhou University, China) ([2]UCSI University, Malaysia)

Abstract
PS Abstract (3)
PS1 Developing High-Speed Working Motion of the Multi Robot in DENSO
Tomoaki Ozaki (DENSO CORPORATION, Japan)

The number of labor force is expected to decrease due to the declining birthrate and aging population. Although many efforts to solve this social issue using automation technology by robots around the world have been implemented, most of the current applications of robots are still repetitive works such as picking and placing in mass production lines in factories, and small progress of the application of robots for high-mix low-volume production lines where the operations are frequently changed. In this paper, we discuss the reasons and the potential solutions for autonomous control technologies including the AI and deep learning. Moreover, the high-speed working motion of the multi robot developed by DENSO will be presented in this paper.

High-Speed Working Motion of the Multi-Robot

PS2 Experimenting with Variable Arm Quadrotors: Realizing Dynamic Configurations for Enhanced Flight Performance
Hazry Desa, Muhammad Azizi bin Azizan (Universiti Malaysia Perlis, Malaysia)

This paper introduces two innovative variable arm concepts for quadrotors, enhancing precise movement control by manipulating bending moments through arm length variations. Its key goal is to identify the optimal arm configuration for smooth and stable quadrotor maneuvers. Exploring two concept designs tailored for quadrotors, the study focuses on regulating manoeuvrability using variable arms, enabling bending moment adjustments. Results validate that the electric actuator with linear guide-type 2 variable arm ensures smooth and stable quadrotor movement.
PS3 Artificial Intelligence and Technologies of Arm-type and Mobile Robots in Industry
Haruhisa Okuda (Mitsubishi Electric Corporation, Japan)

In recent years, labor shortage has become a serious issue in industrial fields. Various technologies including robot and information processing system to realize flexible work like humans are effective solutions to this issue. Artificial intelligence technology of arm-type robots equipped with 3D sensors and force sensors has been applied in the manufacturing field to cope with different intelligent and highly precise tasks in Mitsubishi Electric. In addition, various technologies to expand the scope of application to the service field, as well as to realize highly functional delivery with mobile robots is under development. Furthermore, IoT technology is also being used for easy and quick on-site implementation and efficient operation. This speech introduces these initiatives with actual examples.

OS1-1 Detecting abnormal operations in ICS using finite-state machines
Pei-Wen Chou, Nai-Yu Chen, Jung-Shian Li, I-Hsien Liu (National Cheng Kung University, Taiwan)

In 2021, a water treatment facility in Florida, USA, fell victim to an external malicious attack. In this incident, malicious actors attempted to manipulate the quantities of specific chemicals to impact water quality and safety. Given the intricacies of abnormal operation detection in Industrial Control Systems and the advantages of finite-state machine, we endeavored to apply this approach for the detection of abnormal ICS operations. We conducted a series of tests using the dam control system cybersecurity testbed established by TWISC@NCKU, Taiwan. The results indicate that our approach effectively enhances the efficiency of identifying non-standard operational behaviors, enabling maintenance personnel to promptly identify anomalies.
OS1-2 Industrial Control System State Monitor Using Blockchain Technology
Yun-Hao Chang, Tzu-En Peng, Jung-Shian Li, I-Hsien Liu (National Cheng Kung University, Taiwan)
This paper introduces an innovative approach to enhance data verification and security in intelligent systems through the integration of blockchain technology. The proposed method amalgamates the transparency and decentralization inherent to blockchain with the command and oversight functionalities of PLC to ensure the utmost data integrity. The devised approach synergizes the decentralized attributes of blockchain with the control capabilities of PLCs, thus establishing robust safeguards for data integrity. Through the utilization of blockchain's tamper-resistant ledger, PLCs orchestrate data interactions and enforce real-time monitoring and control. The viability and efficacy of this innovative scheme are substantiated through empirical evaluations and simulations, conclusively affirming its practicality.

OS1-3 Enhancing Dam Security and Water Level Alerting with Blockchain Technology
YingCheng Wu, Jung-Shian Li, Chu-Fen Li, I-Hsien Liu (National Cheng Kung University, Taiwan)

Ensuring the security, monitoring, and timely alerting of water levels in dams is a major challenge. We use blockchain technology to enhance the security and monitoring of dam infrastructure, and also improving the alerting system for water level changes. The use of blockchain technology in dam infrastructure management provides a decentralized, transparent, and tamper-resistant platform for storing and managing data. This ensures the integrity and security of critical data related to dam operations and water levels. This research investigates the enhanced security, monitoring, and alerting capabilities that this integration offers, and aims to contribute to the improved security and efficiency of dam infrastructure, leading to more reliable operations and better protection against potential disasters.

OS1-4 MiniDAM: A Dam Cybersecurity Toolkit
Tzu-En Peng, Meng-Wei Chang, Yun-Hao Chang, Jung-Shian Li, I-Hsien Liu
(National Cheng Kung University, Taiwan)

Testbeds, serving as simulations of real-world scenarios, are of paramount importance for research in cybersecurity related to critical infrastructure. In this paper, we aim to offer a comprehensive exploration of the MiniDAM and our testbed, introducing its physical settings based on real dam operational standards. Furthermore, a comparative analysis between the Secure Water Treatment (SWaT) testbed, MiniCPS, our testbed, and MiniDAM is presented. This paper also includes insights into dataset generation and the integration of other functionalities. The exposition of MiniDAM's features and capabilities serves as a foundation for enhancing resilience and provides valuable support for advancing research within the broader field of dam-related studies.

OS1-5 Case Study of Network-Based Intrusion Detection System Deployment in Industrial Control Systems with Network Isolation

Nai-Yu Chen, Pei-Wen Chou, Jung-Shian Li, I-Hsien Liu (National Cheng Kung University, Taiwan)

Deploying intrusion detection systems is a common cybersecurity measure, and intrusion detection systems typically operate at the ports of gateways. In critical infrastructure, industrial control systems often employ network isolation strategies, lacking the role of gateways. This research primarily explores the deployment of the Snort intrusion detection system in such an environment, combined with specific OT rules. Validation is conducted using the cybersecurity testbed of the dam control system established by TWISC@NCKU in Taiwan. The results indicate that by employing our proposed approach, it is possible to effectively detect abnormal network traffic, addressing the common issue of inadequate monitoring in environments with network isolation.

OS1-6 The AI integration service innovation model of real estate industry in Taiwan

Li-Min Chuang, Chih-Hung Chen (Chang Jung Christian University, Taiwan)

In real estate transactions, the intermediary role is often played by real estate agents. In recent years, with the integration of information and AI, the real estate industry can now provide higher quality services. This study references relevant literature and collects the services currently offered by real estate agents. The main dimensions and sub-dimensions are extracted using the Likert scale. Then, the Fuzzy Analytic Hierarchy Process (FAHP) is employed in a questionnaire study to obtain the relative weights among four main dimensions and twelve sub-dimensions. This research develops propositions and conclusions, summarizing the key factors for real estate transactions in Taiwan's real estate industry. These findings serve as important reference points for the industry.
OS2 Pattern Recognition and Robotics I (5)
Chair Fengzhi Dai (Tianjin University of Science and Technology, China)
Co-Chair Yunzhong Song (Henan Polytechnic University, China)

OS2-1 A Study on Sales Patterns for Vegetable Products in Retail Stores

Yuhao Zhang [1], Shuangshuang Ma [1], Jiashuai Wang [1], Fengzhi Dai [1], Lijiang Zhang [2]
([1] Tianjin University of Science and Technology, China, [2] Xinjiang Shenhua Biotechnology Co., Ltd, China)

In fresh produce supermarkets, the shelf life of vegetable products is typically short, necessitating daily restocking based on historical sales data and the formulation of a rational pricing strategy to maximize the store's profits. This paper, based on sales data for vegetable products in a particular store from July 2020 to June 2023, employs various analytical methods, including multidimensional analysis, clustering, and regression, to explore the interrelationships among different types of vegetables. Furthermore, it combines cost-plus pricing and price elasticity models to establish a pricing framework that optimizes revenue for the supermarket.

OS2-2 Research and Implementation of Cooperative Control for ROS Mobile Robot

Saijie Zhang, Huailin Zhao
(Shanghai Institute of Technology, China)

This paper discusses on the distributed control for the multiple ROS-based robots. A communication platform is built to execute the data transmission. The SLAM mapping and autonomous navigation of the robots are completed. The simulation tools of both Gazebo and Rviz are applied to analyze the multi-point navigation. The proposed distributed control system is tried and the synchronous control of the robots is realized, which achieve more accurate and more synchronous robot motion control. At last, the multi-robot following and multi-robot formatting come true.

OS2-3 An OpenCV-based Method for Workpiece Residue Image Processing
Jiaxin Wang, Hao He, Fangyv Liu, Fengzhi Dai (Tianjin University of Science and Technology, China)

Workpiece residue refers to a thin film formed on the surface of the workpiece during the machining process, due to factors such as cutting fluid, chips, oil stains, etc., which affects the quality and performance of the workpiece. This paper proposes an OpenCV-based method for workpiece residue image processing, aiming to achieve automatic detection and analysis of workpiece residue. By building a workpiece image acquisition system, workpiece residue images of different types and degrees are collected, and the proposed method is verified and evaluated. The experimental results show that the proposed method can effectively detect and analyze workpiece residue, with high accuracy and robustness, providing an effective means for workpiece quality control.

OS2-4 On Nonblockingness Verification and Enforcement of Controlled Nondeterministic Discrete-Event Systems
Xiang Ren, Zipei Wang (Tianjin University of Science and Technology, China)

Discrete event systems, as an important kind of cyber-physical systems, have been widely used in engineering field. In this paper, we first express the dynamics of a controlled nondeterministic discrete-event system (acronym is DES) as an algebraic state-space representation using the semi-tensor product (STP) theory. And then, we discuss the problems of state-based nonblockingness verification and enforcement of nondeterministic DESs. Specifically, we obtain a criterion of verifying whether a given controlled nondeterministic DES is nonblocking. Further, we develop an efficient matrix-based approach to enforce state-based nonblockingness. We illustrate the applications of the proposed theoretical results using an example.

OS2-5 Modeling and Reachability Verification of Controlled Nondeterministic Finite-State Automata
Zipei Wang, Xiang Ren (Tianjin University of Science and Technology, China)

In this paper, we investigate the modeling and state reachability of controlled nondeterministic finite-state automata (NFA). The key feature of a controlled NFA is to admit a supervisor to intervene the behavior of original system. We first express the dynamics of a controlled NFA as an algebraic state-space representation in the framework of the semi-tensor product (STP) of matrices. Then, the necessary and sufficient condition for verifying state reachability of controlled NFA is presented. An explicit formula for calculating all paths of any two states is derived. Finally, we use an example to illustrate the application of the proposed theoretical results.
OS3 Pattern Recognition and Robotics II (9)
Chair Fangyan Li (Tianjin University of Science and Technology, China)
Co-Chair Haozhe Sun (Tianjin University of Science and Technology, China)

OS3-1 Detection and Identification of Daylily Maturity Based on YOLOv8
Fangyan Li (Tianjin University of Science and Technology, China)

To better apply object detection and identification techniques from deep learning to the field of agricultural automation, this paper focuses on the growth process of daylilies. It employs the state-of-the-art YOLOv8 model to achieve accurate assessment of daylily maturity. The backbone network of YOLOv8 draws inspiration from the CSPDarkNet network structure to extract image features. Experimental results demonstrate that the detection accuracy of daylilies based on YOLOv8 exceeds 95.6%, with a recall rate of 90.5% and a mean average precision (mAP) reaching 0.94. Moreover, the identification speed is significantly improved.

OS3-2 Chaos Synchronization and Circuit Design of Chen System and Lü System with Different Structures

Haozhe Sun (Tianjin University of Science and Technology, China)

In this paper, by using nonlinear feedback control, chaos synchronization is achieved between the Chen system and the Lü system with different initial values, and the error curves and state synchronization curves of the corresponding states in the response Lü system and the drive Chen system are plotted. Finally, the simulation circuit model of the synchronization system of the drive Chen system and the response Lü system is designed by Multisim circuit simulation software. Comparing the output curves with the curves obtained by MATLAB simulation software, it can be found that the two curves achieve a good qualitative agreement. The synchronization of the drive Chen system and the response Lü system is accomplished.
OS3-3 A Parking Space Recognition Method Based on Digital Image Technology

Hao He, Fangyv Liu, Jiaxin Wang (Tianjin University of Science and Technology, , China)

In recent years, the number of cars in the city has been increasing, leading to an increasingly prominent issue of urban parking space. Consequently, the automatic identification method for parking spaces has emerged as a crucial research direction. This paper presents a design and implementation scheme for recognizing the status of parking spaces in urban areas based on digital image processing and other technologies. Real-time images of multiple parking spaces are collected and transmitted for splicing and detection purposes to determine their availability. The experimental results demonstrate the feasibility and effectiveness of the proposed method, which holds practical significance in addressing parking space detection problems through digital image processing.
OS3-4 A Design of Intelligent Handling Robot Based on AT89C52

Fangyv Liu, Jiaxin Wang, Hao He (Tianjin University of Science and Technology, China)

Aimed at the shortcomings of the low efficiency and the limitation of the artificial logistics handling, this paper presents a logistics handling robot based on AT89C52 single chip microcomputer. The integration of the power module, sensor, and drive motor module enables automatic obstacle avoidance and information collection.The incorporation of an ultrasonic obstacle avoidance module and an infrared tracking module enhances the capability for obstacle avoidance and path searching, and can easily cope with different workplace. The Yaskawa MPL manipulator is highly suitable for high-speed and high-precision palletizing, picking, packaging, and other industries.

OS3-5 Application and Differences of Robotic Arms, Traditional Machines and Manual Work in Production

Xue Yang, Ying Su, Yuping Mei, Haiquan Wang
(Tianjin University of Science and Technology, China)

This article aims to explore the differences between robotic arms and traditional machines and humans. Firstly, robotic arms are a kind of automated equipment with high flexibility and accuracy, which can perform a variety of complex tasks. In contrast, traditional machines lack flexibility and accuracy, while humans have problems such as low work efficiency and high error rates. Secondly, the emergence of robotic arms can solve many problems in traditional machines and humans, and improve production efficiency and quality. Finally, there is no contradiction between robotic arms, traditional machines and humans, but they can complement each other. By using robotic arms and humans reasonably, we can give full play to their respective advantages and improve the overall production efficiency and economic benefits.

OS3-6 A Deep Exploration of the Mounting Issues Related to Six Rotor UVA
Yuping Mei, Ying Su, Xue Yang (Tianjin University of Science and Technology, China)

In recent years, the hexacopter UAV has developed rapidly, especially the technological breakthrough in the field of automatic driving, which is of great significance in both military and civilian fields. The six-rotor UAV uses six rotors as the power source and adjusts the attitude by changing the rotor speed to further achieve position control. It has excellent hovering ability and sensitivity, and is equipped with a precise positioning system and advanced sensors. However, there are still common problems such as weak mounting capacity and single mounting mode. In view of this problem, this paper will test the fuselage structure, avionics system and power system one by one from two aspects: changing the fuselage structure and installing the motor position.

OS3-7 The Application of Hexacopter UAV in The Field of Climbing Evasion
Ying Su, Yuping Mei, Xue Yang (Tianjin University of Science and Technology, China)

With the development of tourism to climb peaks, the safety of high mountain walls plays an increasingly important role. In the past, the terrain of the mountain wall was too steep and too fast, and people could not patrol the mountain wall climbers, resulting in the safety of climbers could not be guaranteed, and the needs of climbers were difficult to solve in time. In order to solve the above problems, the method of real-time monitoring of UAVs and delivery of materials by UAVs was proposed. Hexacopter UAV is an unmanned small aerial vehicle equipment that can carry out vertical lifting, which is expected to improve the safety factor of climbing mountain walls and solve the needs of climbers in a timely manner.

OS3-8 Deep Learning and Embedded Based Operational Safety System for Special Vehicles
Haoran Gong, Yumei Huang, Jiahao Xie (Tianjin University of Science and Technology, China)

Aiming at the characteristics of special operation vehicles, such as complex working environment, large vehicle weight, long braking distance, and many visual dead angles for drivers, this project designs and implements a special vehicle operation safety system based on deep learning and embedded system. First of all, deep learning model is applied to detect the humanoid target appearing around the vehicle, get the detection frame of the humanoid target and estimate the distance from the target to the camera. According to different distance distances, relevant voice announcements are made to remind the driver to make timely actions such as avoiding or braking the vehicle.

OS3-9 "Green Fruit" - Intelligent Traceable Agricultural Product Production and Marketing Platform Based on Blockchain Technology
Yumei Huang, Jiahao Xie, Haoran Gong, Ziyue Xiao (Tianjin University of Science and Technology, China)

The production process of agricultural products has been greatly improved and optimized through the "Qingguo" intelligent agricultural greenhouse system. Using corrosion-resistant, ageing-resistant, solar-spectrum-converting plastic film, combined with Internet of Things technology, a simple, highly automated and intelligent greenhouse intelligent control system has been created. This not only improves the yield and quality of agricultural products, but also effectively reduces production costs and risks.
OS4 Pattern Recognition and Robotics III (10)
Chair Huahao Li (Tianjin University of Science and Technology, China)
Co-Chair Hongshuo Zhai (Tianjin University of Science and Technology, China)

OS4-1 A Digital Twin Design Based on Robot Workstation
Huahao Li (Tianjin University of Science and Technology, China)

With the introduction of Made in China 2025 and Industry 4.0, digital twins have rapidly become a trend. By interacting with physical objects and virtual models, mapping is completed in the virtual simulation space to reflect the actual operation process of the entire lifecycle of the corresponding device workstation. This article starts from the research background and significance of digital twin technology, the establishment of Solidworks physical model, the construction of PDPS workstation, and virtual simulation. We have completed the construction of a robot seven color panel assembly workstation model and combined it with PDPS to simulate the workstation.
OS4-2 A Study of Chemical Reactor Simulation System Based on PCS7
Hongshuo Zhai (Tianjin University of Science and Technology, China)

This paper introduces a simulation method of plant control, and corrects the system through PID Tuner, and finally gets a reasonable and correct simulation curve. In this paper, PCS7 software is used to build the factory model, and the simulation of four circuits of feed, pressure, liquid level and temperature is built by CFC block in the software. The automatic operation of the system is completed by SFC block. The final simulation curve obtained by PID Tuner tool based on PCS7 software is optimized.

OS4-3 Analysis of Learning Quality Evaluation for University Student Courses with Process Assessment
Yuhao Zhang, Ying Gong, Xuran Wang (Tianjin University of Science and Technology, China)

With the progressive exploration and application of formative assessment in university pedagogy, this evaluative method has become widely adopted for appraising students' everyday learning attitudes and conditions. Drawing upon pertinent data regarding classroom learning experiences of students at a specific university, this paper employs machine learning, K-means clustering, the Topsis evaluation model, and the entropy weighting method to investigate the relationship between formative assessment and the quality of university student learning, culminating in the creation of an evaluation model. This model allows us to pinpoint the key factors influencing student learning attitudes and offers support for formative assessment in the university context.

OS4-4 Motion Analysis and Transfer Applications Based on Posture Recognition
Yuhao Zhang, Mingyue Li, Jianhao Jiao (Tianjin University of Science and Technology, China)

This paper investigates the posture trajectories in human motion using pose recognition technology based on the deep learning framework MediaPipe. By detecting key points on the human body and plotting and calculating these trajectories in the temporal dimension, we further conduct comparative analysis of these trajectories with professional sports coaches' motion guidance to assist athletes in correcting their posture. Additionally, this technology has been deployed on Jetson Nano, enabling its practical application in mobile scenarios and providing robust tools and methods for fields such as rehabilitation therapy, sports training, and animal behavior analysis. This study offers insights into the transfer applications of posture recognition.

OS4-5 Functional Safety Assessment of the Safety Protection System Based on Petri Net
Peng Wang, Mengyuan Hu (Tianjin University of Science and Technology, China)

In this paper, the functional safety evaluation of the safety protection system of gasoline hydrogenation unit was carried out using Petri net. Firstly, the principle and framework of the gasoline hydrogen refueling unit was described. Secondly, the safety integrity level was introduced, and the influencing factors of the safety integrity level were summarized. Thirdly, the Petri net model and the Markov model are compared and the Petri net model is used to verify its security integrity level. Finally,the calculation result demonstrated that the SIL did not reach the target level, and then reached the target level after improvement.This analysis method can provide reference for the safety integrity level evaluation of similar devices.

OS4-6 Pedestrian Attribute Recognition Based on Deep Learning
Peng Wang, Qikun Wang, Shengfeng Wang (Tianjin University of Science and Technology, China)

This paper studied pedestrian attribute recognition based on deep learning, for its importance in the fields of smart city construction. Firstly, the research status of pedestrian attribute recognition and common deep learning models was introduced. Secondly, considering the accuracy decline problem and gradient problem of the neural network, the residual network was used as the main body of the neural network model. Thirdly, the model was trained to classify multiple person attributes through two data sets, Market-1501 and DukeMTMC-reID. Finally, the pedestrian attribute recognition model was tested, and good results were obtained.

OS4-7 Simulation of office air conditioning air supply based on COMSOL
Peng Wang*, Mengda Liu,Qikun Wang (Tianjin University of Science and Technology, China)

This paper analyzed the summer thermal environment of an office in Tianjin University of Science and Technology based on COMSOL software.Firstly,the principle of indoor thermal environment distribution was introduced. Secondly, according to the actual position of the furniture in the office, the mathematical model is constructed based on the basic theory of computational fluid dynamics.Thirdly, the COMSOL software was used for simulation and calculation, combining boundary conditions.Finally, the simulation results are analyzed through the simulated indoor three-dimensional velocity field and temperature field. The simulation results show that the air conditioning supply can well achieve indoor occupants' comfort.

OS4-8 Solo Wheel Technology-Self-balancing Wheelbarrow
Ziyue Xiao, Yumei Huang, Zhencheng Chang, Mingxuan Li
(Tianjin University of Science and Technology, China)

As a new type of personal transportation, self-balancing unicycle has attracted wide attention with its unique design and advanced control system. We aim to study and optimize the self-balancing performance of the unicycle to improve its stability and maneuverability. Firstly, we gain an in-depth understanding of its operation principle. On this basis, an advanced control algorithm is proposed to realize real-time attitude adjustment. Second, for applications in complex environments, we propose an intelligent sensing system to enhance its environment sensing capability.

OS4-9 Second-order self-balancing inverted pendulum

Ziyue Xiao, Zhencheng Chang, Mingxuan Li, Yumei Huang
(Tianjin University of Science and Technology, China)

The team utilizes the second-order inverted pendulum cart based on LQR controller for steady pendulum control with light rods. First, the second-order inverted pendulum is used as a research object to obtain its set of dynamical equations, then, the set of dynamical equations is written in the form of state-space expressions, and finally, the second-order inverted pendulum system of a balanced trolley with a light rod is controlled by a stabilized pendulum using the LQR controller. The inverted pendulum is a typical nonlinear, underdriven and unstable system, which can realize the all-round wind resistance of the rod and occupy less space with high stability.

OS4-10 Design of Nanny's Abnormal Behavior Recognition Bracelet Based on Human Activity Recognition (HAR) Deep Learning Model

Depeng Wang, Yingfan Zhu, Yande Xiang, Ziyue Xiao (Tianjin University of Science and Technology, China)

This article designs a nanny abnormal behavior recognition bracelet. The bracelet is equipped with multiple sensors and a powerful control board, forming a complete nanny abnormal behavior recognition system, which realizes nanny abnormal behavior recognition and alarm in various environments. It uses a gyroscope to collect the three-axis acceleration information of the nanny, and uses the HAR model to infer the nanny's real-time behavior. When the abnormal behavior of the nanny is inferred, STM32 sends the GPS collected positioning information to the employer through ESP32 for timely alarm.

OS5 Intelligent Life and Robotics (6)

Co-Chair Evgeni Magid (Kazan Federal University, Russia)

OS5-1 Research on dynamic obstacle avoidance and complex path planning strategies based on ROS robots

Yi-Wei Chen, Jr-Hung Guo (National Yunlin University of Science and Technology, Taiwan)

Robot Operating System (ROS) is a software system framework used by many robot systems. Although ROS provides a good development environment and related frameworks, ROS is not suitable for public places such as restaurants because of the coming and going of people. Dynamic obstacle avoidance is often handled by stopping the robot, or when there are frequent environmental map changes or when sensors such as optical radar fail, the stop action is also used. However, this often causes path obstructions or delays in completing tasks. Therefore, this study attempts to use images, auxiliary sensors, and various path avoidance strategies to solve the problem of the robot stopping and waiting for the obstacles to disappear. The problem of rapid changes in map paths.

OS5-2 Research on Multi-Robot Formation on Two-Dimensional Plane

Kuo-Hsien Hsia, Chun-Chi Lai, Yi-Ting Liu, Yu-Le Chen
(National Yunlin University of Science and Technology, Taiwan)

Mobile robots are playing an increasingly important role in both service and manufacturing industry. The management of multiple mobile robots is a very important issue on the research of mobile robotics. From a mathematical perspective, this paper discusses the problem of multiple robots on a two-dimensional plane reaching the designated positions in the shortest time to complete formation transformation. We improved the algorithm proposed by Hsia, Li and Su and proposed a new algorithm using a determinant and the Munkres allocation algorithm. Finally, the new algorithm is compared with the path distribution obtained by the Monte Carlo method under different numbers of robots and the excellence of the new algorithm has been verified.
OS5-3 The Development of Utilization Rate and Energy Consumption Monitoring and Networking System

Chung-Wen Hung, Chun-Chieh Wang, Heng-En Chang

(National Yunlin University of Science and Technology, Taiwan)

In this paper, we present a system based on microcontroller unit for measuring the utilization rate of traditional, non-networked machinery. This equipment is designed for use with older machines equipped with andon lights. It employs optocoupler circuits to capture the status of these lights and current transformers to measure their operating and standby currents. Data is transmitted to the server using the Hypertext Transfer Protocol (HTTP) in JavaScript Object Notation (JSON) format. On the server side, a PHP interprets the data, connects to a Structured Query Language (SQL) database, and stores the data using SQL commands. Users can access graphical data through a web-based interface, using it to refine production processes, reduce production costs, and minimize carbon emissions.

OS5-4 MCU Based Edge Computing Platform for Liquid Level Measurement

Chung-Wen Hung, Chun-Liang Liu, Tai-Hsuan Wu

(National Yunlin University of Science and Technology, Taiwan)

An edge computing system based on micro control unit (MCU) for liquid level measurement is proposed in this paper. The system includes a solenoid electromagnet for bottle hit and a microphone to capture sound waves. The signals are converted from time domain to frequency domain by Fast Fourier Transform (FFT), employing an artificial intelligence (AI) model to predict the water level. Artificial Neural Network (ANN) model is applied for classification on the MCU. When optimizing hyperparameters, the accuracy of each parameter combinations should be considered. Ensure the model size suits the limited MCU memory and computing capabilities. Experimental results confirm the system's effectiveness with 99% accuracy.
OS5-5 Potential of genetic algorithms in multi-UAV coverage problem

Ramil Faizullin[1], Tatyana Tsoy[1], Edgar A. Martínez-García[2], Evgeni Magid[1,3]

([1]Kazan Federal University, Russian Federation)

([2]The Autonomous University of Ciudad Juarez, Mexico)

([3]HSE University, Russian Federation)

For a rapid area coverage multiple UAVs are often used simultaneously. However, a path planning for a UAVs group during an area coverage task is computationally challenging. In practice, heuristic algorithms are applied to solve this problem. This paper overviews approaches to an area coverage problem with a group of UAVs using genetic algorithms. The article explores modifications that may be useful for a genetic algorithm for solving the coverage problem as well as representation methods for chromosomes that reflect a path of multi-UAV. Additionally, UAV group collision avoidance strategies during area coverage are considered.

OS5-6 Construction of Anthropomorphic Grippers with Adaptive Control

Evgeny Dudorov[1], Julia Zhdanova[2], Ivan Zhidenko[1], Vladimir Moshkin[2], Alexander Eryomin[3], Evgeni Magid[3], Alexander Permyakov[1]
([1]JSC 'SPA 'Android technics', Russian Federation)
([2]MIREA – Russian Technological University, Russian Federation)
([3]Kazan Federal University, Russian Federation)

A functionality of a service robot that physically interacts with a human is provided primarily by capabilities of its end effector. Rather limited capabilities of industrial robot grippers determined a gradual transition to anthropomorphic grippers. A number of degrees of freedom (DoF) of an end effector ensuring reliable grasping and holding of an arbitrary shaped object should be at least nine, preferably twelve. Such design implementation requires to switch toward underactuated grippers systems. This paper proposes a concept of constructing a group drive, which enables a motion of output links of two or more executive groups from a single motor. The presented technical solutions are based on methods of analyzing complex mechanical systems using functional circuits.

OS6 Intelligence and Optimization (5)

OS6-1 Simulation-Based Enhancement of SNR in Drone Communication through Uniform Linear Array Configurations

Gershom Phiri[1], Mastaneh Mokayef[1], MHD Amen Summakieh[1], M.K.A Ahamed Khan[1], Sew Sun Tiang[1], Wei Hong Lim[1], Abdul Qayyum[2]
([1] UCSI University Malaysia, [2]National Heart and Lung Institute, Imperial College London, UK)

As drones navigate through shared airspace, they often encounter other drones, wireless devices, and communication systems. This coexistence creates potential sources of interference that can degrade the signal-to-noise ratio (SNR). To maintain reliable communication in drone systems, it is crucial to effectively manage and mitigate interference from other drones and wireless devices operating on the same frequency bands. By addressing these challenges, we can ensure a stable and dependable SNR for seamless communication among drones. This paper sheds light on the history of applications and challenges of utilizing flying base stations for wireless networks and analyzes different factors that affect signal-to-noise ratio (SNR) to enhance the performance of drone communication.

OS6-2 Empowering Elderly Individuals through the Intelligent Shopping Trolley

Mastaneh Mokayef[1], Muzaiyanah Binti Hidayab[1], MHD Amen Summakieh[1], M.K.A Ahamed Khan[1], Kim Soon Chong[1], Chin Hong Wong[2], Chua Huang Shen[3], Abdul Qayyum[4]
([1] UCSI University Malaysia, [2] Fuzhou University, China, [3] UOW Malaysia University, Malaysia, [4] National Heart and Lung Institute, Imperial College London, UK)

In this research, we have developed a prototype that aims to improve the weekly shopping experience for senior citizens. Our system tracks the movements of elderly individuals, eliminating the need for them to exert physical force in pushing or pulling the shopping trolley. To achieve this, we utilize a combination of sensors, including a gyroscope and magnetometer, to estimate the user's walking distance and direction. Additionally, we employ WiFi fingerprinting to accurately determine the user's position. Our experiments have yielded satisfactory results in terms of tracking accuracy and the overall functionality of the system. By addressing the specific challenges faced by senior citizens during the routine and essential process of grocery shopping, our smart shopping trolley concept seeks to enhance their experience. Through the integration of tracking technology and sensor-based solutions, we aim to make shopping more convenient and comfortable for elderly individuals. The positive outcomes observed in our experiments validate the effectiveness and feasibility of this approach.

OS6-3 Optimized Microstrip Slot UWB Patch Antenna for Medical Imaging

Maxime Duvacher[1], Mastaneh Mokayef[2], MHD Amen Summakieh[2], M.K.A Ahamed Khan[2], Sew Sun Tiang[2], Wei Hong Lim[2], Abdul Qayyum[3] ([1]Polytech Nantes, France, [2]UCSI University Malaysia, [3]National Heart and Lung Institute, Imperial College London, UK)

This research work presents the development of an Ultra-Wideband (UWB) microstrip patch antenna (MPA) with the specific purpose of tissue characterization. The antenna was carefully designed and simulated to operate within a frequency range of 4.8 to 6.9 GHz, optimized for its intended application. To ensure the best performance, a series of simulations and comparisons were conducted using CST Microwave Studio. Various antenna shapes were tested and evaluated to determine the most effective design. The results of these simulations were highly promising, as they revealed a simulated return loss (S_11) of -33dB. This indicates excellent performance and demonstrates the suitability and acceptability of the proposed antenna for medical imaging such as breast imaging, tumor detection, or monitoring physiological changes.

OS6-4 Development of an Innovative Undergraduate Industrial Automation and Robotics Degree Program

M.K.A. Ahamed Khan[1], Mastaneh Mokayef[1], Ridzuan, A.[1], Irraivan Elamvazuthi, Badli Shah Yusoff [2], Abu Hassan Darusman[3] ([1]UCSI University Malaysia, [2]University Technology Petronos, Malaysia, [3]UNIKL Malaysia France Institute, Malaysia)

In recent years, the need for integrated engineering courses has increased. Due to its multidisciplinary nature, Industrial Automation and Robotics degree course is an ideal example of curriculum integration. This paper discusses several issues such as course offerings, topical content, student profile, student performance and other pertinent matters related to the recent development of an Industrial Automation and Robotics undergraduate degree program at the University of Kuala Lumpur, Malaysia.

OS6-5 Smart Assistive Trolley for Elderly Care and Independence

Dina Ashraf[1], Mastaneh Mokayef[1], MHD Amen Summakieh[1], M.K.A Ahamed Khan[1], Abdul Qayyum[2], Sivajothi A/L Paramasivam ([1]UCSI University Malaysia, [2]National Heart and Lung Institute, Imperial College London, UK, [3] UOW Malaysia University College, Malaysia)

As people age, shopping can become increasingly challenging, especially when it involves pushing heavy trolleys and managing items throughout the entire trip. To address these difficulties, a prototype project was developed with the aim of introducing a robotic trolley. This innovative trolley is designed to autonomously follow senior citizens during their shopping journeys, thanks to face detection technology. The system eliminates the need for physical assistance and provides real-time feedback on the distance covered during the trip. To estimate the walking distance, the trolley incorporates an ultrasonic sensor that activates when the camera detects and tracks the user. The implementation of this project utilizes the OpenCV library, specifically tailored for Python programming. The results of this project have shown significant improvements in the lives of elderly individuals, offering them enhanced comfort and increased independence during their shopping experiences.

OS7 Deep Learning and its Applications (4)
Chair Mastaneh Mokayef (UCSI University, Malaysia)
Co-Chair Takao Ito (Hiroshima University, Japan)

OS7-1 Parallel Cross Window Attention Transformer and CNN Model for Segmentation of Instrument during Surgery

Abdul Qayyum[1], M. K. A. Ahamed Khan[3], Moona Mazher[4], Imran Razzak[5], Steven Niederer[1,2], Mastaneh Mokayef[3], C.S. Hassan[3], Ridzuan, A[3]
([1]Imperial College, London, UK) ([2]The Alan Turning Institute, UK) ([3]UCSI University, Malaysia)
([4]University College London, UK) ([5]University of New South Wales, Australia)

In this work, we present encoder and decoder-based hybrid parallel cross window attention-based transformer during the feature extraction, which consists of the multi-scale channel attention, convolutional layers, and Transformer layers, forming a unified block. Syn-ISS challenge dataset comprised of two tasks. In first task 1, they need to develop deep learning-based method for binary instrument segmentation and in second task multiclass instrument segmentation is required. Experiments conducted on Syn-ISS dataset achieved 0.993 F-score for task 1 and 0.993, 0.975, and 0.951 F-score for shaft, wrist, and jaw segmentation respectively for Task 2.

OS7-2 Magnetic Resonance Spectroscopy (MRS) Reconstruction using Style Transfer Deep Depth wise Framework

Abdul Qayyum[1], M. K. A. Ahamed Khan[3], Moona Mazher[4], Imran Razzak[5], Steven Niederer[1,2], Mastaneh Mokayef [6], C.S. Hassan[6], Ridzuan, A[6]
([1]Imperial College, London, UK) ([2]The Alan Turning Institute, UK)
([3,6]UCSI University, Malaysia) ([4]University College London, UK)
([5]University of New South Wales, Australia)

To analyze the chemical composition of tissues in brain, in vivo magnetic resonance spectroscopy allows non-invasive measurements of neurochemicals in either single voxel or multiple voxels. In this work, we present a deep depth-wise channel attention module (DCAM) based fine-tuned network for magnetic resonance spectroscopy image reconstruction. Besides, we have used channel-wise convolutions and average pooling without dimensionality reduction. We have trained the initial network from scratch on track-1 simulated dataset, however due to the limited dataset, we finetune the network on track-2 and track-3. Experiments are conducted on Edited-MRS-Rec-Challenge dataset1 that showed significantly better performance.

OS7-3 Federated Learning on Brain Disease Research: Segmentation of Cerebral Small Vessel Diseases (CSVD) using Multi-scale Hybrid Spatial Deep Learning Approach

Moona Mazher[1], Abdul Qayyum[2], M. K. A. Ahamed Khan[3], Steven Niederer[2,4], Mastaneh Mokayef[3], Ridzuan, A[3], C. S. Hassan[3]
([1]University College London, UK) ([2]National Heart & Lung Institute, Imperial College, London, UK)
([3]UCSI University, Malaysia) ([4]Alan Turning Institute, London, UK)

In this paper, we propose a hybrid architecture for medical image segmentation to produce efficient representations from global and local features and adaptively aggregate them, aiming to fully exploit their strengths to obtain better segmentation performance in federated learning. Furthermore, we propose a multi-scale feature extraction module embedded at the bottom of the proposed model, which can efficiently extract hidden multi-scale contextual information and aggregate multi-scale features. Experiments on segmentation over three-dimensional rotational angiography of internal Carotid Artery with aneurysm (SHINY-ICARUS) challenge dataset show the effectiveness of the proposed multiscale framework.

OS7-4 Hybrid Classical and Quantum Deep Learning Models for Medical Image Classification

Moona Mazher[1], Abdul Qayyum[2], M. K. A. Ahamed Khan[3], Steven Niederer[2,4], Mastaneh Mokayef[3],
Ridzuan, A[3], C. S. Hassan[3]
([1]University College London, UK) ([2]National Heart & Lung Institute, Imperial College, London, UK)
([3]UCSI University, Malaysia) ([4]Alan Turning Institute, UK)

In this paper, we proposed a hybrid classical and quantum convolutional neural network for Alzheimer's disease (AD) classification. The proposed model was further validated on the brain tumor classification task. The fundamental concept involves encoding data into quantum states, facilitating quicker information extraction, and subsequently utilizing this information to discern the data class. The proposed model results underscore the reliability and robustness and demonstrated by optimal performance accuracies across various datasets, the proposed model substantiates its efficacy in detecting and classifying AD disease and brain tumors.

OS8 Intelligent Control (5)

Co-Chair Weicun Zhang (University of Science and Technology Beijing, China)

OS8-1 Global Stabilization of A Class of Nonholonomic Integrators via Discontinuous Control

Lixia Yan, Yingmin Jia (Beihang University (BUAA), China)

This paper investigates the discontinuous state feedback control for stabilizing a class of nonholonomic integrators with drift terms. The control design relies on constraining state trajectory in an invariant set. To this end, we apply constant controls to drive the states moving into the invariant set and then switch to a continuous control law with suitable gain selections. It is proven in the Lyapunov sense that the proposed control scheme achieves global exponential stabilization of the states, and the control switch would only occur at most once. Numerical simulations are carried out to validate the proposed control law.

$$\mathbb{R}^3 - C \qquad C$$
$$u = u_1 \qquad u = u_2(t)$$
$$C \triangleq \left\{ Z = [z_1, z_2, z_3]' \in \mathbb{R}^3 \mid z_1^2 + z_2^2 > |z_3| \right\}$$

OS8-2 Frequency Dependence Performance Limit of Vibration Absorbers

Jiqiang Wang[1], Xiaoyu Yin[2], Weicun Zhang[3]
([1]Chinese Academy of Sciences, China) ([2]Science & Technology Bureau of Zhenhai District, China)
([3]University of Science and Technology Beijing, China)

Optimal design of vibration absorbers has been extensively investigated. Most of the design methods are approached by optimizing certain performance indices, resulting in a set of optimal parameters that are independent of exogenous forcing frequencies. In practical designs, however, it is often desirable to know the performance limits over a frequency band of interest. This problem is tackled in the present paper where both lower and upper bounds are obtained. A refined upper bound is also derived that can further provide a systematic design methodology. Extensive remarks are also given exploring different avenues useful for design. Numerical examples are given to validate the corresponding designs.
OS8-3 Adaptive Concurrent Learning Algorithm Based on Pontryagin's Maximum Principle for Nonlinear System Optimal Tracking Control with State Inequality Constraints

Yuqi Zhang, Bin Zhang (Beijing University of Posts and Telecommunications, China)

In this article, an adaptive learning algorithm is derived for finite-horizon optimal tracking problems of nonlinear systems. Concurrent learning is implemented to identify the unknown parameters of the system dynamics. Tracking of the desired trajectory and convergence of the developed policy are guaranteed via stability analysis. Different from the adaptive dynamic programming (ADP) infinite-horizon method, the proposed method solves the finite-horizon optimal tracking problems. Simulation results show the effectiveness of the proposed algorithm.
OS8-4 Privacy preserving Mean-square consensus for discrete-time heterogeneous multi-agent systems with Communication Noises

Tongqing Yang[1], Lipo Mo[1], Yingmin Jia[2]

([1]Beijing Technology and Business University, China) ([2]Beihang University (BUAA), China)

This paper studies the privacy preserving consensus of distributed heterogeneous multi-agent systems, which consists of first-order agents and second-order agents. A new protocol is designed for each agent. Then, by applying algebraic graph theory and matrix theory, it is proved that the closed-loop system could achieve consensus. After that, the designed protocol is encrypted by a cryptographic cryptosystem to prevent eavesdropping in the communication link and loss of information privacy between agents while achieving consensus. Finally, the effectiveness of the proposed consensus protocol and privacy protection algorithm are verified by numerical simulations.
OS8-5 Event-Triggered Consensus Control for Nonlinear Singular Multi-Agent Systems under Directed Topology

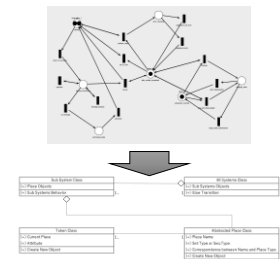
Lin Li, Tong Yuan, Mei Huang (University of Shanghai for Science and Technology, China)

This paper is devoted to the problem of event-triggered consensus for a class of nonlinear singular multi-agent systems under directed topology. An event-triggered sampling mechanism is constructed, which naturally avoids Zeno behavior. And then, a distributed event-triggered consensus protocol is designed. By employing the Lyapunov-Krasovskii functional method and model transformation approach, sufficient conditions that can guarantee the consensus of the considered singular multi-agent systems are obtained, while the consensus control gain matrix and the event-triggered parameter are also given. Finally, a numerical example is included to illustrate the effectiveness of the proposed method.
OS9 Software Development Support Method (4)
Chair Tetsuro Katayama (University of Miyazaki, Japan)
Co-Chair Tomohiko Takagi (Kagawa University, Japan)

OS9-1 An Improved Conversion Technique from EPNAT Models to VDM++ Specifications for Simulation of Abstract Software Behavior

Sho Matsumoto[1], Ryoichi Ishigami[1], Tetsuro Katayama[2], Tomohiko Takagi[1]

([1]Kagawa University, Japan) ([2]University of Miyazaki, Japan)

Formal software models based on EPNAT (Extended Place/transition Net with Attributed Tokens) can be converted to VDM++ specifications that enable simulation of abstract software behavior before implementation processes. However, the conversion technique has two problems, that is, (1) extracting all properties to be checked from the VDM++ specifications requires time and effort, and (2) the structure of the VDM++ specifications has less readability and maintainability. In this study, we improve the conversion technique by (1) adding a function to extract an abstract current state of software, and (2) dividing into classes that correspond to subnets of EPNAT models. This paper shows a new conversion rule, a new structure of VDM++ specifications, a simple example, and the discussion about their effectiveness.


OS9-2 Prototype of RAGESS Which Is a Tool for Automatically Generating SwiftDiagrams to Support iOS App Development

Haruki Onaga[1], Tetsuro Katayama[1], Yoshihiro Kita[2], Hisaaki Yamaba[1], Kentaro Aburada[1], Naonobu Okazaki[1]
([1]University of Miyazaki, Japan) ([2]University of Nagasaki, Japan)

In the development of large-scale and complex mobile applications, it is difficult for developers to continually grasp the overall structure of the app. To support iOS app development, we proposed SwiftDiagram, a visualization of the static structure of Swift source code and confirmed its high usefulness. However, manually drawing SwiftDiagrams is labor-intensive. This paper implements a prototype of RAGESS (Real-time Automatic Generation of SwiftDiagram System), a tool that automatically generates SwiftDiagrams by performing static analysis on Swift source code every time an iOS app build is successful. Compared with other tools, RAGESS is confirmed to enable developers to visualize the static structure of source code effortlessly.
OS9-3 Extension to Support Types and Operation/Function Definitions in BWDM to Generate Test Case Tool from the VDM++ Specification

Shota Takakura[1], Tetsuro Katayama[1], Yoshihiro Kita[2], Hisaaki Yamaba[1], Kentaro Aburada[1], Naonobu Okazaki[1]
([1]University of Miyazaki, Japan) ([2]University of Nagasaki, Japan)

Generating test cases from the formal specification description VDM++, which is a method for disambiguating specifications, is time-consuming and labor intensive. Therefore, our laboratory has developed BWDM, a tool that automatically generates test cases from VDM++ specifications. However, existing BWDM has problems that it only supports integer types and cannot generate test cases for operation and function definitions including recursive structure. Therefore, in order to improve the usefulness of BWDM, this study extends BWDM to solve the above problems. Consequently, it has confirmed that the use of extended BWDM can reduce the test case generation time compared to manual test case generation.

OS9-4 Proposal of ASLA Which Is a Segmentation and Labeling Tool for Document Images Based on Deep Learning

Kanta Kakinoki[1], Tetsuro Katayama[1], Yoshihiro Kita[2], Hisaaki Yamaba[1], Kentaro Aburada[1], Naonobu Okazaki[1]
([1]University of Miyazaki, Japan) ([2]University of Nagasaki, Japan)

The current situation of the electronic documents is only a substitute for paper. As a new way to utilize electronic documents, we focus on dividing electronic documents into regions by their elements and generating keywords and sentences as labels from the contents of the elements. However, these tasks, when performed manually, are time-consuming and labor-intensive. This study proposes a prototype of ASLA (Automatic Segmentation and Labeling tool using AI), segmentation and labeling tool for document images based on deep learning, with the aim of reducing the time required for region segmentation and label generation. To evaluate the usefulness of ASLA, we have compared the time required for region segmentation and label generation using ASLA and by hand, and then confirmed the reduction in time.

OS10 Intelligent Life and Robotics (6)
Chair Evgeni Magid (Kazan Federal University, Russia)
Co-Chair Kuo-Hsien Hsia (National Yunlin University of Science and Technology, Taiwan)

OS10-1 A Design of a Modular Mobile Robot for Rescue Operations

Baris Celiker, Shifa Sulaiman, Tatyana Tsoy (Kazan Federal University, Russia)

Modular robotics is one of the subfields of mobile robotics, which is emerging as a new trend in various sectors. Modular mobile robots can be reconfigured to perform a wide variety of tasks. In this paper, applications of modular mobile robots in various sectors such as industry, space, surgery, rescue and entertainment tasks are discussed. Based on the study, an improved design of a modular mobile robot for navigating through different terrains during a rescue operation is presented. Simulation study of the robot is included to demonstrate a motion capability of the modular mobile robot.

OS10-2 Implementation of Bug1 and Bug2 Path Planning Algorithms for TurtleBot Using ROS Noetic

Ilya Spektor[1], Aidar Zagirov[2], Ramil Safin[2], Evgeni Magid[1,2]
([1]HSE University, Russia) ([2]Kazan Federal University, Russia)

Mobile robots typically operate in a dynamically changing unknown environments. Bug family algorithms were proposed to deal with a path planning of a ground robot in a 2D configuration space of an unknown environment with local data about obstacles that could be collected using only a touch sensor. This paper presents an implementation of Bug1 and Bug2 local path planning algorithms. The implementation brings classical 2D algorithms into a 3D environment of the Gazebo simulation using the Noetic version of the Robot Operation System (ROS). A Turtlebot3 Burger model was used as a target robot and its performance was evaluated in simple convex and maze environments.
OS10-3 Implementation of Alg1 and Alg2 Path Planning Algorithms for Mobile Robots Using ROS Noetic

Anastasia Yankova[1], Timur Gamberov[2], Tatyana Tsoy[2]
([1]HSE University, Russia) ([2]Kazan Federal University, Russia)

Two standard approaches for a robot path planning include a global and a local navigation. The later does not require to store an environment model in a robot memory. This paper presents implementations of two local navigation algorithms, Alg1 and Alg2, with a robot having no prior information about an environment and obstacles. It calculates a path in a real time, continuously changing its states depending on correspondent conditions. The algorithms were implemented for an existing differential drive robot Turtlebot3 Burger using Robot Operation System (ROS). Virtual experiments were performed in the Gazebo simulator employing a simple 3D environment with only convex obstacles and a small 3D maze.

OS10-4 Implementation of VisBug-21 and VisBug-22 Path Planning Algorithms Using ROS Noetic

Viktoriia Mirzoian[1], Maxim Mustafin[2], Evgeni Magid[1,2]
([1]HSE University, Russia) ([2]Kazan Federal University, Russia)

Local navigation algorithms are crucial for autonomous robots operating in unknown environments where a presence of obstacles and dynamic changes pose significant challenges. A focus of these algorithms is to enable a real-time path calculation, allowing a robot to adapt its states dynamically based on corresponding environmental conditions, despite an absence of prior knowledge about surroundings. This paper presents an implementation of the VisBug-21 and VisBug-22 algorithms, designed to address challenges of a local navigation. The algorithms were implemented for a differential drive robot Turtlebot3 Burger using Robot Operation System (ROS). Virtual experiments were performed in the Gazebo simulator employing a simple 3D environment that contained only convex obstacles and a small 3D maze.

OS10-5 DistBug path planning algorithm package for ROS Noetic

Alexander Pak[1], Alexander Eremin[2], Tatyana Tsoy[2]
([1]HSE University, Russia) ([2]Kazan Federal University, Russia)

Algorithms of path-planning in an unknown environment play an important role in robotics. They do not require a prior information about obstacles' locations around a robot and allow calculating a path in a real time. This article presents an implementation of a sensory-based DistBug algorithm, which operates reactively using range data for immediate decision-making without constructing a world model. The algorithm was programmed in Python using robot operating system (ROS) and validated in the Gazebo simulator. For virtual experiments Turtlebot 3 Burger mobile robot was employed. The experiments were conducted in two types of environment: an environment with convex obstacles and a maze. The paper demonstrates analysis of experiments using several standard criteria of a path quality estimation.

OS10-6 On sensor modeling in Gazebo simulator

Niez Yuldashev, Alexandra Dobrokvashina, Roman Lavrenov (Kazan Federal University, Russia)

Sensor modeling in the Gazebo simulator is fundamental to robotics advancement. This review explores sensor modeling intricacies, methodologies, and applications, while emphasizing a critical role of a precise sensor modeling. Application scenarios demonstrate a sensor modeling's broad utility across fields including medical diagnostics, autonomous navigation, and industrial automation. Differences in research focus, methodology, and implementation underline a varied nature of sensor modeling studies. Key challenges include a need for more detailed world models. The paper guides research in sensor modeling and identifies crucial questions.
OS11 Intelligent Life and Robotics (6)
Chair Evgeni Magid (Kazan Federal University, Russia)
Co-Chair Kuo-Hsien Hsia (National Yunlin University of Science and Technology, Taiwan)

OS11-1 An Overview of Kinect Based Gesture Recognition Methods

Alexander Alexeev[1], Tatyana Tsoy[1], Edgar A. Martínez-García[2], Evgeni Magid[1,3]
([1]Kazan Federal University, Russia) ([2]The Autonomous University of Ciudad Juarez, Mexico)
([3]HSE University, Russia)

Visual sensors play an important role in a broad variety of robotic systems applications. Even though Kinect technology appeared over 10 years ago, Kinect sensors are still actively employed by researchers around the world. This paper presents an overview of Kinect and Kinect 2 sensors' applications in a human gesture based control. We analyzed existing research papers to estimate a popularity of particular feature extraction and gesture recognition methods, recommendations on a distance between an object of interest and a sensor, reported accuracy and latency of the sensor. Our analysis is supposed to facilitate a selection of a suitable combination of methods for a particular application of Kinect sensor in gesture recognition while considering its performance.

OS11-2 An investigation on the impact of human-robot interactions during an autonomous obstacle avoidance task

Riham Salman, Shifa Sulaiman, Renata Islamova, Tatyana Tsoy (Kazan Federal University, Russia)

The purpose of this research is to investigate how an interaction between humans and robots influences a safety of an autonomous obstacle avoidance task. The research collected and analyzed data from surveys and interviews using a combination of quantitative and qualitative methodologies. The findings contributed to our understanding of a complex interplay between a human-robot interaction, a perception, and a robot navigation safety. Based on these findings, the study proposed a number of recommendations for improving both physical and psychological safety aspects of an autonomous robot navigation.

OS11-3 A Comparative Analysis of Object Detection Methods for Robotic Grasping

Nikita Kolin, Elvira Chebotareva (Kazan Federal University, Russia)

The objects grasping is one of the fundamental robotic problems. Accurate and efficient real-time object detection is crucial for successful grasping in robots equipped with monocular vision. Deep machine learning has made significant progress in solving problems of object detection and image segmentation. At the same time, classical computer vision methods do not lose their relevance and can also be used for these tasks. In this research, we conduct a comparative analysis of the effectiveness the YOLOv8-seg neural network model versions for solving the image segmentation problem with classical segmentation methods. The obtained results allowed us to formulate some recommendations on the choice of a particular method for object detection depending on the surrounding environment conditions.

OS11-4 Vision-based autonomous navigation for medical examination using a UR3e manipulator

Bulat Abbyasov[1], Aidar Zagirov[1], Timur Gamberov[1], Hongbing Li[2], Evgeni Magid[1]
([1]Kazan Federal University, Russia) ([2]Shanghai Jiao Tong University, China)

Medical robotics is an emerging field of robotics within a healthcare sector. This interdisciplinary field focuses on prototyping, building and developing advanced robots for numerous clinical application. Modern robotic technologies have a tremendous potential for performing medical examination procedures such as ultrasonography using robotic manipulators that act in an autonomous manner. A manipulator navigation plays a key role in a safe and efficient exploration of a human body. This paper presents a development of a vision-based autonomous navigation system for a 6-DOF UR3e robotic arm. The developed system is based on a 3D point cloud and uses MoveIt for path planning. Gazebo was used as a simulation framework to validate the navigation system.

OS11-5 Robot-Assisted Language Learning: Scientific Data Analysis

Karina Sadyikova, Valeriya Zhukova, Roman Lavrenov (Kazan Federal University, Russia)

Robot-assisted language learning (RALL) is a direction in education that uses robots in a foreign languages studying process. In this paper, we present results of our research work devoted to studying trends in a quantity of publications in the field of using social robots for learning foreign languages. Additionally, we analyzed some published paper in the field of RALL, which allowed us to identify several popular robot models used in practical research in recent years. Among these models were the NAO, Pepper and DARWIN OP-2 robots. We have found that these robots are actively used in an educational process for learning foreign languages. In particular, these models are used to improve language and communication skills during implicit learning and interactive games.
OS11-6 Monitoring Beehive Sound Levels with Arduino-based System

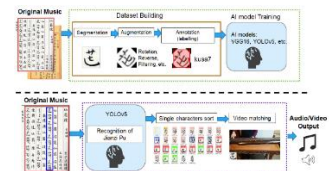
Kulmukhametov Ramis[1], Ramil Safin[1], Tatyana Tsoy[1], Kuo-Hsien Hsia[2], Evgeni Magid[1]
([1]Kazan Federal University, Russia) ([2]National Yunlin University of Science and Technology, Taiwan)

An automated beekeeping is a promising approach to addressing various issues associated with a beekeeping. Among primary problems, a swarming procedure stands out as a major concern. An uncontrolled swarming can lead to significant financial losses. During a swarming period a potential for losing a bee swarm is high, therefore a noise monitoring at this period gains a significant importance. Our long term research aims at a development of an intelligent monitoring system for beehive conditions, based on a hive-generated noises analysis. This paper presents an experiment that collected data about acoustic characteristics of bees' state using an Arduino microcontroller and a MAX9814 microphone module. The obtained data analysis is discussed.

OS12 Machine Learning and its Applications (4)
Chair Masato Nagayoshi (Niigata College of Nursing, Japan)
Co-Chair Takashi Kuremoto (Nippon Institute of Technology, Japan)

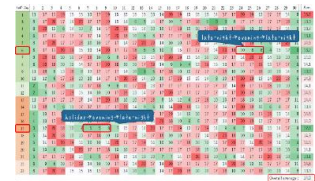
OS12-1 Restoration of Guqin Music by Deep Learning Methods

Takashi Kuremoto[1], Kazuma Fujino[1], Hirokazu Takahashi[1], Shun Kuremoto[2, 3], Mamiko Koshiba[*2],
Hiroo Hieda[3], Shingo Mabu[2]
([1]Nippon Institute of Technology, Japan) ([2]Yamaguchi University, Japan)
([3]Institute for Future Engineering, Japan)

Guqin music played an important role in the history of Asia cultures. The notation of Guqin are remained more than 600, however, only 100 music are played in nowadays. The handwriting Guqin notation named Jianzi Pu is hard to be understood, however, we challenge to restore the Guqin music by deep learning methods and few Jianzi Pu images. VGG16 and YOLOv5 were adopted in the recognition experiment for Guqin music restoration. As a result, YOLOv5 realized an online output of Guqin music as its output of audio or video forms.


OS12-2 Constructive Nurse Scheduling Using Reinforcement Learning Considering Variations in Nurse Work Patterns

Masato Nagayoshi (Niigata College of Nursing, Japan), Hisashi Tamaki (Kobe University, Japan)

It is very difficult to create a work schedule that satisfies all the different requirements in nurse scheduling. For this reason, numerous studies have been conducted on the nurse scheduling problem. However, the created shift schedule is often not practical as it is, because adjustments including various constraints and evaluation criteria are required. Therefore, we have proposed a work revision method using reinforcement learning in a constructive nurse scheduling system. In this paper, we investigate the feasibility of creating a practical work schedule that considers different evaluations of nurses' work patterns, i.e., nurses' life stages.


OS12-3 A Basic Study on Indicator of Transfer Learning for Reinforcement Learning

Satoshi Sugikawa, Kenta Takeoka, Naoki Kotani (Osaka Institute of Technology, Japan)

Reinforcement learning requires a lot of learning time for the agent to learn. Transition learning is a method to reduce this learning time, but it has the problem that the user does not know which knowledge is effective in which environment until it is learned. Therefore, it is necessary for the user to consider the relationship between the source and destination when transferring knowledge. Therefore, this study proposes Indicator of adaptation criteria that can determine this relationship in advance. In simulations, we demonstrate the usefulness of the proposed method by using some example problems.

OS12-4 Machine Learning Approach to Predict Cooling Load for Existing Buildings

Makoto Ohara[1], Hideo Isozaki[2]
([1]International Professional University of Technology in Osaka, Japan) ([2]Kobe University, Japan)

The objective of this study is to predict air conditioning loads for existing buildings using operational data, weather forecasts and visitor forecasts. The proposed prediction method is based on a neural network approach. However, it is important to note that the proposed method does not learn the entire loads. Loads are divided into factors which can be predicted by traditional thermodynamics and factors which are subject to machine learning. The proposed method has been applied to an example instance using operational data from an underground mall in Kobe, and its validity has been confirmed. This result could potentially lead to more efficient use of energy in buildings.
OS13 Robot Control (10)
Chair Yizhun Peng (Tianjin University of Science and Technology, China)

OS13-1 Intelligent Logistics Handling Robot: Design, Control, and Recognition
Yanchao Bi, Jiale Cheng, Limei Wang, Yizhun Peng (Tianjin University of Science and Technology, China)

This study aims to investigate various aspects of intelligent logistics handling robots, including mechanical design, automatic control, and image recognition. With the continuous development of the logistics industry and advancements in automation technology, intelligent logistics handling robots play a crucial role in improving logistics efficiency and reducing costs. Leveraging existing technologies, we have designed and developed an omnidirectional mobile intelligent logistics handling robot equipped with a SCARA-type robotic arm. The robot integrates functions such as task acquisition, global positioning, material detection, warehouse identification, material handling, and stacking, achieving a fully automated and streamlined logistics handling process.

OS13-2 Greenhouse Design Using Visual Recognition and IoT Technology
Yuntian Xia, Yizhun Peng (Tianjin University of Science and Technology, China)

This device is to solve the traditional pesticide spraying method on the human body has a greater impact and other issues, through the STM32-based visualisation of the intelligent greenhouse to achieve automatic spraying of pesticides and remote monitoring and other functions, the establishment of a visualisation of the intelligent greenhouse monitoring platform. This equipment through the MQTT protocol, not only through the Internet of Things platform real-time monitoring of crop growth status in the greenhouse, but also through the platform to determine whether to spray pesticides, data transmission, so as to use the cross slide to control the position of the nozzle, and then through the visual recognition algorithms to improve the accuracy of the visual recognition part of the accuracy of the spraying of plants affected by insect pests, the realization of the digital intelligent greenhouse.

OS13-3 Design of Modular Photovoltaic Environmentally Friendly Portable Stroller
Suqing Duan, Yizhun Peng (Tianjin University of Science and Technology, China)

The work is centered on ROS and integrates speech recognition and natural language processing modules to enhance the environmental awareness of the stroller and monitor the baby's condition to ensure a timely and appropriate response. The Raspberry Pi is the main control unit of the stroller and connects to a cloud-based IoT platform via the MQTT protocol. The platform facilitates seamless communication between the Raspberry Pi and cloud data for efficient data visualization on mobile devices. This innovative solution solves the challenge of balancing parental responsibilities with career advancement, promoting healthier and happier babies while allowing parents to maintain a harmonious work-life balance.

OS13-4 "Teenage Mutant Ninja Turtles" - Design of a Bionic Quadrupedal Rescue Robot
Hongpi Zhao, Yingfan Zhu, Zhihan Zhao, Xin Liang, Lei Lv, Yizhun Peng
(Tianjin University of Science and Technology, China)

"Teenage Mutant Ninja Turtles - Bionic Quadrupedal Rescue Robot is a quadrupedal robot based on the principle of bionics, inspired by the quadrupedal animals in nature. The robot has rescue and life detection capabilities and can perform rescue operations at disaster sites. The design of the robot enables it to operate efficiently and stably in complex environments, and at the same time it has the qualities of bravery and toughness, which are in line with the image of the Teenage Mutant Ninja Turtles. The robot can be used in a wide range of application scenarios, such as earthquake, fire and other disasters, to provide more efficient and safer support for rescue work.

OS13-5 Design of Grass Lattice Planter for Complex Environment Based on Adaptive Suspension Technology

Shaokai Tian, Wenqi Fu, Yizhun Peng (Tianjin University of Science and Technology, China)

The Complex environmental grass grid growers based on adaptive suspension adopted the high-performance stm32 as the master chip, and use the Bluetooth communication module, so that users can easily control the vehicle driving, feeding and the posture of the pressing wheel through the mobile phone application. In addition, we have introduced new mechanical structures such as adaptive suspension to ensure effective planting of grass squares in complex terrain such as sloping land. Our vehicle uses a Mecanum wheel motion system to squeeze seeds by rotating the friction wheels at high speed.

OS13-6 Design of Intelligent Ecological Multifunctional Plant and Animal Breeding System

Suqing Duan, Yuntian Xia, Siyi Wang, Yizhun Peng (Tianjin University of Science and Technology, China)

The intelligent ecological multi-functional system for animal and plant cultivation integrates PLC and MCU automatic control technology. This innovative approach amalgamates aquaculture with horticulture, fostering a symbiotic environment for the breeding of animals and plants. The system's operations are categorized into four key components: mechanical structure, environmental perception, automatic control, and intelligent networking. Its comprehensive functionality encompasses plant monitoring, self-checking of temperature and humidity, group control for fertilizer replenishment, consistent temperature regulation, full-spectrum illumination, advanced filtration, fogging supplementation, versatile water management, fertilizer blending, and water purification through sterilization.

OS13-7 Design of a Fully Automated Logistics Handling Platform

Hongpi Zhao, Jianfeng Qin, Yizhun Peng (Tianjin University of Science and Technology, China)

With the progress of science and technology and the development of society, the world's countries on industrial production efficiency, intelligent manufacturing transformation continues to grow. Therefore, we designed a fully automatic logistics handling platform, which is a multi-modular device based on mechanical design, microcontroller control, visual positioning, the device can realize autonomous identification, autonomous transportation, improve production efficiency, the device has a wide range of applications, can be applied to food packaging, parts processing, intelligent manufacturing and other automation scenarios.

OS13-8 Design and Application of AI-based Brush Calligraphy and Painting Robot

Haibo Li, Yizhe Sun, Shuxin Wang, Yizhun Peng (Tianjin University of Science and Technology, China)

With the rapid development of digital technology and artificial intelligence, the innovation and exploration of traditional painting forms in the field of digital art have become increasingly captivating. The main focus of this research is to create a brush calligraphy and painting robot system based on PLT files. It digitizes user creative instructions to autonomously generate brush calligraphy and landscape paintings. This technology not only advances the deep integration of digital art and traditional culture but also opens up new perspectives and vast possibilities for artistic creation.

OS13-9 Intelligent Wheelchair System: Non-contact Heart Rate and Body Temperature Measurement

Dongpo Ma, Junsheng Zhang, Yizhun Peng (Tianjin University of Science and Technology, China)

With the continuous development of society and human civilization, people, especially the disabled and the elderly, need more and more to use modern high technology to improve their lives and improve the comfort of life. Therefore, this paper introduces a single-chip microcomputer-based non-contact body temperature and facial recognition-based heart rate measurement method and applies it to the intelligent wheelchair system. Monitor the vital signs of the elderly, and give early warnings in time when abnormal values occur, so that family members or caregivers can rescue them in time.

OS13-10 Recognition and Localization Method for Automotive Axle Holes in Assembly Robots

Junsheng Zhang, Dongpo Ma, Yizhun Peng (Tianjin University of Science and Technology, China)

During the production of automotive axle holes, the roundness error at the pipe opening leads to low detection efficiency due to manual measurements, rendering real-time inspection unfeasible. This paper proposes a method for detecting and sorting the roundness of automotive axle holes based on visual inspection. Ensuring accuracy in grasping, it establishes the kinematic model of the robot Aubo_I5. Targeting automotive axle holes for grasping, it employs adaptive threshold segmentation to highlight the section features of the axle hole. The Canny algorithm is then used to extract edge information, and finally, the least squares method is utilized to detect roundness errors for sorting the axle holes based on this error.

OS14 Robotic Manipulation (3)
Chair Kensuke Harada (Osaka University, Japan)
Co-Chair Akira Nakamura (Saitama Institute of Technology, Japan)
Co-Chair Tokuo Tsuji (Kanazawa University, Japan)

OS14-1 Evaluation Standard of Error Recovery Planning Focused on Revival Process from Failures in Robotic Manufacturing Plants

Akira Nakamura[1], Kensuke Harada[2] ([1]Saitama Institute of Technology, Japan) ([2]Osaka University, Japan)

In recent years, many intelligent robots have been used in various fields. In many cases, these robots need to be able to perform not only repetitive tasks but also non-routine tasks. As work errors are more likely to occur in such situations, we have proposed several methods for error recovery. Our method uses both forward recovery and backward recovery to restore work. The former is a recovery method that is often used for minor modifications, and the latter is the recovery from relatively large failures that we mainly use. This paper proposes a method for selecting the best path from several possible recovery paths using a new evaluation method.
OS14-2 Robotic Food Handling Utilizing Temperature Dependent Variable-Stiffness Material

Rozilyn Marco[1], Prashant Kumar[2], Xinyi Zhang[2], Weiwei Wan[2], Kensuke Harada[2]
([1] University of Toronto, Canada) ([2] Osaka University, Japan)

This paper presents a robotic gripper that addresses challenges of automated robotic food handling. Depending on the food material, the robotic gripper should adjust its finger compliance. To cope with this problem, we apply the approach on using a variable stiffness fabric on the finger surfaces of the gripper, where the finger stiffness changes depending on its temperature. This gripper design was validated empirically through force and object-grasping experiments. By using the gripper, hard objects can be grasped with the hard mode of the finger while a fragile object can be safely grasped with the soft mode.

OS14-3 Vegetable maturity evaluation for harvest robots
Reno Muhammad Fadilla, Tokuo Tsuji, Tatsuhiro Hiramitsu, Hiroaki Seki (Kanazawa University, Japan)

We propose a method for detecting vegetables in an image and classifing their maturity by color. Vegetable images are classified according to their maturity and used as training data. We represent the images in different color systems and investigate the accuracy of the classification of maturity. The proposed method can be applied to harvesting robots.

OS15 Artificial Intelligence for Embedded Systems and Robotics (6)
Chair Hakaru Tamukoh (Kyushu Institute of Technology, Japan)
Co-Chair Yuma Yoshimoto (National Institute of Technology, Kitakyushu College, Japan)

OS15-1 YOLO real-time object detection on EV3-Robot using FPGA hardware Accelerator
Dinda Pramanta[1], Ninnart Fuengfusin[2], Arie Rachmad Syulistyo[2], Hakaru Tamukoh[2]
([1]Kyushu Institute of Information Sciences, Japan) ([2]Kyushu Institute of Technology, Japan)

The growing demand for robots necessitates faster and more precise processing. However, running large Artificial Intelligence (AI) models from cloud data centers to mobile robots via inference models uses considerable computation resources, which leads to power limitations, particularly for mobile robots. The use of reconfigurable semiconductor devices at the hardware level is a promising solution to this problem. We introduce the educational kit EV3-Robot with a co-design methodology utilizing Field-programmable Gate Arrays (FPGA) Kria KV260 as a hardware accelerator specifically for object detection. We apply the You Only Look Once (YOLO) model for object detection, which provides real-time results for practical applications. Additionally, we analyze the processing times of the local PC and EV3-Robot.

OS15-2 A Low Computational Cost Hand Waving Action Recognition System with Echo State Network for Home Service Robots
Hiromasa Yamaguchi, Akinobu Mizutani, Arie Rachmad Syulistyo, Yuichiro Tanaka, Hakaru Tamukoh
(Kyushu Institute of Technology, Japan)

This study proposes a low computational cost hand-waving action recognition system for non-verbal communication in home service robots. The system is based on an echo state network, which requires lower computational costs than that of deep neural networks (DNNs), and processes time-series data of skeletal coordinates of humans to recognize hand-waving actions. Additionally, this study proposes and compares two types of preprocessing methods of the skeletal coordinates to ensure the robustness of the human positions on the screen: one method extracts elbow and arm angles, which are invariable regardless of the humans' positions and the other normalizes the skeletal coordinates. The experimental result shows that the proposed system has competitive accuracy and is faster than DNN-based methods and robust to varying human positions.
OS15-3 A Rapidly Adjustable Object Recognition System through Language Based Prompt Engineering
Naoki Yamaguchi, Tomoya Shiba, Kosei Isomoto, Hakaru Tamukoh (Kyushu Institute of Technology, Japan)

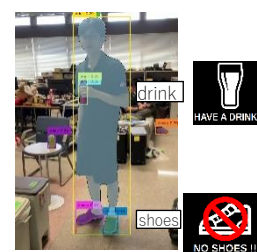
We propose the use of language-based prompt engineering to achieve rapidly adjustable object recognition in RoboCup@Home. The proposed prompt engineering involves humans adding features, such as the color and material of an object, into the text prompts inputted into Language Segment Anything. In this research, we evaluated the effectiveness of our proposed method in three benchmark tests for object recognition at RoboCup@Home held in France in 2023. The results showed that the highest scores were obtained in certain tasks, indicating that it could be applied to a range of recognition tasks.
OS15-4 Development of a SayCan-based task planning system capable of handling abstract nouns

Kosei Yamao[1], Daiju Kanaoka, Kosei Isomoto, Akinobu Mizutani, Yuichiro Tanaka, Hakaru Tamukoh
(Kyushu Institute of Technology, Japan)

The task planning system is required to accomplish various requests from a human in real-world environments. SayCan, one of the task planning systems, has high accuracy. However, its accuracy decreases for requests that include abstract nouns of the ambiguous word/phrase, and the inference time increases as the number of skills increases. We propose a novel task planning system based on SayCan that introduces a function for listening back to abstract nouns and a rule-based skill extraction, enhancing accuracy and reducing inference time. The proposed system facilitates the interpretation of requests and enables appropriate task planning with low inference time. The effectiveness of the proposed system was demonstrated at RoboCup@Home, where it achieved high performance.

OS15-5 RoboCup@Home 2023: Stickler for the Rules Task Solutions

Tomoya Shiba, Hakaru Tamukoh (Kyushu Institute of Technology, Japan)

This paper proposes an approach where home service robots use only two recognition models that can be capable of prompt tuning to detect rule violations in the home. The robots are increasingly required to perform more advanced and complex perceptions beyond their traditional roles such as cleaning. Advanced tasks such as serving and security, for example, usually require multiple AI systems, including person detection, object detection and more. Our approach simplifies this by leveraging the combined capabilities of Grounding DINO and SAM to detect rule violations effectively. The success of our method was proven at RoboCup@Home 2023, where it secured the highest score among all participating teams.


OS15-6 Offloading Intellectual Processing from Home Service Robots to Edge Devices

Yuma Yoshimoto, Mizuki Kawashima, Shun Yonehara
(National Institute of Technology, Kitakyushu College, Japan)

In this study, we focus on extending the operational time of home service robots by offloading intellectual processing to circuit devices such as Field Programmable Gate Arrays (FPGAs), which in turn reduces power consumption. The core of our approach involves developing a method for implementing intellectual processing on FPGAs, coupled with a dynamic circuit reconfiguration technique. This enables the FPGA to adaptively respond to frequent task changes. We present: (a) methods for transitioning circuits from a robot's control computer to FPGA in response to varying tasks, and (b) an evaluation of the effectiveness of using FPGA to extend operational time under these rapidly changing task conditions.

OS16 Industrial Artificial Intelligence Robotics (4)
Chair Eiji Hayashi (Kyushu Institute of Technology, Japan)

OS16-1 A Research on Performance Information Editing Support System for Automatic Piano

Yoshiki Hori, Eiji Hayashi (Kyushu Institute of Technology, Japan)

In 1996, Hayashi et al. from our laboratory developed an automatic piano playing device that requires data with nuances for each note to perform in a human-like piano playing. However, this device lacks the function to infer such nuanced data. Therefore, prior research focused on developing a system to infer data with nuances for each note. Yet, this system required manual inference, consuming a significant amount of time. In this study, we have constructed a system capable of automatically performing inference using deep learning. This system not only improves the accuracy of piano playing inference but also contributes to the efficiency of the inference process.

OS16-2 Development of Autonomous Mobile Field Robots – Accuracy Verification of Self-Localization through Simulation -

Takamasa Hayashi[1], Shintaro Ogawa[1], Yuto Okawachi[1], Tan Chi Jie[1], Janthori Titan[1], Ayumu Tominaga[2], Eiji Hayashi[1], Satoko Seino[3]
([1]Kyushu Institute of Technology, Japan) ([2]National Institute of Technology (Kitakyushu College), Japan), ([3]Kyushu University, Japan)

In recent years, the increase in marine debris has become a significant challenge in terms of its collection. Costal debris, a type of marine debris, can be collected by human hands, but the variety in shapes, types, and sizes presents limitations to human-only collection efforts. To address this, I focused on developing an autonomous mobile robot, establishing a simulation environment was considered crucial for facilitating smooth progress. This paper focuses on self-localization, an essential aspect for autonomous movement. We replicated an actual coastal cleaning site within the simulation environment and evaluated the accuracy of self-localization using an EKF (Extended Kalman Filter) with multiple sensors.

OS16-3 Development of AR System for Grasping String Foods on Introduction of Industrial Robot

Yoshihiro Koyama, Eiji Hayashi (Kyushu Institute of Technology, Japan), Akira Kawaguchi (The City College of New York of The City University of New York, United States of America)

In recent years, the food service industry has been facing a labor shortage. However, the introduction of industrial robots is not easy due to the high cost of equipment and system integration. Therefore, we are developing an Augmented Reality (AR) application for the purpose of introducing robots to small and medium-sized companies. By using this application to perform tasks necessary for introducing robots, such as teaching, cost reductions can be expected when introducing industrial robots. In a previous study, an AR-based grasping and serving simulation system was developed for solidified foods such as fried chicken and rice balls. In this study, we focused on string-shaped food items such as spaghetti, and attempted to develop an AR system for grasping and serving a string-shaped object by controlling a gripper.

OS16-4 An Image Analysis of Coastal Debris Detection -Detection of microplastics using deep learning

Yuto Okawachi[1], Ayumu Tominaga[2], Shintaro Ogawa[1], Takamasa Hayashi[1], Tan Chi Jie[1], Janthori Titan[1], Eiji Hayashi[1], Satoko Seino[3]
([1]Kyushu Institute of Technology, Japan) ([2]National Institute of Technology (Kitakyushu College), Japan) ([3]Kyushu University, Japan)

To address the issue of litter drifting ashore, this study developed a deep learning-based microplastic detection system. The system employed yolov7 as its deep learning network, complemented by SAHI (Slicing Aided Hyper Inference) as an additional vision library. yolov7 is renowned for its efficacy in real-time object detection. Our experimental framework involved four tests, utilizing two variations of yolov7 - the standard model and yolov7-e6e - in conjunction with SAHI. The effectiveness of each test was quantified using metrics such as Intersection over Union (IoU), Precision, Recall, F-measure, and Detection Time in seconds. For our dataset, we gathered images from actual cleanup locations, such as Hokuto Mizukumi Park. The model's discriminator underwent 700 training iterations, with a learning rate set at 0.001.

OS17 Electronics and Kansei Engineering Based on ETT theory (5)
Chair: Tetsuo Hattori (Kagawa University, Hiroshima Institute of Technology, Japan)
Co-Chair: Yusuke Kawakami (NIT (Kagawa College), Japan)

OS17-1 A High-Speed Estimation Method of Parameters in Impulse Response
Toshiki Tanaka, Ivan Tanev (Doshisha University, Japan), Tetsuo Hattori (Kagawa University, Japan)

This paper proposes a high-speed parameters estimation method for compartment model where output function is described by the convolution between input function and impulse response, which is like a time-invariant linear system. The proposed method uses linear regression analysis based on equations that can be obtained from the differentiation of convolution (DOC). In this paper, taking the parameters estimation problem of PET (Positron Emission Tomography) inspection system and RLC series electrical circuit for examples, we show that the method can estimate parameters in those impulse responses.
OS17-2 A Consideration on Amplification Function in BJT Evers-Moll Model and PTT (I)
---- V-I Characteristics ----
Shimon Hattori, Osamu Matoba (Kobe University, Japan), Tetsuo Hattori (Kagawa University, Japan), Toshiki Tanaka (Kinkei System, Japan), Yusuke Kawakami (NIT (Kagawa College), Japan)

In 1989, the notion of PTT (Photon Transport Transistor) has been proposed by B.J. Van Zeghbroeck et al., at IBM Research Center at that time. PTT is an optical coupling device of light emitting diode (LED) or laser diode and light receiving diode (Photo Diode, PD) where the carrier of the base layer is light (Photon) only. Later in 1996, W. N. Cheung and Paul J. Edwards have shown that PTT can be a very low noise amplifier in a positive feedback circuit, based on theoretical calculations of the noise figure. In this paper we consider the amplification principle showing the VI characteristics of the PTT and bipolar junction transistor (BJT).
OS17-3 A Consideration on Amplification Function in BJT Evers-Moll Model and PTT (II)
---- H Parameters in the Small Signal Amplifier Circuit----
Shimon Hattori, Osamu Matoba (Kobe University, Japan), Tetsuo Hattori (Kagawa University, Japan), Toshiki Tanaka (Kinkei System, Japan), Yusuke Kawakami (NIT (Kagawa College), Japan)

The notion of PTT (Photon Transport Transistor) has been proposed in 1989 as an optical coupling device of light emitting diode (LED) or laser diode and light receiving diode (Photo Diode, PD), where the carrier of the base layer is light (Photon) only. In this paper we consider the amplification principle of the PTT and BJT (bipolar junction transistor), by illustrating those h parameters of equivalent small signal amplifier circuit. Moreover, this paper also discusses the similarities and differences between PTT and BJT, based on the derived h parameters.
OS17-4 Color Image Arrangement Using Histogram Matching
Yusuke Kawakami (NIT (Kagawa College), Japan), Tetsuo Hattori (Kagawa University, Japan), R.P.C. Janaka Rajapakse (Tainan National University of the Arts, Taiwan (R.O.C.))

For the arrangement processing of image using its histogram, we previously have presented a Histogram Matching method based on Gaussian Distribution (HMGD). However, in the case where the brightness histogram of input image has multiple peaks, the HMGD processing does not always bring good results. In this paper, we present an improved histogram matching method using the reference histogram that is made by appropriate moving average processing over the histogram of input image. Also in this paper, we show the experimental results.
OS17-5 Methodology for Creativity Oriented STEM Education Based on ETT Theory

Tetsuo Hattori, Toshihiro Hayashi, Mai Hattori, Yoshiro Imai (Kagawa University, Japan),
Asako Ohno (Osaka Sangyo University, Japan), Takeshi Tanaka (Hiroshima Institute of Technology, Japan)

Recently, the necessity of integrated and comprehensive methodology for STEM (Science, Technology, Engineering and Mathematics) education is growing. In this paper, we propose an educational methodology utilizing the viewpoint of Equivalent Transformation Thinking (ETT) theory which has been proposed by Dr. Kikuya Ichikawa in 1955 as a principle of creativity. Especially, we show that the viewpoint is very useful not only for new technology invention but also for STEM Education in the sense that it deepens insights of the contents to be learned, motivates students to study further, and inspires their creativity.
OS18 Computer and Information Engineering (12)
Chair Norrima Mokhtar (University of Malaya, Malaysia)
Co-Chair Heshalini Rajagopal (UCSI University, Malaysia)

OS18-1 Efficient Campus Shuttle Tracking and Management Mobile Application for College Campus

Andrea Tantay Gonzales[1], Kavitha Thamadharan[1], Neesha Jothi[2]
([1] INTI International College Penang, Malaysia) ([2]UCSI University, Malaysia)

Shuttle Stalk, a Real-Time Campus Shuttle Booking and Tracking System was a proposed solution which enables the students to register for the shuttle service through the mobile application, reducing the administrative burden and to track its current location in real-time, allowing them to plan their journeys more effectively. The application developed serves as a comprehensive solution for both students and administrators, providing real-time shuttle tracking and streamlined management capabilities.

OS18-2 GCN Analysis of Task-Based fMRI Data for Diagnosis of Schizophrenia

Tejaswini Thota[1], Reuben Stephen John[1], Dr R Dhanush[1], Dr Amutha S[1]
([1]Vellore Institute of Technology, India)

This study focuses on schizophrenia, characterized by distorted reality and delusions. We propose utilizing a Graph Convolutional Network (GCN) model on a task-based fMRI data to differentiate schizophrenia instances, with and without auditory hallucinations, utilizing healthy participants for comparison. Various node embedding algorithms are compared to extract structural properties, and statistical features for differentiation. The study focuses on identifying specific auditory stimuli that significantly differentiate individuals. Model validation deploys k-fold stratified crossvalidation, with evaluation metrics, including accuracy, precision, recall, F1 macro, and MCC guide the assessment of the GCN model.
OS18-3 AR-Based Application for Campus Navigation

Renuka Devi Rajagopal[1], Akshay S[1], Manoj Rathinam[1], Shakthi B[1], Heshalini Rajagopal[2]
([1]Vellore Institute of Technology, India) ([2]UCSI University, Malaysia)

The "Campus Navigator" is an innovative augmented reality (AR) application designed for seamless campus navigation. It combines geolocation technology, QR code recognition, and predefined geospatial anchors to transition users from outdoor to indoor spaces. Augmented reality overlays provide real-time wayfinding guidance, eliminating the need for traditional maps. The user-centric design and user feedback integration enhance accessibility and user satisfaction. Real-world testing demonstrates promising performance, accuracy, and user engagement. The Campus Navigator transforms campus navigation, with potential for broader applications.

OS18-4 Development of Robotic Assistant for Health Care Sector with A Special Focus to Aid the Geriartric Patients

Narayanan Ganesh (Vellore Institute of Technology, India)

Human manual efforts in their day-to-day tasks are reduced by robotic helpers. This paper analyzes the robot created to assist the aged people. The created robot can be controlled by voice commands with its own inbuilt microphone to pick up human speech orders. This robot can do a variety of movements, turns, grab operations, move an object from one location to another. Personal assistant robot is built using Microcontrollers. The results reveal that the developed robot will be one of the best companions for the geriatric patients and will be an alternate solution will make a new mark in the health care sector.

OS18-5 Development of a Desktop Application Restaurant Management System

Gabriela Maria Ancilla, Heshalini Rajagopa, Ismail Ahmed Al-Qasem Al-Hadi (UCSI University, Malaysia)

The number of restaurants has grown rapidly around the world, the awareness of managing it efficiently has increased. This necessity yields the idea to invent a restaurant management system (RMS). This RMS will bring several benefits such as greater management of a restaurant, reduced resources cost, raise profit, and time-saving by allowing the admin to manage the restaurant easily through the functionality provided in the system. The provided features include adding, updating, and deleting information, stock calculation and auto re-order stock items, ingredients management, and finance calculation.

OS18-6 Face Recognition based on Attendance System

Koh Pei Cong [1], Heshalini Rajagopal[1], Ghassan Saleh[1], Norrima Mokthar[2]
([1]UCSI University, Malaysia) ([2]University of Malaya, Malaysia)

The use of face recognition technology for attendance tracking has grown popular in recent years. Hence, the main goal of this project is to produce an accurate, fast, and robust face recognition based on an attendance system. The system detects the user's unique features, understand the identity of the user through face recognition technology, and thus records the attendance from the face recognition dataset to the user that matches the user, in an attempt to help the user automatically check in with real-time attendance date. The system includes features such as face detection, face recognition, distance estimation, and attendance recording.

OS18-7 U-Reserve: Development of a Facility Reservation System for UCSI University

Esther Chong Jun Lynn[1], Neesha Jothi[1], Ismail Ahmed[1] ([1]UCSI University, Malaysia)

In today's technology-driven era, there is a growing emphasis on efficient and convenient methods to enhance user satisfaction. UCSI University, Kuala Lumpur, currently employs a manual facility reservation system that requires in-person or email submissions. This outdated approach often results in double booking and underutilization of resources. Therefore, this project aims to develop a web-based facility reservation system named U-Reserve. This system is developed by HTML, CSS, JS, JSP, Servlet, and MySQL, focusing on colour tone and font type. These considerations are vital in providing an improved user experience. With U-Reserve, not only the reservation requests and cancellations being streamlined, but informed decisions regarding facility management can also be made by a data-driven dashboard.

OS18-8 The Smart Document Processing with Artificial Intelligence

Raenu Kolandaisamy[1], Heshalini Rajagopal[1], Indraah K[2], Glaret Shirley Sinnappan[3]
([1]UCSI University, Malaysia) ([2]University Utara Malaysia, Malaysia)
([3]Tunku Abdul Rahman University, Malaysia)

This study focuses on the challenges and potential for Intelligent Document Processing (IDP) with Artificial Intelligence (AI) to manage unstructured data. A large amount of data in many different forms, such as information from the IoT, cybersecurity and more are produced during this modern Digital Age which has been widely distributed through a wide range of unformatted formats. IDP utilizes AI technologies like Machine Learning (ML), Natural Language Processing (NLP), and Computer Vision (CV), with the aim of converting unstructured data into structured, usable information. The IDP, are explored in the findings and discussion section that emphasizes its capability to automatically perform redundant tasks, reduce operating costs as well as improve employee productivity.

OS18-9 Digital Security Challenges Faced by Business Organizations

Raenu Kolandaisamy[1], Heshalini Rajagopal[1], Indraah K[2], Glaret Shirley Sinnappan[3]
([1]UCSI University, Malaysia) ([2]University Utara Malaysia, Malaysia)
([3]Tunku Abdul Rahman University, Malaysia)

Over the decades, the forms of cyber-attacks have evolved from disruption level, cybercriminal, followed by cyber espionage and lastly threatening level. Digital security has played a significant role in protecting enterprises from any form of cyber-attacks, especially in today's era of digitalization. Aligning with the global effort in emerging the concept of Industrial Revolution 4.0 (IR4.0) in organizations, where sensitive data and confidential information can be accessed at a fingertip of an employee. This paper discusses the difficulties of implementing digital security solutions in an enterprise in terms of external potential cyber threats, internal cyber security roadblocks within the organization and how Covid-19 pandemic imposed challenges towards cyber security in the organizations.

OS18-10 The Study on Perception on E-Waste Among the People

Raenu Kolandaisamy[1], Heshalini Rajagopal[1], Indraah K[2]
([1]UCSI University, Malaysia) ([2]Utara Malaysia, Malaysia)

E-waste is piling up at an alarming rate, which results in our environment's pollution, while only a few are being disposed of correctly. This research aims to discover people's awareness of e-waste and how to handle it. An online survey was done among 75 respondents, who were asked about their general knowledge of e-waste. Most respondents are aware of the effects of e-waste but lack knowledge on how to tackle them, including questions concerning e-waste management and its causes. In conclusion, the general public must be educated on e-waste to reduce and dispose of e-waste efficiently and effectively.

OS18-11 Emergence of Cybercrimes in Online Social Networks

Raenu Kolandaisamy[1], Heshalini Rajagopal[1], Indraah K[2]
([1]UCSI University, Malaysia) ([2]University Utara Malaysia, Malaysia)

The rise of social networking websites has been seen in recent years. Everyone will be spending most of their time on social networking websites such as Facebook, Instagram and Whatsapp. The great advantage that this social networking website offers benefited many of the users. It can help people to promote themselves or their business to gain more popularity and also customers through these social networking websites. There are many cybercrimes that can be identified which are identity theft, hacking, fraud and so on. The emergence of cybercrimes has created an awareness so that the users will know what the common attacks are and how they can be prevented from being lure and being a victim of this attack. This research will discuss about the attacks and how these attacks can be prevented by the users.

OS18-12 Development of a music recommendation application by using facial emotion recognition

Shengke Xie, Raenu Kolandaisamy, Ghassan Saleh, Heshalini Rajagopal (UCSI University, Malaysia)

Music is an important part of human life and culture, and it can affect people's emotions and moods. However, choosing music from a large library can be a challenging and time-consuming task. In this paper, we propose a facial expression recognition-based music recommendation system that can recommend suitable music which matches the user's current mood. The system uses a camera to capture the user's face and a convolutional neural network model which trained facial emotion recognition database to recognize seven basic emotions: anger, disgust, fear, happiness, sadness, surprise and neutral. The paper contributes to the research of facial emotion recognition and music recommendation and provides a convenient way for people to enjoy music.

OS19 Natural Computing (3)
Chair Marion Oswald (Vienna University of Technology, Austria)
Co-Chair Yasuhiro Suzuki (Nagoya University, Japan)

OS19 -1 A Model of Reaction-diffusion phenomena with Multiset Processing
Yasuhiro Suzuki (Nagoya University Japan)

We propose a model of reaction-diffusion phenomena using Abstract Rewriting System on Multisets ARMS, which is a model of Multiset Processing. Although proposed model is simple, computer simulations confirm that the Turing pattern is generated.

OS19-2 Extract tactile qualities from time series data
Yasuhiro Suzuki (Nagoya University, Japan)

We proposed the Tactile Score to describe time-varying tactile sensation by the time variation of vertical force. Tactile quality is essential in hardness/softness, roughness, and temperature. Hardness and softness can be extracted from the shape of the Tactile Score. Roughness can be extracted from the pattern of hardness and softness. The arbitrary time series data can be interpreted as a tactile score by considering the time variation of the vertical force, and the hardness and softness are extracted from the time series data interpreted as the tactile score. This method can extract different features from conventional data science methods.

OS19-3 Healthcare applications of vibrotactile stimulation developed by Tactile Score

Yasuhiro Suzuki, Rie Taniguchi (Nagoya University, Japan)

We constructed a system to convert the tactile score into vibratory tactile sensation. We conduct basic biological experiments on electronic tactile stimuli and apply the results to medical and healthcare applications. We use two types of electronic tactile stimuli. One is direct vibrating tactile stimulation, and the other is airborne vibrating tactile stimulation. Verification experiments of this system have confirmed cosmetic effects such as skin collagen aggregation, improvement of hypertension and diabetes, and reduction of pain and nerve paralysis. In addition, a clinical study was conducted in which patients with dementia were exposed to vibrotactile sensation (low-frequency sound) via air vibration and an improvement in cognitive function was confirmed.

OS20-1 Image Collection Experiments of a Handy AUV for Offshore Structure Inspection

Keisuke Watanabe, Koki Amano, Shingen Urano, Yasutaka Taniguchi, Konosuke Watanabe
(Tokai University, Japan)

In recent years, in Japan, with the decline in the working population, there has been a noticeable shortage of labor at construction sites and offshore operations. On the other hand, with the aim of realizing a GX society, it is expected that offshore wind power generation platforms will rapidly increase and be deployed offshore. Since it is not easy to access offshore platforms, it is necessary to automate equipment inspection work, and it is expected that the use of AUVs will be particularly desirable for underwater inspection work. The most basic inspection work is assumed to be to collect images of underwater structures. Therefore, in this study, we created an AUV and conducted an image collection experiment using a pier owned by our university as an example to confirm its functionality.

OS20-2 Design of Disassembly-reassembly Type USV for Coral Reef Research

Keisuke Watanabe, Koki Amano, Gaku Minato, Yasutaka Taniguchi, Konosuke Watanabe
(Tokai University, Japan)

Researchers are conducting physical surveys by diving and swimming to study the effects of microplastics and global warming on coral reefs. The area, time, and water depth that can be investigated by diving are extremely limited. In addition, to collect microplastics, it is necessary to tow the nets, but chartering a ship is expensive. Therefore, the authors are developing a system that simultaneously operates a USV and a UUV to simultaneously observe the sea surface and underwater. In this paper, we conducted a conceptual design, carried out fluid force measurements, trajectory tracking experiments, and image recognition using AI, with the aim of realizing a lightweight USV that can be divided during transportation to coral reef areas and reassembled on site for operation.

OS20-3 Optimization method to improve visual SLAM in dynamic environment

Yufei Liu, Kazuo Ishii (Kyushu Institute of Technology, Japan)

Aiming at the problem that the robustness of the classic visual SLAM system is greatly affected by dynamic feature points in the environment, a method of eliminating dynamic feature points using a target detection algorithm is proposed. Use the target detection algorithm YOLOv5 to identify and classify the collected feature points. Then remove the extracted dynamic feature points, use the remaining static feature points for map construction and positioning, and finally test on the TUM data set. The results show that this algorithm effectively improves the positioning accuracy and robustness of the visual SLAM system.
OS20-4 Design of flexible mechanism for flexible manipulator

Huang Jiawei, Kazuo Ishii (Kyushu Institute of Technology, Japan)

Based on the study of the kinematic limitations of the rigid manipulator structure and the characteristics of the existing flexible manipulator in different categories, this paper proposes a structure assumption of flexible manipulator based on the advantages of high load of rigid joint and high flexibility of flexible manipulator. This paper designed a flexible manipulator structure driven by wires. Using the forward kinematics analysis the sport model of the structure. The motion range of the end of the manipulator arm and the length changes of the wires were simulated with the movement of the model.

OS20-5 Driver Drowsiness Detection Method based on Deep Learning

Shi Puwei, Kazuo Ishii (Kyushu Institute of Technology, Japan)

Drowsiness driving will pose a serious threat to the lives of drivers and others. Determining the state of the driver through face recognition has the advantages of low cost and convenience. Therefore, this study deploys the face recognition model to the mobile phone, and finally realizes the recognition of the driver's Drowsiness by the front camera of the mobile phone. The whole research is divided into three parts. The first part is to train the face 68-keypoints recognition model based on the YOLO face algorithm. The second part is to deploy the trained model to the mobile phone using ONNX and NCNN. The third part is to calculate EAR and MAR using several facial key points, and finally complete the recognition of the driver's drowsiness state using EAR and MAR.

OS20-6 An Analysis of Translational Motion for a Mobile Robot with Line-Symmetric Rollers Arrangement

Kenji Kimura[1], Kazuo Ishii[2]

([1]National Institute of Technology, Matsue College, Japan) ([2]Kyushu Institute of Technology, Japan)

In fields such as logistics, robots are required to have efficient mobility. There are various types of rollers used in mobile robots. Among them, omni-rollers have excellent omnidirectional mobility and are easy to control. In this study, mechanism kinematics has been proposed that assumes arbitrary changes in the roller arrangement position on a circular mechanism and the roller arrangement has been evaluated from the viewpoint of speed efficiency. Furthermore, we aim to evaluate the mobility of mobile robots by focusing on their translational components. Moreover, we have examined the behavior of the area of the area generated by the end point of the robot velocity vector and evaluated the velocity efficiency.

OS20-7 Development of Teaching Materials for Robot Programming for Junior High School Students:Student-Based Educational Activities

Kenji Kimura, Youta Takano (National Institute of Technology, Matsue College, Japan)

With the extensive use of robots in recent years, an age of co-existence between humans and robots is expected to arrive in the future. Therefore, providing robot education in the early stages of elementary and junior high school is necessary to stimulate students' interest in robots. Furthermore, educational institutions are becoming more active in robot education as a part of their contribution to the local community. For elementary school students, a Beauto Racer (Vstone) has been adopted as a teaching material for robot education, and teaching materials have been developed for teaching line tracing. In this study, we will develop educational materials for junior high school students on maze exploration using a Beauto Rover (Vstone). The students of NIT, Matsue College took the initiative in this activity. The purpose is to improve their teaching skills.

OS20-8 Design and Software Production of Robotics Educational Design for Elementary and Junior High School Student

Youta Takano, Kenji Kimura (National Institute of Technology, Matsue College, Japan)

The Ministry of Education, Culture, Sports, Science and Technology (MEXT) has been promoting cross-curricular learning including STEAM education in its educational policy for 2021. The purpose of this study is to have students experience not only control engineering but also basic programming techniques, and to have them become interested in mathematical subjects in general, which are the basis for control engineering. The educational design and accompanying software were designed using Beauto Balancer2 (Viston) educational robot and Scratch, a visual programming editor developed by the Scratch Foundation. In addition, workshops were conducted and the lesson design was evaluated by a questionnaire.
OS20-9 Development of visual inspection system for low-reflective material utilizing of a string shadow

Keiji Kamei[1], Tomorou Kawahara[1], Yoshiyuki Daimaru[2]
([1]Nishinippon Institute of Technology, Japan) ([2]Nissan Motor Kyushu, Japan)

Visual inspection of products in manufacturing plant is usually conducted by workers. However, that inspection process by workers occasionally happen oversight due to careless check, so that automatic visual inspection system is needed from manufacturer. Products made of low-reflective material are difficult to inspect by light reflection because contours of defect areas are got blurred. To solve this problem, we propose to inspect products utilizing of a string shadow. Form our research, a string shadow was different between contours of defect area and its of non-defect. On the other hand, former research did not success to detect defect area due to determination algorithm for defect. In this paper, we apply linear approximation of a string shadow to defect detection. From the experimental results, we succeed in detecting defects.

OS20-10 Development of IoT-Based Remote Monitoring Module for Greenhouse Environment to Facilitate Crop Growth Data Analysis

Moeko Tominaga, Yasunori Takemura, Junya Era, Wataru Kaishita
(Nishinippon Institute of Technology, Japan)
Eiji Mizoe, Tomoyasu Furukawa (Kumamoto Fruit and Vegetable Shippers Association Co. Ltd., Japan)

As the shortage of agricultural workforce becomes a concern, IoT proves effective in alleviating labor burdens. Monitoring, storing, and analyzing the growing environment, especially for new crops, is crucial for subsequent agricultural cycles. However, small farms often face challenges in data collection due to cost constraints, particularly with new crops. An agricultural IoT system was developed for small farmers, featuring a module for collecting, accumulating, and visualizing time-series data from sensors. To demonstrate feasibility, the IoT system was implemented and validated by intermittently monitoring banana and coffee growth parameters in a Kumamoto greenhouse over two years. Results confirmed that the proposed IoT remote monitoring module empowers farmers to monitor crop growth environments.

OS20-11 Development greenhouse environment prediction system using IoT data

Yasunori Takemura, Naoya Nishida, Moeko Tominga (Nishinippon Institute of Technology, Japan)
Eiji Mizoe, Tomoyasu Furukawa (Kumamoto Fruit and Vegetable Shippers Association Co. Ltd., Japan)

Currently, the decrease in the working population is a significant problem in agriculture in Japan. In addition, the prices of imported vegetables and fruits have been rising due to international trade problems such as the weak yen. This study has developed an environmental data storage system using IoT to assist the labor force and to understand the cultivation data of crops that have not been cultivated in Japan. Using this big data, we have constructed and evaluated a forecasting system. In this study, we focus on the domestic cultivation of bananas grown in the tropics as the subject to obtain data and make predictions. For learning, a system was constructed to infer the next day's temperature by time-series analysis, using as input data obtained from the IoT. In this paper, we report a comparison of two time series analysis algorithms.

OS20-12 The Development of SaaS for Quantifying the Amount of Drifted Debris on the Coast

Ayumu Tominaga, Ryohei Komori (National Institute of Technology Kitakyushu College, Japan)
Eiji Hayashi (Kyushu Institute of Technology, Japan)

In the process of collecting drifted debris along a coastal area, it has been required to quantify the collection results. This study introduced a Software as a Service (SaaS) equipped with image processing capabilities for the detection and identification of debris in photographs. The SaaS was developed to facilitate the automated weighing of the collected debris. In the beach cleanup event in June 2023, 317 images capturing debris found during the coastal cleanup were gathered on a cloud server from 90 participants via this SaaS. These images were subsequently analyzed by object recognition AI executed on a cloud server, leading to the detection and identification of 954 instances of debris. This result represents the actual amount of debris collected during this cleanup event, and indicates that the achievements of the event were quantified via the SaaS.

OS20-13 Development of an antagonistic wire-driven joint mechanism capable of rapid motion and variable stiffness

Katsuaki Suzuki[1], Yuya Nishida[2], Kazuo Ishii[2]
([1]Kumamoto Industrial Research Institute, Japan, [2]Kyushu Institute of Technology, Japan)

The advancement of digital transformation in manufacturing is expected to demand novel tasks for industrial machinery unlike before. When adding mechanisms or actuators to enhance machine functionality, concerns arise about potential system enlargement and increased complexity. The design concept of integrating multiple functions into mechanisms using a few actuators and components serves as one means to address these issues. We aim to elucidate the structural arrangement capable of achieving three functions, including normal motion, rapid motion, and variable stiffness, using two electric actuators. In this paper, we introduce a newly devised antagonistic wire-driven joint mechanism aimed at improving the variable stiffness function within the articulated mechanism we have developed, enabling three functionalities.

OS20-14 Gakken Hills Interdisciplinary Ekiden Competing with Humans, Animals, and Robots

Takuya Fujinaga[1], Moeko Tominaga[2], Daigo Katayama[3], Kazuo Ishii[3]
([1]Fukuoka University, [2]Nishinippon Institute of Technology, [3]Kyushu Institute of Technology, Japan)

With the advancement of science and technology, the societal implementation of robots has been expected. In recent years, the number of robots exiting in human living spaces has increased, and interaction between humans and robots has become an important issue. The purpose of this study is to propose a future society where humans, animals, and robots coexist. We organize relay races, or ekiden in Japanese, where they compete together as runners to discuss the future society. The competition rules have been established for this ekiden to ensure that each runner can compete fairly. For example, an advantage is given to the time of humans, animals, and robots, so that the results are the same. This paper explains the competition rules and reports the competition results of the 8th race held in 2023.

OS20-15 Development of a Low-Cost Underwater Robot for Research and Education

Takuya Fujinaga (Fukuoka University Japan)

Underwater robots are frequently utilized for underwater observation. When used as tools, commercially available underwater robots are sufficient. However, when utilized for research, development, or education, the required specifications vary based on the purpose, necessitating custom development. Generally, the development of underwater robots demands a significant amount of funds, posing a high barrier for research, development, and education. The aim of this study is to reduce these barriers, facilitating broader implementation of research, development, and education in the field of underwater robotics. This paper explains the development requirements, process and cost of a low-cost underwater robot designed for a robotics competition and discusses key considerations during development.

OS21 Human-Machine Interface (3)

OS21-1 Enhancing Reconnaissance Missions Through Multiple Unmanned Systems in ROS

Anees ul Husnain[1,2], Norrima Mokhtar[1], Takao Ito[3], Siti Sendari[4], Muhammad Farris Kyasudeen[5], Muhammad Badri M Noor[1,6], Heshalini Rajagopal[7]
([1] Universiti Malaya, Malaysia), ([2] The Islamia University of Bahawalpur, Pakistan)
([3]Hiroshima University, Japan), ([4] Universitas Negeri Malang, Indonesia)
([5] University Technology MARA (UiTM), Malaysia)
([6] Ifcon Technology Sdn Bhd, Malaysia), ([7]UCSI University, Malaysia)

The synergistic collaboration between UAVs and UGVs addresses the limitations of individual platforms, offering a versatile solution for reconnaissance tasks in diverse environments. The proposed system employs ROS as the underlying architecture to facilitate seamless communication and coordination among multiple UAVs and UGVs. Optimal coverage is ensured through efficient exploration and coverage of the reconnaissance area, under by comparing raster-scan, expanding spiral and zig-zag area exploration approaches. The article concludes by discussing potential extensions, such as the integration of machine learning techniques for enhanced autonomy and the scalability of the system for larger-scale missions by presenting a ROS-based framework that maximizes the synergy between UAVs and UGVs.

OS21-2 Illumination Effects on Facial Expression Recognition using Empirical Mode Decomposition

Hashimah Ali[1], Wan Khairunizam Wan Ahmad[1], Hariharan Muthusamy[2], Mohamed Elshaikh[1]
([1]Universiti Malaysia Perlis, Malaysia)
([2]National Institute of Technology Uttarakhand, India)

Thus, this paper aims to investigate the illumination effects (brightness variations) on facial expression recognition using empirical mode decomposition reconstruction techniques. In this framework, firstly, the noisy facial expression images were simulated with the illumination effects using different brightness levels of 30%, 40%, 50%, 60%, and 70%. Then, the EMD will decompose the noisy facial expression images into a small set of intrinsic mode functions (IMF), namely IMF1, IMF2, IMF3, and residue. Based on property held by EMD, the signals are decomposed into several IMF components, each with a different time scale. Because the last several IMFs represent the majority of illumination effects, various reconstruction techniques for IMFs have been investigated at various brightness levels. Feature reduction techniques Principal component analysis (PCA) and linear discriminant analysis (LDA) have been employed to reduce the high-dimensional space of IMF features into low-dimensional IMF features. The reduced IMF reconstructions were then used as input to the k-nearest neighbour classifier to recognise the seven facial expressions. A series of experiments have been conducted on the JAFEE database using various reconstruction IMFs together with PCA plus LDA. Based on the results obtained, the reconstruction of IMF1 + IMF2 + IMF3 shows the highest accuracy in high illumination conditions, which is 99.06%.

OS21-3 Supercontinuum Generation Pump By a Molydenum Disulfide Based Soliton Mode-Locked Fiber Laser

Aeryn D. Ahmad[1], Norrima Mokhtar[1], Hamzah Arof[1], Sulaiman Wadi harun[1], Ahmad Haziq Aiman Rosol[2]
([1]Universiti Malaya, Malaysia), ([2]MJIIT, UTM, Malaysia)

In this work, a highly stable soliton mode-locked Erbium-doped fiber laser (EDFL) is passively obtained using a molybdenum disulfide (MoS2) thin film as a saturable absorber (SA). The MoS2 thin film obtained via electrochemical deposition technique is integrated into an EDFL cavity to generate mode-locked pulses operating at 1.88 MHz with a pulse duration of 3.03 ps. Supercontinuum (SC) light is generated using the proposed soliton mode pulses operating at 1560.4 nm as they are injected into a 100 m long highly nonlinear photonic crystal fiber (HN-PCF) after it is amplified to the output power of 17.8 dBm. The SC light operates in a wavelength range starting from 1360 nm to more than 1750 nm with the intensity above -35 dBm. The proposed supercontinuum laser can be seen as a promising light source for metrology and sensing applications.

OS22-1   Adsorption Behavior of Arsenic and Selenium using NiZn Hydroxy Double Salts with Acetate, Chloride, Nitrate, and Sulfate Anions

Kaoru Ohe, Ryosuke Tabuchi, Tatsuya Oshima (University of Miyazaki, Japan)

Arsenic(As) and selenium(Se) has become an increasingly serious water contamination worldwide, so the development of adsorbents to improve the adsorption performance of As and Se is desired. In this study, hydroxy double salt NiZn-AcO, -Cl, -NO$_3$, and -SO$_4$, with acetate, chloride, nitrate, and sulfate anions between layers and the adsorption behavior of As and Se was investigated. The Langmuir isotherm model, characteristic of monolayer adsorption, fit the data best with $R^2 > 0.94$. The adsorption capacity(q_{max}) of As(V) by NiZn-Cl was about twice that of the other adsorbents. The q_{max} of Se(IV) by NiZn-AcO, NiZn-Cl, and NiZn-NO$_3$ was almost the same value as that of Se(VI) and 1.4-1.7 times larger than that of NiZn-SO$_4$. The prepared adsorbent was confirmed to be useful for the removal of As and Se.
Fig.1 Langmuir plots of Se(VI) on NiZn-AcO, -Cl, NO$_3$ and SO$_4$

OS22-2   Parallel acoustic analysis based on the domain decomposition method with higher-order element

Amane Takei[1], Makoto Sakamoto[1], Akihiro Kudo[2]
([1]University of Miyazaki, Japan) ([2]National Institute of Technology, Tomakomai Collage, Japan)

Numerical analysis approaches, such as the finite element method, are widely used for the estimation of the sound field in architectural spaces. Large-scale analyses, using numerical models with over 10 trillion elements, are required for the analysis of a large space such as a concert hall with higher-frequency bands. Large spaces are often limited to low-frequency analysis. In this study, the number of elements is reduced by wave acoustic analysis using higher-order elements. Based on the results using higher-order elements, it is shown that it is possible to analyze a real environment model such as a live music club and a concert hall.

(a)   Visualization results (X-Y)
(b)   Visualization results (X-Z)
Fig.1 Numerical result using concert hall model

OS22-3   Sound field evaluation on the acoustical experiment using non-steady state analysis

Akihiro Kudo[1], Makoto Sakamoto[2], Amane Takei[2]
([1]National Institute of Technology, Tomakomai College, Japan) ([2] University of Miyazaki, Japan)

Identifying acoustic effects of sound waves emitted by a sound source on the listener is important for understanding the localization of sound as perceived by the listener. In this presentation, we will analyze the effect of the presence of a chair on the psychoacoustic effect using a practical model simulating a psychoacoustic experiment consisting of a loudspeaker, a listener, and a chair. Non-steady state analysis is required to analyze changes in acoustic effects over time. To analyze the interference of sound waves in the vicinity of the listener, a short Gaussian pulse-like solitary wave is set up on the loudspeaker's vibrating surface. Since sound waves in the audible band are used for these simulations, a mesh size of less than 25 mm is used. The laboratory is 3m of depth and width, and 2.5m of height, which means that the computational whole target consists of over 15 million elements. This simulation requires a large number of calculations, so a parallel computing method with ADVENTURE_Sound that is an open-source software for sound simulation, is used to run the simulation. From the simulation results of the non-stationary analysis and consider the effect of the presence of the chair on the sound image localization.

Fig.1 Example of results of non-steady state analysis with gaussian pulse

OS22-4 A DeepInsight method with Morphological Analysis

Toyoaki Tomioka[1], Satoshi Ikeda[1], Makoto Sakamoto[1], Takao Ito[2]
([1]Faculty of Engineering, University of Miyazaki, Japan) ([2]Hiroshima University, Japan)

The DeepInsight method is a comprehensive approach aimed at applying convolutional neural networks (CNN) to non-image data. This study specifically focuses on using the DeepInsight method to forecast stock prices, which involve time series data. To achieve this, we employ morphological analysis to extract the necessary word feature for predicting stock prices from news articles. Additionally, t-SNE is utilized to reduce the dimensionality of the high-dimensional data, transforming it into a more manageable, low-dimensional format suitable for stock price prediction. After reducing dimensionality in both news text data and stock price time series data using t-SNE, and subsequently applying CNN for learning from the transformed representations, predictions were made with an accuracy of approximately 60%.

OS22-5 Support for Museum Exhibition of Small Fungi using AR Technology

Kakeru Takemura[1], Ota Hamasuna[1], Fumito Hamakawa[1], Satoshi Ikeda[1], Kaoru Ohe[1], Amane Takei[1],
Makoto Sakamoto[1], Shuichi Kurogi[2]
([1]University of Miyazaki, Japan) ([2]Miyazaki Prefectural Museum of Nature and History, Japan)

There are 25 species of bioluminescent fungi that have been confirmed in Japan, and 12 species have been confirmed in Miyazaki Prefecture. Those fungi are very small. Therefore, it is difficult to observe the structure of fungi exhibited in museums with the naked eye. The purpose of this research is to display 3DCG models of mushrooms using AR (Augmented Reality) technology in order to facilitate observation of these small mushrooms exhibited in museums. Two hundred visitors to the museum were asked to use the application and complete a survey. In order to measure the ease of observation of different app functions and mobile devices used in the survey, we divided the respondents into four groups.

OS22-6 Automatic Selection of High-Grade Dried Shiitake Mushrooms using Machine Learning

Ota Hamasuna[1], Kakeru Takemura[1], Kodai Hasebe[1], Fumito Hamakawa[1], Bidesh Biswas Biki[1], Satoshi
Ikeda[1], Kaoru Ohe[1], Amane Takei[1], Makoto Sakamoto[1], Kazuhide Sugimoto[2]
([1]University of Miyazaki, Japan) ([2]SUGIMOTO Co., Ltd. Japan)

SUGIMOTO Co., Ltd. collects dried shiitake mushrooms directly from approximately 600 producers in Takachiho. Shiitake mushrooms are at their peak in spring and fall, and at peak times, more than 1 ton of mushrooms can be brought in each day. However, shiitake mushrooms are still sorted manually, and sorting this much requires a lot of effort. In this paper, we aim to efficiently determine the quality of shiitake mushrooms using image processing and deep learning.

OS22-7 Predicting High Volatility Cryptocurrency Prices using Deep Learning

Tsutomu Ito[1], Kodai Hasebe[2], Fumito Hamakawa[2], Bidesh Biswas Biki[2], Satoshi Ikeda[2], Amane Takei[2],
Makoto Sakamoto[2], Md Riajuliislam[3], Sabrina Bari Shital[4], Takao Ito[5]
([1]National Institute of Technology, Ube College, Japan) ([2]University of Miyazaki, Japan)
([3]TU Dortmund, Germany) ([4]Daffodil International University, Bangladesh) ([5]Hiroshima University, Japan)

Even if you want to make a profit from cryptocurrency, you are worried that you will lose money, and it is difficult to afford it. There are a vast number of papers that study such unpredictable price fluctuations of cryptocurrency. Currently, it is mainstream to use deep learning to predict the price of cryptocurrency. The goal of this research is to predict the price of cryptocurrency over the long-term using deep learning. The algorithms used are LSTM, GRU, and Bi-LSTM. The cryptocurrency targeted are Bitcoin, Ethereum, Litecoin, and Cardano. Finally, we will compare it with previous research and verify the performance of our model.
OS22-8 Simulation of Weathering Representation using Vertex and UV Information

Tsutomu Ito[1], Fumito Hamakawa[2], Kodai Hasebe[2], Satoshi Ikeda[2], Amane Takei[2], Makoto Sakamoto[2], Takao Ito[3] ([1]National Institute of Technology, Ube College, Japan) ([2]University of Miyazaki, Japan), ([4]Hiroshima University, Japan)

In recent years, three-dimensional computer graphics (3DCG) technology has been developed. In addition, a plethora of research have been published on weathering representations such as rust and moss for realistic representation. However, when outputting simulation results on an image, an enormous number of images are required to display different simulation results in a three-dimensional space. In this paper, a simulation method using vertex information of a 3D model and simple images is proposed. In this method, when the number of vertices is sufficient, the simulation result output does not use images, thus reducing the data increase. This figure is one of the experimental results.

OS23 Industrial Revolution (5)
Chair Hazry Desa (Universiti Malaysia Perlis (UniMAP), Malaysia)

OS23-1 Investigating the Engineering Interventions in the Conservation of Malaysia Heritage Structures: A Review on Preserving Historical Edifices Through Advance Civil Engineering Techniques

Muhammad Azizi Azizan, Nurfadzillah Ishak, Hazry Desa (COE-UAS, UniMAP, Malaysia)

This review delves into the realm of Malaysia's heritage conservation, spotlighting the transformative impact of advanced artificial robotic aid in civil engineering techniques. Through the integration of Fiber-Reinforced Polymers and nanotechnology, historical edifices are fortified, seamlessly blending modern engineering with architectural elegance. Non-destructive testing (NDT) methods, including ground-penetrating radar and Finite Element Analysis (FEA), empower conservationists with deep insights into structural intricacies, guiding targeted interventions. In the digital sphere, 3D laser scanning captures intricate details, while Virtual Reality (VR) simulations facilitate immersive exploration and decision-making. This harmonious fusion of cutting-edge engineering ensures the enduring legacy of Malaysia's architectural treasures.
OS23-2 Drones and Data: A Comprehensive Exploration of UAVs in Data Mining

Muhammad Azizi Azizan, Nurfadzillah Ishak, Hazry Desa (UniMAP, Malaysia)

Encapsulates a comprehensive investigation into the symbiotic relationship between Unmanned Aerial Vehicles (UAVs) and data mining, as encapsulated in the discourse titled "Drones and Data." The technological transitions facilitated by UAVs, emphasizing the integration of machine learning algorithms, cloud-based data processing, and the collaborative synergy between stakeholders. Therefore, this study a glimpse into the intricate web of applications and technological advancements at the intersection of UAVs and data mining. It serves as a scholarly guide through the evolving landscape of "Drones and Data," UAVs play a central role in unlocking unprecedented insights and efficiencies, reshaping the future of data mining.

OS23-3 Development of Variable Arm to Control the Manoeuvrability of Quadrotor

L. Y. Hong, H. Desa and M. A. Azizan (UniMAP, Malaysia)

M. H. Tanveer (Kennesaw State University, USA)

This paper introduces a variable arm concept for quadrotors, enabling manoeuvrability by adjusting arm length. Variations in arm's length impact thrust-generated bending moments, tilting and directing quadrotor movement. The main aim is to create a quadrotor with adaptable arm length to efficiently control maneuvers, reducing the need for extra thrust during flight. The focus is on designing a quadrotor capable of extending or retracting its arms. The proposed idea centers on using the variable arm to alter bending moments and control manoeuvrability. Testing a quadrotor with this adjustable arm showed successful performance in agile manoeuvres. Results confirm the variable arm's ability to induce body rotation, effectively regulating quadrotor manoeuvrability.
OS23-4 Development of IOT-Enabled Smart Water Metering System

S. D. Wen, H. Desa and M. A. Azizan (UniMAP, Malaysia)

A. -S. T. Hussain (Al-Kitab University, Iraq) M. H. Tanveer, R. Patan (Kennesaw State University, USA)

This paper presents a smart IoT water meter for automated readings, aiming to create both a device and a compatible mobile app. Instead of manual reading, the IoT-enabled meter, using a camera and CNN, accurately captures data. It utilizes ESP32 CAM for collection, a laptop as a gateway, and MQTT for transfer. Data is stored in Firebase and analyzed via the app. A functional prototype tested in a housing area collects data, monitored through the app. The analysis evaluates method suitability, offering future improvement recommendations.
OS23-5 Object Detection and Instance Segmentation with YOLOV8: Progress and Limitations

L. J. Lee, H. Desa and M. A. Azizan (UniMAP, Malaysia)

A. -S. T. Hussain (Al-Kitab University, Iraq) M. H. Tanveer (Kennesaw State University, USA)

This research employs object detection and instance segmentation algorithms to distinguish between objects & backgrounds and to interpret the detected objects. The YOLOV8 (You Only Look Once) framework and COCO dataset are utilized for detecting and interpreting the objects. Additionally, the accuracy of detection, segmentation, and interpretation is tested by placing objects at various distances from the camera. The algorithm's performance was evaluated, and the results were documented. In the experiments, a sample of 11 objects was tested, and 8 of them were successfully detected at distances of 45cm, 75cm, 105cm, and 135cm. For instance, segmentation, segmentation maps appeared clean when detecting a single object but faced challenges when multiple objects overlapped.

OS24-Robotics and Intelligent Casting (5)
Jiwu Wang (Beijing Jiaotong University, China)

OS24-1 A high-performance motion planning method based on asymptotically optimal RRT
Tianbin Meng (Beijing Jiaotong University, China), Jiwu Wang (Beijing Jiaotong University, China)

The motion planning algorithm of the robot arm plays an important role in the working process of the robot arm, especially in the complex environment, an efficient algorithm is more conducive to the robot arm to complete the corresponding planning task. Aiming at the problems such as low exploration efficiency and poor planning path in the current motion planning task of robotic arm, we propose a distance constraint mechanism. Based on RRT^* and $Informed-RRT^*$, the algorithm uses halton sequence to generate random points and introduces the current lowest cost path length. To avoid useless nodes extension. The simulation results show that the algorithm with distance constraint mechanism can improve the exploration efficiency and planning quality to some extent.

OS24-2 CSM-RRT*: an improved RRT* algorithm based on constrained sampling mechanism
Hang Yang (Beijing Jiaotong University, China), Jiwu Wang (Beijing Jiaotong University, China),
Xueqiang Shang (Aero Engine Corporation of China, China)

In this paper,an improved RRT* algorithm(CSM-RRT*) based on constrained sampling mechanism is proposed .The entire planning process is divided into two steps: fast exploration and optimization of the initial path.Firstly,with the removing of redundant nodes and saving of collision nodes by constrained sampling strategy,the number of redundant nodes and collision times is reduced which avoids excessive exploration of repetitive and collision regions.The target bias strategy is used to reduce unnecessary expansion while preserving the node tree's ability to explore unknown regions and quickly finding a path connecting the starting and ending points.Subsequently, a dynamic sampling region consists of removed redundant nodes and collision nodes is formed around initial path .By prioritizing exploration within this dynamic region,computational resources can be saved and the asymptotic optimal path can be quickly converged from the initial path.Eventually,simulation results presented in various obstacle cluttered environments confirm the efficiency of CSM-RRT*.
OS24-3 Small Sample Object Detection Based on Improved YOLOv5
Yuxuan Gao(Beijing Jiaotong University, China),Jiwu Wang(Beijing Jiaotong University, China), Zixin Li(Aero Engine Corporation of China)

Object detection is widely used in various production and life, such as mask detection and recognition during the epidemic, face recognition with masks. Object detection algorithm based on deep learning has always been an important research content and implementation method in the field of object detection. Due to the large number of lead seals and fuses, their locations are not fixed, the lead seals and fuses have difficulties such as few sample datasets, complex target background and easy to be blocked, and strong reflective interference, and the conventional image processing methods are difficult to solve the problem of effective object recognition. In this study, by expanding the datasets, using different data enhancement methods, and training in the improved algorithm, the detection accuracy, detection speed, and adaptability were effectively improved.

OS24-4 Research on Gas Pore Prediction Method Based on Sand Core Characteristic Time

Xiaolong Wang[1], Qihua Wu[2], Jiwu Wang[1], Jinwu Kang[3], Na Li[2], Yucheng Sun[2]
([1]Beijing Jiaotong University, China) ([2]Weichai Power Co., Ltd. China) ([3]Tsinghua University, China)

In the production of castings, gas pores are a prevalent defect, particularly in components where air-tightness is crucial, such as cylinder blocks and heads. These defects primarily arise from the intrusion of gases into the casting during the combustion of resin in the sand core. Due to the complexity of the sand core's gas evolution and venting process, predicting gas pores using numerical simulation poses significant computational and time challenges. This paper introduces a rapid prediction method for gas pores based on the characteristic time of the sand core. By setting the heat transfer boundaries, initial conditions, and termination criteria for computation, the thermal conductivity of the sand core is adjusted. The termination computation time is used as the characteristic time of the sand core. This time is then compared with a critical characteristic time to predict the distribution of gas pores. As the analysis of more sand cores is incorporated, the precision of the critical characteristic time improves, leading to more accurate predictions of gas pores in castings.

OS24-5 Optimization Analysis of a Deep Learning-Based Model for Predicting Temperature Fields in the Solidification Process of Castings

Yahui Yang, Jiwu Wang (Beijing Jiaotong University, China) Jinwu Kang (Tsinghua University, China)

In the foundry industry, accurate prediction of the temperature field of castings during solidification is essential to ensure high product quality and improve productivity. This study provides an in-depth investigation of the Unet deep learning model developed specifically for this purpose, focusing on the impact of key training parameters such as optimiser selection, batch size, number of iterations and loss function selection on the prediction performance of the Unet model. The findings provide practical insights on how these parameters can be selected and tuned to improve the accuracy and reliability of model predictions. The results of this study not only provide new ideas for the practice of deep learning applications in the foundry industry, but also help to improve the accuracy and efficiency of the production process.
OS25 Research Towards the Sustainable Development Goals (SDG's) (10)
Chair Ammar A.M. Al Talib (UCSI University, Malaysia)
Co-Chair Takao Ito (Hiroshima University, Japan)

OS25-1 Portable Green Energy Mobile Laptop Charging Station

Ammar A. M. Al-Talib[1], Rodney Tan[1], Ang Aun Jie[1], Idayu M. Tahir[1], Sarah Atifah Saruchi[2], Cik Suhana Bt. Hasan[1], Amar Rizwan[1]
([1]UCSI University) ([2]UMPSA, Malaysia)

Mobile phones and laptop computers require electrical power to recharge when the battery is down.. As a result, it would be very useful if a portable charging station derived from renewable energy harvesting could be built, so that individuals could recharge their phones and laptops whenever needed. The objective of this project is to design and develop a green energy mobile and laptop charging station that uses wind and solar energy and evaluate the performance of the designed station under different working conditions. The efficiency of the power generated to charge the station is achieving 95.6% for solar charging, which is considered a high efficiency for a renewable energy charging station. Based on the analysis of the charging station results, it has been proven that it can provide sufficient power and is safe for use as a portable mobile laptop charging station.

OS25-2 Auto Indoor Hydroponics Plant Growth Chamber

Ammar A.M. Al-Talib[1], Tew Hwa Hui[1], Sarah Atifah Saruchi[2], Idayu M. Tahir[1], Nor Fazilah Binti Abdullah[1]
([1]UCSI University) ([2]UMPSA, Malaysia)

The objective of this project is to build an auto indoor hydroponics plant growing chamber that has an auto monitoring and controlling system. A ESP32 based hydroponics electrical system is built with the attachment of hardware components such as temperature and humidity sensor, light intensity sensor, water level sensor, and water flow rate sensor. The software development of the system is through Arduino IoT Cloud platform, which has an overall suitability in terms of features, cost, and user intuitiveness for starters. Results have shown that ESP32 can ensure stable power supply.. After testing and validation, all of the electrical components are stored in a power enclosure box to prevent contact with liquid. In short, the developed auto indoor hydroponics plant growth chamber has effectively demonstrated the ability in easing the plant cultivation procedure for agricultural community.

OS25-3 A Design and Fabrication of a Solar Agriculture Water Pumping System

Ammar A.M. Al-Talib[1], Idayu M.Tahir[1], Ain Atiqa[1], Amar Rizwan[1], Sarah Atifah Saruchi[2], Yazan Abu Al shaikh[1]
([1]UCSI University) ([2]UMPSA, Malaysia)

This study explores the use of a solar driven water pump. PV technology replaces conventional electricity and diesel pumps by using solar energy to power DC or AC water pumps. The main objective of this study is to design and construct a solar-powered agriculture water pumping system and to evaluate its performance. The solar agriculture water pumping system used in this project consists of a 40-watt monocrystalline solar cell with an efficiency conversion of between 23% – 24%. This can supply power to a 16.8 W DC   Flow   Submersible Pump. It could lift the water up to 5m and a flow range of 700 Liter/Hour. The system also includes a PWM 30A Solar Charge Controller to regulate the input power to a 12V, 7.2A Sealed Rechargeable Battery. Finally, a 20m long watering kit with nozzles irrigation system is connected to a 12V DC Submersible Pump to water the plants.

OS25-4 Design and Performance of a Power Generating Manual Treadmill

Ammar A. M. Al-Talib[1], Sarah Atifah Saruchi[2], Cik Suhana Bt. Hasan[1], Nor Fazilah Binti Abdullah[1], Ain Atiqa[1], Ahmad Jelban[1]
([1]UCSI University) ([2]UMPSA, Malaysia)

Treadmills are one of the most popular training equipment in the gym and at home. The working principle of treadmills is by moving the belt with the human knee bending, which creates mechanical energy to turn the belt. A gear or pulleyand belt system connects to the generator along the axel line of the rolling bars. The power generated by the DC generator is stored in a battery pack and could be used to charge phones or other equipment. It has been found that treadmills can provide an efficiency of 95% when the DC motor is used and 92% when the AC motor is used. The main objective of this study is to design and fabricate a powder-generating manual treadmill and to analyze the performance of the system under differentoperation conditions.

OS25-5 Smart Car Jack Using Internet of Things

Idayu M.T. Noor, Ammar A.M. Al- Talib, Mahmoud E.A. Zeiad, Suhana B.H. Cik,
(UCSI University, Malaysia)

This paper presents a modified car jack design that is safe, easy to operate, and reduces physical effort for lifting and lowering vehicles during automobile repair, especially for roadside situations. The study explores the integration of Internet of Things (IoT) technology in automotive tools, particularly in the development of smart car jacks. The proposed smart car jack offers convenience and enhanced control over vehicle maintenance tasks. Comparative analysis between smart car jacks and traditional jacks reveals several advantages of the former. Smart jacks demonstrate higher lifting capacities and efficiency due to their use of hydraulic systems and advanced motorized mechanisms. The most significant differentiator is the integration of technology in smart car jacks. Equipped with microcontrollers, sensors, and mobile applications, they offer remote control and real-time monitoring features. These technological advancements provide users with enhanced convenience and safety, setting smart jacks apart from their traditional counterparts.
OS25-6 Gas Detection for Biogas System Using Internet-of-Things (IoT)

Ammar A.M. Al Talib, I.H.W. Yang, Idayu M.T. Noor, Haslija A.B. Ayu, Afifi. Z. Nur Muhammad
(UCSI University, Malaysia)

The melting of the polar icecaps, rising sea levels, increase in allergies and infectious disease outbreaks, those are only a few effects of global warming. Global warming remains one of the most detrimental by-products of industrialization. Fossil fuels contribute to the majority of greenhouse gases emitted but remain a popular option for the generation of energy. An easy fix for this conundrum is to utilize other forms of fuel for energy generation which burns cleaner and renewable as opposed to fossil fuels. The solution would be to use biomethane generated from waste products which burn cleaner and comes from a renewable source. In this paper, an IoT based biogas monitoring system for biogas reactors is proposed. An ESP-32 microcontroller system is deployed and tested to detect the presence of gas production. A dashboard plotting the data obtained from sensors is designed to help user monitor parameters.

OS25-7 IoT Based Smart Mushroom Growing Kit

Ammar A.M. Al- Talib, C.K.J. Ting, Noor Idayu M. Tahir, Ain Atiqa, T.Y. Hui
(UCSI University, Malaysia)

This project introduces an IoT-based smart mushroom growing kit to meet the rising global demand for high-quality mushrooms. Various species of mushrooms can be efficiently grown in different environmental conditions with the help of IoT devices that enable farmers to regulate the climate condition according to the specific needs of each type of mushroom. The kit employs sensors and actuators, including temperature, humidity, MQ-135, and ultrasonic sensors, along with an ESP32 camera, controlled by a microcontroller. The collected data is transmitted to an IoT platform via Wi-Fi, facilitating real-time monitoring and control through a user-friendly dashboard on Blynk website and Blynk app. This innovative system optimizes mushroom cultivation by adjusting environmental conditions, offering efficiency and profitability. Users can remotely monitor and regulate the growth environment through their smartphones, enhancing the overall mushroom cultivation experience.

OS25-8 Design and Analysis of Artificial Magnetic Conductor for Metal Shielding Applications in RFID Car Detection Applications

Eryana Hussin[1,2], Azman Zakariya[2], Md. Ashraful Haque[2,3], Nur Izzati Ali[4]

([1]UCSI University) ([2]UTPSA, Malaysia) ([3]Daffodil International University, Bangladesh) ([4]UMP, Malaysia)

This paper presents the design of symmetrical Artificial Magnetic Conductor (AMC) for metal shielding in RFID applications. It integrates a simple straight dipole as the RFID tag representation, optimizing signal fidelity within metallic environments. Tailored for low-frequency RFID use, the multiple-array AMC addresses UHF bandwidth limitations by incorporating slots, ensuring a compact design and expanded bandwidth. This proposed structure enhances performance of the dipole which includes return loss, directivity, and bandwidth.
OS25-9 Effect of Fiber Orientation on the Mechanical Performance of Natural Fiber Polymer Composite Bicycle Frame using Finite Element Analysis

Kok Sem Too, Cik Suhana Hassan, Nor Fazilah Abdullah, Ammar Abdulaziz Majeed Al-Talib
(UCSI University, Malaysia)

In this research, the performance of oil palm empty fruit bunch (OPEFB) fibre-reinforced epoxy composite with varying fibre orientation and stacking sequence as the material for mountain bike frame was studied utilizing ANSYS software. The choice of OPEFB fibre was motivated by the fact that the waste by-product of oil palm extraction in Malaysia alone might reach 70-80 million tons per year, with 90% of oil palm biomass lost as waste. The properties of epoxy OPEFB composite in principal 1, 2, and 3 directions were calculated using Whitney and Riley estimates. 10 stacking sequences and five loading conditions were taken. The results have shown that the fibre orientation of epoxy OPEFB composite on the bicycle frame had little effect on the performance contrary to the number of plies in the laminate or number of laminates which had major effects.
OS25-10 Modelling of Short-Circuit Protection for A Residential Grid-Connected BESS

Kong De Kang, Farah Adilah Jamaludin, Rodney H.G. Tan
(UCSI University, Malaysia)

This research paper presents the power protection study on a grid-connected Battery Energy Storage System (BESS) in a typical Malaysia low-voltage (LV) residential network. The BESS model and control algorithm is developed in MATLAB/Simulink environment to provide a platform for short circuit fault analysis of BESS. The BESS model can charge and discharge its energy with an algorithm-controlled bidirectional AC/DC converter. The paper also presents two cases for BESS short circuit.The protection level on BESS is also optimized by introducing a time-delay characteristics model to coordinate circuit breakers in compliance with standards outlined in IEEE Std 1375-1998, IEC/EN 60898-2, IEC/EN 60947-2, UL 1077, and CSA 22.2. No.235. As a conclusion, BESS was interrupted within stipulated time. In case of internal short circuit protection failure, a backup protection will act on isolating BESS from the grid provided that the discharged current exceeds system capacity.
OS26 Navigating the Digital Frontier: Innovations in the Age of Industry Revolution 4.0 (11)
Chair Wei Hong Lim (UCSI University, Malaysia)
Co-Chair Takao Ito (Hiroshima University, Japan)

OS26-1 An Intelligent Cargo/Warehouse Management System

Zhongheng Sun[1], Zhou Yue[1], Xun Sun[1], Wenzhuo Fan[1], Wenxuan Zhou[1]
([1]Fuzou University, China)

This paper presents a low-cost and user-friendly warehouse management system developed using Arduino and ESP8266 hardware. The system accurately monitors temperature, humidity, and harmful gas concentration, and acts as an intrusion detector in a warehouse environment. It also includes functions for managing and detecting goods using RFID chips and for automatic delivery using unmanned intelligent vehicles. Data is uploaded to a cloud-based relational database in real time. The system provides a cost-effective and efficient solution for warehouse management.

OS26-2 A Comprehensive Approach to Design and Implement an IoT-Enabled Intelligent Shopping Cart System with Obstacle-Aware Navigation and Enhanced Customer Engagement for Elevated Consumer Experiences

Yao Chen[1], Jiacheng Du[1], Bo Peng[1], Ningfei Wang[1], Zehan Huang[1], Wei Hong Lim[2], Sew Sun Tiang[2], Mastaneh Mokayef[2], Chin Hong Wong[1]
([1]Fuzhou University, China) ([2]UCSI University, Malaysia)

Supermarket shopping is a universal experience. This project focuses on enhancing this experience by designing an intelligent, user-friendly shopping cart and an interactive webpage. The cart features include accessing item information, automatic movement, and obstacle detection. Users can view their itemized costs and control the cart's movements through the webpage. Utilizing an ultrasonic module, the cart autonomously navigates and follows specific customers, incorporating automatic barcode scanning for product identification. Connectivity is achieved through a WiFi module using the MQTT protocol, facilitating server communication. This development exemplifies Internet of Things applications, showcasing how internet connectivity can significantly increase convenience in everyday activities.

OS26-3 Design of a Four-Port Flexible UWB-MIMO Antenna for Wearable and IoT Applications

Jia Wei Tan, Sew Sun Tiang, Kim Soon Chong, Mohammad Arif Ilyas, Mastaneh Mokayef, Zhi Ying Yeoh, Wei Kang Lai, Wei Hong Lim (UCSI University, Malaysia)

This paper introduces a compact, four-port MIMO antenna for ultrawideband (UWB) applications, measuring 60×60 mm². Printed on a single-layer flame resistant (FR-4) substrate (permittivity 4.3, thickness 1.6mm), the antenna features four microstrip cells, each orthogonal to its neighbor for improved isolation. It includes a rectangular patch with staircase slits and a stepped feed line. Square stubs at the top center enhance isolation. The antenna boasts a significant return loss (-43.75dB), wide impedance bandwidth (1.967-12GHz), and isolation below -15dB. Its envelope correction coefficient (ECC) is under 0.02 with a moderate 4.4dBi gain. Although its 63% radiation efficiency could be enhanced, the antenna's ultrawide bandwidth and compactness make it suitable for UWB wearable IoT applications.
OS26-4 Investigate Power Efficiency in PLECS and MATLAB Software by Designing USB 5W Charger

Zhi Ying Yeoh, Kim Soon Chong, Sew Sun Tiang, Mohammad Arif Ilyas, Jia Wei Tan, Wei Kang Lai, Wei Hong Lim (UCSI University, Malaysia)

In power electronics, accurately assessing simulation tools is key for precise, reliable electronic system designs. This study compares MATLAB Simulink and PLECS in modeling a 5W USB charger's power characteristic. The charger, using an AC-DC full bridge rectifier and DC-DC flyback topology, delivers a stable 5VDC at 1A. The analysis focuses on power efficiency and thermal characteristics, incorporating real-life components for detailed insights. Results show PLECS, specialized in power electronics, surpasses MATLAB in accuracy and consistency. This research aids in understanding simulation tools' effectiveness, guiding engineers and researchers in power efficiency evaluations for electronic systems.

OS26-5 Design and Simulation and Performance of Grid Connected Photovoltaic System for Small, Tall Building in Malaysia

Wei Kang Lai, Kim Soon Chong, Sew Sun Tiang, Mohammad Arif Ilyas, Jia Wei Tan, Zhi Ying Yeoh, Wei Hong Lim (UCSI University, Malaysia)

In Malaysia's rapidly urbanizing landscape, sustainable energy for small, tall buildings is increasingly vital. This study addresses this need through the design, simulation, and performance analysis of grid-connected photovoltaic systems tailored for these unique structures. Utilizing AutoCAD and PVSyst for design and simulation, the research details rooftop array dimensions, PV panel wiring, and system components aligned with MS 1837-2018 standards. Results indicate the designed system can save 526.70MWh annually, costing RM 339,306.98, with a 9.8% return on investment (ROI) and a 13-year breakeven point, emphasizing its sustainability and economic viability.
OS26-6 A Design of Dual-Band Coplanar Waveguide (CPW) Printed Antenna for 1.9 - 3.6GHz Applications

Jia Wei Tan, Sew Sun Tiang, Kim Soon Chong, Mohammad Arif Ilyas, Mastaneh Mokayef, Zhi Ying Yeoh, Wei Kang Lai, Wei Hong Lim (UCSI University, Malaysia)

A dual-band coplanar waveguide (CPW) printed antenna for IoT application is proposed, mounted on a low-profile RT/duroid 5880 substrate with dieletric constant of 2.2, loss tangent of 0.0009 and a standard height of 0.787mm. This design aims to cover the major frequency bands from LTE to Bluetooth/Wi-Fi band/WiMax/Zigbee, Extended IMT and 5G whereby the bandwidth range between 1.7 GHz to 3.6 GHz. The antenna is miniaturized through the CPW technique and has a rectangular size of 60 x 30 x $1.187mm^3$. The design and simulation of the result records a return loss of -25.12dB, peak gain of 4.23dBi, voltage standing wave ratio (VSWR) close to 1, omnidirectional radiation, and current distribution. Radiation efficiency reaches approximately 94%, with a total efficiency of 89.4% between 1.9GHz-3.6GHz.
OS26-7 Optimized Convolutional Neural Network Towards Effective Wafer Defects Classification

Koon Hian Ang[1], Koon Meng Ang[1], Chin Hong Wong[2,3], Abhishek Sharma[4], Chun Kit Ang[1], Kim Soon Chong[1], Sew Sun Tiang[1], Wei Hong Lim[1]
([1]UCSI University, Malaysia) ([2]Fuzou University, China) ([3]Maynooth University, Ireland)
([4]Graphic Era Deemed to be University, India)

Semiconductor defect inspection is crucial for yield improvement but is hindered by manual inspection's subjectivity and error. This paper employs Convolutional Neural Networks (CNNs) for automated wafer defect classification, addressing the challenges of time-intensive training and complex hyperparameter tuning. We propose the Arithmetic Optimization Algorithm (AOA) to efficiently optimize CNN hyperparameters like momentum, initial learning rate, maximum epochs, and L2 regularization. Our method reduces the trial-and-error in hyperparameter tuning. Using the AOA-optimized ResNet-18 model, our simulations show superior performance in defect classification compared to the unoptimized model, demonstrating its effectiveness and practical potential.

OS26-8 Tackling Photovoltaic (PV) Estimation Challenges: An Innovative AOA Variant for Improved Accuracy and Robustness

Rayan Mohammed Noor Mohammed Bakhit[1], Abhishek Sharma[2], Tiong Hoo Lim[3], Chin Hong Wong[4,5], Kim Soon Chong[1], Li Pan[1], Sew Sun Tiang[1], Wei Hong Lim[1]
([1]UCSI University, Malaysia) ([2]Graphic Era Deemed to be University, India) ([3]Universiti Teknologi Brunei, Brunei Darussalam) ([4]Fuzou University, China) ([5]Maynooth University, Ireland)

Optimizing photovoltaic (PV) cell/module modeling is key to advancing solar power and achieving net zero carbon goals. Challenges in accurate PV parameter estimation arise from environmental variability, aging, and incomplete manufacturer data. Traditional Arithmetic Optimization Algorithm (AOA) often struggles with premature convergence due to imbalanced exploration and exploitation. This paper presents an enhanced AOA variant, incorporating chaotic maps and oppositional-based learning to better balance the optimization process. Our extensive simulations show that this improved AOA variant significantly enhances accuracy and robustness in PV cell/module parameter estimation compared to the conventional method.

OS26-9 Deep Learning in Manufacturing: A Focus on Welding Defect Classification with CNNs

Tin Chang Ting[1], Hameedur Rahman[2], Tiong Hoo Lim[3], Chin Hong Wong[4,5], Chun Kit Ang[1], Mohamed Khan Afthab Ahamed Khan[1], Sew Sun Tiang[1], Wei Hong Lim[1]
([1]UCSI University, Malaysia) ([2] Air University, Pakistan) ([3]Universiti Teknologi Brunei, Brunei Darussalam) ([4]Fuzou University, China) ([5]Maynooth University, Ireland)

Welding is integral to modern manufacturing, yet the complex process often leads to defects, impacting the quality of the final product. Recent advances in deep learning, particularly Convolutional Neural Networks (CNNs), have shown remarkable results in applications like defect recognition. This study evaluated AlexNet, ResNet-18, ResNet-50, ResNet-101, MobileNet-v2, ShuffleNet, and SqueezeNet for their effectiveness in identifying welding defects, using accuracy, precision, sensitivity, specificity, and F-score as metrics. The dataset covered defects like cracks, lack of penetration, porosity, and a no-defect class. Our analysis shows that most of these architectures deliver promising results in accuracy, sensitivity, specificity, precision, and F1-score, highlighting their potential in defect recognition.

OS26-10 Enhancing Global Optimization Performance of Arithmetic Optimization Algorithm with a Modified Population Initialization Scheme

Tin Chang Ting[1], Hameedur Rahman[2], Meng Choung Chiong[1], Mohamed Khan Afthab Ahamed Khan[1], Cik Suhana Hassan[1], Farah Adilah Binti Jamaludin[1], Sew Sun Tiang[1], Wei Hong Lim[1]
([1]UCSI University, Malaysia) ([2]Air University, Pakistan)

Arithmetic Optimization Algorithm (AOA) is widely used to solve global optimization problems. However, it often faces premature convergence challenges in complex optimization scenarios. A key factor affecting AOA's performance is the solution quality of the initial population. The conventional initialization scheme, despite its prevalence, lacks reliability in ensuring high-quality solutions due to inherent stochastic processes. To address this issue, we propose a modified initialization scheme that improves initial population quality by integrating chaotic maps and oppositional-based learning. Through extensive simulation studies, we demonstrate that the enhanced AOA, equipped with this new initialization scheme, exhibits superior performance in solving a range of benchmark functions with improved accuracy.

OS26-11 Enhancing Precision Object Detection and Identification for Autonomous Vehicles through YOLOv5 Refinement with YOLO-ALPHA

Guandong Li[1], Yanzhe Xie[1], Yuhao Lu[1], Jingzhen Fan[1], Yuankui Huang[1], Zongyan Wen[1], Wei Hong Lim[2], Chin Hong Wong[1]
([1]Maynooth University, Ireland) ([2]UCSI University, Malaysia)

Advancing swiftly in contemporary society, the rapid growth of autonomous driving technology suggests its potential adoption across continents. The realization of fully autonomous driving relies on proficiently detecting, classifying, and tracking road objects such as pedestrians and vehicles. This research employs the YOLOv5 neural network, enhancing it with YOLO-ALPHA. Modifications, encompassing freeze and attention mechanisms, serve to refine accuracy and expedite training. Furthermore, adjustments to the activation function aim to stabilize precision and recall. The integration of a FCN based on semantic segmentation theory contributes to improved accuracy in detecting road conditions during autonomous driving. Consequently, this enables the successful and highly accurate functionality of automatic identification.
OS27 Post-narratological Approaches to Cognition in Humans and Robots (5)
Chair: Jumpei Ono (Aomori University, Japan)
Co-Chair: Hiroki Fxyma (Kobe University, Japan)

OS27-1 A Game Framework Based on the Disinformation Warfare in Russo-Ukrainian War

Jumpei Ono (Aomori University, Japan), Takashi Ogata (Iwate Prefectural University, Japan)

From 2022, when Russia began its invasion of Ukraine, to the present, the number of speeches and information directly/indirectly related to Russo-Ukrainian war has continued to increase in mass communication venues such as SNS and TV. This study proposes a game that simulates the spread of disinformation by focusing on the information published by Ukraine as a list of disinformation speakers, especially on the topics they talk about. The game is intended to provide players with psychological immunity against disinformation through the simulation of disinformation dissemination.
OS27-2 Comparative Analysis of Eye Tracking between Veteran and Novice during Radiological Interpretation

Yuka Naito, Jun Nakamura (Chuo University, Japan),
Yoshinobu Ishiwata (Yokohama City University, Japan)

With the development of AI, AI may substitute for physicians in radiological interpretations in the future. The purpose of this paper is to identify factors that could form the foundation for algorithms enabling AI to explore pathological findings. This study focuses on the "angles of gaze trajectory" and conducts a comparative analysis between veteran and novice. The results indicate commonalities and variances in the angles of gaze trajectory between veteran and novice, particularly around 10, 350, and 180 degrees. Both Veteran and Novice have a relatively higher frequency of gaze movement around 10 and 350 degrees compared to other angles. Veteran has a relatively higher frequency of gaze movement around 180 degrees compared to other angles, while novice has a relatively lower frequency around 180 degrees.
OS27-3 Development of Notification System to Prevent Working Productivity from Declining Caused by Increased Carbon Dioxide Concentration

Yohei Kamoda, Jun Nakamura (Chuo University, Japan)

In association with the change of work style to remote, the home environment should be considered in terms of carbon dioxide concentration (CDC) which has negative effects on the human body, such as less cognitive abilities. To challenge this problem, the author developed an alert system that supports remote workers to be notified of an increase in CDC, by combining Raspberry Pi, CDC sensor, and Slack. As a result, the developed alert system was able to support the user in keeping the CDC in the room below the set threshold. In addition, the system shows that a significant increase in CDC can be observed in the room when it comes to insufficient ventilation.

OS27-4 Visualization of the Skilled Physician's Gaze Characteristic during Diagnosis

Taiki Sugimoto, Jun Nakamura (Chuo University, Japan)
and Yoshinobu Ishiwata (Yokohama City University, Japan)

This study examines gaze movement differences in diagnosis between skilled and unskilled physicians, aiming to identify factors influencing diagnostic speed and enhance artificial intelligence's diagnostic capabilities. Results reveal that experienced physicians, on average, spent 61% less diagnostic time than beginners, covering 49% of the gaze distance on the X and Y-axes. (comparison of the cumulative distance of gaze on the screen). Despite increased movement on the Z-axis (comparison of the scrolling speed of the CT scan results), skilled physicians moved 2-3 times faster, effectively narrowing attention and identifying specific areas.

OS27-5 Comparative Analysis of Methods for Visualizing the Sensory Experience of Food and Beverages

Hiroki Fxyma (Kobe University, Japan)

This research explores and compares various methodologies employed in the visualization of taste experiences associated with food and beverages. The study delves into sensory analysis techniques, technological innovations, and artistic representations used to convey the complex and subjective nature of flavor. Through a comprehensive review of existing literature and practical experimentation, the paper evaluates the efficacy of different approaches in capturing and communicating the nuanced aspects of taste, aroma, and texture. The findings aim to contribute to the advancement of sensory science, culinary arts, and consumer research by providing insights into the strengths, limitations, and potential applications of diverse taste visualization methods. As the interdisciplinary field of gastronomy continues to evolve, this research serves as a valuable resource for professionals, researchers, and enthusiasts seeking to enhance our understanding and appreciation of the multisensory aspects of food and beverage consumption.

GS1-1 Deep Learning Based Prediction of Heat Transfer Coefficient Using Spectrogram Images from Boiling Sound

Fuga Mitsuyama, Ren Umeno, Tomohide Yabuki, Tohru Kamiya (Kyushu Institute of Technology, Japan)

Recently, cooling methods based on water boiling have attracted attention as a thermal solution for electronic equipment. In this situation, it is necessary to measure Heat Transfer Coefficient (HTC) to design more efficient cooling systems. In this paper, we propose a method to predict of the HTC from boiling sound data using deep learning techniques. Measuring HTC requires a variety of sensors and modifications to the equipment, which can be costly. Predicting HTC by sound alone can therefore reduce these costs. The accuracy improved by 1.12% compared to the conventional method through the development of Convolutional Neural Network (CNN) incorporate Convolutional Block Attention Module (CBAM).

GS1-2 A Study on Classification of Faulty Motor Sound Using Convolutional Neural Networks

Jamil Md Shafayet, Praveen Nuwantha Gunaratne, Hiroki Tamura (University of Miyazaki, Japan)

This paper is focused towards determining the use of audio classification methods to detect faulty motors by their sound, both with an abnormal noise and noise-free scenarios, so that the requirement of human inspection can be reduced in factories. Here, the soundwaves of motors, having both normal and faulty mechanical parts were acquired using an electronic stethoscope. The audio files were recorded in '.wav' format which later split into chunks. Noise reduction is widely used in audio classification tasks. Among various available methods, the Autoencoder was implemented for noise reduction. Our proposal method is to use various soundwave analysis methods for generating features such as in Mel-Frequency Cepstral Coefficient, Mel-spectrogram, and Spectrogram, and comparing the resulting accuracy. Convolutional neural networks are employed for the purpose of classification. Our proposed method resulted in approx. 97% accuracy in classifying 2 classes having 93 samples of motors and 2.23% loss in noise reduction with autoencoder.

GS1-3 Design and Development of a Flexible Active Ankle Joint Orthosis for Locomotion Assistance

Praveen Nuwantha Gunaratne, Hiroki Tamura (University of Miyazaki, Japan)

Active ankle joint orthosis is an artificial wearable device that is closely fitted to the human ankle and combines human intelligence and intentions with the powered robot joints. However, most of the existing designs have only focused on one degree of freedom (DOF) of the ankle joint: namely plantarflexion-dorsiflexion. Alternatively, a modular power-assist flexible active ankle orthosis is proposed, addressing anthropomorphic architecture of design, and supporting multiple DOFs of ankle for locomotion assistance of the physically weak individuals. The proposed ankle joint orthosis was designed with the aid of CAD tools followed by fabrication of a working model. Electrically powered systems with gear transmissions were adapted to support the principal motions during normal Gait. In parallel, the design of the control algorithm was carried out based on the EMG signals. The future advancements have been focused on developing a novel control method that provides sufficient flexibility to assist a wide variety of lower-limb motions.

GS1-4 A study on the Real-Time Biomechanical Analysis of Lamber Burden Utilizing Stereoscope Cameras

Taufik Hidayat Soesilo, Praveen Nuwantha Gunaratne, Hiroki Tamura (University of Miyazaki, Japan)

Lamber region is susceptible to strain and stress due to various physical activities and occupational task. To study about the lamber burden, researchers have developed many tools but most of existing design can only use static imaging or doesn't provide real-time update. Our proposed system records and examines the change of body posture in real time by utilizing the capabilities of stereoscope cameras. By using MediaPipe algorithms, 2D keypoints representing body joint can be extracted from images. Afterward, using the Direct Linear Transform (DLT) the corresponding 3D keypoints can be calculated using obtained 2D keypoints. With the 3D keypoints the body angles can be computed and used to calculate the wight of the lumbar burden using the digital human model software JACK-like calculation. Finally, our proposed system reached to its aim to study about lamber burden and adjust the person needs in real-time.

GS1-5 Verification of Determination Possibility using Convolutional Autoencoder for Machine Tool Abnormality Detection

Yuta Sumoto, Praveen Nuwantha, Hiroki Tamura (University of Miyazaki, Japan)

The purpose of this research is to clarify the cause of failure and to improve the accuracy of abnormality detection by predicting the noise added to the machine tool from the results of the convolutional autoencoder. Data obtained from an acceleration sensor mounted on the machine tool are reconstructed using a convolutional autoencoder, and the average absolute error is calculated. The maximum value of the average absolute error of the training data is used as the threshold value for abnormality detection. Multiple simulated data with different amplitude values based on a composite sine wave with a specific frequency, white noise, and random numbers within a specified amplitude value were verified. In this paper, the characteristics of each type of noise and the parameters of the optimal model were examined from error rate and error distribution.
GS1-6 Basic Research for High-speed Heart Sound Determination using AI

Riku Nakashima, Praveen Nuwantha Gunaratne, Hiroki Tamura (University of Miyazaki, Japan)

In recent years, many researchers focus on enhancing the current situation of the home healthcare system. In this paper, we developed a system that uses AI to quickly determine whether auscultation sounds are normal or not. In our analysis, heart sounds were imaged, and their abnormalities were identified using machine learning tools. The proposal approach uses a YOLO_v7 model based anomaly detection and the Wavelet Transform was employed to analyze the acquired heart sound data. Our proposal system resulted with an 89% accuracy rate on the basis of 5 seconds of heartbeat data, in various recording environments.
GS1-7 Prediction of High-Energy Electron Flux at Geosynchronous Orbit using a neural network technique

Ami Iwabu, Kentaro Kitamura (Kyusyu Institute of Technology, Japan)

The radiation belt, where the high-energy particles are predominant in near earth space from the low earth orbit (LEO) to the geostationary orbit (GEO), sometimes causes satellite malfunction. Therefore, the objective of this study is to predict the high-energy electron flux at GEO with the energy above 2 MeV after 24 hours with higher accuracy for the safety satellite operation in terms of the space weather science. In this study the various kinds of solar wind data from satellite observations and ground geomagnetic observation data in 1999 were used for the Recurrent Neural Network (RNN). Prediction results were evaluated by the prediction efficiency, which is derived from both predicted and actual variation data. As a result, the prediction using combined data of solar wind and geomagnetic data shows highest prediction efficiency of 0.72.

GS1-8 Image Gradient-based Monocular Visual-Inertial Odometry

Tae Ihn Kim[1]. Jae Hyung Jung[2], Chan Gook Park[2]
([1]Hyundai Motor Company, Republic of Korea), ([2]Seoul National University, Republic of Korea)

This paper presents an image gradient-based monocular visual-inertial odometry (VIO) algorithm, using image gradient measurements, robust to illumination change. Our proposed algorithm follows the multi-state constraint Kalman filter (MSCKF) framework, a sliding windowed extended Kalman filter (EKF). We expand the measurements from the reprojected feature locations on the image coordinates to the corresponding image gradients in the measurement selection. The iterated EKF and low-pass pyramid are adapted to reduce the linearization error in the MSCKF measurement update process. We verify that our proposed algorithm outperforms both conventional indirect and direct MSCKF-based VIO algorithms by evaluating the pose estimation performance using a real-world dataset, including illumination change.

GS2-1 A Method for Embedding Multiple Photographic Images in a Photographic Image

Naoki Kouno, Kanya Goto, Toru Hiraoka (University of Nagasaki, Japan)

A method has been proposed for embedding another photographic image (image B) in a photographic image (image A).   An image (image A') is generated by embedding information of image B in image A, and then an image (image B') is restored by extracting information from image A'. The conventional methods can only embed one photographic image in one photographic image. Therefore, we extend the conventional method and propose a method for embedding multiple photographic images in one photographic image. In our method, as more images B are embedding in image A, the image quality of image A' deteriorates, but the image quality of images B' dose not deteriorate. To verify the effectiveness of our method, experiments using various photographic images were performed.

GS2-2 Generation of Flowing-Line Images Using Vertical and Horizontal Smoothing Filters

Karin Kuroki, Toru Hiraoka (University of Nagasaki, Japan)

We propose a non-photorealistic rendering method for automatically generating flowing-line images from photographic images. Flowing-line images consist of unidirectional lines with smooth curves. Our method is executed by an iterative calculation using vertical and horizontal smoothing filters. To verify the effectiveness of our method, we conducted an experiment using various photographic images to confirm that flowing-line patterns can be generated on the entire image. Additionally, we conducted an experiment to visually examine how flowing-line patterns generated by changing the values of the parameters in our method change.

GS2-3 Human Motion Recognition from Multiple Directions and Its Gait Cycles Analysis

Miki Ooba, Yui Tanjo (Kyushu Institute of Technology, Japan)

It is crucial for individuals to keep walking and stay healthy to prevent receiving nursing care. This paper proposes a method of recognizing walk motions and analyzing the gait cycle of a human focusing on his/her posture. We use 43 structural features defined from human joint coordinates obtained using OpenPose and 18 figural features from human domain images and their difference images. The feature vector containing these 61 features is used for the recognition of walk motion by Random Forest. In the experiment, we applied the method to recognizing six types of motions and analyzed the walk gait cycles of five persons, and obtained satisfactory results.

GS2-4 A Method of Improving the QOL of the People with Visual Impairment by MY VISION

Shun Kitazumi, Yui Tanjo (Kyushu Institute of Technology, Japan)

Visually impaired people face several difficulties in indoor activities, such as spending excessive time in locating objects. This paper proposes a method for assisting object acquisition by detecting desired objects and guiding users to them. The method requests a user to express the object he/she wants to acquire verbally and utilizes speech recognition to detect the specified object. Subsequently, the system guides in voice the user's hand to the location of the desired object. The performance of the method is experimentally shown. The method contributes to enhancing the comfort of indoor activities of visually impaired and, in this way, improves their quality of life.

GS2-5 Human Behavior Segmentation and Recognition Using a Single-camera

Jing Cao, Yui Tanjo (Kyushu Institute of Technology, Japan)

In recent years, elderly people living alone account for a large proportion of the elderly population, and the issue of safety has also been a matter of great concern for the public. Considering the importance of monitoring the behavior and activities of the elderly and detecting abnormal movements, this paper proposes a method that can segment human behavior into each action and identify the action from the videos taken by a single camera. It uses features that can represent the shape of the human area in the depth direction, as well as the features such as motion direction and speed. The performance and effectiveness of the method are verified by experiments.

GS3 Image Processing II (3)
Chair Seiji Ishikawa (Kyushu Institute of Technology, Japan)

GS3-1 Online Classroom Student Engagement Analysis using Enhanced YOLOv5

Shuai Wang, Abdul Samad Shibghatullah (UCSI University, Malaysia)

The rise of online education has highlighted the urgency of addressing cyberbullying in virtual classrooms. This paper presents an innovative method for early cyberbullying detection through the analysis of students' engagement and emotional responses in online classrooms. The SFER-YOLOv5 model, a fusion of Student Facial Expression Recognition and an enhanced YOLOv5 object detection model, introduces key optimizations, including Soft NMS for Non-Maximum Suppression, integration of a Channel Attention (CA) module, and use of Enhanced Intersection over Union (EIOU) as the bounding box regression loss function. This approach proactively identifies reduced engagement and emotional irregularities, providing a framework to mitigate cyberbullying in online classrooms.
GS3-2 A Method of Recognizing Body Movements Based on a Self-viewpoint Video

Iichirou Moribe, Yui Tanjo (Kyushu Institute of Technology, Japan)

The most critical human sensory function resides in vision. This study focuses on utilizing visual information, specifically self-perspective footage, to identify individual movements. Existing researches require third-party filming to recognize body movements and states. The proposed method, on the other hand, simply attaches a camera to the human head and enables the recognition of the subject's actions. Consequently, it becomes easier to monitor daily movements of a human and gather his/her data on   body kinetics. This approach would be beneficial in scenarios involving individuals engaging in risky behavior or, during a certain emergency, providing valuable assistance.

GS3-3 Supporting Safe Walk of a Visually Impaired Person at a Station Platform based on MY VISION

Shintaro Yamada, Yui Tanjo, Seiji Ishikawa (Kyushu Institute of Technology, Japan)

When individuals with visual impairment go out, public transportation such as trains and buses is commonly used. However, many of them experience accidents, such as falling from train platforms or tripping due to unexpected contact with other passengers. To solve this problem, we propose method using the MY VISION system which detects the obstacle that may pose risks to individuals with visual impairment. The proposed method detects obstacles such as passengers pillars and platform edges at train stations. We employ an RGB-D camera for capturing frontal view of a user, use depth images to detect the edge of obstacles and level differences, and give warning to the visually impaired user based on the distance between him/her and the detected obstacle. Experimental results show satisfactory performance of the method.

GS4 Robotics (6)
Chair Jiwu Wang (Beijing Jiaotong University, China)

GS4-1 Development and evaluation of a learning support robot for vector learning

Kosei Machida, Shinichi Imai (Tokyo Gakugei University, Japan)

Vectors studied in high school are a new concept that differs from those studied in previous scalars. Therefore, it has been pointed out that difficulties arise in the conceptual formation of vectors. This study aims to develop a learning support robot that can visualize vector information by robot movements, and to acquire vector concepts for students through classroom practice using the robot. The robot operates on a piece of imitation paper, marking the start and end points and connecting them with arrows to visualize the vectors. In a class using the robot, the student predicts the sum of the vectors, and the robot confirms it. A questionnaire was administered before and after the class. The results revealed significantly higher mean values when comparing the pre- and post-assessments.

GS4-2 Feasibility Study on Methods to Measure the Strain on Young Children's Bodies.

Sachiko Kido, Praveen Nuwantha Gunaratne, Hiroki Tamura (University of Miyazaki, Japan)

This paper investigates the effective methods of measuring the burden on the infant's body. Initially, the "the burden on the body and the lumbar spine burden are the same" was defined. The calculations and comparisons were carried out based on the two methods: the AnyBody Modeling System and the smartphone application Yo-bukun (a lumbar spine burden measurement application). Videos of a five-year-old girl squatting and balancing were filmed, and the lumbar burden was calculated using the AnyBody Modelling System. In addition, while the video was being filmed, an iPhone running the Yo-bukun lumbar burden measurement application was placed close to the heart in order to measure lumbar burden and the amount of burden was calculated. The results were compared with the respective average values and validated.

GS4-3 An Integration of Contact Force Models with Multibody Dynamics Analyses for Human Joint Mechanisms and Effects of Viscoelastic Ground Contact

Shintaro Kasai[1], Dondogjamts Batbaatar[2], Hiroaki Wagatsuma[1]
([1]Kyushu Institute of Technology, Japan) ([2]Mongolian University of Science and Technology, Mongolia)

In human movement and rehabilitation analyses, human joint dynamics is a key to consider the incorporation of spring-damper components, flexible bodies and contact forces analytically. In the present study, an analytical method for human gaits were introduced to integrate those essential elements, and viscoelastic properties of musculoskeletal system were modeled with the absolute nodal coordination formula (ANCF) method representing flexible body motions. A contact force model simulates interactions between different body segments and the environment. The proposed system is applied to a slider crank mechanism, demonstrating its capabilities in human joint motion analysis using integrated dynamic model within the framework of multibody dynamics (MBD), which realizes dynamic/inverse dynamics for human biomechanics.

GS4-4 Haptic Sensation Enhancement via the Stochastic Resonance Effect and Its Application to Haptic Feedback for Myoelectric Prosthetic Hands

Yoshitaka Mizumoto, Taro Shibanoki (Okayama University, Japan)

In this paper, we propose a highly realistic haptic feedback method for myoelectric prosthetic hands. Although several haptic feedback methods have been studied, this study attempts to create realistic sensory feedback through prosthetic hands by not only using feedback methods but also by improving the haptic sensation based on the stochastic resonance effect. In the experiment, contact information obtained from a microphone attached to the fingertip of a prosthetic hand was transferred through a vibrotactile stimulator near the elbow socket, and white noise vibration was also applied near the elbow socket to verify the improvement of tactile sensitivity of the fingertips. The results demonstrated the possibility of transmitting tactile information for myoelectric prostheses through sensory enhancement of the user.
GS4-5 PID Parameter Tuning of a Low-Cost DC Motor Speed Control for Mobile Robot Application

Munkh-Erdene Ayurzana, Erkhembayar Gankhuyag, Naranbaatar Erdenesuren, Dondogjamts Batbaata
(Mongolian University of Science and Technology, Mongolia)

Precise control of DC motors is vital for robotics, industrial automation, and mechatronics. Traditional PID (Proportional-Integral-Derivative) control methods, while widely used, often require offline parameter tuning, which can be time-consuming and suboptimal for real-time applications. This paper proposes a GUI (Graphical User Interface) based approach for PID tuning of a DC motor model. The proposed method utilizes a MATLAB-based parameter estimation model with GUI to continuously monitor and update PID controller parameters based on real-time data from the Arduino-controlled DC motor setup.

GS4-6 Reinforcement Learning DDPG Algorithm Based Wheeled Mobility Aid Robot Control Methods

Junkai Li, Mohd Rizon Mohamad Juhari, Tiang Sew Sun (UCSI University, Malaysia)

Ensuring stability and precise trajectory tracking is crucial when employing wheeled walker robots to enhance mobility for individuals with limited walking ability. We propose a novel trajectory tracking method for wheeled walking robots by combining the Deep Deterministic Policy Gradient (DDPG) algorithm in reinforcement learning with a Proportional Integral Differential (PID) controller. We verify the effectiveness of the research scheme and control strategy through joint simulation experiments. The results demonstrate that the DDPG-based PID controller can automatically adjust parameters to ensure trajectory accuracy and exhibits a strong anti-interference capability.
GS5 Applications I (4)
Chair Jiwu Wang (Beijing Jiaotong University, China)

GS5-1 Unsupervised image registration based on Residual-connected DRMINE for diagnostic metastatic bone tumors

Shogo Baba[1], Tohru Kamiya[1], Takashi Terasawa[2], Takatoshi Aoki[2]
([1]Kyushu Institute of Technology, Japan), ([2]University of Occupational and Environmental Health, Japan)

Computed tomography (CT) scans produce more than 100 images in an examination, which imposes a significant burden on radiologists and entails a potential risk of misdiagnosis. In this study, we focus on the preliminary stage of Computer-Aided Diagnosis (CAD) development specialized in bone metastasis extraction, with a particular emphasis on rigid registration. We propose a novel rigid registration technique by augmenting DRMINE, which estimates mutual information using neural networks, with skip connections and normalization. The proposed method was influenced by the capture area, but it indicated the potential to provide stable registration as the standard deviation decreased for all Full Width at Half Maximum (FWHM).
GS5-2 Developing a smart Belt for Monitoring Elderly Activities Based on Multi-Modal Sensors Integration and Internet of Things

Abdul Jalil, Pujianti Wahyuningsih, Najirah Umar, Muhammad Risal, Suwatri Jura, A. Edeth Fuari Anatasya
(Universitas Handayani Makassar, Indonesia)

This study aims to develop a smart belt for monitoring elderly activities at home based on the integration of multi-modal sensors and the Internet of Things (IoT). The multi-modal sensors used in this study to collect the elderly information are the IMU sensor, vibration sensor, push-button, and ESP32 to process the data. Furthermore, the IoT framework used to transmit the elderly information data from the smart belt to the family's smartphone is a Blynk. In this study, the smart belt can monitor the elderly activities when walking, sitting down, lying down, and sleeping, after that, can give a security warning when the smart belt detects the elderly doing abnormal activities. This study's results show that the smart belt is effectively used to monitor elderly activities to help families when taking care of the elderly at home.
GS5-3 A penalized motion detection model for extracting ionospheric echoes from low signal-to-noise ratio Ionogram video images

Yuu Hiroshige[1], Akiko Fujimoto[1], Akihiro Ikeda[2], Shuji Abe[3], Akimasa Yoshikawa[3]
([1]Kyushu Institute of Technology, Japan) ([2]National Institute of Technology, Kagoshima College, Japan)
([3]Kyushu University, Japan)

Measuring the altitude distribution of electron density in the upper atmosphere, known as the ionosphere, using High-Frequency radio wave reflections often causes the low signal-to-noise ratio of ionospheric echoes due to radio frequency interference. We propose a model for converting low-signal-to-noise-ratio ionospheric echo video images (Ionogram) into noise-reduced images using image processing techniques, for tracing the ionospheric echoes from Ionogram. The proposed method consists of three processing parts: noise removal optimized for individual Ionogram images, extraction of ionospheric echoes by penalized background subtraction technique, and fine-tuning of ionospheric echo signals using a minimum spanning tree algorithm. The proposed model successfully reproduces fine Ionograms with 98% recall and 99% precision.

GS5-4 Verification Experiments on the Lower Back Burden caused by Posture and Environment during Lifting Operations

Tomoka Kimura, Yutaro Fujino, Sachiko Kido, Praveen Nuwantha Gunaratne, Hiroki Tamura
(University of Miyazaki, Japan)

One of the measures to prevent back pain is the use of appropriate posture corrections. In generally, the Squat method (method of keeping the knees bent and the waist as straight as possible) is recommended over the Stoop method (method of keeping the knees straight and the waist bent). The results of previous studies using acceleration and muscle potentials have shown that the lifting with knees in a kneeling position reduces the amount of load born by the lower back. However, few studies discuss the case where there is an obstacle between the subject and the object to be lifted and further, the scenarios where the object is away from the body's center of gravity. Therefore, this research focus on analyzing two types of movements using the AnyBody musculoskeletal mechanics analysis software and the Delsys surface EMG and verifying the amount of lower back burden when there is an obstacle between the lifting object and the subject. This paper presents the verification results.
GS6 Applications II (4)
Chair Masayuki Fujiwara (Kyushu Institute of Technology, Japan)

GS6-1 Development of Smartphone Application for Calculating the Low Back Pain Risk

Seigo Imura, Praveen Nuwantha, Hiroki Tamura (University of Miyazaki, Japan)

This study primarily relies on a smartphone application, developed within our research institute known as Yo-bukun, for the real-time estimation of lumbar burden. The Yo-bukun is capable of estimating the lumbar burden of a subject (the user) by placing an app. installed smartphone in the subject's chest pocket, while the subject is lifting/ relocating an object. The subject's movements are assessed through sensors embedded in the smartphone and certain aspects of their physical information initially fed into the app. are used in the estimation formula for determining lumbar burden. In the current scenario, Yo-bukun lacks the capability to ascertain whether the user is holding an object or not; consequently, it can only estimate the lumbar burden for limited cases of a subject holding an object. To address such limitations, the proposed system integrates voice recognition to facilitate lumbar burden estimation, considering the presence or absence of an object. Further, it was incorporated with the capability to recalculate lumbar burden after measurements, enabling prospective studies.

GS6-2 A Computational Approach for Global Trade Analysis Sensitive to Free Trade Agreement Circumstances: A Case Study Focusing on the Great Mekong Subregion

Ahmad Altaweel[1], Bo-Young Lee[2], Masayuki Fujiwara[1], Jang-Sok Yoon[2], Hiroaki Wagatsuma[1]
([1]Kyushu Institute of Technology, Japan) ([2]Logistics Revolution Korea, Korea)

In the Global Trade Analysis Project (GTAP), GDP and economic statistical indices can be analyzed for forecasting future trends of them in multiple countries by using the GTAP database and GEMPACK utilities, which realize the numerical calculation based on the concept of Computable General Equilibrium (CGE) models. Even by such well-prepared tools with the official database, an appropriate forecasting is still difficult due to the sensitivity to Free Trade Agreement (FTA) circumstances. FTA scenarios with a uniform tariff reduction can be assumed in general, while an abrupt and unreasonable change may occur in the simulation depending on the network structure of trading countries and upper and lower bounds of tariffs in the time course. In the present study, we focused on the Great Mekong subregion (GMS) and explored possible methods to calculate substantially.
GS6-3 Trigger circuit design and system integration for simultaneous measurement of human EEG, motion, and gaze

Masayuki Fujiwara[1], Phan Hoang Huu Duc[1], Laurent Bougrain[2], Patrick Hénaff[2], Hiroaki Wagatsuma[1]
([1]Kyushu Institute of Technology, Japan) ([2]Université de Lorraine, France)

The simultaneous measurement of human EEG, motion, and gaze has the potential to lead to the discovery of new scientific insights. In order to achieve these simultaneous measurements, it is necessary to manage triggers and time information between measurement devices, as well as to correct time offsets. However, the management of accurate triggers and time information requires the design of a dedicated circuit board and the integration of TTL signal voltage information. In this study, we report on the fabrication of a trigger circuit and an experimental system using it to solve these problems. We created a home-made trigger circuit board for voltage integration and combined it with a commercially available microcomputer to realize an integrated trigger circuit and measurement system.
GS6-4 Terminal Synergetic Controller for Car's Active Suspension System Using Dragonfly Algorithm

Tinnakorn Kumsaen[1], Sorn Simatrang[2], Arsit Boonyaprapasorn[3], Thunyaseth Sethaput[4]
([1]Khon Kaen University, Thailand) ([2]Nacres Co., Ltd, Thailand) ([3]Chulachomklao Royal Military Academy, Thailand) ([4]Thammasat University, Thailand)

This research introduces a terminal synergetic controller (TSC) designed for the active suspension system of automobiles through the implementation of the dragonfly algorithm (DA). The proposed controller aims to enhance the dynamic performance of a car's suspension using the DA in tuning the system parameters. The stability of the designed controller is proved through the application of Lyapunov stability theory. Through iterative optimization processes, the TSC approach seeks to achieve an optimal balance between ride comfort and vehicle handling. The simulation results demonstrate that the proposed controller enhances convergence properties and alleviates the presence of chattering. The results indicate that the proposed approach with the optimal parameters provided insights into its potential application in improving the overall suspension system.

GS7 Applications III (6)
Chair Kasthuri Subaramaniam (UCSI University, Malaysia)

GS7-1 Rehabilitating Flood-Damaged Cars for Sustainable Car Rental Services: A Web-Based System

Pon Xiao Qi, Abdul Samad Shibghatullah, Kasthuri Subaramaniam (UCSI University, Malaysia)

The web-based system aims to redefine transportation norms by unlocking the potential of flood-damaged cars. It seeks to reutilize these cars, providing affordable and sustainable transportation options while minimizing landfill waste. The system development approach that the researcher used for this system is Rapid Application Development (RAD) Model. The reason that the researcher chose this methodology is because it enables her to develop the system under limited time while ensuring the quality of the system. There is four stages in Rapid Application Development (RAD) methodology life cycle, which is requirement planning phase, user design phase, rapid construction phase and cutover phase.
GS7-2 Optimizing E-Invoicing Rollout: Adaptive E-Invoicing Rollout (AER) Framework for Navigating Malaysia's Digital Transformation

Koh Chee Hong, Abdul Samad Shibghatulla (UCSI University, Malaysia)

This study presents the Adaptive E-Invoicing Rollout (AER) Framework, developed to guide Malaysia's impending e-Invoicing mandate. It is crafted through a meticulous literature review and expert consensus, highlighting crucial variables such as integration capability, adoption rate, readiness, and compliance. These elements are central to the predictive model, designed to forecast and facilitate successful e-Invoicing implementation. The findings from our extensive review and model application confirm the framework's effectiveness in diverse business environments, demonstrating its adaptability and strategic value. The AER Framework significantly contributes to digital finance strategies, providing an innovative, empirically based tool for not only Malaysia but also other regions in the globe pursuing digital economic transformations.
GS7-3 App Alert System for Smart Phones

Chee Kin Hoe, Kasthuri Subaramaniam, Abdul Samad Shibghatullah (UCSI University, Malaysia)

¥This development is to develop a porotype mobile app that notifies the user to take their phones after shutting down the car. This development is being done to gather feedback from participants who frequently forget to take their phones such as dementia sufferers, careless youngsters and users who park in a dark space. As for the results of the survey, it was extensively researched and analyzed to find out the problems and requirements of users for the app. For the methodology, after extensive consideration the researcher decided to use Modified Waterfall model a derivative from the famous waterfall model. The main factors that influenced the decision is the suitability of the methodology, the confidence of the researcher to use the methodology and the time constraint to develop the app. There are 6 phases in the modified waterfall model which are Requirement Analysis, System Design, Implementation, Testing, Deployment and Maintenance. After developing the app, the user acceptance test was done to see whether how the general public would accept the app. For the result, the app was accepted by most of the participants and they would like the researcher to do further development to improve and maintain the app. Based on the results of the development the researcher can conclude that this app can benefit users in helping them to remember to take their phones from their car. Rather than using the old fashion way which is remember to take the phone. With this app, user can rest assured as they will be always be reminded to take their phones from their car.
GS7-4 Developing Hand Gesture Recognition System in Interpreting American Sign Language

Kong Seh Chong, Kasthuri Subaramaniam, Ismail Ahmed Al-Qasem Al-H (UCSI University, Malaysia)

This research is going to study and gather more information on the hand gesture recognition system in order to bridge the communication between non-signers and signers by implementing the sign language into the system. The system may help people with physical disabilities such as deaf, mute and etc, to have an efficient and direct communication with others without the needs of interpreters. Through the studying of the hand gesture recognition system, there are two main frameworks which are OpenCV and MediaPipe that hold significant value in the system as it is mostly used in computer vision related problem. With this system developed, it can help many signers to avoid the problem of indirect interaction and also enable those who want to learn sign language by practicing hand gesture through the system. The system development approach that the researcher used for this system is Agile Methodology. The reason that the researcher chooses this methodology is because the development of this system mostly deals with the datasets as well as the accuracy of the detection and recognition of hand gestures. Hence, an ability to adapt to changes of agile methodology is needed if there are any problems happen in the system. There are seven of the stages in Agile Methodology life cycle, which are planning phase, designing phase, implementation phase, testing phase, deployment phase, review phase and launch phase. All these seven phases of the Agile methodology will be having some deliverables as their output.
GS7-5 Miniature Enterprise Resource Planning

Adim Khalid Aldireejah, Kasthuri Subaramaniam, Ghassan Saleh（UCSI University, Malaysia）

Organizations aim for maximum efficiency, acquiring a competitive edge, and quickly completing their goals in today's competitive business environment. The achievement of these business objectives depends heavily on enterprise resource planning (ERP). ERP is a software program that combines several elements needed for a company's administration and operation, spanning several sectors like supply chain management, manufacturing, and finance. ERP makes work easier, saves time and money, and gives managers operational insights by automating corporate activities within a single platform. As a result, ERP has become essential for businesses of all sizes that want to advance and maintain their position as industry leaders. This research proposal intends to analyze the key traits, implementation concerns, and challenges associated with ERP systems while also outlining potential fixes. By creating a convenient and affordable mini-ERP solution, the initiative further intends to increase the accessibility of ERP systems to small and medium-sized enterprises (SMEs). The study of current ERP systems, their development, and their advantages and disadvantages will form the basis of the research. It will also investigate the difficulties SMEs have in using common ERP solutions.

GS7-6 Developing Cloud-based Sportswear Website

Lim Wei Yee, Kasthuri Subaramaniam, Raenu Kolandaisamy (UCSI University, Malaysia)

This research is going to develop a cloud-based sportswear website that can handle high volumes of traffic during events or seasonal sales, assist customers in selecting the right size for their sportswear, the interface should have options, size charts, fitting instructions, and recommendations. A study on the existing system will be conducted, design, develop and evaluate on the sportswear website also will be carried out. The system development approach used on this website is Rapid Application Development (RAD) model. The reason to choose RAD is because this method is time efficient, flexibility and adaptability. With RAD, functional software is delivered quickly. We can quickly build prototypes, iterate on them, and gather feedback from stakeholders with a website project. There are four of the steps in Rapid Application Development (RAD) methodology life cycle, which is define the requirements, prototypes, rapid construction and feedback gathering, and cutover.

Abstract

The number of labor force is expected to decrease due to the declining birthrate and aging population. Although many efforts to solve this social issue using automation technology by robots around the world have been implemented, most of the current applications of robots are still repetitive works such as picking and placing in mass production lines in factories, and small progress of the application of robots for high-mix low-volume production lines where the operations are is frequently changed. In this paper, we discuss the reasons and the potential solutions for autonomous control technologies including the AI and deep learning. Moreover, the high-speed working motion of the multi robot developed by DENSO will be presented in this paper.

Keywords: Unmanned Manufacturing, Motion Planning, Deep Neural Networks (DNN), Intelligent robotics

1. Introduction

The decline in the working-age population due to aging is progressing worldwide, becoming a serious social issue. In particularly Japan, we have been facing on a severe decrease in the working-age population, with estimates suggesting a decrease to 52.75 million people (a 29.2% decrease from 2021) by 2050 [1]. To address this issue, DENSO is actively intensifying its research and development efforts in automation technology utilizing robots. At DENSO's factories, we aim to achieve fully unmanned manufacturing and significantly reduce production lead times through the utilization of AI in process design for automation by 2035. We are also advancing the development of robots for automated harvesting of crops in agriculture field and automated disassembling of vehicles in the field of circular economy. As the utilization of robots advances in various sectors of society, such as production and agriculture, our group company DENSO WAVE has developed the human-collaborative robot COBOTTA PRO. COBOTTA PRO is a human-collaborative robot that combines the speed (2,500mm/s) and precision (repeatability ±0.04mm) comparable to industrial robots. It maximizes its operation speed when there are no workers nearby and minimizes the distance required for deceleration and stoppage when a worker approaches, achieving a good balance between productivity and safety aspect.

However, there are still several important issues that need to be addressed for further utilization of robots. Firstly, one of these issues is related to the design of robot movements. The work of teaching and programming for robot motion design requires specialized technicians to physically operate the robot and refine its movements, resulting in significant time and effort when introducing robots. Although the cost of the robot itself is becoming affordable in the market, it cannot be ignored due to its motion design cost when frequent motion changes are made in low-volume, high-mix production. The same issue arises in scenes such as agriculture field or vehicle disassembling outside of factory, where it is difficult to fix the motion of robots due to their variability.

The second issue is related to adapting to changes and variations in the workpieces. In the teaching playback method commonly used in repetitive tasks in factories, it is difficult to manage changes and variations in the workpieces, making it challenging to accommodate misalignment or stacking of the workpieces. Efforts to address these issues have progressed at a practical level by utilizing vision systems. The vision system uses 2D or 3D sensor cameras and recognition algorithms to recognize the position and posture of the workpiece and the surrounding environment, and the robot system as a whole uses this information to generate robot movements according to the situation. However, the range of workpieces that can be handled is still limited, and the recognition capabilities for complex shapes, reflective properties, transparent objects, and even indefinite shapes are still insufficient. Furthermore, the construction of these vision systems requires the actual objects of the workpieces for adjustment, which involves significant time and effort.

Additionally, tasks that involve handling flexible materials are particularly challenging for robots. The tasks such as handling wire harnesses and arranging components that undergo significant shape changes due

to interactions with the robot and the environment are difficult for robots to predict and respond to, making them one of the tasks where automation has not yet advanced in factories.

2. Literature Survey

Efforts to automate teaching are primarily progressing through the development of motion planning techniques. Motion planning is the technology that automatically generates a path connecting the start and end points of robot motion. Traditional manual teaching requires significant effort to create robot paths that are collision-free and have the shortest possible motion time. Motion planning techniques are predominantly based on the sampling-based methods, with Rapidly-exploring Random Trees (RRT [2]) being devised and subsequently improved upon [3], [4], [5]. Currently, these techniques have reached a practical stage where they are implemented within robot simulators and used for pre-verification of motion in simulation environments. However, there are issues related to the trade-off between computation time and the quality of generated paths, as well as the variability in the computation time required for path generation. Further technological advancements are expected to enable real-time motion generation, particularly in complex environments with narrow spaces or multiple robots sharing the workspace, where computation time significantly increases. One promising approach for generating high-quality paths with fast and constant computation time is to utilize Deep Neural Networks (DNN) as an alternative to traditional computation methods. For example, Chi, C., et al. have employed diffusion models to acquire DNN models for generating robot motion paths, which have demonstrated superior performance in terms of discreteness and multimodality compared to conventional imitation learning [6]. As improvements in learning stability and environmental robustness progress, expectations for practical implementation are increasing.

One example of addressing changes and variations in work pieces is the utilization of AI in vision systems. The Dex-Net (The Dexterity Network [7]) project has constructed a large-scale database for object grasping and developed models that predict the gropability of given objects by training DNN using the database as training data. This project utilizes not only real-world data but also synthetic point clouds generated from 3D models, significantly reducing the cost of creating training data. The scalability of both DNN models and training data is expected to enhance generalization, leading to improved performance for unknown objects.

In the Dactyl project by OpenAI, they demonstrate an example of acquiring dexterous manipulation skills using deep reinforcement learning, where a robot with five human-like fingers adeptly manipulates a cube [8]. The Deep Learning techniques often require a large amount of training data to achieve high performance, which presents a challenge for real-world applications. However, Dactyl addresses this issue by employing a technique called domain randomization, which diversifies the physical behavior in the simulation environment. By training solely in the simulated space with varied physics, it is able to acquire movements that can be applied Denso's in the real world. While the current examples in the Dactyl project primarily focus on manipulating rigid objects, it is anticipated that similar techniques will be explored to extend the acquisition of movements for flexible objects in the future.

3. Research in Denso

In order to replace robots with more advanced tasks in the future, it is essential to have coordination among multiple robot arms as a single robot arm has its limitations. However, when trying to apply RRT-based motion planning to multiple robots, as mentioned earlier, the search space expands exponentially with the increase in the number of robots, resulting in a significant increase in computation time. To address this challenge, we incorporated the expertise of skilled teaching engineers into the exploration algorithm and effectively constrained the search range, significantly reducing computation time while maintaining path optimality. Fig. 1 illustrates the relationship between the number of controlled robots and the computation time required to output the initial solutions for the generated paths. With the conventional RRT-based method, the computation time exceeded 31 seconds for two robots, over 32 minutes for three robots, and reached more than 87 hours for four robots (estimated computation time for four robots). However, with the method we developed, the computation time was reduced to approximately 0.4 seconds for two robots, 0.7 seconds for three robots, and 1.6 seconds for four robots.
Fig. 1. Relationship between computation time and number of robots in route generation

Furthermore, by adding post-processing for path optimization, we reduced the robot motion time. Through practical verification in actual pick-and-place operations (In the environment shown in Fig. 2, we conducted a demonstration of placing 75 CDs to three designated locations using three robots.), we confirmed a 23.8% reduction in robot operation time compared to the results

of skilled teaching engineers (The results of skilled teaching engineers: 48.9 seconds, Automatic Generation by Motion Planning: 37.2 seconds).

2-1. View of the actual machine environment
2-2. Overview of the demonstration environment
Fig. 2. The demonstration of pick-and-place operations with multiple robots

Table 1 shows a more detailed comparison. In a multi-robot operation, the amount of movement (joint movement) as well as the degree to which the robot is able to operate simultaneously greatly affect its working time. When we compared these results, we found that there was no significant difference in joint movement between the teaching result and the auto-generated result (The auto-generated result showed approximately 3.7% less movement compared to the teaching result.), but the auto-generated result showed a greater improvement of over 30% in the simultaneous movement rate compared to the teaching result.

In this development case study, we have shown that we can automate advanced teaching tasks that handle multiple robots and generate highly optimal paths compared to skilled teaching engineers. In the future, we intend to make it possible to automatically generate placement of robots and peripheral equipment, and operation procedures, leading to fully automated start-up of equipment.

Table. 1. Comparison of the results of motion generation by teaching and automatic generation algorithms

1-1. Comparison of joint movement

	Joint movement [rad]		Reduction rate [%]
	(a) Teaching method	(b) Proposed method (Automatic generation)	Reduction rate from (a) to (b)
Robot 1	6363.3	6268.7	1.49
Robot 2	5835.7	5352.7	8.28
Robot 3	4209.9	4176.7	0.79
Total	16408.9	15798.1	3.72

1-2. Comparison of simultaneous operation rates of multiple robots

	(a) Teaching method	(b) Proposed method (Automatic generation)	Improvement value from (a) to (b)
Total operation time [sec]	48.9	31.7	-
Maximum possible concurrent operation time [sec]	46.6	29.3	-
Actual Concurrent Operation Time [sec]	28.2	26.8	-
Rate of concurrent operation [%]	60.6	91.4	30.8

4. Conclusion

To expand the applications of robots, the development of technology that automatically generates their movements is desired. Motion planning is an effective technique for automatically generating optimal paths for robots to reach their work points. In this paper, we introduced examples of automatically generating movements, specifically for cases where multiple robots operate simultaneously with high motion speed, to demonstrate the effectiveness of motion planning. The technology for accurately recognizing and manipulating the position and orientation of target objects is still under active research. We are confident that the advancement of deep learning-based techniques will contribute to solving these challenges. Unlike language and images, the cost of generating large amounts of training data is an issue in robot motion. However, by utilizing synthetic point clouds generated from 3D models and physical simulations, successful examples of robot motion

generation applicable to real space are emerging, and further performance improvements can be expected.

Abstract

This paper introduces two innovative concepts for variable arms designed for a quadrotor, enabling precise control of its movement through manipulation of the bending moment via varying arm lengths. The primary objective of this research is to develop and identify the most suitable variable arm configuration that facilitates smooth and stable quadrotor movement. The study delves into two concept designs that are well-suited for the quadrotor application. By employing a suitable variable arm, the quadrotor's maneuverability can be effectively regulated based on the bending moment adjustments made possible by the variable arm. Ultimately, the paper presents the design and performance testing of two types of variable arms. The obtained results confirm that the variable arm of the electric actuator with linear guide-Type 2 exhibits smooth and stable movement.

Keywords: Variable Arm, Quadrotor, Dynamic Configuration, Flight Performance

1. Introduction

The quadrotor, a type of UAV (unmanned aerial vehicle), holds great potential for overcoming terrestrial challenges [1], leading to its widespread use in various industrial and commercial applications such as geographic mapping, surveillance, agricultural tasks like fertilization or pesticide application, and aerial photography [2]. This continuous utilization has spurred the development of the quadrotor to enhance its stability, performance, and multimodal capabilities [3]. Typically, quadrotors are designed with four rotors, positioned at the vertices of a square frame [4]. To understand how the quadrotor operates, Newton's Third Law of Motion comes into play, stating that every action elicits an equal and opposite reaction [5]. When the quadrotor's motor rotates the propellers, it generates a downward force on the air, as explained by the Bernoulli Principle [6]. In a conventional quadrotor, adjusting motor speeds in the four motors allows the control of thrust and facilitates the required movements [7]. However, as the size and weight of the quadrotor increase, more thrust is needed to lift it, often necessitating larger propellers or faster motors, which in turn lead to higher power consumption and reduced flying time [8]. This conventional design approach can be both costly and inefficient [9].

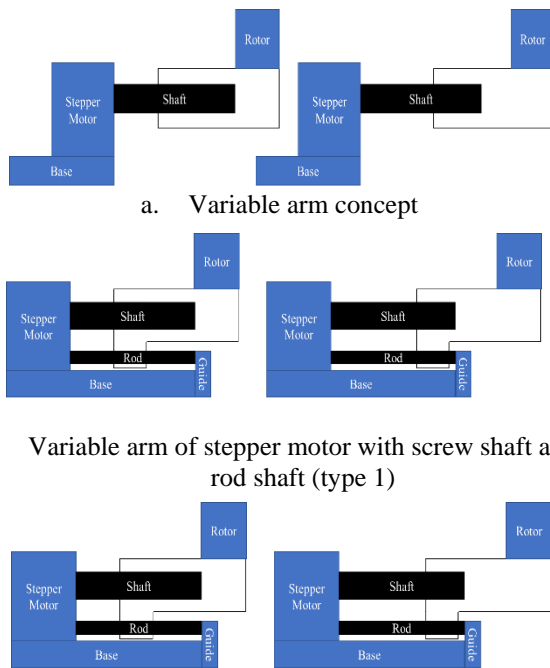
Considering the issues of power consumption and cost, limited research has explored alternative methods to generate more thrust besides varying motor speed and propeller size [10]. One such study by Wu in 2018 proposed controlling the quadrotor through changes in both motor speed and rotor blade pitch angle, affecting the produced thrust and power consumption [11], [12]. Additionally, a simulation analysis in 'Effects of Variable Arm Length on UAV Control Systems' in 2020 highlighted the impact of varying arm lengths on the quadrotor's bending moment. Increasing the arm length resulted in higher bending moments and, consequently, increased thrust production [13]. To address these challenges and explore new possibilities, this project aims to design and test two concept designs for variable arms, ensuring smooth and stable extension and retraction.

2. Design of variable arm
2.1. *Concept design*

Fig. 1 shows three concept designs of variable arms in both the retract and extend positions. Fig. 1(a)

corresponds to a concept design previously introduced in research [14]. However, when a quadrotor's arm experiences thrust, it may undergo deflection and vibration caused by the motor, impacting the arm's extension. To counter this issue, the use of a rod shaft and linear guide method for the variable arm proves effective in preventing arm deflection and ensuring smooth movement. The design depicted in Fig. 1(a) presents challenges in linear translation control due to the possibility of high deflection and the lack of motion guidance. On the other hand, the designs shown in Fig. 1(b) and Fig. 1(c) employ different methods for arm movement control. Fig. 1(b) employs a stepper motor with a screw shaft while Fig. 1(c) utilizes an electric actuator with a linear guide for variable arm control.

a.   Variable arm concept

b.   Variable arm of stepper motor with screw shaft and rod shaft (type 1)


c.   Variable arm of electric actuator with linear guide (type 2)

Fig. 1. Variable arm quadrotor design concept.

2.2. *Variable arm of speed motor with screw shaft and rod shaft (type 1)*

According to Eq. (1), the bending moment is determined by multiplying the force by the length. In conventional quadrotors, maneuverability relies on varying forces to influence the bending moment and consequently rotate the quadrotor's body. This means that the same force can produce different bending moments depending on the length of the variable arm. By manipulating the bending moment, the quadrotor can be directed and moved in a specific direction. For the purpose of testing, variable arms capable of moving within a range of 20 mm to 30 mm have been designed.

$$M = FL \tag{1}$$

Fig. 2 illustrates the variable arm of type 1, utilizing a stepper motor with a screw shaft and rod shaft, in both the extend and retract positions. The 3D drawing is used to calculate the shaft's deflection using Eq. (2) and Fig. 3(a) assists in determining the moment of inertia. The results display the maximum deflection when the variable arm moves from its retracted position to a fully extended position, as depicted in Fig. 3(b).
a.   Retract position
b.   Extend position

Fig. 2. 3D modeling of variable arm steeper motor with screw shaft and rod shaft (type 1).

$$\delta_{max} = \frac{PL^3}{3EI} \tag{2}$$

$$I_x = \frac{\pi r^4}{4} \tag{3}$$

Analyzing Fig. 3(b), it becomes evident that the maximum deflection increases with an elongating length under a constant force. The maximum deflection amounts to approximately 0.001 mm, positioned 66.5 mm away from the support of the bracket design. Given its small magnitude, this deflection does not significantly impact the turning of the screw shaft caused by the deflection of the shaft.
a.   Cross section of screws shaft and rod shaft
b. Maximum deflection of the shafts
Fig. 3. Deflection analysis.

Furthermore, Table 1 presents the specifications of the stepper motor utilized, indicating an RPM range of approximately 15 to 20. With the use of a screw shaft of 0.5 mm pitch, the variable arm is able to move at the speed of 10 mm/min.

Table 1. The planning and control components.

Technical Parameter	Value
Operating Voltage (V)	5
Operating Current (mA)	240
Step Angle	5.625/64
Reduction Ratio	1/64
Phase	4
Frequency (Hz)	100
Friction torque (gf.cm)	600-1200
Pull in torque (gf.cm)	300
Coil	Unipolar 5 lead coil
Decent Torque (mN.m)	34.3
Speed (RPM)	15-20

2.3. *Variable arm of electric actuator with linear guide (type 2)*

Fig. 4 presents the variable arm of type 2, which utilizes an electric actuator with a linear guide, in both the retracted position (Fig. 4a) and extended position (Fig. 4b). Referring to Table 2 reveals that the dynamic load of the linear guide is approximately 140 kgf. Considering the pull exerted by the brushless motor on the variable arm, it results in the moment of P acting on the linear guide.

a. Retract position
b. Extend position
Fig. 4. Variable arm of electric actuator with linear guide (type 2).

Table 2. Specification of MGN7H linear guide.

Technical Parameter	Value
Dynamic Load (kgf)	140
Static Load (kgf)	200
Moment of R (kgf.m)	0.78
Moment of P (kgf.m)	0.49
Moment of Y (kgf.m)	0.49

Given the small size of the 2 kg quadrotor, a force of 2 kgf is required to maintain equilibrium, while around 3 to 4 kgf thrust is needed to lift the quadrotor. In the design configuration, the center of the brushless motor is positioned 26 mm away from the center of the linear guide, enabling the calculation of the bending moment resulting from the thrust force applied to the linear guide, as per Eq. 1. The linear guide proves to be suitable for use, considering a maximum load of 4 kgf and a maximum bending moment of 0.104 kgf.m, leading to very minimal deflection of the linear guide.

Table 3 presents the specifications of the electric actuator used. As indicated in the table, the speed of the electric actuator is approximately 8 mm/s. Moreover, considering the force of 4 kgf, which equates to around 40 N, so the specification of the electric actuator is suitable for the variable arm application.

Table 3. Specification of LA-YR type electric actuator.

Technical Parameter	Value
Input Voltage (V)	12
No Load Speed (mm/s)	8
Load Push Capacity (N)	90
Load Pull Capacity (N)	90
Static Damping (N)	90
Stroke Length (mm)	30

3. Testing on variable arms

Based on the concept designs presented in the previous section, two types of variable arms have been developed, as depicted in Fig. 5 and Fig. 6. The first type is variable arm of stepper motor with screw shaft and rod shaft referred to as type 1. It comprises a total of 11 components, including a motor driver to control the stepper motor, a bracket to secure the stepper motor, the stepper motor itself, a coupling to connect the stepper motor's shaft with the screw shaft, the screw shaft, a brushless motor, the variable arm, a bracket to hold the rod shaft, the rod shaft, a frame, and a linear bushing that ensures smooth movement of the variable arm along the rod shaft.

On the other hand, the second type, variable arm of electric actuator with linear guide known as type 2, is intended for an electric actuator with a linear guide. It consists of 6 parts: an MDD3A driver to control the electric actuator, the electric actuator, a linear guide, a frame, the variable arm, and a brushless motor.
Fig. 5. Variable arm of stepper motor with screw shaft and rod shaft (type 1)
Fig. 6. Variable arm of electric actuator with linear guide (type 2)

Through the utilization of a mobile app equipped with a vibration meter, the vibration of the variable arm in motion is assessed. The phone is placed on the variable arm during the evaluation, and measurements are taken both with and without the operation of a brushless motor. The results are illustrated in Fig. 7 and Fig. 8, displaying the vibration levels with and without the motor's operation for both variable arms.

According to the graphs, it was evident that the brushless motor caused higher vibration, indicating that the motor generates significant vibrations. Additionally, a comparison between the two types of variable arms revealed that type 1 exhibited higher vibration than type 2.
a.   Without operation of brushless motor
b.   With operation of brushless motor

Fig. 7. Vibration data for variable arm of stepper motor with screw shaft and rod shaft (type 1)
a.   Without operation of brushless motor
b.   With operation of brushless motor

Fig. 8. Vibration data for variable arm of electric actuator with linear guide (type 2)

4. Conclusion

Table 4. Comparison between 2 designs – type 1 and type 2.

Design	type 1	type 2
Cost	Low	High
Weight (g)	139	96
Movement speed	Slow	Fast
Stability	High vibration	Low vibration

Based on the observations made during the motion of the two variable arms, the results presented in Table 4 indicate that using type 2 would be a more costly option. This is because electric actuators tend to be expensive when compared to stepper motors. However, it should be noted that the electric actuator demonstrated smooth and rapid movement, reaching approximately 8 mm/s, which made it well-suited for quadrotor control. Additionally, the electric actuator's advantage lies in its lightweight nature, as it utilizes fewer components, thereby minimizing the overall weight impact on the quadrotor.

Type 2 indeed offers a cost-effective solution. However, it comes with certain drawbacks. One major concern is the increased weight due to the presence of multiple brackets and shafts, which can adversely affect the overall performance of the system. Moreover, the movement of the variable arm driven by the stepper motor is not stable, mainly due to the high vibration experienced along the arm and its slow-moving speed. This instability can be attributed to the variable arm's elevated position, leading to a higher center of gravity, with the screw and rod shaft situated at the center of the variable arm. Consequently, this setup causes vibrations that oscillate the arm to the left and right. As a result, the thrust force provided by the brushless motor becomes unstable, impacting the system's overall performance.

Additionally, the pitch of the M3 screw shaft is merely 0.5 mm. As a consequence, with each revolution of the

stepper motor, the variable arm can only move by 0.5 mm. This limited displacement capability results in the variable arm moving at a slow speed of only 10 mm/min, making it less suitable for certain applications that require faster movement.

In summary, type 2 is suitable to use as it provides fast motion and stability which is suitable for quadrotors that are sensitive to motion. Besides type 1, it will be suitable to use when a high-pitch screw shaft or higher RPM motor is used so that it can be moved faster. However, there is room for improvement in the design of type 1. One approach is to consider replacing the rod shaft with a linear guide or exploring other methods to enhance stability. Such modifications could help address the issues related to vibration and slow movement, making it a more suitable option for certain scenarios.

Abstract

In recent years, labor shortage has become a serious issue in industrial fields. Various technologies including robot and information processing system to realize flexible work like humans are effective solutions to this issue. Artificial intelligence technology of arm-type robots equipped with 3D sensors and force sensors has been applied in the manufacturing field to cope with different intelligent and highly precise tasks in Mitsubishi Electric. In addition, various technologies to expand the scope of application to the service field, as well as to realize highly functional delivery with mobile robots is under development. Furthermore, IoT technology is also being used for easy and quick on-site implementation and efficient operation. This paper introduces these initiatives with actual examples.

Keywords: Industry, Arm-type robot, Service, Mobile robot, Artificial intelligence, IoT, 3D sensor, Force sensor

1. Introduction

In recent years, the decline in the working population is accelerating worldwide as the birthrate declines and the population ages and labor shortage has become a serious issue in industrial fields. Many intelligent technologies including robot system and information processing system to realize flexible work like humans are effective solutions to this issue, because there is a serious shortage of skilled and experienced workers. Based on these ideas, Mitsubishi electric corp. has developed the intelligent technologies of arm-type robots equipped with 3D sensors and force sensors in the manufacturing field to cope with intelligent and highly precise tasks [1], [2], [3]. By combining artificial intelligent (AI) technology with these technologies, we have developed technologies such as automatic parameter adjustment technology to achieve optimum motion adjustment quickly, and technology for safe operation by determining abnormal conditions [4].

To spread various applications with intelligent robots, we have developed the teaching-less robot system using intuitive I/F technology to facilitate teaching operations that previously required a high level of expertise and skilled experience. This system includes technologies to generate optimum routes and movements, interference checking algorithm with the surrounding area, and series of technologies for bin picking of random stacked objects using 3D sensor.

There is a growing demand for automation of transport operations not only in factories, but also in various facilities such as logistics, public buildings, commercial facilities, and hospitals. For this reason, multiple technologies to expand the scope of application to the service field, as well as to realize highly functional transportation with mobile robots is under development. In addition, as a future technology that will further expand the scope of robot applications, we are also developing technologies for remote robot operation by humans for non-standardized tasks and troubleshooting. Specifically, we have been developing technologies to convert force information, into visual information that is easily recognized by humans, to decompose summary instructions into robot actions, and to operate multiple types of robots with a common interface.

Furthermore, the increase in the number of target devices monitored in real time with advancement of communication technology and the increase in computer capacity have led to remarkable progress in 3D simulation technology. These technologies are also being used for easy and quick on-site implementation and efficient operation. In this paper, these initiatives with actual examples are described.

2. Teaching-less Robot System
2.1. *Overview of the system*

The use of machines and robots in mass production is increasing due to a shrinking labor force caused by an aging population and declining birth rate. However, there are still challenges in implementing robots in certain production lines, such as those involved in making "Bento" boxes and ready-made dishes. These lines require expertise and time-consuming adjustments due to the soft and irregular shapes of the food products and frequent menu changes. We have developed a teaching-less robot system that utilizes technology and research data accumulated over the years [5]. This system includes arm robots, controllers, 3D vision sensors, force sensors,

a tablet PC and a master PC for control. Task assignments can be easily inputted using a tablet PC and 3D sensor camera. The 3D sensor camera senses the area around the arm robot, allowing for static environment recognition and accurate measurement of spaces. 2D vision sensors installed on the production line detect the conditions of the items moving on the line. Task assignments can be set using voice and touch inputs, and the movement path of the arm robot is displayed using augmented reality. This teaching-less robot system eliminates the need for expert knowledge and time-consuming programming, as it automatically generates optimum movements based on assigned start and endpoints. Autonomous programs generate various approaches to determine the optimum and fastest speed for movements with reducing the need for test runs and saving time. The 3D sensors monitor the production area and ensure smooth workflow. The sensors identify slanted "Bento" boxes, allowing the robot to determine their position and add ingredients accordingly. These technologies not only control the arm robot but also facilitate the expansion of production lines with multiple robots.

2.2. *Surrounding Environment Modeling*

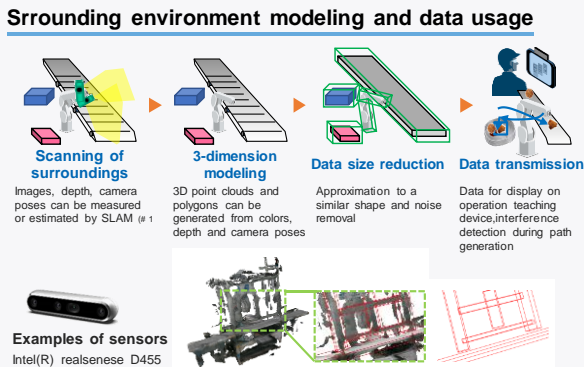
In order to acquire the 3D model of the robot's surrounding environment, we have used our original simultaneous localization and mapping (SLAM) method which use only an inexpensive camera (Fig. 1). This camera can be used for interference detection during path generation and displayed on the operation teaching device. We have achieved processing time by simplifying 3D models and reducing data size (approximately 60% reduction).


Fig. 1. Surrounding Environment Modeling

2.3. *Intuitive UI for easy robot teaching*

We have developed the intuitive user interface (UI) system which use tablet-touching and voice-controlled operation to realize easy teaching operation of robots. Various specifications such as the workpiece sizes and positions can be confirmed beforehand by checking the simulated movies using the augmented reality (AR) technology. After the motion instruction is completed,

the robot's motion can be confirmed in advance on a tablet PC, thus ensuring the safety of the operator (Fig. 2).
Fig. 2. Intuitive UI for easy robot teaching

2.4. *Automatic Generation of Optimum Path*

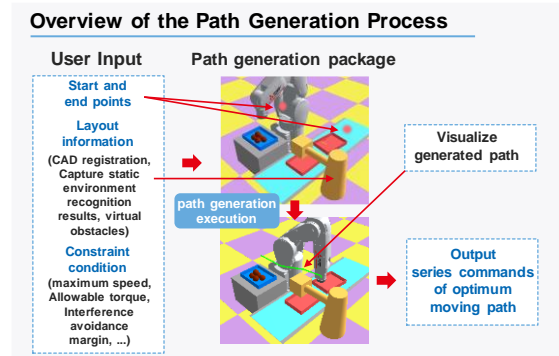
We have developed the automatic calculation method which generate optimum path without interfering to peripheral equipment by simply specifying start and end points. It can derive the avoidance route that minimizes the operating time by considering the amount of movement of each joint and allowable torque (Fig. 3).


Fig. 3.　Automatic Generation of Optimum Path

2.5. *Irregular Shape Object Recognition*

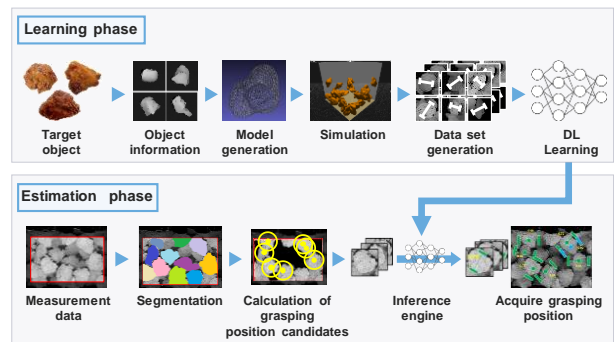
To packing food objects using random bin-picking method with 3D sensor, each object is distinguished according to segmented region, and each grasping position is estimated with high accuracy at high-speed using the deep learning (DL) based AI algorithm (Fig. 4).


Fig. 4.　Irregular Shape Object Recognition

Prior learning of the DL network for determining optimum grasping position according to the shape of each object is operated. Then this algorithm calculates segmented region of each object using the trained DL network.

3. Robot Technologies in Service Field

3.1. *Mobile Robots for Transportation*

The demand for the Autonomous Mobile Robot (AMR) is increasing due to the decrease in the working population and the increase in demand for various types of transport (factories, distribution warehouses, commercial facilities, hospitals etc.). To meet these demands, we have been developing the system that can be redesigned to variation of transport configurations. We have also developed the series of technologies to enable robots to run safely and autonomously in response to changes in facility rules and conditions through the control system that controls multiple robots. In addition to these technologies, we have also realized autonomous vertical and horizontal movement in coordination with facilities such as elevators and access control systems [6], [7] (Fig. 5).

We have been also conducting actual experiments with mobile robots in various situations (e.g., transporting books in reading rooms, making announcements while moving, and transporting items in backyards) as a field test of mobile robots that can coexist with people (Fig. 6).
Fig. 5.   Integrated Control System for AMR
Fig. 6.   Field Test image of AMR

3.2. *Remote Robotics for Dexterous Operation*

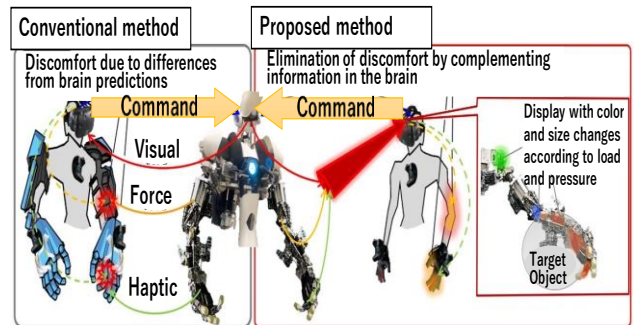
The technologies for remotely operating robots are useful for individual operations in non-standardized tasks and for troubleshooting operations in automated tasks. Force-haptic information is often important in these tasks, but feedback of these information to the operator typically requires a complex operation system. We proposed the "Visual Haptics" architecture that converts force-haptics information into visual ones that are easily precepted by humans (Fig. 7). The cognitive process in this method utilizes visual and force-haptic cross modalities. We have showed its effectiveness through quantitative experiments [8].


Fig. 7.   Visual Haptics" architecture

Furthermore, we have showed its effectiveness in various situations through demonstration systems [9] (Fig. 8).

Fig. 8.   Operation Test Scene

4. IoT Platforms for Data Integration

Mitsubishi Electric is ready to provide the digital transformation (DX) services including multiple IoT platforms that organically connect data from facilities, equipment, mobile applications functioning in various fields such as manufacturing, logistics, business facilities, hospitals, etc., with the aim of contributing to area value enhancement and advanced operational management. The various data collected in these distributed platforms can be used to accelerate the creation of new value-added products and seamless indoor/outdoor services (Fig. 9).

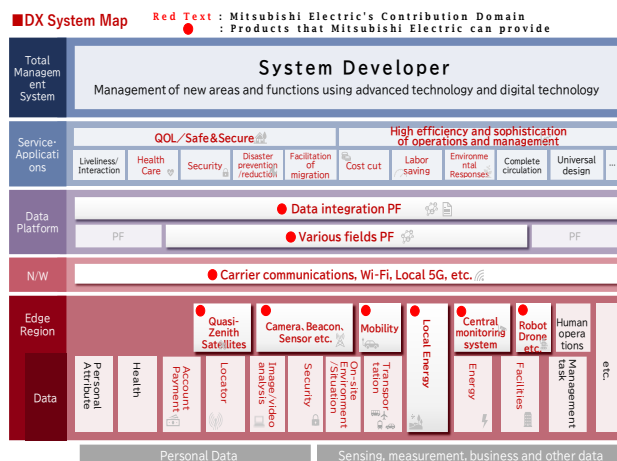
Haruhisa Okuda


Fig. 9.   DX System including IoT Platforms

5. Conclusion

At the first in this paper, the teaching-less robot system was described, which is using intuitive I/F, optimum routes and movements generation, interference checking algorithm and series technologies for 3D random bin picking. At the second, as the robot technologies in service field, the system that realize the flexible and safety control of multiple AMR and the remote robotic technologies for dexterous operations are showed with actual examples. At the last, the integrated IoT platforms for connecting data from facilities, equipment and mobile applications functioning in various fields is described. Various solutions using these initiatives will be provided in the near future.

Abstract

In 2021, a water treatment facility in Florida, USA, fell victim to an external malicious attack. in this incident, malicious actors attempted to manipulate the quantities of specific chemicals to impact water quality and safety. Given the intricacies of abnormal operation detection in Industrial Control Systems and the advantages of finite-state machine, we endeavored to apply this approach for the detection of abnormal ICS (Industrial Control System) operations. We conducted a series of tests using the dam control system cybersecurity testbed established by TWISC@NCKU, Taiwan. The results indicate that our approach effectively enhances the efficiency of identifying non-standard operational behaviors, enabling maintenance personnel to promptly identify anomalies.

Keywords: FSM, ICS Security, PLC, Dam Gate Testbed

1. Introduction

In 2021, a water treatment facility in Florida, USA, faced an external malicious attack, where attackers attempted to manipulate the quantities of specific chemicals, severely jeopardizing water quality and safety. [1] How to effectively detect abnormal operation of ICS has become an important challenge?

The integration of FSM methods involves comprehensive monitoring and analysis of system states [2], such as utilizing finite state machines. Taking equipment malfunction as an example, the awareness that its operation may deviate from normalcy prompted the design of a method for detection, employing FSM to monitor changes in PLC states. This amalgamation of state and anomaly detection enables swift identification and response to potential issues, ensuring the stable operation of the system.

This research focused on applying FSM methods to detect abnormal operations within ICS, aiming to enhance detection efficiency and accuracy. This research uses the dam control system cyber-security testbed built by TWISC@NCKU to conduct relevant research and verification. The results show that the scheme is feasible and effective, and the method can be effective at a very low cost. It can identify non-standard operating behaviors and help personnel identify abnormal situations immediately.

2. Methodology

2.1. *Programmable Logic Controller*

A Programmable Logic Controller (PLC) [3] automates control by executing instructions stored in its memory. Crucial in industries, it interfaces with systems like Finite State Machines (FSM) for more efficient monitoring.

PLC states indicate its operations during automation. "DI" and "DO" signify Digital Input and Output, reflecting signal statuses (e.g., switches). "AI" and "AO" represent Analog Input and Output, detailing continuous signal conditions. Together, they showcase the PLC's performance across various inputs and outputs.

Its architecture consists of a CPU, input, and output modules. The CPU processes logic and manages device communication. Inputs gather data from sensors, while outputs control actuators. This robust design ensures stable operation in demanding industrial environments.

2.2. *Finite-State Machine*

In recent years, Finite State Machines (FSMs) have been widely applied in various fields, including software development [2] and machine learning [4]. The strength of FSM methodology lies in its intuitive system model, aiding in the comprehension, design, and testing of intricate system behaviors. Its simplicity and scalability render it an effective tool for describing and controlling system behaviors.

In the context of anomaly detection, FSMs are employed for modeling normal system behavior by defining states and transitions. (Fig.1) This approach involves monitoring system operations, detecting state transitions deviating from expected behavior, and providing real-time alerts. The integration of FSM-based anomaly detection is widely adopted to enhance the efficiency of system behavior modeling and anomaly detection [5], highlighting the pivotal role of FSMs in comprehending system behavior and addressing challenges in anomaly detection.
Fig. 1. Finite-State Machine

2.3. *Modbus/TCP*

Modbus is widely employed as a communication protocol in industrial environments, facilitating information exchange among industrial devices such as PLCs and sensors [6]. Despite the convenience of plaintext data transmission provided by Modbus/TCP, it inherently poses potential security risks, making it susceptible to unauthorized access and cyber attacks.

In the context of my research, using Modbus/TCP as an example, although it facilitates communication among industrial devices, careful consideration of associated security risks is crucial. The use of plaintext data transmission introduces the risk of information exposure, thereby compromising the integrity and confidentiality of the system. Therefore, during the implementation of Modbus/TCP, robust security measures must be implemented to mitigate potential risks and enhance the resilience of critical infrastructure.

Simultaneously, by utilizing Modbus commands to read the memory addresses of PLCs [7], specific states such as DI and DO can be understood, with these states stored in specific memory variable addresses. Through Modbus queries, real-time insight into the current status of the PLC can be obtained. This underscores the importance, in practical applications, of handling Modbus communication security cautiously to ensure that the system's operation remains resilient against potential risks and cyber threats.

2.4. *Critical infrastructure testbed*

The research through a series of tests conducted at the Dam Control System Cybersecurity Testbed established by TWISC@NCKU in Taiwan [8]. This simulation validation ensures that the dam system accurately and promptly responds to abnormal conditions during actual operations. The simulation of gate control scenarios on the testbed verifies the correct response of gate operations to simulated abnormal events during actual operations, ensuring the stable operation of the dam system under abnormal conditions. This integrated validation on the testbed contributes to ensuring the safety and reliability of dam systems, enhancing the efficiency of responding to abnormal events during actual operations.

3. Construct the PLC status set based on continuous discovery

3.1. *System architecture*

In response to cybersecurity and abnormal detection issues in critical infrastructure, this paper proposes the design of an experimental platform for simulating the abnormal detection system of dam gates. (Fig. 2) Each gate is operated by a Programmable Logic Controller (PLC), which is equipped with registers for accessing relevant instructions and data. Consequently, this

information can reflect the current state of the environment, such as the requirement for the abnormal indicator light to be in the off state before any operations can take place.
Fig. 2. Anomaly Detection Diagram

3.2. State set construction process Virtual Dam Gate Abnormal Detection testbed

The testing platform employs the Modbus communication protocol to scan the state of Programmable Logic Controllers (PLCs). The scanning interval is set at 0.1 seconds, with a 1-second pause after each scan to simulate real operating conditions. This operation is repeated infinitely to observe changes in two key variables: scan frequency and state variation. Through an infinite number of scans, we will record the results of each observation, laying the foundation for subsequent discussions to thoroughly analyze potential variations and system behaviors. The objective of this testing platform is to gain a comprehensive understanding of the abnormal detection performance of the virtual dam gate system.

```

4. Experiment Results

This system effectively communicates the various states and operational stages of the gate through distinct light variations. When the gate is in remote monitoring

mode, the remote light is illuminated, indicating normal system operation. However, if floodgate discharge is required, personnel must adhere to regulations and physically attend the site, prompting a switch to on-site mode with the power light activated.

Following the commencement of operations, the ascending light is activated if gate opening is necessary, signifying the gate's upward movement. Upon reaching a specified height while fully opening the gate, the ascending light ceases, and both the on-site and power lights illuminate, denoting complete gate opening. Upon achieving full gate openness at the base, the fully open light illuminates, the ascending light extinguishes, and the descending light activates, indicating an impending gate descent. Operation Process Diagram in Fig. 3.

However, during operation, anomalies such as short circuits or system malfunctions might occur, potentially causing gate loosening or jamming during ascent, leading to an overload condition. In such instances, the system should promptly react, for instance, by activating the corresponding warning light to alert operators to perform maintenance or emergency procedures.

In summary, this system proficiently communicates the diverse statuses and phases of gate operations through distinctive light cues. Additionally, it promptly issues warnings during abnormal situations, ensuring operational safety and manageability. Experimental results as shown in Fig .4.
Fig. 3. Operation Process Diagram
Fig. 4. Experimental results

5. Conclusion

Given the complexity of abnormal operation detection in industrial control systems (ICS), we opted to

Pei-Wen Chou, Nai-Yu Chen, Jung-Shian Li, I-Hsien Liu

employ the Finite State Machine (FSM) method for anomaly detection in ICS operations. Through a series of tests conducted at the Dam Control System Cybersecurity Testbed established by TWISC@NCKU in Taiwan, our results demonstrated the effectiveness of our approach in improving the efficiency of identifying non-standard operational behaviors, enabling maintenance personnel to promptly recognize anomalies. This study not only constitutes a technical exploration but also emphasizes addressing potential anomalies in unique scenarios. In summary, this research provides a comprehensive and effective approach to ICS security, particularly in the realm of abnormal operation detection.

Abstract

This paper introduces an innovative approach to enhance data verification and security in intelligent systems through the integration of blockchain technology. The proposed method amalgamates the transparency and decentralization inherent to blockchain with the command and oversight functionalities of PLC to ensure the utmost data integrity. The devised approach synergizes the decentralized attributes of blockchain with the control capabilities of PLCs, thus establishing robust safeguards for data integrity. Through the utilization of blockchain's tamper-resistant ledger, PLCs orchestrate data interactions and enforce real-time monitoring and control. The viability and efficacy of this innovative scheme are substantiated through empirical evaluations and simulations, conclusively affirming its practicality.

Keywords: Industrial Control System, Programmable Logic Controller, Blockchain, State Monitor

1. Introduction

In recent years, with the continuous development of industrial automation, Industrial Control Systems (ICS) have played a crucial role in modern production environments [1]. These systems possess complex architectures, and their proper functioning is paramount to ensuring the stability and efficiency of the production process. However, with the ongoing advancement of digital technology, industrial environments have become more susceptible to data tampering and security threats. Our research is based on the application of blockchain technology, which, with its decentralized and transparent nature, introduces a new level of data security. By integrating blockchain into Programmable Logic Controllers (PLC) ensures the availability and integrity of the data.

2. Related Work

The related work in our study revolves around the application of Industrial Internet of Things (IIoT) and blockchain technology.

2.1. *Industrial Control Systems and Blockchain*

Researchers have explored the integration of blockchain technology with Industrial Control Systems (ICS) to enhance security and privacy within the Industrial Internet of Things (IIoT). Notable studies, such

as Z.-H. Sun et al. [2] survey of enterprise and literature reviews to identify specific industrial requirements in various supply chain scenarios, and G. Puthilibai et al. [3] proposal of a secure wireless solution based on blockchain technology for IIoT, and W. Zhou and J. Jin's development and evaluation of a distributed access control system using blockchain and smart contract technologies [4], collectively contribute to advancing the understanding and application of blockchain in the industrial domain.

2.2. *Blockchain Consensus*

Blockchain technology originated from Satoshi Nakamoto's "Bitcoin: A Peer-to-Peer Electronic Cash System" [5] and is a decentralized database technology. Various consensus protocols, including Proof of Work (PoW), Proof of Stake (PoS), Practical Byzantine Fault Tolerance (PBFT), are chosen based on blockchain use cases, performance requirements, and trust levels. The application of PoA (Table. 1) in the Industrial Internet of Things (IIoT) is notable, providing features such as a simplified block verification process, resulting in lower block generation times, and consequently, improved overall efficiency in industrial environments. X. Chen et al. measured the latency performance of Internet of Things (IoT) applications on private Ethereum blockchains, focusing on two consensus algorithms: Proof of Work (PoW) and Proof of Authority (PoA) [6]. The Study show that PoA Ethereum network has a lower Block-Oriented Latency (BOL) than the PoW one due to a simpler block verification process [7].

Table 1. PoA Overview

Energy Efficiency	PoA consumes lower energy compared to other consensuss, making it suitable for applications that demand efficiency.
Transaction Throughput	PoA provides higher transaction throughput, supporting a large volume of real-time transactions, aligning with the needs of industrial control systems.
Applicability	Particularly well-suited for industrial control systems, meeting their strict requirements for efficiency, real-time capabilities, and security.

3. Methodology

3.1. *System Design*

By utilizing Proof of Authority (PoA) blockchain (Fig. 1) [8] as the record framework for the industrial control system. PoA blockchain employs an authority node consensus mechanism where designated nodes are responsible for generating and validating new blocks.
Fig.1. Blockchain Structure

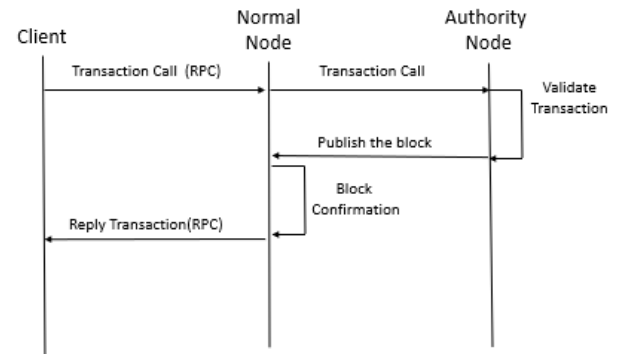
Clients are also participants in the blockchain network, with their primary responsibility being the submission of transactions or information to the blockchain. Clients utilize the Remote Procedure Call (RPC) protocol to communicate with blockchain nodes. This mode of communication allows clients to send remote requests, such as transaction submission requests, while nodes process these requests, participate in the consensus mechanism, and provide feedback on the final outcomes to the clients. (Fig. 2).


Fig.2. PoA Message Sequence Chart.

3.2. *Data Analysis*

By conducting tests in various scenarios using the same Genesis Block configuration and same mining setting to evaluate our blockchain performance [9]. Firstly, we will explore the multi-node scenario by establishing multiple nodes to simulate a decentralized environment, evaluating the system's performance in a decentralized setting. Subsequently, our focus will shift to the multi-authority scenario, where we increase the number of authority nodes to assess system performance in a multi-authority context. We will emphasize the measurement of Transactions Per Second (TPS) [10], employing different test cases and ensuring experiment repeatability to guarantee result stability. Ultimately, we will present the data distribution using box plots for intuitive comparisons, coupled with statistical analysis to gain deeper insights into the system's performance characteristics under various conditions.

4. Results and Discussion

4.1. *System Simulation*

By emulating the communication between the Human-Machine Interface (HMI) and the Programmable Logic Controller (PLC). The HMI, serving as an authoritative node, is responsible for block generation, transaction verification, as well as establishing connections with the database (DB). On the other hand, the PLC operates as a regular node, handling the synchronization and reception of transactions through client RPC. (Fig. 3).
Fig. 3. Integration of blockchain with PLC.

4.2. *Experiment Result*

We measured the service rate variations of a PoA blockchain under the same conditions for other variables (Table 2). Specifically, we assessed the impact of different node counts (from 1 to 3) (Fig. 4) and different validator counts (from 1 to 3) (Fig. 5) on the Transactions Per Second (TPS). Each scenario underwent 30 test iterations, and each test iteration included 1000 transactions.

Table 2. experiment setting

Genesis block	
Period	15 secs
Epoch	30000
Difficulty	0x010
Mining Setting	
CPU	Intel(R) Core(TM) i5-8250U CPU
Thread	1
Software	
PoA blockchain	Geth/v1.10.26-stable-e5eb32ac/windows-amd64/go1.18.5
Client	Nethereum 4.18
Fig. 4 TPS under different number of nodes
Fig. 5 TPS under different number of validators

The figures above illustrates that there is minimal variation in Transactions Per Second (TPS) across scenarios with 1-3 nodes and 1-3 validators. We hypothesize that the performance of Proof of Authority (PoA) may be more closely associated with the speed of transmission rather than the number of nodes.

5. Conclusion

In this study, we conducted practical experiments on the record-keeping functionality of the Proof of Authority (PoA) blockchain in a real-world Cyber-Physical System (CPS) environment. Additionally, we evaluated the performance of the PoA blockchain under different node counts and validator counts.

In the future, our focus will be on developing a comprehensive blockchain solution for CPS, addressing the undeniable cybersecurity needs of critical infrastructure. We will also continue to monitor the performance assessment of this solution.

Abstract

Ensuring the security, monitoring, and timely alerting of water levels in dams is a major challenge. We use blockchain technology to enhance the security and monitoring of dam infrastructure, and also improving the alerting system for water level changes. The use of blockchain technology in dam infrastructure management provides a decentralized, transparent, and tamper-resistant platform for storing and managing data. This ensures the integrity and security of critical data related to dam operations and water levels. This research investigates the enhanced security, monitoring, and alerting capabilities that this integration offers, and aims to contribute to the improved security and efficiency of dam infrastructure, leading to more reliable operations and better protection against potential disasters.

Keywords: Water Dam, Blockchain, Infrastructure Security

1. Introduction

Water dams play an important role as fundamental components of critical infrastructure, fulfilling essential functions in water resource management, flood control, and energy production. Recent cyber incidents, exemplified by the reported data destruction attack on a Ukrainian power plant by Russian hackers on April 8, 2022 [1], underscore the vulnerabilities of critical infrastructure. This incident exemplifies the growing threats faced by critical infrastructure worldwide [2], emphasizing the need for innovative approaches to enhance the security, monitoring, and responsiveness of such infrastructure.

As demands on these dams increase due to population growth and climate change, ensuring security, effective monitoring, and timely response to potential issues of water dams becomes important [3]. The decentralized and tamper-resistant properties of blockchain present a possible solution to enhance the security and monitoring of dams to changing conditions. We propose the network architecture and operational workflow for the integrated system. The integration of blockchain technology aims to enhance the security, monitoring, and alerting systems of dam infrastructure, addressing current shortcomings and leading to more reliable operations and better protection against potential disasters.

2. Background

2.1. *Regulatory and Policy*

Strategies for easing security risks must consider regulatory and policy frameworks. This involves aligning security measures with industry standards, governmental

regulations, and cybersecurity best practices to ensure a comprehensive and effective approach. Regulations should contain scenarios involving abnormal water levels. Policies can ensure the implementation of advanced monitoring systems capable of detecting sudden or unexpected changes in water levels. This ensures timely responses to mitigate potential risks associated with extreme water level variations.

Regulatory frameworks must not only recognize the potential for abnormal water levels but also involve the importance of consistency in gate status and water level readings. These consistencies can arise from various factors, including technical problems, sensor inaccuracies, or even intentional manipulations. Addressing these issues in policies is an important step toward enhancing the resilience of dam infrastructure.

In the scenario of gate status and water level inconsistencies, dam operators face the challenge of accurately assessing the true conditions of the dam. A gate that is reported as closed in the control system, while physically open, can lead to an underestimation of the water level, posing risks of flooding downstream. On the contrary, a reported open gate when it is closed might result in an overestimation of water levels, potentially impacting water resource management.

Regulatory and policy considerations play an important role in addressing security risks in dam infrastructure. By incorporating events such as gate abnormal openings, water level fluctuations, equipment reading problems, and extreme weather events, regulatory frameworks contribute to a comprehensive and adaptive approach to safeguarding critical infrastructure.

2.2. *Data Integrity*

The potential for unauthorized access and manipulation of critical operational data poses a significant security risk. Unauthorized individuals or external malicious hackers may attempt to gain unauthorized access to sensitive information related to water levels or operational parameters. This external threat could lead to misleading dam operators, compromise decision-making processes, and introduce risks to the safety and functionality of the dam [4].

The risk also extends to internal employees who may intentionally manipulate operational data. This insider threat poses unique challenges as it involves individuals with legitimate access to the system. Internal data tampering can mislead dam operators, compromise decision-making, and lead to potential risks in the safety and functionality of the dam. Implementing measures to detect and prevent both external and internal data tampering is important for maintaining the integrity of

operational data [5]. Manipulating these important data sets could lead to inaccurate assessments, potentially resulting in inadequate responses to changing conditions and an increased vulnerability to operational failures.

2.3. *Blockchain Technology*

As technological advancements continue to appear in critical infrastructure, the integration of blockchain technology is seen as a possible solution for enhancing the security and transparency of dam operations. Blockchain technology enhances the security of dam infrastructure by providing a transparent and immutable record of all transactions and data related to the operation of gates, water levels, and other important parameters.

The decentralized property of blockchain ensures that data is distributed across a network of nodes, reducing the risk of a single point of failure or unauthorized access. The tamper-resistant property of blockchain ensures the integrity of data generated by sensors and monitoring systems. This feature is important in relation to intentional data manipulations that could compromise the reliability of water level readings.

3. DamChain Architecture

The DamChain architecture is designed to enhance the security and monitoring of dam infrastructure through the integration of blockchain technology. Our proposed architecture integrates the decentralized and tamper-resistant features of blockchain to build an architecture for managing important data related to dam operations and water levels.

3.1. *Network Architecture*

The network architecture of the integrated system is an important component depending on the design of the blockchain network. Choosing the right consensus mechanism is important. Moreover, incorporating blockchain technologies and a consensus mechanism can play an important role in implementing the blockchain network to the requirements of dam operations.

We designed the network architecture in Fig. 1. The network architecture demonstrates the application of blockchain technology in the management of dam infrastructure. By recording water level data and dam operations on the blockchain, the system achieves transparent information storage and protection against tampering. Operators can monitor the dam's status by observing data on the blockchain.
Fig. 1 Network Architecture

3.2. *Operational Workflow*

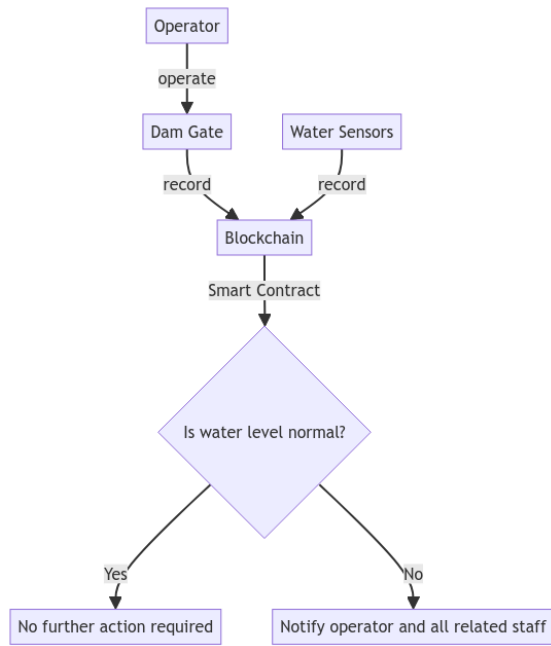
An essential aspect of the regulatory model and operational workflow is the continuous monitoring of compliance with established policies. This involves regular audits and reviews to identify any differences from the regulatory framework. The operational workflow involves the interaction between the operator, dam gate, water sensors, and the blockchain. The flowchart in Fig. 2 illustrates the process.


Fig. 2 Operational Workflow

In this workflow, the operator operates the dam gate, and the actions are recorded on the blockchain. Water sensors also record data, and a smart contract evaluates whether the water level is normal. If yes, no further action is required; if no, the operator and all related staff are notified.

4. Experiment

The integrated system uses Geth (Go Ethereum) as the blockchain implementation and is hosted on a system with the following specifications in Table 1.

Table 1. System Specifications

Processor	Intel Core i5-7500 CPU @ 3.40GHz
Operating System	Windows 10 Enterprise 64-bit
RAM	16GB

The experiment result is shown in Fig. 3. The result is in an average transaction throughput of 115.575 transactions per second, and shows the evaluation of the system ability to handle and record dam operations within the specified hardware and software environment.
Fig. 3 Transaction Count

An additional experiment was conducted to evaluate the average response time of the system to water level alert events. The result indicates an average response time of 5.06425 seconds in Fig. 4. The experimental evaluation of the system provides reasonable insights into its performance and capabilities within a real-world dam management scenario.

Fig. 4 Response Time

YingCheng Wu, Jung-Shian Li, Chu-Fen Li, I-Hsien Liu
5. Conclusion

The study demonstrates the possible benefits of integrating dam infrastructure management with blockchain technology. The integration not only enhances security and monitoring but also shows the possibilities for resilient and efficient operations. The regulatory and policy frameworks underscored the importance of continuous monitoring to address unexpected challenges.

The integration system introduces how important data related to dam operations and water levels is managed. The blockchain technology ensures data integrity, providing an indisputable record of transactions. This is important in critical infrastructure scenarios to prevent unauthorized access or data tampering. Moreover, the implementation of the system addresses the need for water level alerting. These features enhance security and monitoring to dam security and water level alerting.

Abstract

Testbeds, serving as simulations of real-world scenarios, are of paramount importance for research in cybersecurity related to critical infrastructure. In this paper, we aim to offer a comprehensive exploration of the MiniDAM and our testbed, introducing its physical settings based on real dam operational standards. Furthermore, a comparative analysis between the Secure Water Treatment (SWaT) testbed, MiniCPS, our testbed, and MiniDAM is presented. This paper also includes insights into dataset generation and the integration of other functionalities. The exposition of MiniDAM's features and capabilities serves as a foundation for enhancing resilience and provides valuable support for advancing research within the broader field of dam-related studies.

Keywords: Dam Testbed, Critical Infrastructure, Industrial Control System, Cyber-Physical System, Cybersecurity

1. Introduction

Critical infrastructures [1] have significantly enhanced our quality of life over years of development. Since the introduction of the Industry 4.0 [2] concept, ensuring the security of Cyber-Physical Systems (CPS) [3] has become a primary objective across various industrial sectors. CPS involves the seamless integration of computation, networking, and physical processes. Through CPS, we gain the capability to monitor both the physical processes and network traffic within a system, thereby enhancing overall system performance and resource allocation.

However, despite the advancements, numerous vulnerabilities persist within the CPS of critical infrastructures, posing potential risks to public safety [4]. Dam facilities, in particular, experience failures and security breaches annually. The cyberattack on the Bowman Avenue Dam in 2013 underscored the potential crisis posed by malicious actors targeting these systems. Conversely, Some failures are attributed to anomalies in

inflow, often triggered by extreme weather conditions. For instance, the collapse of the Laos Dam and the Sandford Dam failure in 2018 were both consequences of heavy rainfall.

The security of dam CPS can no longer be ignored after the tragedies that happened around the world. As a result, a testbed with a toolkit that contains both physical and network aspects of data for further research in a dam scenario is needed.

2. Research Background

Our research is primarily based on the concept of Cyber-Physical Systems (CPS), focusing on the investigation of the widely referenced SWaT Testbed [5] and MiniCPS [6]. Subsequently, we compare their features with our own testbed and toolkit.

2.1. *Cyber-Physical System*

CPS represents an innovative paradigm that integrates computational algorithms and physical processes to create intelligent and interconnected systems. These systems enable seamless communication and collaboration between the digital and physical worlds, allowing for real-time monitoring, control, and optimization of diverse applications.

R. Alguliyev et al. [7] illuminated the principle of CPS operation and philosophical issues of CPS raised, and also proposed a tree of attacks on CPS. J. Shi et al. [8] described and summarized the features of CPSs, then three classic cases were given with research challenges and suggestions for future work.

2.2. *SWaT Testbed & MiniCPS*

When it comes to testbeds and toolkits in the field of CPS, the SWaT Testbed and MiniCPS are frequently referenced.

2.2.1. *SWaT Testbed*

Secure Water Treatment (SWaT) is a water treatment testbed for research in the field of cybersecurity. SWaT consists of a six-stage process of water treatment with frequently used industrial components, such as Programmable Logic Controllers (PLCs) made by Allen-Bradley, Human Machine Interfaces (HMIs), Supervisory Control and Data Acquisition (SCADA) workstation, Historian, etc. The SWaT Dataset systematically generated from the testbed is also provided for CPS researchers to do further analysis and other related works.

2.2.2. *MiniCPS*

MiniCPS is a toolkit built on top of Mininet [9] to provide an extensible, reproducible research environment for network communications, control systems, and physical-layer interactions in CPS. MiniCPS was also used to model the communication and control aspects of SWaT while illuminating example applications.

MiniCPS focuses on high-fidelity network emulation and being a framework for all fields of CPS. However, the full-fledged physical process simulation was considered to be out of the scope of MiniCPS since it does not aim to be a performance simulator. Furthermore, MiniCPS can only run on Linux operating systems due to its reliance on Mininet. MiniCPS also put very little emphasis on Visualization, such as Graphical User Interface (GUI).

The issues mentioned above could pose challenges to the reproducibility of research for researchers in specific domains.

3. Dam Cybersecurity Toolkit Architecture

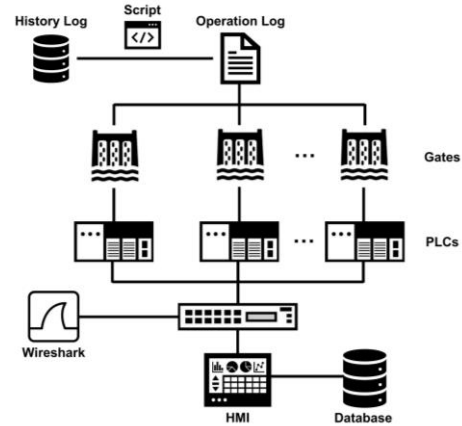
For the physical part of our toolkit, we utilize the PLCs that had been used in a real dam field environment in Taiwan. We also obtained the dam history log which consists of related information during the period, such as water level, opening of the gates, gates inflow, gates outflow, etc.


Fig. 1. Architecture of The Dam Cybersecurity Toolkit

The architecture of the dam cybersecurity toolkit is shown in Fig. 1. We further process the history log with the script based on the operational standards of the real dam to generate the operation log which defines how PLCs should work while facing the situation of the corresponding history log. As shown in Fig. 2, we also use our HMI to monitor the states of the PLCs, the overall operation is recorded in the database, and Modbus/TCP packets between HMI and PLCs are simultaneously

captured using Wireshark for CPS researchers in the dam field to conduct further analysis and experiments that need related dataset, such as machine learning [10].

Fig. 2. MiniDAM HMI

4.   Applications of The Dam Cybersecurity Toolkit
4.1. *Dam Environment Simulation*

In contrast to MiniCPS, MiniDAM places a heightened focus on Cyber-Physical Systems (CPS) within dam field environments. Leveraging pertinent Programmable Logic Controllers (PLCs) and historical logs derived from actual usage in dam fields, we meticulously construct a tailored Graphical User Interface (GUI) to facilitate operational tasks. This approach enables us to bridge the gap between theoretical models and real-world dam scenarios. As a result, we generate a diverse array of datasets corresponding to various operational scenarios. These datasets serve as valuable resources for dam domain researchers, offering them rich materials for in-depth analysis and exploration of the intricacies within dam environments.

4.2. *Dataset Generation*

In addition to recording related information in the database during operation. Modbus/TCP packets are also captured using Wireshark. As shown in Fig. 3, HMI and PLCs communicate with each other using Modbus/TCP protocol. We can generate datasets for different non-normal scenarios by modifying the logic within the script.

As illustrated in Fig. 4, due to significant variations in water flow in Taiwan during the summer season, a comparison of the history log and dataset regarding the water capacity difference over the period of the summer of 2017 was conducted within a normal scenario defined according to operational standards. We observed that the dataset and history log exhibit similar characteristics, demonstrating the validity of our operation log and the similarity between the dataset and the actual field.
Fig. 3. Modbus/TCP Packets Dataset
Fig. 4. Comparison of The History Log and Dataset regarding The Water Capacity Difference over The Period of 2017 Summer in a Normal Scenario

5. Conclusion

In this study, we introduce MiniDAM's physical settings based on the real dam operational standards and how our toolkit differs from MiniCPS. Furthermore, we illustrate the features of MiniDAM, including dataset generation.

In the future, we are heading to build a comprehensive CPS interface for the dam operations to extend the testbed's [11] functions. Thoroughly define how virtual and physical devices interface with our toolkit, taking into account hydrological information for broader watershed analysis.

Abstract

Deploying intrusion detection systems is a common cybersecurity measure, and intrusion detection systems typically operate at the ports of gateways. In critical infrastructure, industrial control systems often employ network isolation strategies, lacking the role of gateways. This research primarily explores the deployment of the Snort intrusion detection system in such an environment, combined with specific OT rules. Validation is conducted using the cybersecurity testbed of the dam control system established by TWISC@NCKU in Taiwan. The results indicate that by employing our proposed approach, it is possible to effectively detect abnormal network traffic, addressing the common issue of inadequate monitoring in environments with network isolation.

Keywords: Industrial Control Systems, Critical infrastructure, Network Isolation, Network-Based Intrusion Detection System

1. Introduction

The cybersecurity landscape in critical infrastructure, particularly Industrial Control Systems (ICS), faces escalating threats [1], exemplified by the recent CISA AA22-103A alert. This alert, prompted by internal ICS intrusion cases, underscores operators' vulnerability to targeted attacks, emphasizing the need for robust cybersecurity measures [2]. Deploying Intrusion Detection Systems (IDS) is standard, but challenges arise in ICS scenarios with network isolation policies.

This study delves into deploying Network-Based Intrusion Detection System (NIDS), focusing on the Snort intrusion detection system within network-isolated ICS [3]. Departing from conventional approaches, it addresses challenges posed by network isolation, offering nuanced network security tailored to ICS requirements. Snort, typically installed at gateway, assumes a novel role within network-isolated ICS. The research is motivated by the recognition that existing IDSs may fall short in effectively monitoring ICS within network isolation, prompting a reevaluation of intrusion detection strategies.

To validate the approach, this study leverages the TWISC@NCKU dam control systems cybersecurity testbed in Taiwan, providing insights into real-world applicability. The research's significance lies in addressing insufficient monitoring in network-isolated

environments. Developing Snort rules to detect "Close PLC Gate Controller" commands enhances ICS's capacity to defend against potential threats, fortifying critical infrastructure against evolving cyber threats. This introduction establishes the groundwork for exploring NIDS deployment in network-isolated ICSs, aiming to provide effective and tailored cybersecurity solutions for safeguarding ICSs.

2. Background
2.1. Isolation of Industrial Control Networks

This study explores ICS cybersecurity through Purdue Enterprise Reference Architecture (PERA) [4], renowned for its comprehensive approach. PERA's distinctiveness lies in its lack of a gateway component, challenging conventional norms in critical infrastructure. This absence leads to a nuanced examination of network isolation strategies in ICS. While considering the Industrial Demilitarized Zone (IDMZ), its inapplicability due to the absence of a gateway is acknowledged. Consequently, our research underscores the need to enhance security by introducing NIDSs between the first and third layers of the PERA. Integrating PERA into intrusion detection improves understanding, optimizes deployment, and strengthens resilience against inappropriate network behaviors in industrial settings.

2.2. Network-Based Intrusion Detection System

Network-Based Intrusion Detection Systems (NIDS) are indispensable for cybersecurity, providing vigilant monitoring and timely alerts against potential intrusions in network traffic. The deployment of intrusion detection in ICSs, where network isolation is prevalent, poses a significant challenge. This study investigates the viability of integrating Snort, an open-source Intrusion Detection System, with tailored Operational Technology (OT) rules for such environments. Our methodology seamlessly incorporates Snort into ICSs, effectively addressing the complexities introduced by network isolation. Operating on signature and rule-based matching, Snort adeptly identifies abnormal network traffic and potential threats, solidifying its role as a reliable NIDS tool for ICSs in network-isolated environments. This integration significantly enhances cybersecurity by enabling the detection and response to potential intrusions within the constraints of network isolation.

2.3. Internal ICS Attack Scenarios

This study explores NIDSs deployment in Industrial Control Systems (ICS) within network-isolated environments. Our investigation identifies vulnerabilities, particularly in instances of command injection and IDE access attacks [5], posing risks to the confidentiality, integrity, and availability of ICS.

Examining NIDS deployment in ICS reveals internal attack methodologies. The TWISC@NCKU collaboration establishes a secure gateway control system testing platform at the third layer, emphasizing the critical role of sensor readings on Human-Machine Interface (HMI) in dam operations. Our research introduces cross-layer attack methodologies tailored to dam operations, disrupting sensor readings through Modbus/TCP packet injections to Programmable Logic Controllers (PLCs). Focusing on countering malicious shutdowns, specifically targeting PLC controllers, we develop security measures and IDSs to fortify ICS against evolving threats in complex network environments. This study offers practical solutions to enhance ICSs' security.

3. ICS Network Intrusion Detection Methods

To explore the deployment of NIDS in ICS, we developed a comprehensive framework encompassing SNORT deployment, PLC, NIDS, and HMI establishment. Initially, we utilized Twido to construct an HMI, offering monitoring and control for the PLC (TWDLCAE40DRF). To simulate an attack, we deliberately shutdown the controllers of PLC and employed Wireshark to capture Modbus packets. Subsequently, SNORT was implemented with a focus on configuring it as a NIDS.

NIDS is intended to be deployed at the third layer, specifically in the operational management segment, with the database at its core storing information displayed on the HMI. In this scenario, the objective of NIDS is to monitor the operational management layer of ICS to detect potential intrusion threats.
Fig. 1. NIDS, PLC, HMI Integration Architecture

During the integration of PLC and NIDS, we ensured seamless communication and monitored PLC communication to identify anomalies, with a particular emphasis on effectively detecting abnormal network behavior in an isolated network environment (Fig. 1). This comprehensive experimental procedure aims to assess the effectiveness of SNORT in ICS, contributing

to an improved understanding of cybersecurity enhancement in network-isolated environments.

In the pursuit of validating our proposed approach, we leverage the OT testbed provided by TWISC@NCKU. This cybersecurity testbed, specifically designed for dam control systems, serves as the foundation for our experiments. Its realistic representation of industrial control scenarios enables a practical examination of SNORT's deployment within a network-isolated environment.

Our investigation extends to the formulation of NIDS rules, particularly focusing on the integration of SNORT with tailored OT rules. The development of rules aims to detect attack techniques, with a special emphasis on countering malicious shutdowns, specifically targeting PLC controllers [6] (Fig. 2). This strategic development of rules contributes to fortifying ICS against evolving threats, thereby enhancing overall system security.

```
alert tcp any any -> any 502
(msg:"Detected Modbus/TCP Packet with
Data '41ff00'"; content:"|00 00 00 00
00 06 ff 90|"; depth: 8;
content:"41ff00"; sid:10000004;)
```
Fig. 2. Snort Rule for PLC Shutdown Detection

4. Experiment

In the experimental phase, we meticulously configured simulation parameters and established the experimental environment, focusing on realistic attack scenarios targeting Programmable Logic Controllers (PLCs). We simulated a shutdown attack on the controllers of PLC, capturing Modbus packets using Wireshark. Snort was configured as a NIDS with specific OT rules [7]. All experiments were conducted in the realistic dam control system testbed provided by TWISC@NCKU at National Cheng Kung University in Taiwan, ensuring authentic and reliable results. The configuration aimed to evaluate Snort's deployment effectiveness in industrial control systems with network isolation.

Utilizing the established experimental environment, a total of 30 experiments were conducted, each lasting 20 minutes and involving 0 to 20 instances of attacks. The attacks followed the methodologies outlined in Section 2.3. Background traffic, consisting of normal HMI [8] and PLC communication, was present in the environment (Fig. 3). The results indicated that, with an average of 4560 experimental packets, approximately 6.5 attacks were detected, resulting in a detection rate of 99.4%. The lowest detection rate, around 83%, occurred when interference devices were activated. In conclusion, there

is a 99.4% probability of detecting attack packets, demonstrating the robustness of the proposed approach.
Fig. 3. Background Traffic in the Environment

5. Conclusion

This study delves into the deployment of NIDS, with a specific focus on Snort, in network-isolated ICS. Traditional intrusion detection systems often face challenges in ICS scenarios with network isolation, where they typically operate at gateway ports. Leveraging the cybersecurity testbed for dam control systems at TWISC@NCKU in Taiwan, our research validates Snort's efficacy in detecting abnormal network traffic, addressing the common issue of insufficient monitoring in network-isolated environments.

In the pursuit of enhancing the overall security of network-isolated ICS, this study emphasizes the necessity of adapting intrusion detection strategies to the unique challenges posed by critical infrastructure. Looking ahead, future research aims to broaden the scope by exploring additional attack scenarios. Due to current limitations in experimental settings, there are plans to incorporate Engineering Working Station (EWS) and introduce common IT attack scenarios to assess their effectiveness. This expansion will provide a more comprehensive understanding of the capabilities and limitations of intrusion detection systems in safeguarding network-isolated ICS against a diverse range of cyber threats.

Abstract

This paper aims to explore the innovative model of integrating AI (Artificial Intelligence) services in the Taiwanese real estate industry. The research employs literature analysis and the Fuzzy Analytic Hierarchy Process (FAHP) as the methodological approach. A FAHP questionnaire survey was conducted among real estate professionals in the Tainan region of Taiwan. Through the calculation of relative weights among various dimensions, the study identifies key factors related to the adoption of AI-based innovations by real estate agents in Taiwan. These findings serve as crucial references for the real estate industry in transactional and operational management.

Keywords: Real Estate Agency, Artificial Intelligence (AI), Service Innovation, Fuzzy Analytic Hierarchy Process (FAHP)

1. Introduction

Real estate transactions involve not only the buyers and sellers but also a crucial intermediary—the real estate agent. These agents play pivotal roles in property transactions, serving as key figures in advertising, marketing, and negotiation processes.

Quality real estate agents leverage effective communication and professional marketing strategies to facilitate successful transactions, guiding both parties towards the common goal of closing deals.

This paper asserts that real estate agents consistently improve overall marketing performance through various innovative services. However, the study suggests that by incorporating an AI-driven integration of innovative services, it is possible to identify key factors influencing various sales strategies employed by real estate agents. The research believes that uncovering these factors can significantly contribute to the operational performance of real estate agencies.

The objectives of this study are as follows:

(1)To examine relevant literature and identify key factors in service innovation, developing primary and secondary dimensions.

(2)To integrate AI technology into the reviewed dimensions and conduct a questionnaire study using the Fuzzy Analytic Hierarchy Process (FAHP) to obtain the relative weights of four main dimensions and twelve sub-dimensions.

(3)To draw conclusions and summarize the key factors in the integration of AI-based service innovations in the Taiwanese real estate industry. These findings serve as vital references for industry operational performance and business development.

2. Literature Review

Innovation has emerged as a pivotal force propelling the development of the service economy [1]. Within the real estate industry reports, there is a growing trend to incorporate elements such as digitization, new technologies, the sharing economy, tenant relationships, as well as new services and business models [2], [3], [4].

AI has the potential to drive market capabilities, utilizing various AI methods such as customer-oriented, industry-oriented, and cross-functional integration approaches to better understand consumer demands. These methods are then applied to the marketing behaviors of companies [5]. To streamline AI-driven innovation, service organizations need to develop an integrated Dynamic Capability Framework (DCF) that focuses on the ethical application of technology, talent, organizational culture, and structure to optimize the entire service journey [5].

This paper gathers insights from domestic and international scholars and experts to explore literature related to service innovation and the application of AI in

the field of real estate. Through this review, the study synthesizes and constructs the main dimensions of service innovation, including customer engagement, business models, technology integration, and process innovation. The subsequent sections provide detailed discussions on each of these dimensions.

At the "customer engagement" level, customers are paramount in the real estate industry. Real estate agents must fully comprehend customer needs to seize crucial transaction opportunities. Therefore, the concept of customer engagement necessitates the integration of various transaction methods, considering potential impacts on company behavior. To achieve this, companies need to understand customer demands, identify the value customers seek beyond normal transaction processes, recognize customer roles, and anticipate the roles customers and the company play in interacting with each other [6].

At the "business model" level, business models have become essential means for the commercialization of innovative ventures. They are perceived to provide a framework for companies to create and extract value from innovative ideas or technological developments, emphasizing that innovation concepts or technological developments alone do not represent any "single target value." The commercialization of such concepts occurs through business models [7], [8].

At the "technology integration" level, the rapid development and widespread deployment of technology integration form the foundation for many service innovations. The significance of technology integration for service-oriented enterprises and industries, as well as the importance of service innovation, has long been recognized [9]. Understanding the four dimensions of service innovation—service concept, customer interface, service delivery system, and technology—many service innovations involve some combination of these dimensions [10].

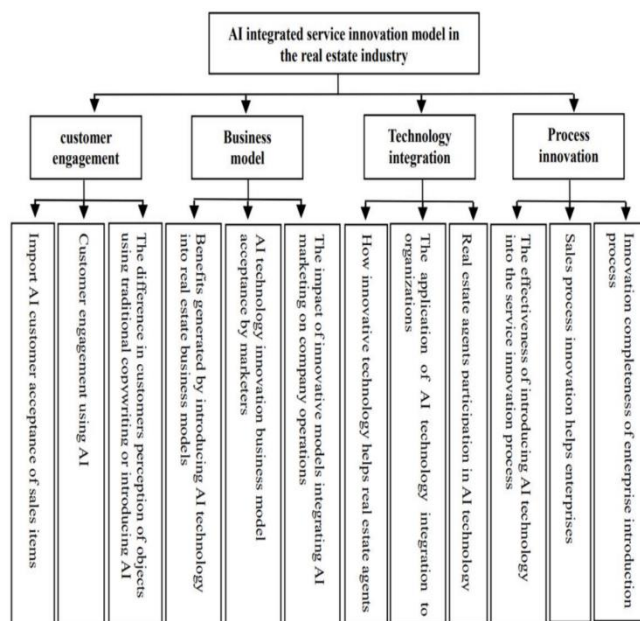
At the "process innovation" level, revolutionary approaches to enhance business performance must address how to perceive and build businesses and how to improve them. Businesses should not be viewed from the perspective of functions, departments, or products, but rather from the standpoint of key processes. Adopting a process-oriented approach means adopting the customer's viewpoint. Processes are the structures for performing operations required to create value for customers. Therefore, a crucial measure of processes is customer satisfaction with the process outputs, as they are the ultimate arbiters of process design and ongoing performance [11].

For real estate sales, the use of technology and digitization has become a fundamental marketing method. As information technology continues to advance, an increasing number of real estate agents are incorporating AI technology into their sales promotions. This involves integrating various service innovations and streamlining operational processes to address the dynamic demands of the real estate market, thereby strengthening business operations and achieving profitability goals.

3. Constructing an AI-Integrated Service Innovation Model in the Real Estate Industry

3.1. *Research Framework*

This study synthesizes the results of focus group discussions to establish a determined research framework for an AI-integrated service innovation model in the real estate industry. The developed framework comprises four main dimensions and twelve evaluation indicators, as illustrated in (Fig. 1).

Figure 1 Research Framework


3.2. *Research Subjects*

To investigate the integration of AI technology in service innovation within the Taiwanese real estate industry, this paper focuses on real estate professionals in the Tainan region as the primary study participants. Employing purposive sampling, 12 scholars and industry experts specializing in AI and the real estate industry were selected to participate in the FAHP questionnaire. Prior to conducting the FAHP survey, the researchers provided an overview of the study's objectives to these participants and engaged willing real estate professionals in the FAHP questionnaire survey operations.

4. Empirical Evidence of AI-Integrated Service Innovation Models

In this paper, the multiplication of the four evaluation indicators by their respective dimensions results in composite weights.

As can be seen from Table 1, the most important evaluation indicators recognized by the 12 real estate industry players are "customer acceptance of AI for sales objects" (the comprehensive weight is 0.223), and "the benefit of sales process innovation to the enterprise" (the comprehensive weight is 0.173, ranking No. 2. Ranked third is "The difference in customer perceptions of objects using traditional copywriting or the introduction of AI" (the comprehensive weight is 0.101), ranking fourth is "The effectiveness of AI technology introduced into the service innovation process" (the comprehensive weight is 0.084), ranking The fifth is "The benefit of innovative technology to real estate agents" (the comprehensive weight is 0.083), and the evaluation indicators ranked sixth to twelfth are: "The acceptance of AI technology innovation business model by marketers" (the comprehensive weight is 0.067) , "Customer participation in using AI" (the comprehensive weight is 0.059), "The benefits generated by the introduction of AI technology into the real estate business model" (the comprehensive weight is 0.056), "The organizational application of AI technology integration" (the comprehensive weight is 0.054) , "Innovation completeness of enterprise introduction process" (the comprehensive weight is 0.041), "The impact of the innovative model integrating AI marketing on company operations" (the comprehensive weight is 0.030), and "The participation of real estate agents in AI technology" (the comprehensive weight is 0.029).

Table 1 The comprehensive weights for the AI-integrated service innovation model

Dimension	Weights	Evaluation indicators	Weights	Comprehensive weight
customer engagement	0.383	Import AI customer acceptance of sales items	0.582	0.223
		The difference in customers' perception of objects using traditional copywriting or introducing AI	0.263	0.101
		Customer engagement using AI	0.155	0.059
Process innovation	0.298	Sales process innovation helps enterprises	0.579	0.173
		The effectiveness of introducing AI technology into the service innovation process	0.283	0.084
		Innovation completeness of enterprise introduction process	0.138	0.041
Technology integration	0.166	How innovative technology helps real estate agents	0.502	0.083
		The application of AI technology integration to organizations	0.325	0.054
		Real estate agents' participation in AI technology	0.173	0.029
Business model	0.153	AI technology innovation business model acceptance by marketers	0.436	0.067
		Benefits generated by introducing AI technology into real estate business models	0.369	0.056
		The impact of innovative models integrating AI marketing on company operations	0.195	0.030

5. Conclusions

The four key findings of this study are listed below:

5.1. *The most important evaluation indicator for customer participation is "Customer acceptance of sales items imported into AI"*

"Customer participation" is the most important aspect considered by real estate industry players, among which "customer acceptance of AI for sales items" is the most important. For customers, no matter what kind of real estate property is needed or what sales method is used, the primary evaluation factor is whether the customer can accept and like it. It is also worth noting that no matter what kind of technology is used to promote the sale of objects, the key point is to let customers fully understand the characteristics, price, regional market and housing conditions of the object, which is the best way to achieve the final sale.

5.2. *The most important evaluation indicator of process innovation is "the benefit of sales process innovation to the enterprise"*

"Process innovation" is the second most important aspect considered by real estate industry players, among which "the benefit of sales process innovation to enterprises" is the most important. Research shows that the vast majority of real estate industry operators agree that continuous innovation in sales processes, in addition to the benefits to enterprises, It is obviously helpful, but it will also be a great help for marketers to implement business promotion. The possible reason is that with the changes of the times and in response to different customer needs, only innovating the sales process in a timely manner can effectively improve operational efficiency. In other words, real estate industry players cannot just focus on sales performance. Grasping the pulse of the market and establishing a process innovation mechanism are indispensable key factors.

5.3. *The most important evaluation indicator for technology integration is "the benefit of innovative technology to real estate agents"*

"Technology integration" is the third most important aspect considered by real estate industry players, among which "the benefit of innovative technology to real estate agents" is the most important. The main reason is that information technology is changing with each passing day, and AI is penetrating into every person. Today, the main purpose of promoting technology-based real estate brokerage is to create convenience, security, and innovation between operators and consumers. At this time, it must rely heavily on the integration and linkage of various technological

knowledge and information equipment. For example, through smart technology-related technologies, people can view houses remotely or use 360-degree panoramic views, so that they do not need to visit the house in person. Instead, they can use technology to filter suitable objects to save money. time and improve sales performance.

5.4. *The most important evaluation indicator of the business model is "marketing staff acceptance of AI technology innovation business model"*

"Business model" is an aspect that real estate industry players consider to be less important. Among which, "AI technology innovation business model marketers' acceptance" is the most important. The main reasons should be the age and acceptance of new technology applications by real estate agents and marketers. There is a large gap in levels, and not every colleague may be quick or familiar with the application mode of AI technology, and some consumers have not popularized the operation method of information technology for house viewing. There are still most consumers who can only discover the house through on-site viewing. The actual problem lies, but with the increasing popularity of smart systems and equipment, AI technology will gradually become more popular in the future, and the public will also have a certain degree of concept. The promotion of this business model will still be a key point in the future.

Abstract

In fresh produce supermarkets, the shelf life of vegetable products is typically short, necessitating daily restocking based on historical sales data and the formulation of a rational pricing strategy to maximize the store's profits. This paper, based on sales data for vegetable products in a particular store from July 2020 to June 2023, employs various analytical methods, including multidimensional analysis, clustering, and regression, to explore the interrelationships among different types of vegetables. Furthermore, it combines cost-plus pricing and price elasticity models to establish a pricing framework that optimizes revenue for the supermarket.

Keywords: vegetables for sale, vegetable pairing, cost plus pricing, pricing strategy

1. Introduction

Nowadays, with the continuous improvement of people's living standards, fresh merchants are opening in various places. In the sale of vegetable commodities, because the fresh-keeping period of vegetable commodities is relatively short, and the product phase becomes worse with the increase of sales time, it is of great significance for merchants to replenish according to the historical sales and demand of various types of vegetables in the past.

In the actual operation of the store, the store should consider the types of various vegetables, origin, shelf life, purchase time, season, store space and other factors to reasonably replenish different vegetables. In addition, the store should also consider the consumption time of customers, the number of types of dishes, market conditions and other factors to determine the price. The research on reasonable replenishment and pricing of vegetables has important guiding significance for the sale of vegetables in real life.

This paper will explore the distribution of different vegetable sales from different dimensions, and combined with the cost plus pricing [1] and price elasticity model [2] to explore and set a set of pricing relationships to maximize the profits of supermarkets.

Yuhao Zhang, Shuangshuang Ma, Jiashuai Wang, Fengzhi Dai, Lijiang Zhang

The rest of this paper is organized as follows. The second part studies the law of vegetable sales according to the data of previous years. Section III introduces the construction of the pricing model. In Section IV, the evaluation model and the obtained results are analyzed. Section 5 summarizes the main contents of this paper.

2. Rules of Vegetable Sales

The data statistics the flow details of vegetable products sold in a store from July 1, 2020, to June 30, 2023, which contains six vegetable categories and the corresponding single product sales volume and sales unit price. In the following, the sales rules of vegetables will be analyzed from three dimensions: quarterly, weekday and non-weekday, and freshness.

2.1. The quarterly factor

By summarizing the total sales volume of the six categories of goods in each quarter, the visualized data are presented in Fig.1.
Fig.1. quarterly factor chart

As can be seen from the Fig.1, the sales volume of each vegetable category shows periodic changes over time. The sales volume of the third quarter of 2020, the third quarter of 2021 and the third quarter of 2022 to the third quarter of 2023 show the same trend. The trend between the third quarter of 2021-the third quarter of 2022 and the two cycles may be different because the COVID-19 pandemic has affected sales.

2.2. Working days and non-working days

In real life, people often have meals at work on weekdays and buy fewer vegetables every day. On non-working days, that is, Saturday and Sunday, people are more willing to buy more vegetables to eat. The average sales volume of six types of vegetables on weekdays and non-working days are shown in Fig.2.
Fig.2. weekday and non-weekday factors

It can be seen from Fig.2 that each category sells well on Saturday and Sunday, and the sales volume is large, which reflects that the average sales volume of the six vegetable categories on non-working days is stronger than that on working days.

2.3. Freshness of vegetables

In a day, from morning to evening, the freshness of dishes gradually decreases. The average daily sales volume of the six vegetable categories is divided into three periods by time, and the sales volume of each vegetable category in the morning, middle and late periods is summed up, to analyze the distribution of the freshness of dishes in the store on the sales rule, The data are visualized in Fig.3.
Fig.3. freshness factor map of vegetables

It can be seen from Fig.3 that the sales volume of all dishes is the largest in the morning, followed by the afternoon, and the least in the morning. This result is consistent with the actual life, and reminds the merchants to prepare all the goods in the morning, and carefully replenish the goods in the afternoon and evening.

2.4. The distribution law of sales volume of each single product

Each major category of vegetables contains a variety of single vegetable products. The single vegetable products are divided into 7 categories by K-means clustering

method [3], and the trend of the average sales volume of each category of single product over the quarter is drawn, which is shown in Fig.4.
Fig.4. regular trend chart of single product sales

The average sales volume and sales volatility (standard deviation) of each category of single product are calculated, and combined with the quarterly sales trend of single product, the sales rule of single product is shown in Fig.5.

Category	Average Sales Volume/KG	Sales Volatility (Standard Deviation)	Quarterly Trend
First Category	About 663.58, at a medium level	About 529.82, relatively small	Sales volume is relatively stable, without obvious peaks or valleys
Second Category	About 754.04, also at a medium level	About 1211.53, high volatility	Sales volume has some fluctuations, with some seasonal effects
Third Category	About 54.89, significantly lower than other categories	About 88.17, lowest volatility	Sales volume is overall low and stable
Fourth Category	About 2278.61, significantly higher than other categories	About 858.75	There are several quarters with very high sales volume, possibly seasonal products
Fifth Category	About 2347.03, also a high sales volume category	About 1203.68, high volatility	Sales volume fluctuates greatly in different quarters
Sixth Category	About 739.19, at a medium level	About 1029.03, also high volatility	Sales volume has some fluctuations
Seventh Category	About 1598.93, high sales volume	About 2503.23, highest volatility	There are several quarters with very high sales volume, large seasonal impact

Fig.5. summary of single product sales rules

3. Building A Pricing Model

The purpose of establishing the pricing model is to maximize the profit obtained by the merchants [1]. Firstly, the purchase price and sales volume of each category of vegetables in the future should be predicted according to the previous data, and then the cost markup rate and elastic demand should be added for modeling.

3.1. Cost-plus pricing

Cost-plus pricing is a method to determine the price of a product based on the cost of the product, plus a certain profit margin [2]. This method is simple and easy to implement, which can ensure that the costs and profits of enterprises are compensated, and is also conducive to

maintaining the stability of prices. The calculation formula of the cost-plus pricing method is as follows.

$$\text{Price} = \text{unit cost} + \text{unit cost} \times \text{cost margin} \quad (1)$$

3.2. Price elastic demand

Price elastic demand refers to the response degree of quantity demanded to price changes, which is usually expressed by the ratio of the percentage change in quantity demanded to the percentage change in price, that is, the price elasticity coefficient of demand.

3.3. Buildup of model

The impact of establishing the selling price and cost markup rate on sales volume for each vegetable category is as follows.

$$Q_i = \alpha_i + \beta_{1i}P_i + \beta_{2i}R_i + \epsilon_i \quad (2)$$

Here, α_i is the intercept term. β_{1i} and β_{2i} are the coefficients representing the influence of selling price P_i and cost markup rate R_i on sales volume Q_i, and ϵ_i is the error term.

The price elasticity, denoted as $\beta_{2i}=E_i$, is defined as:

$$E_i = \frac{\Delta Q_i/Q_i}{\Delta P_i/P_i} \quad (3)$$

To maximize the profit for supermarkets, we establish a constraint equation for profit Π.

$$\Pi = \left(P_i - C_i \times (1 + L)\right) \times (E + 1) \times D \quad (4)$$

Here, P_i is the selling price, C_i is the cost, L is the loss rate, E_i is the price elasticity's impact on sales volume, and D is the demand quantity.

4. Interpretation of Result

According to the above model construction, six types of vegetable commodity data are brought into the model and calculated with Python to obtain the final answer.

4.1. Evaluation of the model

Advantages:

(1) By comprehensively considering the relationship between sales volume, cost markup and price elastic demand, merchants can maximize profits. This comprehensive consideration can help merchants more comprehensively consider the impact of various factors when formulating pricing strategies.

(2) The use of historical data for forecasting can provide certain reference basis to help merchants make a reasonable estimate of future sales volume and purchase price.

(3) The cost-plus pricing method is simple and easy to implement and can ensure that the costs and profits of enterprises are compensated, which is conducive to the stability of prices.

(4) Considering price elastic demand, that is, the sensitivity of demand to price, can help merchants better understand the changes in market demand and make corresponding adjustments when setting prices.

Disadvantages:

(1) The model excludes the influence of special factors such as weather and source of goods, which may have an important impact on the sales volume and purchase price. Therefore, in practical applications, it may be necessary to further consider the influence of these factors.

(2) The model does not consider the pricing strategies of competitors and the impact of market changes, which may limit the applicability of the model in the real market environment.

5. Conclusion

Through THE ANALYSIS OF THE flow records of vegetable commodities in a store, the sales relationship between different vegetable categories is explored, and the basic pricing model is obtained, which makes the store maximize the profit, which will help the store replenishment and pricing.

Abstract

In this paper, the control of multiple mobile robots TurtleBot is studied for the robot operating system (ROS). A distributed control and communication platform is built to solve the problem of data transmission between multiple robots, and the configuration of robot workstations that can be monitored and remotely controlled is completed. On this basis, the SLAM mapping and autonomous navigation of the robot are completed. The SLAM mapping algorithm of Gampping is selected. With the help of Gazebo simulation platform and Rviz visualization tool, the local path planning of TEB is used to realize the autonomous navigation and multi-point navigation of the robot based on the known environment. On the basis of the constructed distributed control system and the control of a single robot, the research on the coordination of multiple robots is further carried out, and the synchronous control of the robot is realized by using a single node and multi-thread method. By changing the commands issued by the topic, the control of multiple robots for different attributes is released synchronously to achieve more accurate and more synchronous robot motion control. With the help of TF tools, multi-machine following and multi-machine formation are completed, and based on the path planning of a single robot, the navigation of multiple robots is realized.

Keywords: ROS, Multi-robot cooperation, Distributed control

1. Introduction

Robot Operating System (ROS) is an open source standard for the robotics industry. It integrates sensors, motors, and controllers into reusable modules through a distributed messaging architecture to achieve mobility, operation, navigation, and recognition tasks [1]. With the continuous development of the Robot Operating System (ROS), ROS has gradually entered various fields to complete various task requirements. However, when dealing with some complex tasks, it still seems to be somewhat inadequate, and sometimes it is necessary to cooperate with the staff to meet the requirements. Therefore, the research on multi-robot cooperative control is particularly important. The realization of multi-robot collaboration can not only cope with complex work scenarios and complete complex work requirements, but also improve work efficiency and enhance the intelligence of robots. Moreover, with the development of artificial intelligence, robots have ushered in new development opportunities. Based on the ROS multi-robot patrol algorithm simulation and benchmark test framework, the development of multi-robot systems, virtual reality and robot interaction has become popular. In the future, ROS will develop rapidly in the fields of navigation and positioning, 3D object recognition, motion planning, multi-joint manipulator motion control, machine learning, human-machine interaction, robot collaboration and so on. communication, because in the process of collaboration, task allocation, data transmission and information generalization are involved. Robots need to communicate frequently to obtain location information and working

2. Cooperative control of ROS mobile robot

The basis of collaboration between robots is two-way

status of other devices. Therefore, to realize the cooperative control of mobile robots based on ROS, we first need to build a communication platform, and all devices are connected to the platform, and use this as a benchmark for communication and wireless connection. At the same time, in order to facilitate the management and monitoring of all robot devices, a remote workstation device needs to be set up. The workstation can remotely connect any robot device for management, and can also monitor the working status and task progress of all robots.

2.1. *Design of distributed control system*

A distributed communication and control platform is built for robots to provide network support for robot collaboration.

A. *Static IP settings and master-slave IP configuration*

In order to ensure the normal communication function between robots and between robots and remote control terminals (workstations), each device needs to be connected to the same network, which can be provided by the wireless signal of the router or maintained by the hot spot service of the mobile phone. Because the general wireless network will assign different IP addresses to different users, although different robot devices are in the same network, because the IP address is different, and can not communicate, so the network provider is required to manually set up static IP and set up a multi-machine communication environment in the. bashrc file of each device. The setting of static IP is very simple. It only needs to change dynamic acquisition to manual acquisition in IPV4, and set fixed IP address, default routing, subnet mask and DNS.

ROS is a distributed computing environment. A running ROS system can contain multiple nodes distributed on multiple computers. According to the configuration of the robot operating system, multiple nodes between multiple computers, different nodes running on the same computer may need to communicate with each other at any time. Therefore, ROS requires a complete two-way connection between all robots on all ports for network configuration, and each computer must announce itself through a name that all other computers can parse.

B. *ssh Remote Connection*

In the distributed architecture of multi-processors, file transmission may be frequently involved between different robot systems. For example, ROS programs are written on

the workstation, and eventually need to run on the client. It is necessary to upload related directories and files from the workstation to the client. In fact, the design of the control system of multiple robots often adopts the mode of remote management of the workstation. After the network and function of each robot client are configured for the first time, in order to facilitate the update of the robot firmware, the processing when the operation is wrong and the iterative upgrade of the function package, it is also convenient to monitor the whole system. A remote workstation solves these problems. The problem is how to realize remote connection on the workstation and log in to the client for management. ROS gives the answer, which provides two remote control tools, ssh and vnc. Here only introduce ssh this way.

SSH (Secure Shell) is an encrypted network protocol for secure network services such as secure data communication, remote command line login, and remote command execution between two networked computers. It encrypts all data transmitted between two computers and provides secure and authenticated communication over an insecure network. It is commonly used by system administrators to manage remote servers and by developers to securely access and transfer files between machines. The whole process of data transmission is transparent and safe, using openssh tools will enhance your system security. The SSH implementation architecture is divided into two parts: client and server. The client is the requester and requests to upload files. The server is the receiver, receiving and downloading files from the client. The workstation belongs to the client and sends data to the robot. The robot belongs to the server. The implementation process is divided into four steps: install SSH client and server respectively ; the server starts the SSH service ; client remote login server ; realize data transmission.

C. *Optimization of ssh usage*

The client needs to enter the password every time it logs on to the server, and it also needs to enter the password when uploading and downloading files, which actually brings great inconvenience to the transmission of files. How to optimize the use of SSH, make the server trust the client, give the client a permission without password access, simplify the login steps with the help of the key, realize the secret-free login, and improve the efficiency of the operation. The implementation idea of optimization is to generate a pair of public key and private key. The private key is stored locally, and the public key is uploaded to the server. When each login, the local directly uploads the

private key to the server. The server can find the matching public key, and it is identified as a legitimate user. The ssh connection is directly created, and the client does not need to enter the password.

D. *Communication between robots*

The ROS kernel (roscore) is the basis of ROS operation, which has a parameter server. A running ROS has and only has one ROS kernel, and everything on ROS depends on this kernel [2]. ROS is a distributed framework based on the development and integration of many Nodes (nodes). Therefore, how to connect and manage many nodes is a problem that ROS must solve, which introduces a communication mechanism. In the communication mechanism, ROS Master (master node, node manager) manages and schedules the communication process between nodes in the network, and provides a service for configuring global parameters in the network. There are three basic communication modes of ROS, namely topic communication (publish-subscribe mode), service communication (request-response mode) and parameter server (parameter sharing mode).

2.2. *Synchronization control of mobile robot*

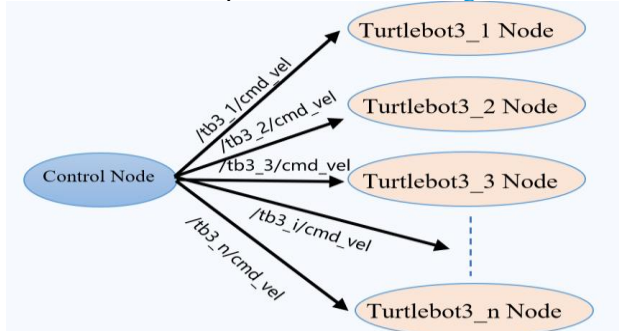
There are two control schemes to realize the synchronous control of robots. The first scheme is that the controller synchronously publishes multiple topics, and each topic corresponds to the ns attribute of different robots. The detailed process is shown in Fig. 1.


Fig. 1 The controller synchronously publishes multiple topics

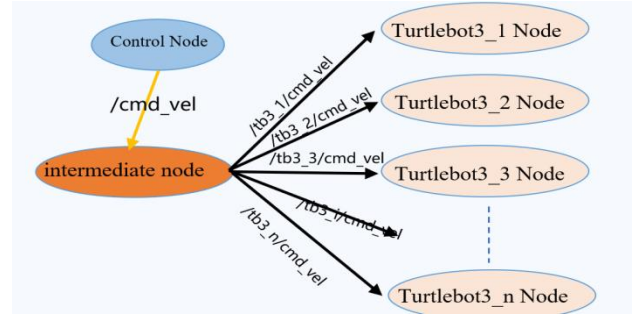
The second scheme is to create an intermediate node, which receives the control instructions of the controller and processes them. After adding the ns attributes of different robots, it is released to the robot for control. Fig. 2 shows the implementation of scheme 2.


Fig. 2 Intermediate nodes assist in publishing

Both schemes allow the robot to obtain the same motion control. Scheme 1 needs to modify the code of the original given controller. After modification, it is impossible to control a single robot independently. Scheme 2 retains the original control node and still retains the control characteristics of a single robot. When multiple robots need to be controlled, only one more intermediate node needs to be run. Therefore, Scheme 2 is more practical.

2.3. *Mobile robot queuing to follow*

In order to realize the following of multiple robots, the following between two robots is considered first. If robot A follows robot B, the relationship between the position and attitude of the two robots must be known. Then through the coordinate transformation, the coordinate system transformation matrix between the two robots can be obtained, as well as the displacement vector randomly transformed to the pilot. The robot follows the simulation as shown in Fig. 3.
Fig. 3 Multi-robot following simulation

As long as the relationship between the coordinates is calculated in real time, ROS provides four methods to obtain the coordinate relationship of robot pose, which can be obtained by SLAM mapping, odometer, global camera, motion capture device and so on. After obtaining the coordinates, it can be sent to the TF tool in ROS by broadcast. Then subscribe to the relationship between the

two robots in the TF tool. The distance and attitude angle difference between the two rob real-time follow can be achieved through the TF tool. ots can be obtained by the pose relationship between the two robots. The speed and angular velocity instructions are issued by PID control to realize the following control of the robot.

The key to realize multi-machine following is to use TF (Transformations Frames) tool, which is a tool for monitoring and calculating robot pose information, providing pose monitoring, coordinate transformation and other functions. In the robot operating system, the TF toolkit includes Broadcaster, Listener, and TF conversion tools. The broadcaster broadcasts the position relationship between each robot and the world coordinate system to the TF tool through the topic; listener obtains the relative position of the two robot coordinate systems by viewing the TF toolkit.

2.4. *Multi-robot formation of mobile robot*

The principle of formation and following is that the TF tool is needed to obtain the relationship between the robot coordinate systems, but the following needs the transformation of the coordinate systems of the pilot and the random. The random moving target point is the coordinate origin of the pilot. The pilot moves, and the coordinate origin moves accordingly. TF will broadcast its pose in real time to control the random speed and angular velocity to achieve the purpose of real-time following. The coordinate system and coordinate transformation are shown in Fig. 4.
Fig. 4 Formation coordinate system and coordinate transformation

Compared with the following, the realization of the formation needs to establish a virtual coordinate system of the specified position around the leader, and obtain the change of the position and attitude of the virtual coordinate system following the leader coordinate system in real time

through the TF tool. The remaining formation aircraft track the position and attitude of the specified virtual coordinate system respectively, and the robot formation movement of various formations can be realized. By using the TF tool and the basic communication method to publish the virtual coordinate system of each specified position, the robot formation problem is transformed into the tracking problem of the target point. It is necessary to modify the callback function in the control of the pilot robot to realize the release of the specified virtual coordinates. Because the virtual coordinate is relative to the position of the pilot robot, it can be adjusted according to the required formation. In this paper, three formation modes are demonstrated, including horizontal line, triangle and square escort formation, and the position and transformation of virtual coordinates of triangle formation are given. They are shown in Fig. 5, 6 and 7.
Fig. 5. Horizontal formation simulation
Fig. 6 Triangle formation simulation
Fig. 7 Square escort formation simulation

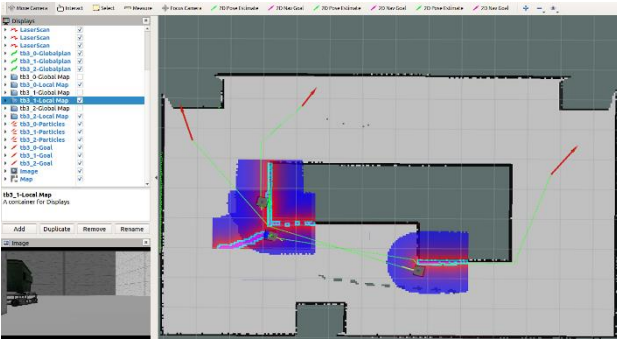
2.5. *Cooperative navigation of mobile robot*


Fig. 8 Robot cooperative navigation

Fig. 8 shows the scene of three robots navigating at the same time in the same environment, and the three robots will determine their own movement routes through cooperation to avoid the risk of collision with each other, and move to the established target point in the shortest time and most efficiently.

A. *Robot path planning*

Before path planning, it is necessary to build a grid map of the robot 's working environment through SLAM mapping [3], because the robot 's navigation process needs to create target points on the map, and in the path planning process, the path planned by the robot will be displayed on the map in real time. Mapping algorithms are also diverse, including unscented Kalman filter UKF-SLAM, FAST-SLAM, Gmapping, etc [4], [5]. In this paper, the Gmapping mapping algorithm based on lidar data is selected. The basic idea of Gmapping algorithm is to obtain the information of the surrounding environment through lidar when the robot moves, and then construct a map and locate the position of the robot through filtering and matching algorithms.

In this paper, the TEB algorithm [6] is used to avoid obstacles. Firstly, several rough paths that can reach the target point are taken as the original paths. Then, various constraints are considered on each path, such as time, collision, speed, acceleration, etc., and these constraints are used to construct the optimization problem. Finally, the optimization problem of each initial path is solved, and a better path than initialization is obtained. Then, a better path is selected from the optimized path, and the result of local path planning can be obtained.

B. *Robot cooperative navigation*

ROS multi-robot cooperative navigation is to complete the cooperative work of multiple robots in the same environment to achieve navigation and exploration of the environment. In ROS, multi-robot cooperative navigation usually uses multiple nodes to achieve. Each robot has its own navigation nodes, which can exchange information with each other through ROS communication mechanism. In cooperative navigation, robots need to understand each other's position and state in order to coordinate their actions. When implementing ROS multi-robot cooperative navigation, the following aspects need to be considered:

Communication mechanism: ROS provides a variety of communication mechanisms, including Topic, Service and Parameter Server. In multi-robot cooperative navigation, topics and services are usually used to achieve communication between robots.

Position estimation: The robot needs to accurately estimate its position and posture. Laser radar, vision sensors and other sensors can be used to achieve position estimation.

Obstacle avoidance algorithm: In the navigation process, the robot needs to avoid obstacles and avoid collisions.

Cooperative planning algorithm: In multi-robot cooperative navigation, robots need to coordinate their actions to avoid mutual interference. Collaborative planning algorithms can be used to achieve collaborative action.

3. Conclusion

Since the birth of ROS in 2007, the research and development of this distributed framework system with nodes as processing units and functional units has flourished, and robot distributed control has great prospects in the development of service-oriented robots and warehouse logistics robots. As one of the popular development directions of robots in the future, multi-machine collaboration not only provides a solution to deal with complex working environments in the working process of robots, but also greatly improves the working efficiency of robots. The working requirements of service-oriented robots are not only the quality of service, but also the efficiency of their work. With the fast-paced operation of society, we are mostly in a ' fast-food ' attitude towards

Saijie Zhang, Huailin Zhao

life. The efficiency of a single robot is limited, and the management of multiple robots is complex. Therefore, a multi-machine cooperative control system that can be autonomously managed, information shared, divided and autonomous, and autonomously coordinated is developed, that is, swarm intelligence. It meets the requirements of high efficiency and simple management. Warehouse logistics robot is a system that

pursues time efficiency. How to ensure its work efficiency and achieve the required accuracy at the same time is more convenient for the management of multiple robots in the whole system. Multi-machine coordination of distributed control may give its answer. Let the robot coordinate autonomously, and at the same time share data in real time and allocate tasks, which is convenient for management and efficient.

An OpenCV-based Method for Workpiece Residue Image Processing

Jiaxin Wang*, Hao He, Fangyv Liu, Fengzhi Dai
Tianjin University of Science and Technology, Tianjin, China

Email: *13293455078@163.com

Abstract

Workpiece residue refers to a thin film formed on the surface of the workpiece during the machining process, due to factors such as cutting fluid, chips, oil stains, etc., which affects the quality and performance of the workpiece. This paper proposes an OpenCV-based method for workpiece residue image processing, aiming to achieve automatic detection and analysis of workpiece residue. By building a workpiece image acquisition system, workpiece residue images of different types and degrees are collected, and the proposed method is verified and evaluated. The experimental results show that the proposed method can effectively detect and analyze workpiece residue, with high accuracy and robustness, providing an effective means for workpiece quality control.

Keywords: Workpiece residue, OpenCV-based, Image processing, Automatic detection and analysis

1. Introduction

With the continuous development of technology, artificial intelligence and machine learning have achieved remarkable results in many fields. Especially in the manufacturing industry, workpiece residue has a great impact on product quality and production efficiency. In order to solve this problem, many researchers have proposed a method of workpiece residue detection based on image processing. These methods process and analyze the image to identify the work parts and residues, so as to realize the automatic detection and classification of residues in the production process.

In the manufacturing industry, the strict requirements for product quality make the detection of workpiece residue an important task. Whether at home or abroad, many researchers are exploring how to effectively realize the automatic detection of workpiece residue. However, existing methods often have some problems, such as poor detection of workpiece and residue with complex shapes and sizes, or require a large number of known samples and expensive computational resources for training and learning.

This paper introduces a method of detecting workpieceresidue based on OpenCV image processing. OpenCV (Open Source Computer Vision Library) [1] is a widely used open source computer vision library. It contains rich image processing and analysis functions [2], and provides many efficient and practical tools and techniques, which are widely used in various image processing fields. Firstly, the image is preprocessed, including grayscale, binarization, noise removal and smoothing, to extract the features of the workpiece and residue. OpenCV's object detection algorithm and deep learning model are then used to identify areas where residue is likely to exist. Finally, geometric shape model and machine learning algorithm are used for post-processing to determine the location and size of the residue. This method can analyze the image in the production process and automatically identify the workpiece and residue. The experimental results show that the method can detect the workpiece residue effectively and improve the production efficiency and product quality.

2. Methodology

2.1. *Image preprocessing*

The image is read and preprocessed using OpenCV library. The pre-processing includes gray-scale, binarization, noise removal, smoothing, etc.[3], [4], in order to extract the features better. Grayscale is the conversion of color images to grayscale images in order to reduce computation and improve processing speed. Binarization is the conversion of a grayscale image into a binary image to highlight the differences in the object and background in the image. Noise removal and smoothing are designed to reduce noise and detail in images to improve the accuracy and stability of target detection. Some of the core code is shown in Fig.1.

Fig. 1 Preprocessing phase code

Jiaxin Wang, Hao He, Fangyv Liu, Fengzhi Dai

2.2. *Feature extraction*

In the pre-processed image, the features of the workpiece and residue are extracted. These features may include color, shape, texture, etc. OpenCV's feature extraction algorithms (such as SIFT, SURF, ORB, etc.) [5] are used to extract these features. These algorithms can automatically identify key points and feature descriptors in images, thus improving the accuracy and robustness of target detection. At the same time, edge detection is carried out to extract and draw the contour [4]. Some of the core code is shown in Fig. 2.

Fig.2 Feature extraction phase code

2.3. *Target detection*

Use OpenCV's object detection algorithms, such as Haar cascades [5] or deep learning models [6], to identify areas where residue may be present. Haar cascade is an object detection algorithm based on feature classification, which identifies objects in an image by combining a series of simple features together. Deep learning model is a kind of object detection algorithm based on neural network. By training and learning a large amount of data, a classifier can be used to classify and identify new samples. Some of the core code is shown in Fig. 3.

Fig.3 Target detection phase code

2.4. *Post-processing*

After possible residue areas are detected, some post-processing is performed to determine if these areas are indeed residue. For example, a geometric shape model is used to identify areas that do not match the shape of the workpiece, or a machine learning algorithm is used to classify and identify areas. Finally, the detected residue is marked out and the detection result is output. Some of the core code is shown in Fig. 4.

Fig.4 Post-processing phase code

2.5. *Result display and output*

Finally, the detected workpiece and residue are marked on the image, and the detection result is output. The qualified workpiece is marked with green "YES", and the image of the unqualified workpiece with residue is marked with red "NO".

3. Experimental Results and Analysis

3.1. *Related work*

In the field of image processing, many researchers have proposed various methods of workpiece residue Detection [7]. Among them, the method based on template matching is a simple and commonly used method. By matching the image to be detected with the standard template, the method finds the matching area with the template, and then identifies the workpiece and residue. However, this method is poor for the detection of workpiece and residue with complex shapes and sizes. To solve this problem, some researchers have proposed an approach based on machine learning [7], [8]. By training and learning a large number of known samples, a classifier is obtained, which can be used to classify and recognize new samples. However, this method requires a large number of known samples, and the training process of the classifier consumes a lot of time and computational resources.

In order to verify the validity of the proposed method, we conducted a series of experiments. The experimental results show that the method can detect the residue effectively and improve the production efficiency and product quality.

3.2. *Experiment settings*

We used a set of real artifact images as the experimental data set. The images include artifacts of various shapes and sizes as well as residues. The proposed method is verified by experiments, and the results are compared with traditional template matching methods and machine learning methods.

3.3. *Experimental result*

We use metrics such as accuracy, recall, and F1 scores to evaluate the performance of the approach presented in this paper. Accuracy refers to the proportion of correctly classified samples to the total number of samples; The recall rate refers to the proportion of the samples recalled

in the correctly classified samples to the total number of real samples. The F1 score is a harmonic average of accuracy and recall. Specific experimental results are shown in the following Table 1.

Table 1. Performance comparison of different methods

Method	accuracy	recall rate	F1 score
Template Matching	0.82	0.76	0.79
Machine Learning	0.85	0.82	

3.4. *Advantages*

1. Real-time: The method can detect the workpiece residue in the image in real time, so as to find the problems in the production process in time, improve production efficiency and product quality.

2. High efficiency: The method can automatically identify the workpiece and residue in the image, avoiding the tedious and time-consuming traditional manual detection, and improving the detection efficiency.

3. Accuracy: The method adopts advanced image processing and machine learning technology, which can accurately detect the workpiece and residue, avoiding the situation of missing and false detection.

4. Versatility: The method can be applied to different types and shapes of workpieces and residues, with strong versatility, can be widely used in various production fields.

5. Scalability: The method can improve the accuracy and efficiency of detection through continuous learning and training, and can also expand its function and application scope by adding new features and algorithms.

In short, the method of detecting workpiece residue based on OpenCV image processing can improve production efficiency and product quality, reduce production cost and risk, and has important practical significance and application value.

4. Conclusion

This paper presents an OpenCV based image processing method for detecting workpiece residue. Through feature extraction and object detection of the pre-processed images, the workpieces and residues can be accurately identified and classified. Compared with the traditional manual detection method, this method has higher detection efficiency and accuracy, and can effectively improve production efficiency and product quality. At the same time, the method has good universality and expansibility, and can be widely used in various production fields.

On Nonblockingness Verification and Enforcement of Controlled Nondeterministic Discrete-Event Systems

Xiang Ren*, Zipei Wang

College of Electronic Information and Automation, Tianjin University of Science and Technology, 300222，China

Email: *renxtust@163.com

Abstract

Discrete event systems, as an important kind of cyber-physical systems, have been widely used in engineering field. In this paper, we first express the dynamics of a controlled nondeterministic discrete-event system (acronym is DES) as an algebraic state-space representation using the semi-tensor product (STP) theory. And then, we discuss the problems of state-based nonblockingness verification and enforcement of nondeterministic DESs. Specifically, we obtain a criterion of verifying whether a given controlled nondeterministic DES is nonblocking. Further, we develop an efficient matrix-based approach to enforce state-based nonblockingness. We illustrate the applications of the proposed theoretical results using an example.

Keywords: Discrete event systems, nondeterministic, nonblockingness, semi-tensor product theory

1. Introduction

With the development of information and network technologies, discrete event systems (DESs) have received considerable attention in information physics systems for many years, synthesizing multidisciplinary methods such as automatic control and computer science, see, e.g., [1], [2]. Verification and synthesis are two main research issues in the field of DESs. We refer the readers to the recent survey papers [3] for more details.

In the above-mentioned literature, the DESs of interest, in general, are deterministic DESs. The case of nondeterministic DESs has not been considered widely so far since they have more complex dynamic evolution behaviors than deterministic DESs. It should be pointed out that, however, there are many realistic plants that need to be modeled as nondeterministic DESs. Therefore, how to model and analyze effectively the dynamics of controlled nondeterministic DESs are still an interesting topic for both computer and control researchers.

In classical DESs, the nonblockingness is a basic and important problem in the study of DESs. Also, some efficient approaches have been proposed. For instance, in [4], the authors studied the problem of blocking detection of DESs by means of language-based approach. In this paper, we develop a new methodology to investigate how to model controlled nondeterministic DESs by using the STP of matrices. Based the proposed new model, we further study the property verification and enforcement of nonblockingness.

The rest of this article is organized as follows. The second section presents some basic notations, concepts and a matrix-based expression needed in this paper. In the third part, we formulate the state-based nonblockingness property verification problem, and we show how the proposed approach can be to applied to enforce nonblockingness. In the fourth section, an example is presented to illustrate the application of the proposed approach. The fifth part summarizes the main content of this paper.

2. Preliminaries

2.1. *Notations*

In this subsection, we introduce some notations, which will be used in the sequel. $\square^n$ is the set of all vectors of dimension n ; $|X|$ is the cardinality of set X ; $M_{m \times n}$ is the set of $m \times n$ matrices; $M_{(i,j)}$ is the (i, j) element of matrix M ; $Col_j(M)$ is the j-th column of matrix M ; $Col(M)$ is the set of all columns of matrix M ; $0_n := \underbrace{[0,0,\cdots,0]}_{n}$;

$1_n := \underbrace{[1,1,\cdots,1]}_{n}$; $\delta_n^0 := \underbrace{[0,0,\cdots,0]}_{n}^T$; $\delta_n^k := Col_k(I_n)$,

$1 \le k \le n$; $\Delta_n := \left\{ \delta_n^1, \delta_n^2, \cdots, \delta_n^n \right\}$; $\tilde{\Delta}_n := \left\{ \delta_n^0, \delta_n^1, \cdots, \delta_n^n \right\}$; $L \in M_{m \times n}$ is a logical matrix (resp., generalised logical matrix) if $Col(L) \subseteq \Delta_m$ (resp., $Col(L) \subseteq \tilde{\Delta}_m$). We denote the set of $m \times n$ logical matrices (resp., generalised logical matrix) by $L_{m \times n}$ (resp., $\tilde{L}_{m \times n}$); If matrix $L \in \tilde{L}_{m \times n}$,

then it can be expressed as $L \in \left[\delta_m^{i_1}, \delta_m^{i_2}, \cdots, \delta_m^{i_n} \right]$ and it is briefly denoted as $L \in \delta_m \left[i_1, i_2, \cdots, i_n \right]$, where $i_k \in \{0, 1, \cdots, m\}$, $1 \le k \le n$.

2.2. *Semi-tensor product (STP) of matrices*

In this subsection, we recall the notions of STP and swap matrix. We refer the readers to [5] and/or [6] for more details on them.

Definition 2.1 ([5]): Let $A \in \mathrm{M}_{m \times n}$, $B \in \mathrm{M}_{p \times q}$. The STP of A and B is defined as
$$A \cdot B = (A \otimes I_{t/n})(B \otimes I_{t/p}), \qquad (1)$$
where t denotes the least common multiple of n and p, i.e., $t = lcm(n, p)$; $\otimes$ is the Kronecker product.

Definition 2.2 ([5]): A swap matrix $W_{[m,n]}$ is a $mn \times mn$ logical matrix, which is defined as
$$
\begin{aligned}
W_{[m,n]} = \delta_{mn}[&1, m+1, 2m+1, \cdots, (n-1)m+1, \\
&2, m+2, 2m+2, \cdots, (n-1)m+2, \qquad (2)\\
&\cdots, m, 2m, 3m, \cdots, nm].
\end{aligned}
$$

Lemma 2.1([5]): Let $X \in \square^m$ and $Y \in \square^n$ be two column vectors. Then
$$W_{[m,n]} XY = YX, \quad W_{[n,m]} YX = XY. \qquad (3)$$

2.3. *System model*

In this subsection we recall the formalism used in the paper. More details on DESs can be found in [2].

A DES is modeled as a nondeterministic finite automaton (NFA) $G = (X, \Sigma, \delta, X_0, X_m)$, where X is the finite set of states, Σ is the finite set of events called alphabet or input symbols, $X_0 \subseteq X$ is the set of initial states, $X_m \subseteq X$ is the set of marked states (or accepted states), $\delta : X \times \Sigma \to 2^X$ is the partial transition function(2^X denotes the power set of X), which describes the system dynamics: given states $x, y \in X$ and an event $\sigma \in \Sigma$, $y \in \delta(x, \sigma)$ means the execution of σ from state x takes the system to state y. Note that $\delta(x, \sigma)$ is undefined when the event σ cannot be executed from the state x. $\delta(x, \sigma)!$ denotes $\delta(x, \sigma)$ is well-defined. Obviously, the transition function can be extended to $\delta : X \times \Sigma^* \to 2^X$ in terms of $\delta(x, e) := \delta(\delta(\cdots \delta(\delta(x, e_{j_1}), e_{j_2}) \cdots), e_{j_t})$, where $e = e_{j_1} e_{j_2} \cdots e_{j_t} \in \Sigma^*$, Σ^* denotes the set of finite strings on the alphabet Σ, including the empty string $\bullet$. The objective of this paper is to investigate the controlled nondeterministic DESs. In this regard, the event set Σ can

be partitioned into two disjoint subsets, i.e., $\Sigma = \Sigma_c \bigcup \Sigma_{uc}$, where Σ_c denotes the set of controllable events, Σ_{uc} denotes the set of uncontrollable events. We here assume that all events in Σ are observable.

In general, we wish to adjoin a supervisor or a controller S to interact with G in a feedback manner. More precisely, the transition function of G can be controlled by S in the sense that the controllable events of G can be dynamically enabled or disabled by S after each transition. Formally, a *state-feedback supervisor*, denoted by S, is a function $S : X \to 2^{\Sigma_c}$ that determines the set of events $S(x) \subseteq \Sigma_c$ to be disabled at each state $x \in X$, while events not belonging to the set $S(x)$ remain enabled at state x. The *controlled system* (or called *supervised system*) consisting of G and S, denoted by S/G, is another nondeterministic finite automation given as
$$S/G = (X, \Sigma, \delta_S, X_0, X_m), \qquad (4)$$
where X, Σ, X_0 and X_m are as defined above, δ_S is the partial transition function of S/G, i.e.,
$$
\delta_S(x, \sigma) = \begin{cases} \delta(x, \sigma), \text{if } \delta(x, \sigma)! \text{ and } \sigma \notin S(x) \\ \text{undefined, otherwise.} \end{cases} \qquad (5)
$$

We use the notation $\mathrm{H}(x)$ to denote the set of feasible events of G at state x. Thus supervisor S is called permissible if for all $x \in X$, $S(x) \subseteq \mathrm{H}(x) \bigcap \Sigma_c$. Note that it is not difficult to see that nondeterministic DESs can be viewed as special case of controlled nondeterministic DESs with $S(x) = \varnothing$ for all $x \in X$. The controlled nondeterministic DES S/G is depicted in Fig.1.
Fig. 1. The controlled nondeterministic DES S/G

3. Nonblockingness of Controlled Nondeterministic DESs

3.1. *Matrix-based expression of controlled nondeterministic DESs*

In order to obtain the matrix expression of the dynamics of controlled nondeterministic DESs, let us first give an equivalent description of the controlled system (4). For the nondeterministic DES G, we define a control pattern as a Boolean function: $\gamma : \Sigma_c \to \{0, 1\}$ and

we use the notation $\Gamma = \{0,1\}^{\Sigma_c}$ to denote the set of all Boolean functions on Σ_c. $\gamma \in \Gamma$ is interpreted as follows: for any $\sigma \in \Sigma_c$, $\gamma(\sigma) = 1$ means that the control pattern γ allows σ to happen, while $\gamma(\sigma) = 0$ means that the control pattern γ refuse σ to happen. Note that it is convenient to extend each $\gamma \in \Gamma$ to a function $\gamma : \Sigma \to \{0,1\}$ by defining $\gamma(\sigma) = 1$ for each uncontrollable event $\sigma \in \Sigma_{uc}$. Further, we define a partial function of the form $f : X \to \Gamma$, called the *state-feedback control function* or *state-feedback* for short, that maps each state x in X into control pattern γ, i.e. $\gamma(\sigma) = f(x)(\sigma)$. Thus the controlled nondeterministic DES consisting of the state-feedback f, control pattern γ and nondeterministic DES G is described as

$$G_\gamma^f = (X, \Sigma, \delta_\gamma^f, X_0, X_m), \qquad (6)$$

where X, Σ, X_0 and X_m are as defined above; δ_γ^f denotes the partial transition function of G_γ^f, which is defined as

$$\delta_\gamma^f(x,\sigma) = \begin{cases} \delta(x,\sigma), & \text{if } \delta(x,\sigma)! \text{ and } f(x)(\sigma) = 1 \\ \text{undefined}, & \text{otherwise.} \end{cases} \qquad (7)$$

For event $e_j (1 \le j \le m)$, we define a $n \times n$ matrix F_j as

$$F_{j(s,t)} = \begin{cases} 1, & \text{if } \delta_n^s \in \delta_\gamma^f(\delta_n^t, \delta_m^j) \wedge \delta_m^j \square e_j \in \Sigma_{uc} \\ r_{tj}, & \text{if } \delta_n^s \in \delta(\delta_n^t, \delta_m^j) \wedge \delta_m^j \square e_j \in \Sigma_c \\ 0, & \text{otherwise,} \end{cases} \qquad (8)$$

where F_j is called transition structure matrix *w.r.t.* event e_j. Thus, the *transition structure matrix* (TSM) of controlled nondeterministic DES (6) is defined as

$$F = [F_1, F_2, \cdots, F_m], \qquad (9)$$

where F is a $n \times mn$ symbol matrix.

Theorem 3.1: Given a controlled nondeterministic DES (6), the dynamics of (6) can be equivalently described as

$$x(t+1) = Fu(t)x(t), \qquad (10)$$

where F is the TSM of system (6), which is defined in (9); $x(t) = (x_1(t), x_2(t), \cdots, x_n(t))^T$ is the vector form of state at step t, $x_i(t)$ denotes the number of different paths from the set of initial states to the state $x_i = \delta_n^i$ with a feasible event string of length $t - 1$; $u(t) \in \Delta_m$ is vector form of event at step t.

Proof: We here omit this proof.

Remark 3.1: When the state-feedback f is known, the dynamics of (6) can be equivalently described by the following equation

$$x(t+1) = F_c u(t)x(t), \qquad (11)$$

where $x(t)$ and $u(t)$ have the same interpretation as in Theorem 3.1; F_c is the TSM of (6), which is represented as

$$F_c = \left[F_1^c, F_2^c, \cdots, F_m^c \right] \in \tilde{L}_{n \times mn}, \qquad (12)$$

where the $n \times n$ matrix F_j^c is defined as

$$F_{j(s,t)}^c = \begin{cases} 1, & \text{if } \delta_n^s \in \delta_\gamma^f(\delta_n^t, \delta_m^j) \\ 0, & \text{otherwise.} \end{cases} \qquad (13)$$

3.2. *Nonblockingness verification of controlled nondeterministic DESs*

In classical DESs, the problem of nonblockingness verification is a basic and important topic. A controlled deterministic DES, also denoted by S/G is said to be nonblocking if and only if $L(S/G) = \overline{L_m(S/G)}$, where $L(S/G)$ and $\overline{L_m(S/G)}$ stand for the language generated and language marked by S/G, respectively. See, e.g., [2] for more details. As a generalization of deterministic model, we now investigate the nonblockingness of controlled nondeterministic DESs. We for simplicity use a *state-based description* to present the notion of nonblockingness. We call it *state-based nonblockingness*, while the nonblockingness defined in [2] is called *the language-based nonblockingness*. Actually, these two concepts are equivalent.

Definition 3.1: Given a controlled nondeterministic DES (6), a state $x \in X$ is called a *nonblocking state* if it is reachable from initial state set X_0 and it can reach a marked state from X_m. (6) is called *nonblocking* if its each state is nonblocking.

Remark 3.2: 1) By Definition 3.1, we know that a state of (6) is a *blocking state* if and only if it is not reachable from the set of initial states, or it can not reach any marked state. 2) For the controlled nondeterministic DES (6), there exist two forms of blocking state, i.e., *deadlock state* and *livelock state*. More specifically, $x \in X$ is a deadlock state of (6) if it is an unmarked reachable state and $H(x) = \varnothing$; $x \in X$ is a livelock state of (6) if it can not reach any marked state and $H(x) \ne \varnothing$.

In what follows, we give a *matrix-based criterion* to verify the nonblockingness of controlled nondeterministic DES (6). Consider the controlled nondeterministic DES (6) with the matrix-based expression (11), from the definition of the TSM F_c presented in (13) and the viewpoint of graph theory, we readily know that the matrix $\sum_{j=1}^{m} F_j^c$ stands for the *adjacency matrix* of the directed graph representation of the controlled nondeterministic DES (6). Thus, state

$x_q = \delta_n^q$ is reachable from $x_p = \delta_n^p$ in t steps if and only if $(\sum_{j=1}^{m} F_j^c)^t_{(q,p)} > 0$. In this regard, we define a matrix $M =: \sum_{\alpha=1}^{n} (\sum_{j=1}^{m} F_j^c)^{\alpha}$, called *reachability matrix* of controlled nondeterministic DES (6), where $n = |X|$, $m = |\Sigma|$. Using it, we have the following result.

Proposition 3.1: Given a controlled nondeterministic DES (6) with the matrix-based expression (11), then

1) The set of states reachable from the set of initial states X_0 is

$$\mathrm{R}(X_0) = \{\delta_n^k \mid M_{(k,p)} > 0, \delta_n^p \in X_0, 1 \le k \le n\}, \quad (14)$$

where $M = \sum_{\alpha=1}^{n} (\sum_{j=1}^{m} F_j^c)^{\alpha}$ is the reachability matrix of (6).

2) The set of states that can reach X_m is

$$\tilde{\mathrm{R}}(X_m) = \{\delta_n^k \mid M_{(q,k)} > 0, \delta_n^q \in X_m, 1 \le k \le n\}, \quad (15)$$

where M is as defined above.

Proof: We here omit this proof.

Remark 3.3: By convention, we assume that $X_0 \subseteq \mathrm{R}(X_0)$ and $X_m \subseteq \tilde{\mathrm{R}}(X_m)$ hereinafter. Using Definition 3.1 and Proposition 3.1, the following main result on the verification of nonblockingness for the controlled nondeterministic DES (6) is very straightforward.

Theorem 3.2: Given a controlled nondeterministic DES (6) with the matrix-based expression (11), then (6) is nonblocking if and only if the following condition holds:

$$\mathrm{R}(X_0) = \tilde{\mathrm{R}}(X_m) = X, \quad (16)$$

where $\mathrm{R}(X_0)$ and $\tilde{\mathrm{R}}(X_m)$ have the same interpretation as in (14) and (15), respectively.

Notice that, from Theorem 3.2, it is not difficult to see that using our approach to verify nonblockingness of controlled nondeterministic DESs is very efficient and straightforward in comparison to the existing ones in the sense that it involves only some basic matrix manipulations that are completed via polynomial time.

3.3. *Nonblockingness enforcement of controlled nondeterministic DESs*

We know that, for uncontrolled DESs, the trimness property is closely related to the concept of nonblockingness. For instance, when a given original system does not satisfy the nonblockingness property, we can to enforce it via trim operation to restrict the system's behavior, see, e.g.,[2]. It is also meaningful for the case

of controlled nondeterministic DESs, since a controlled nondeterministic DES, denoted by S/G, has a generated language and a marked language associated it. In this subsection, we present a matrix-based approach to enforcing nonblockingness property called nonblockingness enforcement hereinafter.

Consider the controlled nondeterministic DES (6) with the matrix-based expression (11), and we assume that, without loss of generality, system (6) is blocking. Using Lemma 2.1, equation (11) can be rewritten as

$$x(t+1) = \bar{F}_c x(t) u(t), \quad (17)$$

where $\bar{F}_c = F_c W_{[n,m]} \in \mathrm{M}_{n \times mn}$, called the *dual* TSM of (6). Partition matrix $\bar{F}_c$ into $\bar{F}_c = [\bar{F}_1^c, \bar{F}_2^c, \cdots, \bar{F}_n^c]$, where $\bar{F}_i^c \in \mathrm{M}_{n \times m}, 1 \le i \le n$. Also, construct matrix:

$$\bar{F}^{trim} = [\bar{F}_1^{trim}, \bar{F}_2^{trim}, \cdots, \bar{F}_n^{trim}], \quad (18)$$

where

$$\bar{F}_i^{trim} = \begin{cases} \bar{F}_i^c, & \text{if } \delta_n^i \in \mathrm{R}(X_0) \bigcap \tilde{\mathrm{R}}(X_m) \\ 0_{n \times m}, & \text{otherwise.} \end{cases} \quad (19)$$

Based on the above-constructed matrix (18), we have the following result.

Theorem 3.3: Given a controlled nondeterministic DES (6) with the matrix-based expression (11), then the controlled nondeterministic DES described by the following equation is nonblocking.

$$x(t+1) = F^{trim} u(t) x(t), \quad (20)$$

where $F^{trim} = \bar{F}^{trim} W_{[m,n]}$, $\bar{F}^{trim}$ is defined in (18).

Proof: we here omit the proof of Theorem 3.3.

Remark 3.4: From Theorem 3.3, we can obtain that, when the DES (6) is blocking, the computational complexity of enforcing the nonblockingness property by using the proposed approach is also polynomial time, i.e., $o(n^2 m)$, where n and m are the numbers of state nodes and event nodes, respectively. An example concerning the supervisory control of a submarine guard system is presented (see Example 4.1 below) to illustrate the effectiveness and application of the proposed results.

4. Illustrative Example

In this section, we give an example to illustrate the proposed results.

Example 4.1: Let us consider the supervisory control of a submarine guard system. A sea region is divided into several sections in terms of the shape of the seabed and it is depicted in Fig. 2. Two submarines, namely, and, cruise and guard the sea region. has its own separate repair port and home harbor, i.e., section No. 5 and No. 2,

respectively. has repair and home harbor in section No. 4. Due to the seabed form and the sea underwater streams, as well as different size of the submarines, possible and controllable transitions of the submarines between these sections are also shown in Fig. 2.
Fig. 2. Space guarded by the submarines.

At the beginning of inspection, A is in section No. 5 and B in section No. 4. It is required that each submarine can return its home harbor. Additionally, meeting of submarines A and B in any section of the sea region must be prohibited for safety reasons. The task of the supervisory control is how to synthesize the cruise trajectory of A and B to prevent the violation of the requirements described above.

Now we use the proposed approach to solve it.

According to Fig. 2, the dynamics of submarines A and B can be modeled by two finite-state automata shown in Fig. 3(a) and Fig 3(b), respectively. That is, $G_1 = (X_1, \Sigma_1, \delta_1, x_0^1, X_m^1)$ with the initial state $x_0^1 = 5$, and the marked state $X_m^1 = \{2\}$, while $G_2 = (X_2, \Sigma_2, \delta_2, x_0^2, X_m^2)$ with the initial state $x_0^2 = 4$ and the marked state $X_m^2 = \{4\}$.
Fig. 3. (*a*) represents a DFA model of the submarine A cruise; (*b*) represents a DFA model of the submarine B cruise.

For the automation G_1, identifying $5 \square \delta_5^1$, $2 \square \delta_5^2$, $0 \square \delta_5^3$, $3 \square \delta_5^4$, $1 \square \delta_5^5$; $a_{j-1} \square \delta_{10}^j (1 \le j \le 6)$. While for G_2, identifying $4 \square \delta_3^1$, $3 \square \delta_3^2$, $0 \square \delta_3^3$; $b_k \square \delta_{10}^{7+k} (1 \le k \le 3)$.

According to lemma in reference [7], the dynamics of $G_1 \| G_2$ (called the parallel composition of G_1 and G_2) can be described by the following algebraic form

$$x(t+1) = Fu(t)x(t), \tag{21}$$

where $F = [F_1, F_2, \cdots, F_9, F_{10}] \in \tilde{L}_{15 \times 150}$, i.e.,

$F = \delta_{15}[0,0,0,1,2,3,0,0,0,0,0,0,0,0,0,4,5,6,0,0,0,0,$
$0,0,0,0,0,0,0,0,0,0,0,7,8,9,0,0,0,0,0,0,0,0,$
$0,0,0,0,0,0,0,10,11,12,0,0,0,0,0,0,0,0,0,0,$
$0,0,0,13,14,15,0,0,0,0,0,0,0,0,0,0,0,0,0,0,$
$0,10,11,12,0,0,0,0,0,0,0,0,0,0,0,4,5,6,2,0,$
$0,5,0,0,8,0,0,11,0,0,14,0,0,3,0,0,6,0,0,9,0,$
$0,12,0,0,15,0,0,1,0,0,4,0,0,7,0,0,10,0,0,13].$

Using Lemma 2.1, system (21) can be rewritten as

$$x(t+1) = \tilde{F}x(t)u(t), \tag{22}$$

where $\tilde{F} = FW_{[15,10]} \in \tilde{L}_{15 \times 150}$.

Partitioning $\tilde{F} = [\tilde{F}_1, \tilde{F}_2, \cdots, \tilde{F}_{15}]$, where $\tilde{F}_k \in \tilde{L}_{15 \times 10}$, $1 \le k \le 15$. Since states $00 \square \delta_5^3 \delta_3^3 = \delta_{15}^9$ and $33 \square \delta_5^4 \delta_3^2 = \delta_{15}^{11}$ are forbidden states², all events attached to δ_{15}^9 and δ_{15}^{11} should be deleted and each state that can reach δ_{15}^9 or δ_{15}^{11} in 1 step by an uncontrollable event is also forbidden state. To this end, by applying Proposition 3.1, the sets of states reachable from δ_{15}^9 and δ_{15}^{11} in 1 step are $\{\delta_{15}^7, \delta_{15}^{12}\}$ and $\{\delta_{15}^{12}, \delta_{15}^{14}\}$, respectively. The sets of states that can reach δ_{15}^9 and δ_{15}^{11} in 1 step are $\{\delta_{15}^6, \delta_{15}^8\}$ and $\{\delta_{15}^8, \delta_{15}^{10}, \delta_{15}^{14}\}$, respectively. According to the conclusion of reachability analysis in reference[8], we have $\delta_{15}^9 \xrightarrow{\delta_{10}^{10}} \delta_{15}^7$, $\delta_{15}^9 \xrightarrow{\delta_{10}^4} \delta_{15}^{12}$, $\delta_{15}^6 \xrightarrow{\delta_{10}^3} \delta_{15}^9$, $\delta_{15}^8 \xrightarrow{\delta_{10}^{10}} \delta_{15}^9$; $\delta_{15}^{11} \xrightarrow{\delta_{10}^{10}} \delta_{15}^{12}$, $\delta_{15}^{11} \xrightarrow{\delta_{10}^5} \delta_{15}^{14}$, $\delta_{15}^8 \xrightarrow{\delta_{10}^4} \delta_{15}^{11}$, $\delta_{15}^{10} \xrightarrow{\delta_{10}^8} \delta_{15}^{11}$, $\delta_{15}^{14} \xrightarrow{\delta_{10}^6} \delta_{15}^{11}$. Thus, state δ_{15}^{14} is also forbidden state. Analogous to δ_{15}^9 and δ_{15}^{11}, we have $\delta_{15}^{14} \xrightarrow{\delta_{10}^7} \delta_{15}^5$, $\delta_{15}^{14} \xrightarrow{\delta_{10}^9} \delta_{15}^{15}$, $\delta_{15}^{13} \xrightarrow{\delta_{10}^8} \delta_{15}^{14}$.

Based on the above analysis, we construct matrix

$$\tilde{F}_{c_1} = [\tilde{F}_1^{c_1}, \tilde{F}_2^{c_1}, \cdots, \tilde{F}_{15}^{c_1}], \tag{23}$$

where

$$\tilde{F}_i^{c_1} = \begin{cases} 0_{15 \times 10}, & i = 9,11,14 \\ \tilde{F}_i, & \text{otherwise.} \end{cases} \tag{24}$$

Consequently, system (22) becomes

$$x(t+1) = \tilde{F}_{c_1} x(t)u(t), \tag{25}$$

The next step to preserve nonblockingness of the controlled DES (25). Using Proposition 3.1, we can obtain easily that $R(\delta_{15}^1) = \{\delta_{15}^1, \delta_{15}^2, \delta_{15}^3, \delta_{15}^4, \delta_{15}^5, \delta_{15}^6, \delta_{15}^7, \delta_{15}^8, \delta_{15}^{10}, \delta_{15}^{13}\}$, $\tilde{R}(\delta_{15}^4) = \{\delta_{15}^1, \delta_{15}^2, \delta_{15}^3, \delta_{15}^4, \delta_{15}^5, \delta_{15}^6, \delta_{15}^7, \delta_{15}^{10}, \delta_{15}^{12}, \delta_{15}^{13}, \delta_{15}^{15}\}$. We know that states δ_{15}^8, δ_{15}^{12} and δ_{15}^{15} are forbidden states. Thus, let

$$\tilde{F}_{c_2} = [\tilde{F}_1^{c_2}, \tilde{F}_2^{c_2}, \cdots, \tilde{F}_{15}^{c_2}], \tag{26}$$

where

$$\tilde{F}_i^{c_2} = \begin{cases} 0_{15\times10}, & i = 8,12,15 \\ \tilde{F}_i^{c_1}, & \text{otherwise.} \end{cases} \quad (27)$$

Hence, the controlled system (25) becomes

$$x(t+1) = \tilde{F}_{c_2} x(t)u(t), \quad (28)$$

Again, using Lemma 2.1, we rewrite system (28) is

$$x(t+1) = \tilde{F}_{c_3} u(t)x(t), \quad (29)$$

where $\tilde{F}_{c_3} = \tilde{F}_{c_2} W_{[10,15]}$, specifically,

$\tilde{F}_{c_2} = \delta_{15}[0,0,0,1,2,3,0,0,0,0,0,0,0,0,0,4,5,6,0,0,0,0,$
$0,0,0,0,0,0,0,0,0,0,0,7,0,0,0,0,0,0,0,0,0,0,0,0,$
$0,0,0,0,0,0,0,0,10,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,$
$0,0,0,0,13,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,$
$0,10,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,4,0,0,2,0,$
$0,5,0,0,0,0,0,0,0,0,0,0,0,0,0,3,0,0,6,0,0,0,0,$
$0,0,0,0,0,0,0,0,1,0,0,4,0,0,0,0,0,0,0,0,0].$

It is readily verified that the controlled DES (29) satisfies the requirements described above. Consequently, the cruise trajectory of submarines A and B, by resorting to the algebraic representation (29), is depicted in Fig. 4.
Fig. 4. The cruise trajectory of submarines *A* and *B* in the submarine system.

5. Conclusion

In this paper, we used matrix-based form to model the dynamics of controlled nondeterministic DESs. Using it, we investigated the verification of nonblockingness property of controlled nondeterministic DESs. Also, the criteria of verifying nonblockingness was presented in terms of the methodology described in this paper. Furthermore, the proposed approach can be applied to enforce nonblockingness of controlled nondeterministic DESs.

We hope that our work can establish the foundation for a new theory of supervisory control of controlled nondeterministic DESs. Future work will investigate the problem of synthesizing property-enforcing supervisor for controlled nondeterministic DESs by means of the proposed theoretical framework.

Abstract

In this paper, we investigate the modeling and state reachability of controlled nondeterministic finite-state automata (NFA). The key feature of a controlled NFA is to admit a controller (also called a supervisor) to intervene the behavior of an original system. We first express the dynamics of a controlled NFA as an algebraic state-space representation in the framework of the semi-tensor product (STP) of matrices. Then, the necessary and sufficient condition for verifying state reachability of controlled NFA is presented. An explicit formula for calculating all paths of any two states is derived. Finally, we use an example to illustrate the application of the proposed theoretical results.

Keywords: Discrete event systems, nondeterministic finite-state automata, reachability, semi-tensor product of matrices

1. Introduction

Discrete event systems (DESs), also called plants, have received considerable attention within the automatic control and computer science communities for many years, see, e.g., [1], [2].

Nondeterministic plants can be viewed as a generalization of deterministic plants. It is useful when designing a system at a higher-level of abstraction so that lower-level details of system are omitted to obtain higher-level models that may be nondeterministic. It is well-known that controlled DESs modeled by controlled finite automata have more complex structures and dynamics than uncontrolled DESs. Therefore, how to model and analyze effectively the dynamics of controlled nondeterministic DESs are still an interesting topic.

In classical DESs, the reachability is a basic and important problem in the study of DESs. For instance, [3] studied the matrix expression and reachability verification of finite automata (including deterministic and nondeterministic). The approach in these two papers are based on algebraic state-space representation. In this paper, we develop a new methodology to investigate how to model controlled nondeterministic finite-state automata (NFA) using the STP of matrices.

The rest of this article is organized as follows. The second section presents some basic notations and concepts needed in this paper. In the third part, we present a matrix-based expression for the dynamics of controlled NFA. In the fourth section, we give a methodology of verifying state reachability of controlled NFA, and an explicit formula of finding all paths of any two states is also provided, if exists. In the fifth section, an example is presented to illustrate the application of the proposed approach. The sixth part summarizes the main content of this paper.

2. Preliminaries
2.1. *Notations*

In this subsection, we introduce some notations, which will be used in the sequel. $\square^n$ is the set of all vectors of dimension n; $|X|$ is the cardinality of set X; $\mathrm{M}_{m \times n}$ is the set of $m \times n$ matrices; $M_{(i,j)}$ is the (i,j) element of matrix M; $Col_j(M)$ is the j-th column of matrix M; $Col(M)$ is the set of all columns of matrix M;

$$0_n := \underbrace{[0,0,\cdots,0]}_{n} \; ; \quad 1_n := \underbrace{[1,1,\cdots,1]}_{n} \; ; \quad \delta_n^0 := \underbrace{[0,0,\cdots,0]}_{n}^T \; ;$$

$\delta_n^k := Col_k(I_n)$, $1 \le k \le n$; $\Delta_n := \left\{ \delta_n^1, \delta_n^2, \cdots, \delta_n^n \right\}$; $\tilde{\Delta}_n := \left\{ \delta_n^0, \delta_n^1, \cdots, \delta_n^n \right\}$; $L \in \mathrm{M}_{m \times n}$ is a logical matrix (resp., generalised logical matrix) if $Col(L) \subseteq \Delta_m$ (resp., $Col(L) \subseteq \tilde{\Delta}_m$). We denote the set of $m \times n$ logical matrices (resp., generalised logical matrix) by $\mathrm{L}_{m \times n}$ (resp., $\tilde{\mathrm{L}}_{m \times n}$); If matrix $L \in \tilde{\mathrm{L}}_{m \times n}$, then it can be expressed as $L \in \left[\delta_m^{i_1}, \delta_m^{i_2}, \cdots, \delta_m^{i_n} \right]$ and it is briefly denoted as $L \in \delta_m[i_1, i_2, \cdots, i_n]$, where $i_k \in \{0, 1, \cdots, m\}$, $1 \le k \le n$.

2.2. *Semi-tensor product (STP) of matrices*

In this subsection, we give some necessary basic knowledge of the STP of matrices used in the paper.

Definition 2.1 ([4]): Let $A \in \mathrm{M}_{m \times n}$, $B \in \mathrm{M}_{p \times q}$. The STP of A and B is defined as
$$A \cdot B = (A \otimes I_{t/n})(B \otimes I_{t/p}), \tag{1}$$

where t denotes the least common multiple of n and p, i.e., $t = lcm(n, p)$; $\otimes$ is the Kronecker product.

Remark 2.1: When $n = p$, $A \cdot B = AB$. Hence, the STP is a generalization of the standard matrix product. Throughout this paper the matrix product is assumed to be the STP. We mostly omit the symbol "$\cdot$" hereinafter.

Definition 2.2 ([4]): A swap matrix $W_{[m,n]}$ is a $mn \times mn$ logical matrix, which is defined as

$$W_{[m,n]} = \delta_{mn}[1, m+1, 2m+1, \cdots, (n-1)m+1,$$
$$2, m+2, 2m+2, \cdots, (n-1)m+2, \quad (2)$$
$$\cdots, m, 2m, 3m, \cdots, nm].$$

Lemma 2.1([4]): Let $X \in \square^m$ and $Y \in \square^n$ be two column vectors. Then

$$W_{[m,n]}XY = YX, \quad W_{[n,m]}YX = XY. \quad (3)$$

2.3. System model

In this subsection we recall the formalism used in the paper.

A nondeterministic DES is modeled as a NFA $G = (X, \Sigma, \delta, X_0, X_m)$, where X is the finite set of states, Σ is the finite set of events called alphabet or input symbols, $X_0 \subseteq X$ is the set of initial states, $X_m \subseteq X$ is the set of marked states (or accepted states), $\delta : X \times \Sigma \to 2^X$ is the partial transition function(2^X denotes the power set of X), which describes the system dynamics: given states $x, y \in X$ and an event $\sigma \in \Sigma$, $y \in \delta(x, \sigma)$ means the execution of σ from state x takes the system to state y. Note that $\delta(x, \sigma)$ is undefined when the event σ cannot be executed from the state x. $\delta(x, \sigma)!$ denotes $\delta(x, \sigma)$ is well-defined. Obviously, the transition function can be extended to $\delta : X \times \Sigma^* \to 2^X$ in terms of $\delta(x, e) := \delta(\delta(\cdots \delta(\delta(x, e_{j_1}), e_{j_2}) \cdots), e_{j_t})$, where $e = e_{j_1} e_{j_2} \cdots e_{j_t} \in \Sigma^*$, Σ^* denotes the set of finite strings on the alphabet Σ, including the empty string $\cdot$. The objective of this paper is to investigate the controlled NFA. In this regard, the event set Σ can be partitioned into two disjoint subsets, i.e., $\Sigma = \Sigma_c \bigcup \Sigma_{uc}$, where Σ_c denotes the set of controllable events, Σ_{uc} denotes the set of uncontrollable events. We here assume that all events in Σ are observable.

In general, we wish to adjoin a supervisor or a controller S to interact with G in a feedback manner. More precisely, the transition function of G can be controlled by S in the sense that the controllable events of G can be dynamically enabled or disabled by S after each transition. Formally, a *state-feedback supervisor*, denoted by S, is a function $S : X \to 2^{\Sigma_c}$ that determines the set of events $S(x) \subseteq \Sigma_c$ to be disabled at each state $x \in X$, while events not belonging to the set $S(x)$ remain enabled at state x. The *controlled system* (or called *supervised system*) consisting of G and S, denoted by S/G, is another nondeterministic finite automation given as

$$S/G = (X, \Sigma, \delta_S, X_0, X_m), \quad (4)$$

where X, Σ, X_0 and X_m are as defined above, δ_S is the partial transition function of S/G, i.e.,

$$\delta_S(x, \sigma) = \begin{cases} \delta(x, \sigma), if \ \delta(x, \sigma)! \ and \ \sigma \notin S(x) \\ undefined, \ otherwise \end{cases} \quad (5)$$

We use the notation $H(x)$ to denote the set of feasible events of G at state x. Thus supervisor S is called permissible if for all $x \in X$, $S(x) \subseteq H(x) \bigcap \Sigma_c$. Note that it is not difficult to see that NFA can be viewed as special case of controlled NFA with $S(x) = \varnothing$ for all $x \in X$. The controlled NFA S/G is depicted in Fig. 1.
Fig. 1. The controlled NFA S/G

3. Matrix-Based Expression of Controlled NFA

In order to obtain the matrix expression of the dynamics of controlled NFA, let us first give an equivalent description of the controlled system (4). For the NFA G, we define a control pattern as a Boolean function: $\gamma : \Sigma_c \to \{0,1\}$ and we use the notation $\Gamma = \{0,1\}^{\Sigma_c}$ to denote the set of all Boolean functions on Σ_c. $\gamma \in \Gamma$ is interpreted as follows: for any $\sigma \in \Sigma_c$, $\gamma(\sigma) = 1$ means that the control pattern γ allows σ to happen, while $\gamma(\sigma) = 0$ means that the control pattern γ refuse σ to happen. Note that it is convenient to extend each $\gamma \in \Gamma$ to a function $\gamma : \Sigma \to \{0,1\}$ by defining $\gamma(\sigma) = 1$ for each uncontrollable event $\sigma \in \Sigma_{uc}$. Further, we define a partial function of the form $f : X \to \Gamma$, called the *state-feedback control function* or *state-feedback* for short, that maps each state x in X into control pattern γ, i.e., $\gamma(\sigma) = f(x)(\sigma)$. Thus the controlled NFA consisting of the state-feedback f, control pattern γ and NFA G is described as

$$G_\gamma^f = (X, \Sigma, \delta_\gamma^f, X_0, X_m), \quad (6)$$

where X, Σ, X_0 and X_m are as defined above; δ_γ^f denotes the partial transition function of G_γ^f, which is defined as

$$\delta_\gamma^f(x,\sigma) = \begin{cases} \delta(x,\sigma), & \text{if } \delta(x,\sigma)! \text{ and } f(x)(\sigma) = 1 \\ \text{undefined, otherwise.} \end{cases} \quad (7)$$

Similarly, the state-feedback f is called permissible if for all $x \in X$, $\sigma \in H(x) \bigcap \Sigma_{uc}$, we have $f(x)(\sigma) = 1$. There is a bijective correspondence between the state-feedback f and the state-feedback supervisor S, i.e., $\forall x \in X$ and $\forall \sigma \in H(x) \bigcap \Sigma_c$, $f(x)(\sigma) = 1$ (resp., $f(x)(\sigma) = 0$) if and only if $\sigma \notin S(x)$ (resp., $\sigma \in S(x)$). In this regard, we will use for simplicity the controlled system (6) instead of system (4) to present our results. Our objective, in this section, is to model the controlled NFA in the framework of the STP of matrices.

Let us consider the controlled NFA(6), we assume that the set of states is $X = \{x_1, x_2, \cdots, x_n\}$, and the set of events is $\Sigma = \{e_1, e_2, \cdots, e_m\}$. To obtain the dynamics of (6), identifying $x_i \Box \delta_n^i (1 \le i \le n)$, $e_j \Box \delta_m^j (1 \le j \le m)$, we call δ_n^i and δ_m^j the vector forms of x_i and e_j, respectively. Thus the state set X and event set Σ can be identified with Δ_n and Δ_m, respectively, where $\Delta_n = \{\delta_n^1, \delta_n^2, \cdots, \delta_n^n\}$ and $\Delta_m = \{\delta_m^1, \delta_m^2, \cdots, \delta_m^m\}$. Therefore, $x_s \in \delta_c^f(x_t, e_j)$ can be expressed equivalently as $\delta_n^s \in \delta_c^f(\delta_n^t, \delta_m^j)$, where δ_c^f represents the partial transition function of G_γ^f defined in (7). For brevity, we use the notation r_{ij} to denote the state-feedback $f(x_i)(e_j)$, i.e., $r_{ij} = f(x_i)(e_j)$ where $x_i \in X$ and $e_j \in \Sigma_c$ are the state and controllable event of controlled NFA(6), respectively.

For event $e_j (1 \le j \le m)$, we define a $n \times n$ matrix F_j as

$$F_{j(s,t)} = \begin{cases} 1, & \text{if } \delta_n^s \in \delta_\gamma^f(\delta_n^t, \delta_m^j) \wedge \delta_m^j \Box e_j \in \Sigma_{uc} \\ r_{ij}, & \text{if } \delta_n^s \in \delta(\delta_n^t, \delta_m^j) \wedge \delta_m^j \Box e_j \in \Sigma_c \\ 0, & \text{otherwise,} \end{cases} \quad (8)$$

where F_j is called transition structure matrix *w.r.t.* event e_j. Thus, the *transition structure matrix* (TSM) of controlled NFA (6) is defined as

$$F = [F_1, F_2, \cdots, F_m], \quad (9)$$

where F is a $n \times mn$ symbol matrix.

Based on the above representations and the STP of matrices, we can obtain the following result on the matrix expression of dynamics of controlled NFA (6).

Theorem 3.1: Given a controlled NFA (6), the dynamics of (6) can be equivalently described as

$$x(t+1) = Fu(t)x(t), \quad (10)$$

where F is the TSM of system (6), which is defined in (9); $x(t) = (x_1(t), x_2(t), \cdots, x_n(t))^T$ is the vector form of state at step t, $x_i(t)$ denotes the number of different paths from the set of initial states to the state $x_i = \delta_n^i$ with a feasible event string of length $t-1$; $u(t) \in \Delta_m$ is vector form of event at step t.

Let us assume (10) holds when $t = p-1$, i.e., $x(p) = Fu(p-1)x(p-1)$. And let $u(p) = \delta_m^k$ for any $1 \le k \le m$. Then

$$Fu(p)x(p) = F_k(x_1(p), \cdots, x_n(p))^T$$
$$= (\sum_{i=1}^{n} F_{k(1,i)} x_i(p), \cdots, \sum_{i=1}^{n} F_{k(n,i)} x_i(p))^T.$$

Using (8), one has

$$\sum_{i=1}^{n} F_{k(j,i)} x_i(p) = \sum_{i \in \Lambda_j} F_{k(j,i)} x_i(p), 1 \le j \le n,$$

where $\Lambda_j = \{i \mid 1 \le i \le n, \delta_n^j \in \delta_\gamma^f(\delta_n^i, \delta_m^k)\}$. From the above assumption, we know that $x_i(p)$ stands for the number of different paths from the initial state $x(1) = \delta_n^{i_0}$ to state δ_n^i with a feasible string of length $p-1$, then $\sum_{i \in \Lambda_j} F_{k(j,i)} x_i(p)$ represents the sum of the number of different paths by which the initial state set $x(1) = \sum_{\lambda=1}^{l} \delta_n^{i_\lambda}$ can reach state δ_n^i with a feasible string of length $p-1$, and δ_n^i can reach δ_n^j with the event $u(p) = \delta_m^k$. Consequently, we define $x_j(p+1) := \sum_{i \in \Lambda_j} F_{k(j,i)} x_i(p)$, which implies $x(p+1) = Fu(p)x(p)$. By mathematical induction, the proof is completed.

By Theorem 3.1, we know readily that verifying whether or not any two states of controlled NFA (6) are reachable can be determined by both the transition function δ defined in G and the state-feedback f. In particular, when the state-feedback f is known, the matrix F becomes a constant matrix. More concretely, F is a generalised logical matrix. In this case, we replace F with F_c. Therefore, by Theorem 3.1, we have the following result.

Corollary 3.1: Given a controlled NFA (6) in which the state-feedback f is known, the dynamics of (6) can be

equivalently described by the following equation

$$x(t+1) = F_c u(t)x(t), \quad (11)$$

where $x(t)$ and $u(t)$ have the same interpretation as in Theorem 3.1; F_c is the TSM of (6), which is represented as

$$F_c = \left[F_1^c, F_2^c, \cdots, F_m^c \right] \in \tilde{L}_{n \times mn}, \qquad (12)$$

where the $n \times n$ matrix F_j^c is defined as

$$F_{j(s,t)}^c = \begin{cases} 1, & \text{if } \delta_n^s \in \delta_\gamma^f(\delta_n^t, \delta_m^j) \\ 0, & \text{otherwise.} \end{cases} \qquad (13)$$

Remark 3.1: It should be pointed out that our approach are also suitable for the controlled deterministic DESs in the sense that deterministic DESs can be viewed as special case of nondeterministic DESs. In particular, when the controlled DES (6) is deterministic, i.e., $|X_0| = 1$ and $|\delta(x, \sigma)| \leq 1$ for all $x \in X$ and $\sigma \in \Sigma$, the state that is reachable from initial state with a feasible event string $e = \sum_{k=1}^{t-1} e_{jk} \in \Sigma^*$ is unique, which means that there exists only one $1 \leq i \leq n$ such that $x_i(t) = 1$ in (11). Namely, $x(t) \in \Delta_n$. In contrast, if there is no a state that is reachable from initial state with $e = \sum_{k=1}^{t-1} e_{jk} \in \Sigma^*$, then we have $x(t) = \delta_n^0$.

4. Reachability of Controlled NFA

4.1. *Reachability verification*

We, in this subsection, verify the reachability property of controlled NFA (6) by means of equation (11). We first give the following lemma, which is crucial to find all paths from the set of initial states to any target state for the controlled NFA (6).

Lemma 4.1 ([5]): Let $\bullet_{i=1}^t \delta_{m_i}^{j_i} = \delta_{m_1 \times m_2 \cdots m_t}^l$, then the formulas $\delta_{m_i}^{j_i} = S_i \bullet \delta_{m_1 \times m_2 \cdots m_t}^l$, $i = 1, 2, \cdots, t$ hold, where

$$\begin{cases} S_1 = I_{m_1} \otimes 1_{m_2 \times \cdots \times m_t}, \\ S_2 = [\underbrace{I_{m_2} \otimes 1_{m_3 \times \cdots \times m_t}, \cdots, I_{m_2} \otimes 1_{m_3 \times \cdots \times m_t}}_{m_2}], \\ \vdots \\ S_{t-1} = [\underbrace{I_{m_{t-1}} \otimes 1_{m_t}, \cdots, I_{m_{t-1}} \otimes 1_{m_t}}_{m_2 \times \cdots \times m_{t-1}}], \\ S_t = [\underbrace{I_{m_t}, \cdots, I_{m_t}}_{m_2 \times \cdots \times m_t}]. \end{cases} \qquad (14)$$

To present the main results on reachability of the controlled NFA (6), we for brevity need to introduce the following notation: let $\alpha = (a_1, a_2, \cdots, a_n)^T$ be a nonnegative column vector of dimension n, we define $\Xi(\alpha) := \{\delta_n^k \mid a_k \neq 0, 1 \leq k \leq n\}$. For instance, let $\alpha = (1, 2, 0, 3)^T$, then $\Xi(\alpha) = \{\delta_4^1, \delta_4^2, \delta_4^4\}$.

Theorem 4.1: Given a controlled NFA (6) with its dynamics (11), let $X_0 = \{\delta_n^{i_1}, \delta_n^{i_2}, \cdots, \delta_n^{i_l}\}$ and $x^* = \delta_n^q$ be the set of initial states and target state of (6), respectively. Then

1) $x^* = \delta_n^q$ is reachable from X_0 in t steps if and only if there exists a positive integer $k (1 \leq k \leq m^t)$ such that

$$\delta_n^q \in \Xi(Col_k((F_c W_{[n,m]})^t x(1))), \qquad (15)$$

where $x(1)$ represents the vector form of the initial state set X_0, i.e., $x(1) = \sum_{\lambda=1}^l \delta_n^{i_\lambda}$.

2) Assume that $L_t^q(X_0)$ denotes the set consisting of all event strings of length t by which the initial state set X_0 can reach $x^* = \delta_n^q$ in t steps, then

$$L_t^q(X_0) = \{e = e_{k_1} e_{k_1} \cdots e_{k_t} \in \Sigma^* \mid \text{there is } k \text{ of satisfying} \\ (15) \text{ such that } \delta_{m^t}^k = e_{k_1} e_{k_1} \cdots e_{k_t}\}, \qquad (16)$$

where the feasible event string of $e = e_{k_1} e_{k_1} \cdots e_{k_t}$ can be easily obtained from the formula $\delta_{m^t}^k = e_{k_1} e_{k_1} \cdots e_{k_t}$ in terms of Lemma 4.1.

Proof: we here omit the proof of Lemma 4.1.

From (11), we have

$$\begin{aligned} x(t+1) &= F_c u(t) x(t) \\ &= F_c W_{[n,m]} x(t) u(t) \\ &= (F_c W_{[n,m]})^2 x(t-1) u(t-1) u(t) \\ &\vdots \\ &= (F_c W_{[n,m]})^t x(1) u(1) u(2) \cdots u(t) \\ &= ((F_c W_{[n,m]})^t x(1)) \bullet_{j=1}^t u(j). \end{aligned} \qquad (17)$$

Note that the following corollary gives a criterion to verify whether any two states of a controlled NFA are reachable or not. Also, an effective approach of finding all paths of any two reachable states is provided.

Corollary 4.1: Given a controlled NFA (6) with its dynamics (11), let $x_p = \delta_n^p$ and $x^q = \delta_n^q$ be any two states of (6). Then

1) $x^q = \delta_n^q$ is reachable from $x_p = \delta_n^p$ in t steps if and only if there exists a positive integer $k (1 \leq k \leq m^t)$ such that

$$\delta_n^q \in \Xi(Col_k((F_c W_{[n,m]})^t \delta_n^p)). \qquad (18)$$

2) Let $L_t^q(p)$ be the set consisting of all event strings of length t by which $x_p = \delta_n^p$ can reach $x^q = \delta_n^q$ in t steps, then

$L_t^q(p) = \{e = e_{k_1}e_{k_1}\cdots e_{k_t} \in \Sigma^* \mid$ there exist k of satisfying

(18) such that $\delta_{m^t}^k = e_{k_1}e_{k_1}\cdots e_{k_t}\}$,　　　(19)

where the event string $e = e_{k_1}e_{k_1}\cdots e_{k_t}$ can be obtained from $\delta_{m^t}^k = e_{k_1}e_{k_1}\cdots e_{k_t}$ in terms of Lemma 4.1.

Proof: Obviously, here we omit its proof.

Remark 4.1: From Corollary 4.1, we readily know that if the controlled NFA (6) is deterministic, then the number of different paths from state $x_p = \delta_n^p$ to $x^q = \delta_n^q$ in t steps coincide with the number of k satisfying (18). In contrast, when the controlled NFA (6) is nondeterministic, we for convenience assume that

$$\Upsilon = (\gamma_1, \gamma_2, \cdots, \gamma_n)^T := \sum_{j=1}^{m^t} Col_j((F_c W_{[n,m]})^t \delta_n^p) \ .$$ Then the

number of different paths from $x_p = \delta_n^p$ to $x^q = \delta_n^q$ in t steps is equal to γ_q.

4.2. *Comparison with the existing approaches*

There are several papers addressing modeling and reachability analysis in DESs in terms of the algebraic state-space approaches, see, e.g., [3] and [6]. Among them, [3] investigated matrix expression and reachability verification of finite automata in which all events are controllable and the cardinality of the set of initial states equals 1. We know that the controlled DESs have more complex structures and dynamics than the uncontrolled DESs as an external control input is allowed to intervene the behaviors of original systems. Again, they did not consider to adjoin a supervisor to interact with an original system. These restrictions significantly simplify the behavior of the system. Obviously, their approaches are different completely from the approach using in this paper since we do not make the above-mentioned these restrictions.

[6] is most closely related to our work, but there are some fatal errors therein. Concretely, the authors asserted that they presented a sufficient and necessary condition to verify whether or not any two states of a controlled DES are reachable (see, e.g., Theorem 2 in [6]). Also, an algorithm was designed to find all paths from one state to another one if they are reachable (see, e.g., Algorithm 1). These results were obtained from Corollary 1 in [6]. It should be pointed out that, however, Corollary 1 addressed the problem of which states are reachable from a given state and a given input string of length t for a controlled DES, which means a contradiction with the previous assertion. Furthermore, the state-feedback control specification was defined as $f : X \to \Gamma$ in [6]. In this regard, $r_j = f(\tilde{F}^t \ltimes \delta_n^i \quad u(j))(\sigma_{j+1})$ is undefined in (11) of [6] since $\tilde{F}^t \ltimes \delta_n^i \quad u(j)$ is not necessarily the vector form of a state for a controlled nondeterministic system, which means that equation (11) in [6] is incorrect. We refer the reader to [6] for the interpretations of these notations. As a part of our work, these errors presented in [6] were corrected and the interesting issues mentioned in [6] were discussed systematically in a more generalized DES.

5. Illustrative Example

In this section, we use an example to illustrate the proposed results.

Example 5.1 : Let us consider the uncontrolled NFA, $G = (X, \Sigma, \delta, X_0, X_m)$ depicted in Fig. 2, where $\Sigma_c = \{e_2, e_3\}$, $\Sigma_{uc} = \{e_1, e_4\}$, $X_0 = \{e_1, e_4\}$, $X_m = \{x_5\}$. The state-feedback supervisor S is given as $S(x_3) = \{e_2, e_3\}$.
Fig. 2. An uncontrolled NFA.

We now verify the state reachability of the controlled system S/G consisting of the uncontrolled NFA G shown in Fig.2 and the state-feedback supervisor S.

By Corollary 3.1, the dynamics of the uncontrolled system S/G can be expressed as

$$x(t+1) = F_c u(t)x(t), \tag{20}$$

where $x(1) = \sum_{j=1,4} \delta_n^j$,

$$F_c = \begin{bmatrix} 0&0&0&0&0&0&0&0&0&0&0&0&0&0&0&0&0&0&0&0 \\ 1&0&0&0&0&0&0&0&0&0&0&0&0&0&0&0&0&0&0&0 \\ 0&0&0&0&0&0&1&0&0&0&0&0&0&0&0&0&0&0&0&0 \\ 0&0&1&0&0&0&1&0&0&0&0&1&0&0&0&0&0&0&0&0 \\ 0&0&0&0&0&0&0&0&1&0&0&0&0&0&0&0&0&1&1&0 \end{bmatrix}.$$

When $t = 1$, we have

$$Col_1(F_c W_{[5,4]}x(1)) = (0,1,0,0,0)^T,$$
$$Col_4(F_c W_{[5,4]}x(1)) = (0,0,0,0,1)^T,$$
$$Col_j(F_c W_{[5,4]}x(1)) = (0,0,0,0,0)^T, j = 2,3.$$

By applying Theorem 4.1, states x_2 and x_5 are reachable from the set of initial states X_0 in 1 step, and the corresponding event strings of length 1 are $e = e_1$ and $e = e_4$, respectively. Specifically, we have $x_1 \xrightarrow{e_1} x_2$; $x_4 \xrightarrow{e_4} x_5$.

When $t = 2$, we have

$$Col_2((F_c W_{[5,4]})^2 x(1)) = (0,0,1,1,0)^T,$$
$$Col_3((F_c W_{[5,4]})^2 x(1)) = (0,0,0,1,0)^T,$$
$$Col_{14}((F_c W_{[5,4]})^2 x(1)) = (0,0,0,0,1)^T.$$

with all the other columns equal to δ_5^0. By Theorem 4.1, states x_3, x_4 and x_5 are reachable from X_0 in 2 steps, and the corresponding event string of length 2 are $e = \delta_{16}^2 = \delta_4^1 \delta_4^2$, $e = \delta_{16}^2 = \delta_4^1 \delta_4^2$ or $e = \delta_{16}^3 = \delta_4^1 \delta_4^3$, and $e = \delta_{16}^{14} = \delta_4^4 \delta_4^2$, respectively. Specifically, we have

$$x_1 \xrightarrow{e_1} x_2 \xrightarrow{e_2} x_3 \ ; \quad x_1 \xrightarrow{e_1} x_2 \xrightarrow{e_2} x_4 \quad \text{or} \quad x_1 \xrightarrow{e_1} x_2 \xrightarrow{e_3} x_4 \ ; \quad \text{and}$$
$$x_4 \xrightarrow{e_4} x_5 \xrightarrow{e_2} x_5 \ .$$

When $t = 3$, we have

$$Col_5((F_c W_{[5,4]})^3 x(1)) = (0,0,0,1,0)^T,$$
$$Col_8((F_c W_{[5,4]})^3 x(1)) = (0,0,0,0,2)^T,$$
$$Col_{12}((F_c W_{[5,4]})^3 x(1)) = (0,0,0,0,1)^T,$$
$$Col_{54}((F_c W_{[5,4]})^3 x(1)) = (0,0,0,0,1)^T$$

with all the other columns equal to δ_5^0. Using Theorem 4.1, states x_4 and x_5 are reachable from X_0 in 3 steps, and the corresponding event string of length 3 are $e = \delta_{64}^5 = \delta_4^1 \delta_4^2 \delta_4^1$, $e = \delta_{64}^8 = \delta_4^1 \delta_4^2 \delta_4^4$ or $e = \delta_{64}^{12} = \delta_4^1 \delta_4^3 \delta_4^4$, and $e = \delta_{64}^{54} = \delta_4^4 \delta_4^2 \delta_4^2$, respectively. Specifically, we have

$$x_1 \xrightarrow{e_1} x_2 \xrightarrow{e_2} x_3 \xrightarrow{e_1} x_4; \quad x_1 \xrightarrow{e_1} x_2 \xrightarrow{e_2} x_3 \xrightarrow{e_1} x_5;$$
$$x_1 \xrightarrow{e_1} x_2 \xrightarrow{e_2} x_4 \xrightarrow{e_4} x_5, \quad x_1 \xrightarrow{e_1} x_2 \xrightarrow{e_3} x_4 \xrightarrow{e_4} x_5;$$
$$x_4 \xrightarrow{e_4} x_5 \xrightarrow{e_2} x_5 \xrightarrow{e_2} x_5 \ .$$

The cases of $t \geq 4$ are similar to $t = 1, 2, 3$, the details are omitted here for space limitations.

6. Conclusion

In this paper, we proposed a new framework that is matrix-based form to model the dynamics of controlled NFA. Using it, we investigated the verifications of reachability property of controlled NFA. Also, the criteria of verifying this property was presented in terms of the methodology described in this paper.

Future work will concentrate on investigating the problem of synthesizing property-enforcing supervisor for controlled nondeterministic DESs by means of the proposed theoretical framework.

Abstract

To better apply object detection and identification techniques from deep learning to the field of agricultural automation, this paper focuses on the growth process of daylilies. It employs the state-of-the-art YOLOv8 model to achieve accurate assessment of daylily maturity. The backbone network of YOLOv8 draws inspiration from the CSPDarkNet network structure to extract image features. The introduction of cross-stage connections in the middle layers of the network enhances the efficiency of feature propagation. The neck section adopts the PAFPN bidirectional channel network to further process the features extracted by the backbone network, facilitating the smooth transmission of information from the bottom to the top layers. The Head section utilizes the Decoupled-Head structure to generate the output for object detection. The trained model had a mAP which reached up to 94%, an accuracy rate up to 95.6%, a recall rate up to 90.5%. Moreover, the identification speed is significantly improved.

Keywords: Deep Learning, Object Detection, YOLOv8, Daylily

1. Introduction

With the gradual maturity of AI technology, the focus of agricultural harvesting is gradually shifting to automation. The agricultural sector has been continuously exploring how to leverage modern computer vision technology to enhance crop production efficiency and quality. In the production and management of agricultural products, understanding the maturity of plants is crucial for achieving optimal harvesting and resource utilization. As an important edible plant, the timely monitoring and accurate assessment of the maturity of daylilies are essential for agricultural production [1]. Traditional harvesting of daylilies typically relies on manual inspection and experiential judgment, which poses challenges in terms of high labor costs and low efficiency. With the rapid development of computer vision and deep learning technologies, object detection techniques have gradually become an effective means to address this issue. For instance, Song [2] constructed and trained a Faster R-

CNN model implemented by VGG16, which demonstrated good detection performance for fruit images under different time and lighting conditions. Liang [3] proposed improvements on the SSD network based on VGG16 and ZFNet for real-time mango detection. The enhanced algorithm achieved higher accuracy compared to Faster R-CNN, although the deep network structure led to slower computation speed. Zhen [4] introduced a vegetable image classification method, utilizing the Caffe open-source deep learning framework. They improved the VGG network by adding a Batch Normalization layer to the VGG-M network, enhancing the convergence speed and accuracy of the network (VGG-M-BN) with a vegetable classification recognition accuracy of up to 96.5%. Xue [5] aimed to improve the accuracy of immature mango detection in orchard scenes. They modified the YOLO V2 algorithm, developing a tiny-yolo network structure by combining multiple feature layers. This addressed the challenging issue of detecting overlapping and occluded parts of mangoes, achieving a detection accuracy of

97.02%. Zhao [6] proposed an apple localization method based on the YOLOv3 deep convolutional neural network. This method ensures the detection of apples in complex environments while balancing efficiency and accuracy.

The main contributions of this paper include the construction of a large-scale daylily image dataset, detailed annotation of daylily features at different growth stages, and the design of an architecture and training methodology based on the YOLOv8 model. Through experiments, the proposed approach has been demonstrated to exhibit high accuracy and practicality in the automatic detection and identification of daylily maturity.

2. Data Acquisition and Annotation

2.1. Data acquisition

The datasets for this experiment are all derived from manual field shooting with an f/1.6 wide-angle camera. Image categories encompass immature daylilies, mature daylilies, and overly mature daylilies. The dataset includes single and multiple targets, unobstructed and clustered daylily samples, captured under different weather conditions (sunny and cloudy) and at various time intervals. After acquiring a sufficient amount of video footage, the videos were decomposed frame by frame and converted into static image data. To curate the dataset, images with minimal variations in daylily features within the same second or in close proximity were excluded, as well as those that lacked specific images of daylily maturity flowers. The initial dataset was then refined by retaining images with distinct characteristics and clearly identifiable daylily buds. In order to expand the diversity of data, this paper uses the ACE image enhancement algorithm and histogram equalization algorithm to enhance the daylily dataset. In the end, we obtained a dataset of 2060 daylily images.

2.2. Images annotation and dataset production

To ensure the accuracy of training data, prior to experimentation, the daylily dataset was meticulously annotated, defining precise labels for optimal training outcomes. The Labelme annotation software was uniformly used for annotating daylily images. Based on characteristics such as color and shape of daylily flowers, the images were categorized into three classes: immature daylily, mature daylily, and overmature daylily. Immature daylilies, characterized by unopened flower buds, exhibit deep green or green coloration. These buds are relatively small and not ready for harvesting. Harvestable daylilies have bright yellow-green buds, larger in size, and fully developed, ready for picking. Overly mature daylilies have either opened or wilted buds, displaying bright yellow or dark yellow coloration with petal-like structures. The annotation process is shown in Fig. 1. The marked data is a JSON file, which is converted to a txt file . The dataset was split into 80% for training and 20% for testing and validation collectively. The testing set was utilized to assess the model's generalization capabilities post-training, while the validation set was employed for fine-tuning hyperparameters and conducting preliminary assessments of the model's performance.

Fig. 1 Dataset labels

3. Methodology

This study selected YOLOv8n as the foundational framework for research. YOLOv8, being at the forefront of object detection technology, is recognized for its efficient detection speed and accuracy across various object detection tasks. The algorithm takes the input image and resizes it to a fixed size, dividing the resized image into a grid of cells. Each cell is responsible for predicting objects that fall within its boundaries. For each cell, the algorithm predicts B bounding boxes and the probability C for each category, each containing 5 values: (x, y, w, h, c). These (x, y) values represent the center of the bounding box relative to the cell boundary, and (w, h) represent the width and height of the bounding box. This C value indicates the confidence of the algorithm in the prediction. Non-maximal suppression (NMS) is applied to remove redundant bounding box predictions. NMS compares the overlap of the predicted bounding box, leaving only the

one with the highest confidence, and IoU evaluates the accuracy of the bounding box prediction from 0 to 1, with higher values indicating better overlap between the predicted bounding box and the true bounding box. The

offering an innovative and intelligent solution for agriculture.

The YOLOv8 model comprises three main components: the backbone, neck, and head network.CSPDarknet53 serves as the backbone network for YOLOv8, primarily responsible for extracting high-level features from input images. It extracts features at multiple levels and outputs feature maps at different scales. These feature maps possess varying receptive fields and semantic information, aiding the model in better handling targets of different sizes and complexities. In contrast to earlier versions of YOLOv5, YOLOv8 eliminates the less user-friendly Focus module, and the initial network layers are directly accomplished by straightforward and conventional convolutions. CSPDarknet53 is an improvement upon Darknet53, introducing the CSPNet (Cross Stage Partial Network) structure. This structure involves cross-stage partial connections, enhancing information propagation efficiency. It divides feature maps into two parts, with one part directly passed to the next stage, and the other part subjected to further processing. This contributes to strengthening information propagation and feature fusion within the network.

The neck still employs the PaFPN (Path Aggregation Feature Pyramid Network) structure to construct the YOLO feature pyramid, facilitating comprehensive fusion of multi-scale information. In comparison to YOLOv5, the only difference lies in the reduction of a 1x1 convolutional layer in the upsampling operation during the top-down process. Additionally, the C3 module has been replaced with the C2f module. Notably, the channel numbers returned from the three scales are kept equal to the channel numbers output by the backbone for the three scales.

The Head section adopts a decoupled structure, separating the classification and detection heads. Two parallel branches independently extract category and position features, followed by a 1×1 convolution layer for each to perform classification and localization tasks. Simultaneously, the use of anchor boxes is discarded.

The loss calculation process comprises two main components: positive and negative sample assignment strategy and loss computation. Considering the superior performance of dynamic assignment strategies, YOLOv8

final output is the detection result, including the category label, bounding box coordinates, and confidence score.

Leveraging its capabilities, the study applies YOLOv8 to the detection of daylily maturity, algorithm directly incorporates TOOD's Task Aligned Assigner. It selects positive samples based on the weighted scores of classification and regression. Loss computation includes classification and regression. Binary Cross Entropy (BCE) Loss is still employed for classification. For the regression branch, it is bound to the integral representation introduced in Distribution Focal Loss, thus utilizing Distribution Focal Loss and CIoU Loss. The three losses are weighted using a certain proportion. The final training results are generated accordingly.

4. Experiments

4.1. Experimental environment

To ensure the rigor of the experiments, both the training and testing processes in this paper were conducted on the same experimental platform. The experimental environment was built and configured based on Ubuntu 18.04, with a NVIDIA GeForce GTX 1070 graphics card, Intel Core i5-9400F CPU, and programming platform Anaconda 2022.05. The CUDA version used was 11.2, and the deep learning framework employed was PyTorch 1.10 +CUDA11.1 support. The programming language used was Python 3.7.

4.2. Model training and evaluation

Through multiple experiments in the early stage, the maximum convergence of daylily target detection model training was obtained. The optimal number of iterations was 400 times, and 400 iterations were used for model training to ensure the consistency of experimental parameters. The basic parameters of the model are set to epoch=400 and batch size=16, and the initial learning rate is set to 0.01 using the SGD optimizer.

In this paper, an objective criterion was used to evaluate the daylily identification line. we use precision (P), recall (R), and mAP (mean average precision) to evaluate the model trained in this paper. As shown in Equation (1).

$$P = \frac{TP}{TP + FP}$$

$$R = \frac{TP}{TP + FN} \quad (1)$$

$$mAP = \frac{1}{C}\sum_{k=i}^{N} P(k)\Delta R(k)$$

where TP is the true number of positive samples and FP is the false number of positive samples, FN is the number
of values, k is the threshold, P(k) is the accuracy, and R(k) is the recall.

5. Result

The results of different species of daylily tested on this model are shown in Fig. 2. The P-R curve and R curve of the model are shown in Fig. 3.

of spurious negative samples, C is the number of categories, and N is the reference threshold. The number
(a) P-R Curve

(b) R-Curve

Fig. 2 Detection result of the algorithm
Fig. 3 Performance parameters

6. Conclusion

After completing the model training, we conducted validation on daylilies at different growth stages. Experimental results indicate that the proposed method exhibits high accuracy and robustness in detecting and

identifying the maturity of daylilies. The accuracy achieved is above 95.6%, with a recall rate of 90.5% and a mean Average Precision (mAP) of 0.94. Furthermore, our model demonstrates stability under varying lighting conditions and significant detection performance across daylilies with different shapes and colors.

Our model not only provides a reliable solution for the intelligent cultivation of daylilies but also offers effective support for agricultural decision-making. The stability of performance in diverse lighting conditions and its ability to detect daylilies of varying shapes and colors make it a valuable tool for farmers. This research lays the foundation for agricultural intelligence, enhancing the productivity and decision-making capabilities of farmers.

Abstract

In this paper, by using nonlinear feedback control, chaos synchronization is achieved between the Chen system and the Lü system with different initial values, and the error curves and state synchronization curves of the corresponding states in the response Lü system and the drive Chen system are plotted. Finally, the simulation circuit model of the synchronization system of the drive Chen system and the response Lü system is designed by Multisim circuit simulation software. Comparing the output curves with the curves obtained by MATLAB simulation software, it can be found that the two curves achieve a good qualitative agreement. It prove that the circuit model of the synchronization system is correct and the synchronization of the drive Chen system and the response Lü system is accomplished.

Keywords: Chaos; Chaos synchronization of different systems; Nonlinear feedback control; Chaotic circuit

1. Introduction

In 1999, Professor Guanrong Chen of the University of Houston discovered a new chaotic attractor, the Chen system, using engineering feedback control [1]. which is similar to the Lorenz system but not topologically equivalent, with a more complex structure and more diverse dynamic behavior.In 2001, Jinhu Lü and Guanrong Chen discovered a new chaotic system, the Lü system, that system links the Lorenz system and the Chen system and represents a continuous evolution between the two systems [2].

In this paper, the above two systems are taken as the research objects to analyze their chaotic properties, and based on this, the two systems are synchronized to chaos by using the method of nonlinear feedback [3], and then numerical simulation is carried out by using the MATLAB software, and the simulated circuits are designed, and the circuit simulation is carried out in Multisim, which is designed to provide sufficient theoretical support for the future application of the heterostructured chaos synchronization of the Chen system and the Lü system to be successfully applied in the field of confidential communication.

2. Chaos Synchronization and Circuit Design of Chen System and Lü System with Different Structures

2.1. Modeling of the Drive Chen system

$$\begin{cases} \dot{x}_1 = a_1(y_1 - x_1) \\ \dot{y}_1 = (c_1 - a_1)x_1 - x_1 z_1 + c_1 y_1 \\ \dot{z}_1 = x_1 y_1 - b_1 z_1 \end{cases}$$

$$(1)$$

Where, x_1, y_1, $z_1 \in R$ is the state variable of the system and $a_1 = 35$, $b_1 = 3$, $c_1 = 28$ is the typical parameter of Lü system.

2.2. Modeling of Response Lü Systems

$$\begin{cases} \dot{x}_2 = a_2(y_2 - x_2) + u_{c1} \\ \dot{y}_2 = -x_2 z_2 + c_2 y_2 + u_{c2} \\ \dot{z}_2 = x_2 y_2 - b_2 z_2 + u_{c3} \end{cases}$$

(2)

Where, x_2, y_2, $z_2 \in R$ is the state variable of the system and $a_2 = 36$, $b_2 = 3$, $c_2 = 20$ is the typical parameter of Lü system. $u_c = [u_{c1}\, u_{c2}\, u_{c3}]^T$ is the required synchronization controller, through which the synchronization of two chaotic attractors with very different structures can be realized.

2.3. Design of Synchronization Controller

Subtracting the corresponding terms in the mathematical model Eq. (1) of the driving Chen system from the terms in the mathematical model Eq. (2) of the response Lü system, the error system model is shown as Eq. (3) below:

$$\begin{cases} \dot{e}_1 = \dot{x}_2 - \dot{x}_1 \\ \quad = a_2(y_2 - x_2) - a_1(y_1 - x_1) + u_{c1} \\ \dot{e}_2 = \dot{y}_2 - \dot{y}_1 \\ \quad = -x_2 z_2 + c_2 y_2 \\ \quad -[(c_1 - a_1)x_1 - x_1 z_1 + c_1 y_1] + u_{c2} \\ \dot{e}_3 = \dot{z}_2 - \dot{z}_1 \\ \quad = x_2 y_2 - b_2 z_2 \\ \quad -(x_1 y_1 - b_1 z_1) + u_{c3} \end{cases}$$

(3)

Where $e = [e_1 \quad e_2 \quad e_3]^T = [x_2 - x_1 \quad y_2 - y_1 \quad z_2 - z_1]^T$, e_1, e_2, e_3 is the state variable of the error system. The synchronization controller is designed as:

$$\begin{cases} u_{c1} = (a_1 - a_2)(y_1 - x_1) - k_1 e_1 \\ u_{c2} = x_2 z_2 - x_1 z_1 + (c_1 - c_2)y_1 \\ \quad +(c_1 - a_1)x_2 - k_2 e_2 \\ u_{c3} = -x_2 y_2 + x_1 y_1 + (b_2 - b_1)z_1 \\ \quad -k_3 e_3 \end{cases}$$

(4)

Where k_1, k_2, $k_3 \geq 0$, Eq. (4) is substituted into Eq. (3), and the mathematical model of the error system is obtained as shown in Eq. (5).

$$\begin{cases} \dot{e}_1 = \dot{x}_2 - \dot{x}_1 \\ \quad = a_2(e_2 - e_1) - k_1 e_1 \\ \dot{e}_2 = \dot{y}_2 - \dot{y}_1 \\ \quad = c_2 e_2 + (c_1 - a_1)e_1 - k_2 e_2 \\ \dot{e}_3 = \dot{z}_2 - \dot{z}_1 = -b_2 e_3 - k_3 e_3 \end{cases}$$

(5)

The error system is then written in the form of $\dot{e} = f(e, t)$. If the equilibrium state of error system at the origin is uniformly asymptotic and stable in a large range, it indicates that the chaos synchronization of different structure has been realized between Chen system and Lü system.

The value of the synchronization controller parameter $k = [k_1 \quad k_2 \quad k_3]^T$ is determined by the Lyapunov second method.

According to Lyapunov's second method, firstly take the positive definite Lyapunov function $V(\tilde{e}) = 1/2[(a_1 - c_1)e_1^2/a_2 + e_2^2 + e_3^2]$, and then take its derivative:

$$\begin{aligned} V(\tilde{e}) &= \frac{a_1 - c_1}{a_2}e_1 \dot{e}_1 + e_2 \dot{e}_2 + e_3 \dot{e}_3 \\ &= (a_1 - c_1)e_1 e_2 - (a_1 - c_1)e_1^2 \\ &\quad -\frac{k_1(a_1 - c_1)}{a_2}e_1^2 + c_2 e_2^2 \\ &\quad +(c_1 - a_1)e_1 e_2 - k_2 e_2^2 \\ &\quad -b_2 e_3^2 - k_3 e_3^2 \\ &= -\left[\frac{k_1(a_1 - c_1)}{a_2} + (a_1 - c_1)\right]e_1^2 \\ &\quad -(k_2 - c_2)e_2^2 - (k_3 + b_2)e_3^2 \end{aligned}$$

(6)

According to Lyapunov's second method, if $V(\tilde{e})$ is positively definite and $\dot{V}(\tilde{e})$ is negatively definite, then the error system is uniformly asymptotically stable in a large range at the origin. At this time, the variable coefficients of the error system should satisfy:

$$\begin{cases} -[\frac{k_1(a_1 - c_1)}{a_2} + (a_1 - c_1)] < 0 \\ -(k_2 - c_2) < 0 \\ -(k_3 + b_2) < 0 \end{cases}$$

(7)

Solved:

$$\begin{cases} k_1 > -a_2 = -36 \\ k_2 > c_2 = 20 \\ k_3 > -b_2 = -3 \end{cases}$$

(8)

If $(k_1, k_2, k_3) = (0, 25, 0)$, the synchronous controller u_c is as follows:

$$\begin{cases} u_{c1} = -(y_1 - x_1) \\ u_{c2} = x_2 z_2 - x_1 z_1 + 33 y_1 \\ \quad -7x_2 - 25 y_2 \\ u_{c3} = -x_2 y_2 + x_1 y_1 \end{cases}$$

(9)

So far the synchronization controller has been designed.

The numerical simulation diagram of the chaotic synchronization controller of Chen system and Lü system with different structures built in Simulink is shown in Fig. 1.

After setting up the simulation environment, click the run button, and the corresponding state error curve is shown in Fig. 2.

The corresponding state synchronization curve is shown in Fig. 3.

Through careful observation of the images, it can be seen that the controller makes the corresponding state error curve gradually converge to zero with the passage of time, and the corresponding state synchronization curve follows the running trajectory of Chen driving system. This is enough to indicate that all the above derivations of all equations on the different structure chaos synchronization of Chen system and Lü system are correct, and Chen system and Lü system can achieve different structure chaos synchronization.

Fig. 3 State synchronization curve: （a）x1-x2；（b）y1-y2；（c）z1-z2

2.4. Design and construction of an analog circuit model for heterostructure chaotic synchronous control

The circuit model of the synchronous controller is designed and constructed, and the circuit of the synchronous controller is designed by the method of improved modular circuit design.

The state expression of the control circuit is shown in Eq. (10).

$$\begin{aligned}
\tau_0 u_{c1} &= \tau_0[-(y_1 - x_1)] \\
&= -\tau_0 y_1 - \tau_0(-x_1) \\
&= -\frac{1}{R_{14}C_4}y_1 - \frac{1}{R_{15}C_4}(-x_1) \\
\tau_0 u_{c2} &= \tau_0[10x_2z_2 - 10x_1z_1 \\
&\quad +33y_1 - 7x_2 - 25y_2] \\
&= -10\tau_0(-x_2z_2) - 10\tau_0 x_1 z_1 \\
&\quad -33\tau_0(-y_1) - 7\tau_0 x_2 - 25\tau_0 y_2 \\
&= -\frac{1}{10R_{16}C_5}(-x_2z_2) \\
&\quad -\frac{1}{10R_{17}C_5}x_1 z_1 - \frac{1}{R_{13}C_5}(-y_1) \\
&\quad -\frac{1}{R_{19}C_5}x_2 - \frac{1}{R_{20}C_5}y_2 \\
\tau_0 u_{c3} &= \tau_0(-10x_2y_2 + 10x_1y_1) \\
&= -10\tau_0 x_2 y_2 - 10\tau_0(-x_1y_1) \\
&= -\frac{1}{10R_{21}C_6}x_2 y_2 \\
&\quad -\frac{1}{10R_{22}C_6}(-x_1y_1)
\end{aligned}$$
(10)

Substitute $\tau_0 = 100$ into Eq. (10) and take $C_4 = C_5 = C_6 = 10\text{nF}$, and the calculation is as follows:

$$\begin{aligned}
R_{14} = R_{15} &= \frac{1}{\tau_0 C_4} = \frac{1}{100 \times 10 \times 10^{-9}} \\
&= 1\text{M}\Omega \\
R_{18} &= \frac{1}{33\tau_0 C_5} = \frac{1}{33 \times 100 \times 10 \times 10^{-9}} \\
&= 30.3\text{k}\Omega \\
R_{19} &= \frac{1}{7\tau_0 C_5} = \frac{1}{7 \times 100 \times 10 \times 10^{-9}} \\
&= 142.8\text{k}\Omega \\
R_{20} &= \frac{1}{25\tau_0 C_5} = \frac{1}{25 \times 100 \times 10 \times 10^{-9}} \\
&= 40\text{k}\Omega \\
R_{16} = R_{17} = R_{21} = R_{22} &= \frac{1}{100\tau_0 C_5} \\
&= \frac{1}{100 \times 100 \times 10 \times 10^{-9}} = 10\text{k}\Omega
\end{aligned}$$
(11)

The analog circuit for the synchronous control of Chen system and Lü system is shown in Fig. 4.

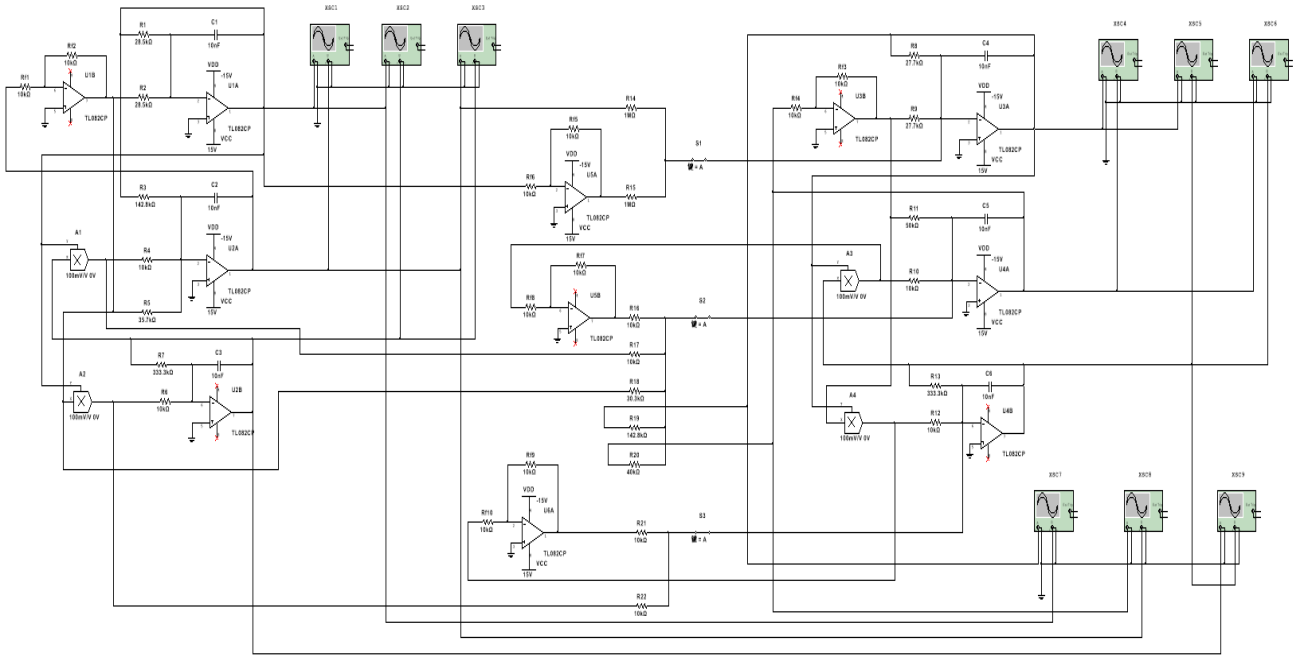
Build the analog circuit shown in the above figure in Multisim software. Wait for the oscilloscope to display the waveform, observe the corresponding waveform, and obtain the corresponding synchronization curve shown in Fig. 5 and the corresponding error curve shown in Fig. 6.


Fig. 4 Analog Circuit for Synchronous Control of Chen System and Lü System
Fig. 5 Synchronization state curve:（a）x_1-x_2；（b）y_1-y_2；（c）z_1-z_2
Fig. 6 Error curve:（a）e_1；（b）e_2；（c）e_3

3. Conclusion

In this paper, the driving Chen system and the responding Lü system are first mathematically modeled separately,

and then the synchronous controllers are designed to achieve the purpose of removing all nonlinear terms. The parameters of the controller are solved according to Lyapunov's second method. The controller allows the numerical simulation of the system in MATLAB to show that the corresponding state error curves gradually converge to zero over time and the corresponding state synchronization curves follow the trajectory of the Chen drive system.

The simulation circuit model of the Chen chaotic system and the Lü chaotic system with heterostructure chaotic synchronization is designed and constructed with the help of Multisim software using a modified modular approach. The installation of separate switches for the structural compensator and the controller to ensure individual control is a critical step in the design of the system, and the observation of the oscilloscope showing the corresponding error curves reveals that the curves quickly converge to 0 after the switches are closed, and the whole experiment shows that the designed synchronization controllers perform the control role. The heterostructured chaotic synchronization control of Chen system with Lü system and its circuit design are implemented.

A Parking Space Recognition Method Based on Digital Image Technology

Hao He*, Fangyv Liu, Jiaxin Wang
Tianjin University of Science and Technology, Tianjin,300222, China
E-Mail: *hehao0310252022@163.com

Abstract

In recent years, the number of cars in the city has been increasing, leading to an increasingly prominent issue of urban parking space. Consequently, the automatic identification method for parking spaces has emerged as a crucial research direction. This paper presents a design and implementation scheme for recognizing the status of parking spaces in urban areas based on digital image processing and other technologies. In this paper, the real-time pictures of multiple parking Spaces are collected to identify the parking space, so as to determine the use of the parking space. The experimental results demonstrate the feasibility and effectiveness of the proposed method, which holds practical significance in addressing parking space detection problems through digital image processing.

Keywords: OpenCV, parking spot detection, convolutional neural network, intelligent transportation

1. Introduction

In recent years, with the popularity of family cars, urban road traffic and urban parking space management problems become increasingly prominent.

In the new intelligent parking management system, the method of identification of parking space status is also improved with the progress of technology. At first, all kinds of sensors are used to recognize and judge the status of parking Spaces, but these methods have disadvantages: ultrasonic recognition method makes the error of the sensor larger because there are multiple echoes. The method of infrared identification of parking space status is affected by the change of ambient light source and heat source, resulting in high misjudgment rate. Geomagnetic detection is extremely inconvenient to install.

In response to the above problems, experts in related fields began to look for new solutions. A new research hotspot has been formed. According to the research findings, it has certain advantages to use digital image technology for real-time monitoring of parking lots and to analyze and judge the use of parking Spaces within the scope of video surveillance through image algorithms. Therefore, this paper studies the parking space recognition method based on digital image technology.

This paper is divided into four parts. The first part is the background. The second part is an introduction to the development environment, briefly introducing Python, OpenCV and CNN. The third part introduces the system process, including pre-processing, parking space division, CNN model construction and parking space detection. The fourth part summarizes the main content of this paper.

2. Introduction to development environment

2.1. Introduction to Python

Python was designed in the early 1990s by Guido van Rosum of the National Center for Mathematical and Computer Science Research in the Netherlands as a replacement for a language called ABC. Python provides efficient high-level data structures, as well as easy and effective object-oriented programming. Python's syntax and dynamic typing, as well as the nature of the interpreted language, make it a programming language for scripting and rapid application development on most platforms, as versions are updated and new features of the language are added, it is gradually used for independent, large-scale project development [1]. Python is one of the most popular programming languages for beginners, and the Python interpreter is easy to extend with new functions and data types in C, C++, or other languages that can be called through C. Python can also be used as an extension language in customizable software. Python's rich standard library provides source code or machine code for every major system platform.

2.2. Introduction to OpenCV

OpenCV is an open-source library for machine vision and machine learning, based on Apache2.0. It boasts excellent compatibility and can be deployed across multiple operating systems including Linux, Windows, Android, and Mac OS. Comprising both C and C++ languages as a whole, it also provides interfaces for Python, Ruby, MATLAB, and other programming languages to facilitate development work in various language preferences. OpenCV incorporates a vast array of general algorithms in the fields of image processing

and computer vision. Its functionalities encompass object recognition, face recognition, action recognition, motion tracking among others. As such, it stands as a pivotal software library within the realm of image processing and machine vision [2], [3].

2.3. *Introduction to CNN*

The human visual system is processed hierarchically in the visual cortex of the brain, and the working process of the brain's processing of visual information is a continuous iterative and abstract process. Starting with the original image of pupil intake, some cells in the cerebral cortex find the edge and direction of the object. Then, the brain determines the general shape of the object in front of the eyes and abstracts. Then the big brain further determines the class of the object. Finally, through the analysis of the information, the conclusion is drawn. CNN network, full name Convolutional neural network, is a deep learning model inspired by the human visual nervous system. It can be divided into convolution layer, pooling layer and fully connected layer. Convolution layer is used to extract local features in image. Pooling layer is used to greatly reduce the magnitude of parameters. The fully connected layer is used to output the result. Convolutional neural network (CNN) is a classic algorithm of deep learning, which is widely used in computer vision, natural language processing and other fields, and can better process data information with stable effects such as pixels and audio and video without additional feature engineering requirements.

3. Methodology

The system design process can be roughly divided into pre-processing, parking space division, CNN model construction and training, parking space recognition and other stages. In the pre-processing stage, the information will be processed and only the effective information will be retained. Parking Spaces are extracted and stored as samples in the stage of parking space division. In the model training stage, the two-classification model will be trained to recognize whether there is a car in the parking space. Finally, the images are monitored in real time and the gaps are marked.

3.1. *pretreatment*

Due to the influence of various natural factors, the difference between the target object in the picture and the backscene image is not high, the available information is weak, and the parking space can not be recognized directly. Therefore, a variety of processing of the original image is required. For example, removing noise and enhancing image detail to distinguish the target object from the background image.

In order to facilitate post-processing, background filtering should first be carried out to filter out irrelevant background information in the image and facilitate subsequent recognition. The method is to define the mask, set the maximum and minimum thresholds, and convert information outside the threshold interval into zero value information.

The second step is binary processing, which converts the image into grayscale. This is because the grayscale image only retains the brightness information and omits a lot of irrelevant information, which effectively reduces the amount of calculation in the later stage.

The third step is Canny edge detection, which is divided into four steps: Gaussian filtering, calculating gradient value and gradient direction, filtering non-maximum value, double threshold detection method. It can effectively determine real and potential edges, and can better detect most of the required boundaries [4].

The original image is shown in Fig. 1. and the pre-processed image is shown in Fig. 2.

Fig. 1 Original image
Fig. 2 Pretreatment result

3.2. Parking space division

Through observation, it can be found that the parking lot is composed of different straight lines, which can be further divided by detecting these straight lines. The method is to use Hough transform, a feature detection algorithm widely used in computer vision, to find out some features in graphics. Hough transform obtains more accurate results by giving the type of shapes to be identified, and then determining the shape of the object through voting mechanism in the parameter space, and filtering out objects with too large or too small intervals. Some cracks or other line segments in the image may be mistaken for parking space lines, and the parking space lines are basically vertical or horizontal. The irregular line segments can be further eliminated by calculating the slope of the line segments to improve the accuracy.

3.3. CNN network training

After the parking space image is obtained, it is divided into training set and test set according to the proportion of 70% and 30%, and then divided into occupied set and non-occupied set according to whether or not the vehicle occupies the parking space, which is used for subsequent model training.

This model training uses VGG16 network, VGGNet is a

neural network jointly developed by Oxford University and Google DeepMind in 2014, which is composed of 13 convolutional layers +3 fully connected layers. The convolutional layer is the core of the convolutional neural network. The essence of the convolutional process is based on a small moment matrix, that is, the convolutional kernel. The pixel matrix of each layer of the image is continuously scanned by step size, and the scanned value is multiplied by the number of the convolution check position, and then added and summed. Convolution kernel is equivalent to a filter, used to extract image features, convolution kernel generally has 3*3 and 5*5 sizes, usually used is 3*3 size, training effect is better. The fully connected layer refers to the connection between each node of the N-1 layer and the n layer, that is, the activation function input of the node of the n layer is the weight of all the nodes of the N-1 layer, which is used to synthesize the features extracted from the previous side. It plays the role of "classifier" in the whole convolutional neural network.

Due to the small size of the data set, in order to get a better model, the third step is to carry out data enhancement operations. Data enhancement can be divided into online enhancement and offline enhancement according to the use method. Offline enhancement is suitable for small data sets and can effectively increase their size. The multiplier of enhancement depends on the number of images converted, such as rotating all images to double the data set. There are two types of commonly used data enhancement, supervised and unsupervised. The commonly used one is supervised data enhancement, which is based on the existing data set and expands the existing data by analyzing the completeness of the data and adopting certain rules. Supervised data enhancement can be subdivided into single sample data enhancement and multi-sample data enhancement. In practice, single sample data enhancement is more used.

Finally, the data of the training set is imported into the model for training. The accuracy of the test set obtained after the completion of all programs is 91.4%, and the accuracy rate is consistent with the prediction period. Later, VCC16 can be changed to ResNet50 to further improve the accuracy, but the training speed of ResNet50 is slower than that of VCC16, so from the perspective of efficiency, VCC16 is finally chosen.

The results of parking space detection are shown in Fig. 3.

Fig. 3 Parking test results

4. Conclusion

The program will process and detect the picture in real time, and the vacant parking Spaces in the picture are marked green, and the occupied parking Spaces are not marked. Some areas in some pictures are incorrectly marked, such as the guiding line area of the parking lot is marked as empty parking space, which can be further improved by modifying the CNN model. The detection and statistics of the remaining areas are basically in line with expectations, and the processing and detection of parking space information is realized.

Through OpenCV and convolutional neural network, real-time monitoring of parking space occupancy is realized, which can be applied to urban parking lots for convenient management. In addition, the system can be further optimized to increase speed and adapt to more complex scenarios, thus providing more efficient and timely data for parking lot management.

Abstract

At present, manual logistics handling is inefficient and limited, manual operation is not only difficult to manage and maintain, but also has certain security risks in the handling process. This paper presents a logistics handling robot based on AT89C52 single chip microcomputer. The integration of the power module, sensor, and drive motor module enables automatic obstacle avoidance and information collection. The incorporation of an ultrasonic obstacle avoidance module and an infrared tracking module enhances the capability for obstacle avoidance and path searching, and can easily cope with different workplace. Handling robot arm structure reference Yaskawa MPL manipulator,the Yaskawa MPL manipulator is highly suitable for high-speed and high-precision palletizing, picking, packaging, and other industries.

Keywords: logistics handling; robot; MCU; modularization; obstacle avoidance

1. Introduction

With the rapid development and application of technology in the 21st century, the logistics transportation and handling industry has also ushered in great changes and development. Manual handling in the logistics production line has many years of history, however, the traditional manual handling has many shortcomings, such as large physical consumption, low degree of automation, low efficiency, environmental impact and so on. Nowadays, many domestic logistics enterprises still use a lot of physical handling and manual operation in the daily logistics handling operation. This situation in the current logistics industry can no longer adapt to the development needs of the market.

Although manual logistics handling still plays an important role in reality, it also faces some status quo and drawbacks, including human resource dependence, the influence of human factors, low efficiency and rising labor costs. Therefore, the use of handling robots can improve the efficiency of logistics handling, reduce costs, improve safety, and provide greater flexibility and adaptability. With the continuous development of technology, handling robots will play an increasingly important role in the logistics industry.

However, the current handling robot still has some shortcomings and still faces certain difficulties in the complex and dynamic environment. For example, objects of different shapes and sizes, different types of ground, and the presence of people and other robots can have an impact on the robot's operation and navigation. The accuracy and flexibility of handling robots still need to be improved. This paper proposes the design of logistics handling robot based on AT89C52 single chip microcomputer, and optimizes the current handling robot on the system to realize the autonomous tracking of the handling robot, avoid obstacles and complete the automatic picking of objects by the robot arm, so as to achieve the purpose of more efficient and safe logistics handling.

The rest of this article is organized as follows.The second part of the design of the robot, first introduces the system design of the robot, and then introduces the design of the drive module and the robot arm according to the system design. The third part is hardware design, which introduces the main hardware used by the robot. The fourth part of the module test, mainly ultrasonic obstacle avoidance module and infrared tracking module for testing, data analysis. The fifth part summarizes the main content of this paper.

2. Design of Handling Robot

2.1. Robot system design

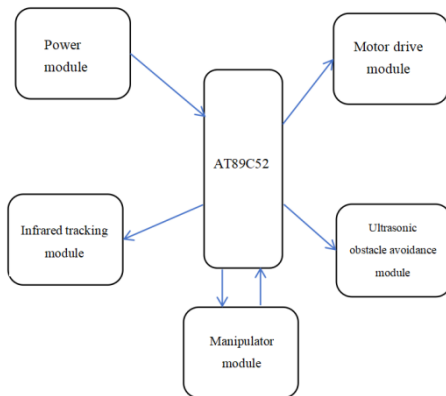
The design of this paper is based on the modular design of AT89C52 microcontroller. The functions of the whole design system are divided into power module, motor drive module, ultrasonic obstacle avoidance module, infrared tracking module and robot arm module. The control of the robot arm is achieved through a vision sensor, through which information about the desired object is obtained [1]. The System composition diagram is shown in Fig. 1.


Fig.1 The system composition diagram

2.2. Drive module design

The whole work flow of the handling robot starts from the designated starting work area and gets the route information through the road condition feedback, so as to reach the designated area in accordance with the set route to complete the corresponding work. Therefore, the design of the driving module of the robot in this paper needs an automatic tracking system to realize. The automatic tracking system flow is shown in Fig. 2.
Fig. 2 The automatic tracking system flow

The infrared tracking module uses the TCRT5000 infrared sensor as the path detection sensor to realize the detection of the road track route [2].

2.3. Robot arm design

Mechanical arm structure reference Yaskawa MPL series mechanical arm, Yaskawa MPL series mechanical arm structure is simple, fewer parts, parts of low failure rate, reliable performance, simple maintenance and maintenance, less inventory parts required. The MPL structure has high control performance and precision, can meet the complex motion control needs, and can be flexibly configured and expanded to adapt to different application scenarios and requirements.

The Yaskawa MPL manipulator has a modular design, and individual joints and components can be installed and replaced independently. This design makes repair and maintenance easier and faster, reducing downtime and repair costs. The Yaskawa MPL0100 robot arm model and fixture model is shown in Fig. 3.
Fig.3 Yaskawa MPL0100 robot arm model and fixture model

3. Hardware Design

3.1. Main control chip

The main controller of the control system uses AT89C52 microcontroller, AT89C52 microcontroller has powerful functions and flexibility, suitable for a variety of embedded systems and control applications, belongs to CMOS8-bit microcontroller. Its advantages are mainly reflected in low power consumption, high performance, and flash memory [3], [4]. Receive the input signal collected by the sensor, and output the control signal to the driver chip, so as to control the robot to walk along the specified route and stop to the specified destination.

3.2. Power supply

In the whole system design, AT89C52 MCU is the control

center, and it is powered by 2 3.7V power modules. Information acquisition through the sensor, its operating voltage requirement is 5V, the use of AMS1117 regulator to achieve voltage regulation, AMS1117 is a cost-effective regulator, relatively low price, stable and reliable performance, At the same time, the AMS1117 regulator has the advantages of simple and easy to use, stable and reliable, low power consumption, overload protection, multiple output voltages and high cost efficiency. The operating voltage of the motor drive module in the device is 5 V, if the voltage is greater than 5 V, it is directly supplied by the power module.

3.3. Drive motor

The robot is usually driven by DC reducer motor, which can output large torque through the deceleration of the gear box [5]. After comparison and selection, the model JGB37-550 DC gear motor is selected. The JGB37-550 DC gear motor has the advantages of high torque, good stability, wide speed regulation range, high energy efficiency, high reliability and easy installation, which makes it widely used in many industrial and commercial applications.

3.4. Controls the robotic arm chip

In order to identify the grasping material workpiece, the color and shape of the material workpiece are used to identify the target. The recognition sensor adopts OpenMV3 vision module with MCU interface. There is a camera on the OpenMV3 module for taking images of objects, and the images taken are processed by AT89C52 microcontroller.

4. Module Testing

4.1. Ultrasonic obstacle avoidance module test

According to the actual working environment of the handling robot, the indoor environment is selected for ultrasonic obstacle avoidance test, obstacles are set, and ECH0 of the HC-SR04 ultrasonic module is connected to the needle J9-P2.0, TRIG is connected to J9-2.1, VCC is connected to J9-VCC, and GND is connected to J9-GND. The LCD1602 liquid crystal was installed in the LCD1602 socket of the single chip microcomputer, and the contrast of the liquid crystal was adjusted. Ultrasonic obstacle avoidance module test data is shown in Table 1.

Table 1. Ultrasonic obstacle avoidance module test data

Ultrasonic ranging(mm)	Ruler ranging(mm)	Error(%)
266.8	266.0	0.15
350.6	350.0	0.17
439.8	439.0	0.18
658.8	658.0	0.12
772.1	771.0	0.14

The error between the ultrasonic obstacle avoidance module's ranging value and the actual ruler's ranging value is less than 2%, which can realize automatic obstacle avoidance.

4.2. Infrared tracking module test

Natural light has a certain influence on the receiving ability of the infrared receiving tube, so the indoor environment test matching the actual use environment is used. Before the test, connect P3.2~3.5 of the pin J11 and P3.2~3.5 of the AT89C52. Place the robot on the white test bench, turn on the power, and fine-tune the potentiometer RW3 and RW4 in a clockwise manner until LED2 and LED light up. Infrared tracking module test data is shown in Table 2.

Table 2. Infrared tracking module test data

Transfer robot	Left infrared tube	Right infrared tube
Go forward	1	1
Back up	0	0
Turn left	1	0
Turn right	0	1

5. Conclusion

This paper takes the handling robot as the research object, uses the AT89C52 single chip microcomputer as the main control chip, uses the infrared tracking module, ultrasonic obstacle avoidance module, power module, motor module and robot arm module to design the handling robot, optimizes the shortcomings of some handling robots in the general working environment, improves the efficiency of logistics handling and reduces the risk of manual logistics handling.

Intelligent handling robot has broad development prospects. With the continuous progress of technology and the expansion of application fields, intelligent handling robots will play an important role in various industries, improve work efficiency, reduce costs, and

promote the intelligent transformation of the industry.

Application and Differences of Robotic Arms, Traditional Machines, and Manual Work in Production

Xue Yang*, Ying Su, Yuping Mei, Haiquan Wang

College of Electronic Information and Automation, Tianjin University of Science and Technology, 300222，China

E-mail: *wybzdwzdbzd@126.com

Abstract

This article aims to explore the differences between robotic arms and traditional machines and humans. Firstly, robotic arms are a kind of automated equipment with high flexibility and accuracy, which can perform a variety of complex tasks. In contrast, traditional machines lack flexibility and accuracy, while humans have problems such as low work efficiency and high error rates. Secondly, the emergence of robotic arms can solve many problems in traditional machines and humans, and improve production efficiency and quality. Finally, there is no contradiction between robotic arms, traditional machines and humans, but they can complement each other. By using robotic arms and humans reasonably, we can give full play to their respective advantages and improve the overall production efficiency and economic benefits.

Keywords: robotic arm, traditional machine, human, production efficiency, economic benefit

1. Introduction

Robotic arms are a kind of automated equipment with high flexibility and accuracy, which can perform a variety of complex tasks. In contrast, traditional machines lack flexibility and accuracy, while humans have problems such as low work efficiency and high error rates.

The emergence of robotic arms can solve many problems in traditional machines and humans, and improve production efficiency and quality.

There is no contradiction between robotic arms, traditional machines and humans, but they can complement each other. By using robotic arms and humans reasonably, we can give full play to their respective advantages and improve the overall production efficiency and economic benefits.

The rest of this article is organized as follows. The second section introduces the appearance differences between robotic arms and traditional machines. In the third part, the application of robotic arms in manufacturing can solve many problems. In the fourth part, robotic arms and human labor can complement each other. At the same time,

robotic arms also need human supervision and management to ensure their normal operation and production safety. In the future, with the continuous advancement and development of technology, robotic arms will be applied and developed in more fields.

The picture of the robotic arm board is shown in Fig. 1.
Fig. 1 The picture of the robotic arm

2. The Different Appearances

Xue Yang, Ying Su, Yuping Mei, Haiquan Wang

Machine arms and traditional machines have distinct differences in appearance.

2.1. Traditional machines

Traditional machines often have a rigid mechanical structure, consisting of various metal and plastic components and parts. Their shape and size are relatively fixed, and they can only be produced and processed on a large scale in factories.

The picture of the traditional machines is shown in Fig. 2.
Fig. 2 The picture of the traditional machines

2.2. Robotic arms

The design of robotic arms typically adopt a more flexible mechanical structure, with multiple movable joints and arms, as well as various sensors and actuators at the end. These joints and arms can move independently, allowing the machine arm to adapt to various work environments and tasks. In addition, machine arms are usually equipped with various sensors, such as visual sensors, tactile sensors, and force sensors, to perceive the surrounding environment and perform precise operations.

The picture of the is robotic arms shown in Fig. 3.
Fig. 3 The picture of the robotic arms

Traditional human production has been unable to keep up with basic standards, which can easily lead to a decline in economic efficiency [1]. Therefore, in appearance, machine arms are more flexible, complex, and intelligent compared to traditional machines

3. The Application of Robotic Arms

The application of robotic arms in manufacturing does provide solutions to many problems. Here is a detailed explanation of some specific applications and advantages of robotic arms in manufacturing.

3.1. Substitution for dangerous and heavy work

In the manufacturing industry, there are many dangerous, heavy, and repetitive tasks that can have negative effects on workers' physical and mental health. Robotic arms can take on these tasks, avoiding direct contact with hazardous environments while reducing their workloads. For example, in the automotive manufacturing process, robotic arms can be used for heavy lifting, welding, and painting, which are more dangerous tasks, thus protecting workers from work-related injuries.

3.2. Improving production quality

The precise control and repeatability of robotic arms enables them to perform production tasks more accurately than humans. Through pre-set programs or precise sensor technology, robotic arms can ensure consistency and product quality during the production process. On assembly lines, robotic arms can precisely assemble and tighten components, ensuring that each product meets specifications and quality requirements.

3.3. 24-hour uninterrupted work

Robotic arms can work continuously without needing to rest or sleep. They can work for 24 hours straight, which improves production efficiency and production cycles. In contrast, humans need to rest and recover and cannot work continuously for long periods of time. Therefore, robotic arms are very useful in situations where high production volume and rapid production are required.

In short, the application of robotic arms in manufacturing can solve many problems, including the replacement of dangerous work, improving production quality, 24-hour uninterrupted work, and increasing production efficiency and economic efficiency. With the

continuous progress and development of technology, the application of robotic arms will become more and more extensive, bringing more innovation and value to the manufacturing industry.

4. The collaboration

4.1. Collaboration between robotic arms and traditional machines

Robots are highly automated and precise machines that can perform a series of repetitive physical tasks. Traditional machines are more versatile machines that can perform a wider range of tasks. By combining robots with traditional machines, we can create a more efficient and flexible production line.

For example, in the manufacturing industry, traditional machines can complete a series of complex processing tasks, while robotic arms can be responsible for repetitive tasks such as handling, assembly, and inspection. This collaborative approach allows traditional machines and robotic arms to each leverage their strengths, thereby improving overall production efficiency. At the same time, this collaboration can also reduce production costs, as robotic arms can replace humans in performing dangerous or high-intensity tasks, reducing the reliance on human labor.

4.2. Cooperation between robotic arm and human

The collaboration between robotic arms and human beings can be divided into two aspects: one is human-computer interaction, and the other is machine-assisted human.

Human-robot interaction refers to the execution of tasks by a robot arm under the guidance of a human. In this mode, humans can control the actions of the robot arm by entering commands or operating it. This collaborative approach is often used for dangerous or high-intensity work, such as deep-sea operations or space exploration. Through human-robot interaction, humans can fully utilize their creativity and flexibility while avoiding some dangerous tasks.

Machine-assisted human labor refers to the use of robotic arms as an assistive tool to help humans complete complex tasks. For example, in the medical field, robotic arms can assist doctors in surgical operations, thereby improving the accuracy and efficiency of the procedure. This collaborative approach can free humans from tedious

or high-intensity work, thereby improving work efficiency and quality.

The picture of the cooperation between robotic arm and human is shown in Fig. 4.

Fig. 4 The picture of the cooperation between robotic arm and human

In general, there is no contradiction between robotic arms, traditional machines, and human labor, but rather a collaborative relationship. By using robotic arms and human labor in a reasonable manner, we can fully leverage their respective strengths and improve overall production efficiency and economic benefits. In the future, as technology continues to advance and innovate, this collaborative approach will become increasingly common and important.

5. Conclusion

Through in-depth research, it is found that there is no contradiction between robotic arms, traditional machines, and human labor, but rather they can collaborate with each other to improve overall production efficiency and economic benefits.

In summary, robotic arms, traditional machines, and human labor each have their own advantages and disadvantages, and are suitable for different production scenarios. In the future, with the continuous advancement and innovation of technology, we can fully leverage their respective strengths to improve overall production efficiency and economic benefits. At the same time, we also need to focus on how to better achieve human-machine collaboration, improve production safety, and product quality.

The picture of the human-machine collaboration is shown in Fig. 5.

A Deep Exploration of the Mounting Issues Related to Six Rotor UVA

Yuping Mei*, **Ying Su**, **Xue Yang**
Tianjin University of Science and Technology, Tianjin, China

E-mail: **2070909305@qq.com*

Abstract

In recent years, the hexacopter UAV has developed rapidly, the technological breakthrough in the field of automatic driving, which is of great significance in both military and civilian fields. The six-rotor UAV uses six rotors as the power source and adjusts the attitude by changing the rotor speed to further achieve position control. It has excellent hovering ability and sensitivity, and is equipped with a precise positioning system and advanced sensors. However, there are still common problems such as weak mounting capacity and single mounting mode, in view of this problem, this paper will test the fuselage structure, avionics system and power system one by one from two aspects: changing the fuselage structure and installing the motor position.

Keywords：the hexacopter UAV, weak mounting capacity, changing the fuselage structure, installing the motor position

1. Introduction

With the continuous development of science and technology, drones have become an important tool in the modern military and civilian fields.

As a new type of UAV, hexagoning UAV has the characteristics of high flight altitude and long endurance, so it has a wide range of application prospects in military reconnaissance, geological exploration, agricultural plant protection and other fields.

However, in actual use, hexagoning UAVs often encounter some technical and performance problems in the process of mounting, such as weak mount capacity and single mount mode, which limits its wider application. Therefore, it is of great significance to conduct in-depth discussion and research on the mounting problem of hexagoned UAV.

2. The Development Process and Characteristics of Hexagoning UAVs

2.1 Development history

The development history of hexagoning UAVs can be traced back to the earliest quadrotors. With the continuous innovation of technology and the continuous expansion of demand, hexarotor UAVs, as a multi-rotor aircraft, have gradually emerged in various fields. Early six-rotor UAVs were mainly used in scientific research and military applications to perform tasks that required high maneuverability and flexibility. With the rise of aerial photography technology, hexacopter UAVs have begun to be widely used in the civilian field for aerial photography, monitoring and survey work. In recent years, the application of hexacopter UAVs in emergency rescue, agriculture, logistics and other fields has also increased.

2.2 Features

Just as shown in Fig. 1, the hexacopter UAVs have the following characteristics. (1) The multi-rotor design: Compared to quadcopter drones, six-rotors employ more

rotors, making them more stable during vertical take-off, landing and hovering. This design improves mobility and adaptability to complex environments, making it ideal for performing specific tasks. (2) High maneuverability: Hexacopter UAVs have excellent maneuverability due to more rotors and are able to flexibly cope with a variety of flight missions. This mobility makes it particularly advantageous when performing search and rescue missions in emergency situations. (3) Load capacity: Hexacopter drones typically have a higher load capacity and are able to carry more sensors, cameras, or other equipment.

Fig. 1 A hexacopter UAV

This makes it stand out for tasks that require large equipment, such as scientific research, monitoring, and surveys. Diversification: Due to its flexibility and stability, the application of hexacopter UAV in various fields is constantly expanding, including but not limited to military reconnaissance, aerial photography, agricultural spraying, cargo transportation, etc., showing diversified application scenarios.

3. The Function of the Six-wing UAV is Realized

3.1 Positioning system

Global Positioning System (GPS): GPS is one of the most common and widely used positioning systems that determines the location, speed, and altitude of a drone through satellite signals. It provides global location information for flight, but in some environments, such as urban canyons or dense woodlands, there may be signal occlusion issues.Inertial

Navigation System (INS): An inertial navigation system uses sensors such as accelerometers and gyroscopes to measure the linear acceleration and angular velocity of an aircraft to estimate its position and orientation. However, errors that accumulate over time can lead to navigation drift and are therefore often used in conjunction with other positioning systems.

Visual positioning system: Hexacopter drones can achieve visual positioning through cameras or multiple cameras. Computer vision algorithms can identify landmarks, landmarks, or environmental structures to

determine the drone's position relative to these reference objects.

3.2. Sensor system

Inertial Measurement Unit (IMU): The IMU includes accelerometers and gyroscopes to measure the linear acceleration and angular velocity of the aircraft, supporting flight control and navigation. Magnetometer: Magnetometers are used to detect the geomagnetic field to help determine the direction and heading of an aircraft.

Barometer: A barometer is used to measure atmospheric pressure, which provides altitude information. It is often used in combination with other sensors to improve the accuracy of altitude measurements.

Millimeter-wave radar: Provides high-precision obstacle detection and ranging capabilities, suitable for flying in complex environments.

Infrared sensor: Used to detect thermal radiation for target detection and identification at night or in low-light conditions. Optical Flow Sensor: Used to measure motion relative to the ground to help achieve hovering and stable flight.

Temperature sensors: monitor the ambient temperature and play an important role in some special applications such as meteorological research, cold chain logistics, etc.

4. Analysis of the Current Situation of the Mounting Problem of Hexagophoid UAV

4.1 Mountability issues

Load capacity limitations: The structure and power system of a hexacopter drone may not be designed to withstand large or heavy equipment, resulting in reduced performance or unstable flight when loaded.

Reduced flight time: Large loads often cause the drone to consume more power, resulting in a lower flight time. The weak payload capacity may limit the durability of the UAV to perform tasks in the air.

Height impacted: Hexacopter drones with heavy loads can lead to increased sensitivity to altitude changes and difficulty in stable flight at different altitudes, especially at low altitudes or in complex environments.

Reduced handling performance: Large or heavy loads may increase the inertia of the drone, making it more sluggish or inflexible when maneuvering, affecting the maneuverability of the flight.

4.2 Single mount type

The reason for the single type of hexacopter UAV mount may involve the following factors:

Technical limitations: When manufacturing hexacopter drones, technical and engineering constraints may result in limited payload types. For example, flight controls, powertrains, or structural design may make it more complex or impractical to support multifunctional mounts.

Cost considerations: Versatile mount systems can add to manufacturing costs and complexity. In order to keep costs under control or to offer a more competitive price, manufacturers may choose to adopt a design with a single mount type.

Regulatory and compliance: Regulatory requirements in specific industries or regions may impose restrictions on the design and use of drones, leading manufacturers to select specific payload types to comply with regulatory requirements.

5. The Solution to the Mounting Problem of the Six-wing UAV

In response to the above problems, we put forward some possible solutions and suggestions:

5.1. Performance optimization

Structural and powertrain optimization：The structure and power system of the drone were redesigned to enhance its load capacity. This could include the use of lighter but stronger materials, optimized motor and propeller configurations, and improved battery technology to provide greater power output. A fixed-time control scheme based on integral terminal sliding mode can be designed to realize the trajectory tracking control of UAV, and the fixed-time convergence performance of the closed-loop control system is analyzed through the Lyapunov theory [1].

Multi-Functional Mounting System: Design a system that supports multi-functional mounting, allowing for quick replacement and integration of different types of devices or sensors. Sensors such as gyroscope, accelerometer and magnetometer can be used to obtain the current attitude information of the aircraft in real time, the whole flight control system can be designed as a whole by using the modular idea, and the complementary filtering algorithm based on the quaternion and the cascade PID control algorithm can be used to realize the current attitude solution and control output of the aircraft.

Intelligent flight control system: The intelligent flight control system is introduced to achieve more accurate flight control through advanced algorithm and sensor data fusion, and improve stability and maneuverability when loading loads. Fault-state controllers can be designed using a backstepping method that sacrifices yaw control to achieve hovering and simple trajectory tracking.

Efficient Power Management: Optimize power management systems to increase battery capacity and performance to support sustained flight time when mounting large equipment. The use of advanced energy storage technology and power management systems is a key factor.

System integration and collaborative optimization: Implement comprehensive optimization in the entire system, including the collaborative work of the mounting system, flight control system, power system, etc. By considering the individual components together, the overall performance can be improved. Technological Improvements

5.2. Function optimization

Design a universal mount system: Design a system that supports multi-functional mounts, allowing users to swap out different types of devices or sensors. Such a system can increase the flexibility of the drone, making it suitable for a variety of application scenarios. Simulink was used to model the UAV with six degrees of freedom, and the motion attitude characteristics of the UAV during the gliding process, the influence of ailerons on the motion of the UAV, and the movement attitude characteristics of the UAV in the environment of wind interference were analyzed [3].

Modular design: The modular design allows the mount system to be easily integrated and replaced. This allows users to quickly adjust the mount to the needs of the specific task, thus achieving versatility.

Open interface standards: Develop or adopt open interface standards to ensure that a wide range of devices and sensors are compatible with the drone's payload system. This helps drive industry standards and improve device interoperability.

Technology Upgrades and Updates: Regular technology upgrades and updates are carried out to support the integration of new types of devices and sensors. This helps to keep the drone's technology competitive and adapt to the development of emerging technologies. Combined with the sliding mode observer to estimate the fault information matrix, a fault-tolerant controller for a six-rotor actuator based on the switching system was designed by using the handover control algorithm. The simulation analysis shows that the designed fault-tolerant control system has good control performance and robustness, which can effectively reduce the impact of actuator monowing damage on flight [2].

6. Future Research Directions and Development Trends

With the continuous development of science and technology, the research on the mounting problem of hexapopter UAV will become an important direction in the future. In future research, we can try to apply advanced materials and technologies to the mounted equipment to improve the performance and stability of the equipment, and at the same time, we can further study the co-design method of the aircraft and the mounted equipment to achieve better coordination and overall performance. These research results will provide stronger support for the application of hexagophoid UAVs and promote the continuous progress of UAV technology.

7. Conclusion

In this paper, the mounting problem of hexacopter UAV is studied in depth, and the types of mounting equipment and their influence in different application scenarios are discussed. Through the analysis of camera mounting, multi-rotor design, high maneuverability, etc., the development process and characteristics of six-rotor UAV are comprehensively demonstrated.

The paper mentions the methods to solve the problem of weak payload capacity, including structural optimization, multi-functional payload system and intelligent flight control system.

Finally, the importance of improving the adaptability and flexibility of UAVs to meet the needs of different missions was emphasized. Through the discussion of the single problem of sensor and mount type, it provides useful theoretical support for the field of UAV research and points out the direction for future technology development.

E-Mail: *sy789464@outlook.com

Abstract

With the development of tourism to climb peaks, the safety of high mountain walls plays an increasingly important role. In the past, the terrain of the mountain wall was too steep and too fast, and people could not patrol the mountain wall climbers, resulting in the safety of climbers could not be guaranteed, and the needs of climbers were difficult to solve in time. In order to solve the above problems, the method of real-time monitoring of UAVs and delivery of materials by UAVs was proposed. Hexacopter UAV is an unmanned small aerial vehicle equipment that can carry out vertical lifting, which is expected to improve the safety factor of climbing mountain walls and solve the needs of climbers in a timely manner.

Keywords: Hexacopter UAV，real-time monitoring，delivery of materials，mountion climbing

1. Introduction

In order to ensure the sustainable development of climbing tourism, it is urgent to improve the safety of high-altitude operations. This study mainly analyzes the feasibility and problems of hexacopter UAV in the field of climbing. The stability and load-bearing capacity of the hexacopter UAV determine the bright future of the hexacopter UAV in the field of climbing. Among them, the most significant application of hexacopter UAVs in the field of climbing is to provide magnificent high-altitude shooting conditions. As climbers conquer steep peaks and climb steep rock faces, hexacopter drones with high-definition cameras can record the scene. Aerial footage can not only be used to monitor the climbing process, but also can be used as promotional material to promote climbing projects and attractions, and attract more people to participate in climbing. In the case of very mature UAV monitoring technology, the real-time recording and monitoring of high-altitude conditions by the hexagoter can play a very good role in the climbing tourism industry.

2. Introduction of six-rotor UAV

2.1. The concept of a six-rotor drone

UAV is a small unmanned aerial vehicle with the advantages of flexible flight performance such as vertical lifting, hovering, and loading. The six-rotor UAV has three groups with a total of six motors placed coaxially up and down to provide lift, adjust the attitude by changing the rotor speed, and realize the position control through the change of attitude.

2.2. Features of the six-rotor UAV

The six propellers of the hexagoning UAV are distributed in hexagonal vertex positions, with six propeller speeds as six input forces and six degrees of freedom as outputs. The rotation direction of the six propellers is not the same, and when encountering strong external interference or part of the rotor is disturbed, the output of multiple propellers controlling the rest of the propellers can show good stability [1].

(1) The flight altitude of the hexcaopter

Hexacopter drones typically fly at altitudes between 1,500 and 3,000 meters, but there are some professional drones that can fly to higher altitudes. The technologies that determine the flight altitude of hexacopter UAVs mainly include the following aspects: flight control systems, aviation power systems, communication and navigation systems, and meteorological and environmental sensors. The combined effect of these technologies determines the flight altitude of the drone.

The flight control system is one of the key factors that

determine the flight altitude of the drone, which includes the flight controller, attitude stabilization system, and altitude control system. These systems work together to ensure that the drone can fly stably and maintain a predetermined altitude [2].

The aerodynamic system includes engines, propellers, and power system controls. These systems provide the power needed to fly and influence the drone's climb performance and altitude performance.

Communication and navigation systems also play a vital role in the flight altitude of the drone. Satellite navigation systems (such as GPS) and ground console devices provide precise navigation and positioning information for six-rotor drones in the air, allowing them to accurately control altitude and position.

Meteorological and environmental sensors can detect meteorological factors such as air pressure, temperature, humidity, etc., helping the drone adjust its flight altitude and attitude according to the current environmental conditions.

To a large extent, these technologies have been very mature, especially in the professional field, the flight altitude control technology of UAVs has been very sophisticated, and has provided reliable technical support for various application scenarios.

(2) The volume of the hexacopter

The size of drones can generally be divided into miniature, small, medium, and large. The size of small UAVs is generally between 30 cm and 1 meter, and it is suitable for aerial photography, agricultural plant protection, environmental monitoring and other fields. Among them, medium-sized UAVs are between 1 meter and 5 meters in size, which are suitable for use in search and rescue, logistics and distribution, geological survey and other fields. The carrying capacity of a drone is usually related to its size. Medium-sized UAVs have a large carrying capacity and can already carry relatively heavyweight equipment and materials, such as rescue equipment, survey and monitoring equipment, etc.

3. The application status of six-rotor UAVs

At present, the application field of hexacopter UAV is expanding day by day, covering military, civilian and commercial aspects. In the military field, hexacopter UAVs can be used for reconnaissance, surveillance, target positioning and strike, providing a new way of intelligence acquisition and combat. In the civilian field, UAVs are widely used in aerial photography, geological survey, agricultural plant protection, weather monitoring and forest fire prevention. Drones also play

an important role in commercial areas such as logistics and distribution, building inspection, and power inspection. With the continuous progress of technology, UAVs are gradually used in emergency medical rescue, disaster monitoring and rescue, providing a new means of ensuring the safety of people's lives and property. The development of hexacopter UAVs has not only enriched the application field, but also provided people with more efficient and safer solutions, becoming an indispensable part of modern society. This study introduces the application of hexacopter UAV in the field of climbing, and solves the gap that there is no hexacopter UAV involved in the climbing tourism industry.

4. Analysis of the advantages of hexacopter UAVs in the field of climbing

4.1. High-altitude monitoring function

The high-definition high-magnification zoom camera embedded in the six-rotor drone can clearly see objects one to two kilometers away from the drone. Picture of a high-altitude surveillance drone is shown in Fig. 1. Equipping the six-rotor drone with a stable gimbal gimbal stabilization function, coupled with the smoothness and regularity of the drone's flight, can obtain enough stable images and lenses for surveillance even at full zoom. Regardless of the aircraft's movement, the gimbal maintains its orientation and inclination. The drones responsible for surveillance can navigate autonomously. "Waypoints were previously introduced on the map via a desktop computer or tablet, where waypoints were added by clicking on the map and navigation was stored in the drone's memory. The waypoint can be grouped into one or more points of interest. Navigation can be easily initiated via radio control, so there is no need to use a computer or tablet in the field, and the drone can be in the air in a matter of minutes.

Fig. 1 A high-altitude surveillance drone

4.2. Navigation features

Hexacopter drones play an important navigational role in the field of rock climbing. Rock climbers often need to face complex terrain and changeable environments during climbing, and the navigation

function of drones can provide valuable auxiliary information for climbers.

Equipped with high-precision cameras and navigation equipment, drones can see the climbing route, rock wall structures, and the terrain faced by climbers from the air. This bird's-eye view provides climbers with a new perspective and helps them better understand the complexity and difficulty of the climbing route so that they can develop a targeted climbing strategy. Its real-time monitoring function can help climbers timely obtain changes in the climbing route, such as rock collapse, climate change, etc., and provide timely warnings and risk warnings for climbers. This real-time monitoring is critical for the safety of climbers, allowing them to better respond to unexpected situations and reduce the likelihood of accidents [3].

The navigation role of hexacopter drones in the field of rock climbing can provide climbers with a full range of information support, help them better cope with challenges, and improve the safety and success rate of climbing.

4.3. Aerial teleportation function

For the preparation of rock climbing competitions and climbing events, drones can be used as a fast transmission tool to transmit competition equipment and judging equipment to the required locations, improving the work efficiency of organizers and participants. Climbers often need to carry a variety of equipment, food and water during the climb, and drones can be used as a high-altitude teleportation tool to help climbers deliver these supplies to the designated location. For climbers, there are often difficult parts of the climbing route to pass, such as steep cliff walls, inaccessible caves, etc. Drones can carry ropes, gear, and food to reach places that climbers can't, delivering them safely to where they are, providing them with the support they need. Climbers can also be provided with emergency supplies during the climb, such as delivering much-needed clothing, food, and medicine to climbers in case of inclement weather to help them get through the storm. Photos of actual transportation of hexarotor drones is in Fig. 2.

Fig. 2 Actual transportation of hexarotor drones

In general, the high-altitude teleportation function of drones in the field of rock climbing provides convenient material support for climbers, provides more safety and convenience during climbing, and adds new possibilities and innovations to rock climbing activities [4].

5. Development prospects and challenges of hexacopter UAVs in the field of climbing

The application of hexacopter drones in the field of climbing shows great potential, but at the same time, it is also necessary to pay attention to issues such as privacy protection and environmental protection. When using drones for high-altitude shooting, it is necessary to comply with local aviation regulations to ensure that they do not interfere with the flight of other aircraft. In addition, when flying, it is necessary to strictly comply with local environmental protection laws and regulations to avoid affecting the local ecological environment.

6. Conclusion

The application of hexacopter drones in the field of climbing provides more safety and technical support for climbers, expands the possibilities of climbing activities, and brings new innovations to climbing sports. With the continuous progress of technology and the expansion of applications, it is believed that the role of UAVs in the field of climbing will become more prominent, bringing more convenience and safety to climbing sports.

Deep Learning and Embedded Based Operational Safety System for Special Vehicles

Haoran Gong*, Yumei Huang, Jiahao Xie
Tianjin University of Science and Technology, Tianjin, China

*E-mail: *1465157817@qq.com*

Abstract

Aiming at the characteristics of special operation vehicles, such as complex operating environment, heavy vehicle weight, long braking distance, and many visual dead angles for drivers, this project designs and implements a special vehicle operation safety system based on deep learning and embedded system. Firstly, the deep learning model is applied to detect the humanoid target appearing around the vehicle, get the detection frame of the humanoid target, and estimate the distance from the target to the camera; using the advantage of the embedded system which is relatively small can be easily deployed on the heavy vehicle. According to different distances, the system will issue relevant voice prompts to remind the driver to take timely measures such as avoiding or braking.

Keywords：special operation vehicles，Deep Learning，Embedded system，Complex working.

1. Introduction

Blind spots in the field of vision of specialised vehicles during operations are a serious safety challenge that can lead to a wide range of accidents, as the vehicles tend to be large-bodied. These drivers may not be able to directly observe the blind spots in their field of vision, increasing the risk of hazards to workers, other vehicles and obstacles.

For example, in specialised vehicles such as excavators or loader trucks (Fig. 1 below). drivers may not be able to directly see pedestrians or workers around them due to the special construction of the equipment itself, increasing the risk of run-over or collision accidents. In addition, when turning, working or reversing, the blind spot in the field of vision may also result in the driver not being able to perceive other vehicles behind the side, which may lead to a collision accident. Drivers are also less likely to be aware of fixed obstacles such as rocks and pillars, which can lead to collisions [1].

Fig. 1 Common Heavy Vehicles

In order to counteract these risks, specialised vehicles can take appropriate measures. To this end, we have designed a system that helps drivers to better avoid and detect obstacles in a timely manner, for example by installing auxiliary cameras and sensors. The use of advanced assistance systems, the strengthening of the driver's field of vision and the incorporation of a hazard warning system reduce the probability of safety accidents caused by blind spots or obstacles in the field of vision of specialised vehicles during operations [2].

The rest of this paper is organised as follows. Part II describes the hardware usage scheme. The third part describes the innovative points of the design as well as the leading advantages. The fourth part explains the application scenarios using the design. Part V summarises the main points of the paper.

2. Hardware usage programme

Haoran Gong, Yumei Huang, Jiahao Xie

2.1 Jetson nano

Hardware selection, we take into account the cost-effectiveness and durability of the two major aspects of the main development board selected NVIDIA series of development boards - Jetson nano development board.

Here to introduce this development board type: Jetson nano is NVIDIA's development of high-performance GPU equipped with a microcontroller, is to achieve deep learning and parallel computing necessary microcontroller. It is broken down into four different types of development boards. They are: Jetson Nano, Jetson TX, Jetson Xavier NX, and Jetson AGX Xavier, where we choose Jetson Nano. Because of its low energy consumption and low cost it takes the lead among the other three microcontrollers. And its arithmetic power has been increased by tens to hundreds of times, even more than a small part of the current computer CPU, and NVIDIA also equipped with a full set of SDK for it. the following Fig. 2 is the picture of Jetson Nano development board, Fig. 3 is the development board core board [3].

Fig. 2 Development Board   Fig. 3 Core Board
The jetson nano performance metrics (representative) are shown in Table 1.

Table 1 jetson nano performance metrics

arithmetic power	40TOPS
GPU	1024-core NVIDIA Ampere architecture GPU with 32 Tensor cores
CPU	6-core Arm® Cortex®-A78AEv8.2 64-bit CPU 1.5MB L2+4MB L3
RAM	8GB+68GB
Camera Interface	2 CSI interfaces
output	5W-10W

2.2 surveillance camera

Cameras are generally selected industrial cameras, such as Hikvision cameras or select Dahua cameras. The advantages of these two cameras are high-definition, clear images, large shooting angle, can be rotated and in the dim light conditions, has a strong night vision effect. They provide a more accurate video feed to the central processor. Fig. 4 below shows the Hikvision camera shooting debugging screen.
Fig. 4 Debug screen

3. Innovative design and advantages

3.1. Deep Learning

The initial idea of our design is to first recognise the human figure, and then to warn the driver by triggering an alarm when the human target walks into a relatively dangerous area of the vehicle's operation.

Due to the relative complexity of the special vehicle operating environment, traditional computer vision and image processing algorithms are relatively fuzzy and difficult to deal with to identify the humanoid target from the environment, and often triggers the alarm system incorrectly (e.g., a roadblock or reflective clothing), therefore, deep learning models are used in this project to complete the identification of the humanoid target, which is shown in Fig. 5.

Deep learning is a research direction in the field of machine learning. Deep learning uses deep neural networks for modelling and uses large amounts of data to optimise the parameters in the model to achieve high accuracy and robustness.

We have designed a deep learning model that can recognise targets within 50 to 100 metres in terms of distance, up to 9000 types of objects (yolo-9000) in terms of type, and hundreds or even thousands of targets in a single frame at the same time.

Fig. 5 Initial identification of deep learning models

3.2. *Technical difficulties*

There are many types of special vehicle operating scenarios such as harbours, construction sites, mining sites, as in Fig. 6. intensive construction of people, many obstacles and close vehicle traffic. Sand, gravel, goods, and materials are piled up. These serious obstacles to our acquisition of the surrounding image information.

Fig. 6 List of construction scenes at mines and construction sites

In addition, because it is assembled on the carrier, it is required to have low energy consumption; and the space inside the vehicle is narrow, which can only accommodate smaller equipment for normal operation, so we can only compress its size.

Due to the ever-changing environments in complex places, we cannot predict what will happen next. So we need as little false recognition or frame skipping as possible. Too many misjudgements can cause

unnecessary distractions for the driver. In addition, if the vehicle is travelling fast in a complex scene, there may be a requirement for the real-time performance of the model.

Generally in complex scenes there will be a large number of staff and supervisors. We want to recognise and estimate their distance to their own vehicle as much as possible.

3. 3. *Problem-solving responses.*

For the human-type and object-type densification problems, we have prepared datasets for training. A certain amount of data is collected to form the dataset for training and the dataset for testing. The amount of data is usually 2000 images, which contain at least 5000 humanoid targets. The dataset is labelled using manual annotation (Fig. 7). At the same time, the surrounding environment is constructed (Fig. 8).

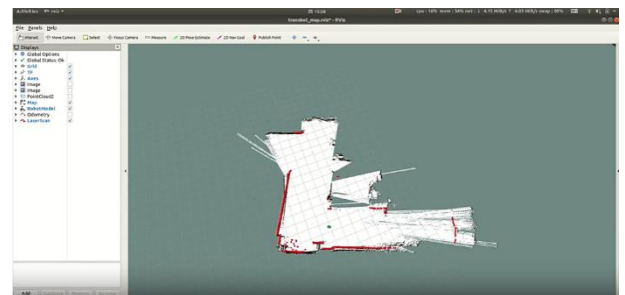
Fig. 7 Dataset labelling


Fig. 8 Environmental scanning

The mainstream deep learning yolov5 and the deep neural network Pedestrian net, which is specialised for humanoid and vehicle detection, are deployed on jetson nano [4].

The model uses ResNet34 as the basic underlying layer and combines advanced techniques such as feature fusion, local zoom, and exact query. The original model is 84.62MB, after pruning 7.85MB, then use Tensor RT for assisted optimisation, generate the physics engine in

semi-precision form, and then deploy the physics engine into deep learning, then after a series of operations can be done on a development board to deal with four to eight video signal sources.

Finally, the target detection metadata is sent in the form of a request to the thread responsible for estimating the distance and voice announcement, and multiple calculations are performed to compare the estimated relative distance with a pre-set threshold to minimise the impact of erroneous judgements. Finally, an alarm is triggered to warn the driver to be careful of the surroundings.

4. Job Scenario Application.

4.1. *yard operation*

Heavy vehicles loading and unloading in port yards face serious visual challenges, with a large number of visual dead zones and blind spots. At the same time, the construction site is a noisy environment with a large number of people, which makes it difficult for the driver of the operating vehicle to detect people in the vicinity of the vehicle in a timely manner in complex situations, thus spawning many safety hazards.

We use a four-channel video signal source to assist the operation. The four video sources are processed simultaneously on a single jetson nano, which can achieve 10 frames per second for each source. The communication is done through a pos switch and finally a voice alarm system.

4. 2. *Shield Tunneling*

Shield Tunnel Battery Vehicle is an electric vehicle specially designed for shield tunneling project, and its main task is to transport materials and transfer personnel at the tunnel construction site.

However, due to the poor line of sight in the tunnel and the heavy load of the vehicle, there is a great safety hazard in the construction. The main reasons include: the existence of a blind field of vision, the existence of a no-signal section in the tunnel, the absence of reminders during operation, the possible failure of the brakes, and improper operation.

We made a solution to these situations in the follow-up processing, first of all, the tunnel front and rear of about fifty metres distance sweep, the construction workers to collect data, and then through our are reinforcing the night vision effect algorithm will be the situation in the

tunnel for light reinforcement, passed to the pos switch, and finally complete the exploration of the environment around the shield tunnel machine. Fig. 9 below shows a comparison of the colour of the enhanced picture in dark conditions for the night vision effect.
Fig. 9 Night Vision Enhanced Picture Colour Before and After Comparison

Fig. 10 below shows the final physical model drawing and the final physical picture.

Fig. 10 Physical models and final objects

5. Synthesis

This paper describes the various safety hazards of specialised vehicles in complex situations and how to deal with them. A machine has been designed to assist special vehicle drivers to avoid accidents. It can be adapted to various complex sites including yards, harbours and mines. By coping with various conditions

with ease. It is believed that in the future, it can help more drivers and escort the safe operation of special vehicles.

"Green Fruit" - Intelligent Traceable Agricultural Product Production and Marketing Platform Based on Blockchain Technology

Yumei Huang*, Jiahao Xie, Haoran Gong, Ziyue Xiao
Tianjin University of Science and Technology, Tianjin, China

E-mail: *3033665674@qq.com

Abstract

The production process of agricultural products has been greatly improved and optimised through the intelligent agricultural greenhouse system. Using intelligent irrigation, measuring CO_2, IoT and other technologies, it creates a greenhouse intelligent control system that is simple to operate, highly automated and intelligent. In addition, using the double combination of front-end architecture and applets, it can record all the growth process, perfectly integrating the intelligent mode + big data application. Create a tailor-made ID for agricultural products. Under our design, we break the traditional automation mode, which is more conducive to understanding the whole growth process of agricultural products.

Keywords: Internet of Things; automation; big data application; intelligent agriculture.

1. Introduction

The aim of the paper is to discuss the many advantages brought by the traceable smart greenhouse model in terms of agricultural production, food safety and market competitiveness, as well as the initial system modelling and related technologies established [1].

From the perspective of food safety and security By integrating product traceability technologies, it is possible to trace the entire process of agricultural products from planting and growing to harvesting, processing and marketing. This helps to monitor potential sources of contamination, diseases or other risk factors, and to identify and deal with problems in a timely manner, thereby improving food safety. Automated control allows real-time monitoring of environmental parameters in the greenhouse, such as temperature, humidity and light, which can precisely control the growing conditions of crops. Through meticulous data recording, farmers can optimise planting strategies to improve the quality and yield of their produce. The increased resource efficiency enables smart greenhouse technology to enable precise irrigation and fertiliser application, as well as efficient energy use. This helps to reduce water wastage, fertiliser use and energy expenditure, and improve the sustainability of agricultural production. The Internet of Things (IoT) in this plays an extremely crucial role and offers many opportunities for innovation and efficiency gains in agricultural production. It can deliver real-time metrics of various parameters in the model to the network and feedback to the user's mobile phone. The user can observe the crop growth at any time. So, IoT can monitor various environmental parameters in the greenhouse in real time, such as temperature, humidity, light, soil moisture, and so on. This real-time monitoring enables farmers to understand the growth of their crops more accurately and quickly adjust the conditions of the greenhouse to optimise the production environment. When problems arise, such as disease, pest infestation or other production challenges, the traceability system can quickly pinpoint the source of the problem. This helps farmers take quick action to minimise losses and maintain continuity of production [2].

Each crop can be identified with its own identity card. Smart greenhouses generate large amounts of data through sensors and monitoring systems, which can be used for data storage. Farmers can make more informed decisions based on actual environmental and production data, and buyers can learn about their growth.

The rest of the paper is organised as follows. Section 2 presents the structure and principles of the system model. Part III presents the feasibility study of the system model. Part IV gives the physical pictures of the constructed model and the verification process to finalise the correctness of the designed. Part V summarises the main points of the paper [3].

2. Introduction to the system model

Intelligent greenhouse control system is a scientific system for intelligent management of greenhouses.

Yumei Huang, Jiahao Xie, Haoran Gong, Ziyue Xiao

Environmental data is collected through the corresponding sensor equipment. Then, through various commands set by the system, the management work is completed automatically.

At the same time, the data collected by the sensors will be analysed and the results will be fed back to the farmers. Under the guidance of agricultural experts, the yield is increased and the quality is improved. In the whole system, QCA9531 gateway module is used as the core component, and the core programme is burned into it. At the same time, all kinds of sensors, rolling shutters, fans, water valve controllers, cameras and other hardware devices will be accessed. When the power is to be turned on, it can be run and controlled automatically according to the programme. The use of sensors to obtain environmental data, when detected more than the threshold value of the fruits and vegetables, will start the corresponding actuator.

2.1 CO2 Sensor

Carbon dioxide (CO_2) sensor is composed of LED-PR measuring unit, LED driving circuit, LDO power supply, photoelectric signal processing circuit, temperature measuring circuit and microprocessor, which is shown in Fig. 1 below.
Fig. 1. Sample sensors

Firstly, a suitable location should be chosen to install the CO_2 sensor. The location should be chosen to represent the average CO_2 concentration of the plant growing area in the greenhouse. The sensor is usually installed in a hanging position to ensure that it can accurately measure atmospheric CO_2. before use, the CO_2 sensor needs to be calibrated to ensure the accuracy of its measurement. Calibration can be carried out by using a standard gas with a known CO_2 concentration, according to the model number of the sensor and the guidelines provided by the manufacturer. Then, connect to the monitoring system. CO_2 sensors are usually connected to the monitoring or control system of a smart greenhouse. This can be achieved through a wired or wireless connection. The sensor sends real-time measured CO_2 concentration data to the monitoring system, enabling the farmer to remotely monitor and manage CO_2 levels in the greenhouse. The farmer can set thresholds based on plant growth

requirements and optimal CO_2 concentration ranges. Once the measured CO_2 concentration exceeds or falls below the set threshold, the system triggers appropriate control measures, such as adjusting the ventilation system or CO_2 supply unit.

The CO2 sensor monitors the CO2 concentration in the greenhouse in real time and transmits the data to the monitoring system. These data are usually recorded and archived for future analysis and reference, as shown in Fig. 2 below.
Fig. 2 Sensor characteristic curve

The Y-coordinate represents the output signal, with a maximum value close to 330mV; the X-coordinate represents the concentration of CO2, with a minimum value close to 210ppm.

2.2 temperature detector

Temperature detection is very important for greenhouse intelligent control system. As shown in Fig. 3, the temperature sensor is used to collect the surrounding environmental factors, read the temperature data, and through the signal processing function, the peripheral devices, as shown in Fig 4, respond accordingly and transmit the temperature data wirelessly to the cloud platform. When the temperature is higher than the preset temperature e, the MCU drives a relay to control the fan rotation to reduce the temperature. When the temperature is lower than the preset temperature, the MCU drives the relay to control the collector to heat up [14].

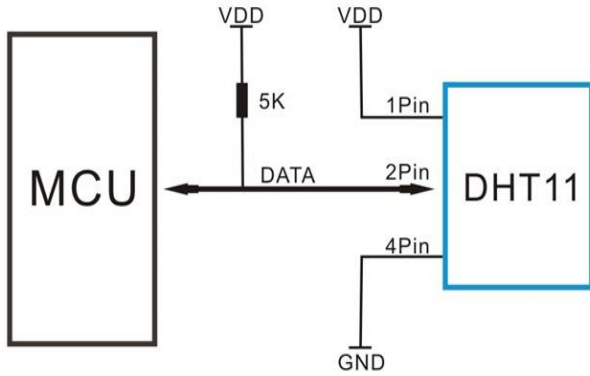
Fig. 3 Temperature sensor DHT11


Fig. 4 Typical Circuit Applications

2.3 Soil moisture sensors and automatic irrigation systems

The soil moisture sensor is chosen to be installed per $1m^2$ of soil by selecting the LM393 soil moisture sensor, as shown in Fig. 5, based on the needs of the crop and the layout of the greenhouse. Typically, the sensor is buried near the root system of the plant to ensure that it can accurately measure the moisture in the soil. Soil moisture sensors usually require a power supply (Eq. (1)). The corresponding values for Equation I are shown in Table 1. Sensors usually use low-power electronic components that can be powered by batteries or other suitable power sources. Then connected to the monitoring system: The soil moisture sensor is connected to the monitoring system of the shed. Real-time soil moisture values are fed back to the platform to provide numerical feedback for subsequent soil rehydration. The premise is to set threshold values for soil moisture based on crop needs and optimal growing conditions. These thresholds will be used in the irrigation system [4].

Fig. 5 LM393 Soil moisture sensors

$$Q(t) = \int_0^t I(\tau)d_\tau + Q_0$$

(Battery power at time t)   (1)

Table 1 symbols denote meaning

Q(t)	Battery power at time t
$I(\tau)$	Current as a function of time
τ	integral variable
Q_0	Initial battery charge

The design of the automatic irrigation system is a multi-level, multi-component project as shown in Fig. 6 need to receive the sent data from the soil moisture sensor to determine whether irrigation is required. By setting a default upper and lower threshold of normal humidity ($\pm 3\%$) in the software. When the soil moisture is lower than the set lower threshold, the pump is activated to deliver water to the underground pipeline and spray it out to drench and moisten the soil to achieve the effect of irrigation. At the same time, the soil moisture sensor continuously checks whether the humidity has risen above the middle of the upper and lower thresholds, and if it meets the requirements, it stops the delivery; if it does not meet the requirements, it continues to cycle the process until it reaches the normal humidity range (Fig. 7).

3. System feasibility study

The application of IoT technology in smart agriculture has enabled real-time monitoring and control of parameters in the greenhouses, providing a high degree of environmental control and visibility. This helps farmers to understand the situation in the greenhouse in real time and take necessary measures to meet the needs of the crop and improve yield and quality.

The traceability system provides a reliable guarantee of the quality and safety of agricultural products through QR codes and database technology [5]. Consumers can easily access detailed information about the products, which builds trust and improves their market competitiveness.

The high degree of automation of the greenhouse system makes it very easy and convenient for farmers to operate. Monitoring of environmental parameters, water and nutrient supply in the greenhouse can be automated through automatic control systems. This reduces the dependence on a lot of manpower and farmers can focus more on monitoring and managing the system rather than having to physically work in the greenhouses for long hours.

By accurately monitoring and controlling environmental conditions, the system is expected to significantly improve the yield and quality of produce. Because the growing environment in the greenhouse can be finely tuned, crops can be optimised for optimal light, temperature and humidity conditions at different stages of growth, leading to increased yields and improved product quality.

4. Physical pictures and verification process

The model is now completed in terms of technology development, with hardware models, WeChat small programmes, traceability systems [6], e-commerce website development. website, and in the future it will enter the data interaction stage and improve the audience

universality test [7], which are shown in Fig. 8, Fig. 9 and Fig. 10.

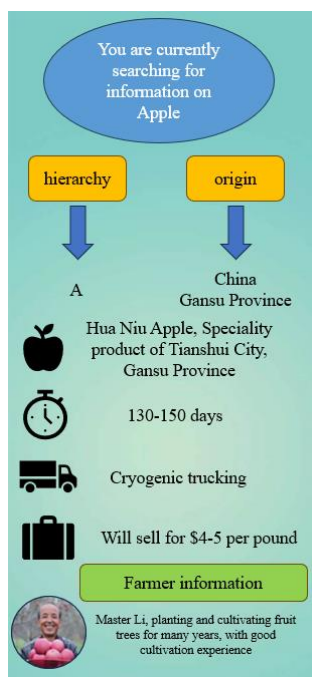

Fig. 10 Crop "ID"

5. Synthesis

The paper mainly describes the growing of crops in smart greenhouses under the fully automated mode. "Traceable Smart Greenhouse" is a modern agricultural production system that uses advanced technology and Internet of Things (IoT) to improve the efficiency of agricultural production and realise precise agricultural management. Including: intelligent sensor technology, Internet of Things, automation control, precise fertiliser application and water management. It improves the efficiency, quality and sustainability of agricultural production, while ensuring product quality through a traceability system to provide consumers with safer, traceable agricultural products [8].

Abstract

With the rapid development of intelligent manufacturing industry and the proposal of Made in China 2025 and Industry 4.0, Digital Twins DT has rapidly become a craze. Through the interaction between the physical object and the virtual model, the mapping is completed in the virtual simulation space, so as to reflect the actual operation process of the whole life cycle of the corresponding equipment workstation. The main structural content of this article is the research background and significance of digital twin technology, the current research status at home and abroad, the establishment of Solidworks physical models, the construction of PDPS (Process Designer&Process Simulate) workstations, and virtual simulation. Completed the construction of the robot seven color board assembly workstation, established a model of the assembly workstation, and combined this model with PDPS to simulate the workstation. Finally, the principle of connection communication and the achievement diagram were elaborated.

Keywords: Digital Twin, Robotic Assembly Workstation, Virtual simulation, PDPS

1. Introduction

"Made in China 2025" and "Industry 4.0" strategic plan proposed, so that intelligent manufacturing and artificial intelligence and a series of intelligent technologies and related development strategies continue to be proposed and implemented, therefore, digital twin technology has become a basic principle of intelligent manufacturing direction, and has received the general attention of all parties. Digital twin technology is the basis of intelligent manufacturing. It is gradually penetrating into manufacturing, medical care, urban management and other fields. The practical application of digital twin technology in control, perception, big data, artificial intelligence, modeling and other fields has also seen a centralized outbreak and growth [1].

As an advanced stage of digital development, digital twin will promote the integration of intelligent, information and digital development processes of integrated enterprises [2]. The development of digital twins has reached an unprecedented height, and now digital twins are not only an inevitable trend of national industrial development in the future, but also an important embodiment of the level of scientific and technological development.

The specific research content of this design:

First of all, the overall design and planning of the digital twin of the virtual simulation of the robot assembly workstation should be carried out. The following five aspects need to be studied and analyzed respectively:

(1) Understand and learn the overall structure and specific layout of the robot assembly workstation. Be fully prepared to build a layout in PDPS.

(2) Make and build models of ABB robot 1410 assembling workstation and other robot bases and other parts in SolidWorks 2019.

(3) Import all the models built in SolidWorks into the PDPS simulation software. Then build the workstation and write the robot motion instructions and paths. In the PDPS simulation software according to the actual layout of the assembly workstation.

(4) Carry out assembly simulation of all processes and route debugging in PDPS software to achieve the effect of workstation assembly and operation simulation.

(5) Communication steps and principles of virtual and real equipment of PDPS and robot assembly workstation.

2. General idea of system design

The system is mainly composed of off-line simulation module, twin module and auxiliary function module.

The overall process design flow chart of the robot assembly workstation system structure is shown in Fig. 1.
Fig.1.Process layout design flow chart of the system

The process mainly includes: the ABB1410 model industrial robot is placed in the No. 1 station and No. 2 station respectively, so that the robot carries out the handling and assembly work on the three seven-color panels and a cover plate on the storage platform in turn, and then transported to the No. 2 station robot operates the cover screw. After the screw is fixed, a set of processes is completed, and finally the object is transported to the finished product area by the transfer track.

3. Robot assembly workstation

The industrial robot used in the robot assembly workstation is an industrial robot specially designed for assembly. Compared with other industrial robots, the assembly robot has the advantages of strong flexibility, high precision, small working range, and can be used in combination with other operating systems. The main driving mode of the system is electric driving mode. The research scene of this paper should be carried out in the assembly of seven-color plates, and the advantages of industrial application are to improve production efficiency and reduce human capital.

For the model built above, the specific parameters are sorted out as follows. The model selection and size table of robot assembly workstation are shown in Table 1 below:

Table 1. Model selection and size table (Unit: mm)

No.	Name	Length	Width	Height
one	path	2400	575	800
two	Transport car	600	400	80
three	Bottom plate	200	200	30
four	Cover plate	200	200	20
five	Color palette one	150	150	20
six	Seven color palette number two	150	$75\sqrt{2}$	20
seven	Color palette number three	150	$75\sqrt{2}$	20
eight	Robot chassis	Radius 350	0	500
nine	Storage table	130	60	80

4. PDPS workstation construction and program design and simulation

The construction of the assembly workstation is mainly based on the layout of the robot training base to simulate the construction of the layout. Through the actual working principle and path of the robot, the coordinate position of the robot and the location of the material workpiece are first determined. Secondly, the trajectory and mode of movement of the robot are understood, and then the layout is carried out through the built model. As shown in the figure, the basic layout is composed of two ABB1410 robots, corresponding to station No. 1 and station No. 2 of the workstation. Station No. 1 is responsible for the assembly of 7 color board No. 1, 7 Color Board No. 2, 7 color Board No. 3 and the cover plate. It is transported to station No. 2 by the conveyor rail, and is responsible for fixing the screws on the four corners of the cover plate at station No. 2. Fig. 2 shows the preliminary model construction:
Fig. 2. Basic layout of robot assembly workstation

The robot assembly workstation is mainly composed of two stations, namely P10 station and P20 station. The robot at P10 station is mainly responsible for the handling and assembly of the 7-color board and the 7-color board cover plate, while the robot at P20 station is mainly responsible for the final assembly of the 7-color board by fixing the bottom plate and the 7-color board cover plate by screws at four corners.

The overall planning of the coordinate system of the robot assembly workstation, through which the coordinates of the robot and the robot base are connected, can be roughly divided into the establishment of the coordinate system of the seven-color plate and the cover plate, the coordinate system of the transport car and the chassis, and the motion coordinate system of the assembly robot OP10 station and the robot OP20 station. As shown in Fig. 3 below.
Fig.3. Coordinate diagram of robot and workstation

5. TIA+PLCSIM+NETTOPLCSIM+KEPServerEX virtual debugging

Open our robot assembly workstation in production line mode and click Add Zone, where the path and location can be observed [3]. Click on the motion simulation, and the robot station OP10 starts to carry and assemble the red triangle plate, yellow triangle plate, purple triangle plate and transparent cover plate successively. Meanwhile, the robot station OP20 also synchronously fixed the screws of the four stations of the cover plate. When the assembly is completed, sensor B receives the signal. The signal is received by NetToPLCsim. And the channel 4 signal shared by KEPServerEX, the PDPS workstation receives the virtual map of the OPC signal 1, and the conveyor begins to move. When the sensor A receives the position signal, which is the same as the signal B, the signal becomes 0, the conveyor belt stops moving, and the robot station OP10 and OP20 start handling and assembly. When the stop button is pressed, the signal is disconnected and the robot assembly workstation stops moving. The workstation of the robot is shown in Fig. 4.
Fig.4. Robot motion diagram

6. Conclusion

In this paper, a simple control system can be realized through the construction and simulation of the basic model of PDPS software based on the working mode and basic method of robot assembly workstation. Do model construction, basic operation methods, path debugging. The virtual reality technology can realize human-computer interaction. The digital twin based on the robot assembly workstation mainly takes the assembly process of the seven-color panel as an example to simulate and simulate the actual robot assembly production line in the virtual space. The digital twin pursues the life cycle of the whole process, and this

design only adopts two stations of the robot assembly workstation for simulation and simulation. I hope it can provide some help for the research of relevant personnel.

A Study of Chemical Reactor Simulation System Based on PCS7

Hongshuo Zhai

Tianjin University of Science and Technology, Tianjin, China

E-mail: 1936130557@qq.com
www.tust.edu.cn

Abstract

Since 1960, the reason for the rapid development of industrial control and its systems is the rapid development of the key process control theory, and their application in science and technology is more and more extensive. In general, the factory site has a series of hazards, and people tend to take a remote, accurate approach to remote control. In this research, PCS7 software is used to simulate the remote control of chemical reactor, and reasonable and correct simulation can be obtained after PID correction.

Keywords: PCS7, PID correction, process control, chemical reactor

1. Introduction

Normal human life is inextricably linked to a series of chemical reactions.

The chemical reactor is defined as a vessel for reaction. The device is widely used in various fields, and the ultimate goal is to obtain reactants that meet the requirements while ensuring production efficiency.

However, due to the presence of a large number of harmful gases in the chemical reaction site that are not conducive to the human body and the environment, affecting the physical and mental health of the practical operator, and because of the high requirements of the chemical reaction parameters, the previous on-site operation has been transformed into a more accurate and safe remote control.

This paper mainly adopts PLC-SIM as the controller, and the controlled object and control method are realized by PCS7. Firstly, the infrastructure of chemical reactor PCS7 is introduced, and then the structural model and automatic operation are built by CFC block and SFC block. Finally, the loop is designed and PID correction is carried out to obtain appropriate graphics.

2. PCS7 Project Basic Framework

In most cases, a project has ES stations, OS stations, AS stations and buses, and each station port has its special function [1], which is shown in Figure 2-1.
Figure 2-1 PCS7 framework

2.1. Engineer station

The engineer station (ES station) can achieve a series of operations such AS new construction, editing project files, and communication between AS station and OS station. In general, the design of ES station is completed in the software SIMATIC Mananger, and the configuration mainly consists of two links : AS station configuration and OS station configuration.

The configuration of automation station involves the compilation of continuous function diagram and sequential function diagram, factory level design, hardware configuration, communication network configuration and so on.

In the operator station, the process screen design and operation function design interface are mainly, and there are data archiving and protocol design.

2.2. Automation station

The automation station (AS station) is the control station of the Siemens DCS monitoring system, and the main modules of the station are: RACK, PS, CPU, I/O module, etc.

The CPU in PCS7 usually uses 400, in RACK, there are CP modules for the purpose of communication, but some CPU modules also have the function of communication directly, such as PROFIBUS DP interface or PROFIBUS DP serial communication module, through which to achieve device communication.

The automation station operates the system with fast industrial Ethernet access or the engineer station accesses the ET200 distributed I/O station using the Profibus-DP fieldbus. Note: The "block" in PCS7 is very critical, it is related to the work of the CPU in the software STEP7, the specific utility is shown in Table 2-1.

Table 2-1 Utility of blocks

Block	Utility
Tissue block (OB)	The function is to store the user master program and control successively.
System Function Block (SFB) and System Function Call Block (SFC)	They are stored in the S7 CPU so that they can implement some of the reserved functions.
Functional Block (FB)	It is a block that stores the user's own design.
Function call block (FC)	A subroutine that does not take up memory, but can be used repeatedly.
Background Data block (INSTANCE DB)	When a function block and a system function block are used, the block automatically connected with the block. No manual addition is required.
Data block (DB)	Its purpose is to store user data.
System Data Block (SDB)	It stores hardware configuration data.

2.3. Operator station

Most of the time operator stations are where we use the computer as a medium for control purposes. The OS configuration occurs at the engineer station, so it is feasible to consider the OS station project as part of the ES station project. Operator stations under distributed operating systems also have some basic two categories, the following is their introduction.

(1) Operator station server

The function of the operator station server is to pass the value in the program to another client that it has contact with, that is, the operator station client, and transfer the content of the OS station to the corresponding AS function block.

(2) Operator station client

The Data connection between the operator station client and the operator station Server is established through the Terminal Bus, and the data in the operator station server is accessed through Server Data.

The operator stands on the design, the configuration design of the above machine screen is the main work, should have the switch, operation panel CFC and SFC block writing and other functions, simulate the factory screen equipment diagram, in addition, there are data to archive and so on.

2.4. Factory bus and terminal bus

Plant Bus and Terminal Bus adopt Industrial Ethernet, which is consistent with IEC 802.3. This communication mode is mainly applied in network structure, most of which use optical fiber network as communication structure. Both the factory bus and the terminal bus will have good stability, and its role is to achieve reliable communication between various industrial communication buses.

For some medium or large specifications of industrial actual sites, it will have a high ball, for some industrial sites require a relatively smooth, fast contact device, PCS7 to provide it with optical fiber network and equipped with industrial Ethernet technology to achieve fast communication. The system uses advanced optical fiber connection technology and high-speed optical interconnection equipment, making it a new milestone in the field of communication. Among them, the latest and fastest Ethernet communication technology combines the scalable performance of switching technology with the high security of optical fiber ring network, and has a high data transfer rate and 1Gbit/S transfer rate, industrial twisted pair (ITP) and optical cable (FOC) can be used.

3. Mathematical Modeling and Automatic Operation of the Controlled Object

In PCS7, an engineering application, there are many ways to construct mathematical models.

3.1. CFC block

Also known as continuous function diagram, it is based on the function block to establish a numerical model of the controlled object, which has the function block of the

configured proportion, integration, differentiation, delay and operation, such function block is configured on the PCS7 has been programmed.

CFC block is used to build the object model, and operation block is used to construct the mathematical formula, so as to realize the mathematical modeling process of the controlled object.

For the establishment of the mathematical model of chemical reactor, the mathematical modeling of liquid level object, pressure object, feed object and temperature object was obtained by referring to the data and using CFC block.

1. Liquid level objects

Mainly: integral link and inertia link.

$$G(S)=\frac{3.25}{1+5.47S} * \frac{2.13}{0.97S} \qquad (3-1)$$

2. Objects of stress

Mainly: inertia link and integral link.

$$G(S)=\frac{2.78}{1+5.29S} * \frac{0.91}{5.58S} \qquad (3-2)$$

3. Feed flow

Mainly: the inertial link of its principal and subordinate reactants.

$$G(S)=\frac{1.87}{1+5.49S} \qquad (3-3)$$

$$G(S)=\frac{2.39}{1+4.68S} \qquad (3-4)$$

4. Temperature object

Mainly: the second stage of the lag time [2].

$$G(S)=0.6 * \frac{1}{4.29S} * \frac{1}{3.93S} \qquad (3-5)$$

3.2. SFC block

In the process of running, the simulation system automatically executes the sequence control program, uses SFC to initialize the initial value of the control parameters required by the whole control system, and executes each control loop in turn, which is shown in Figure 3-1.

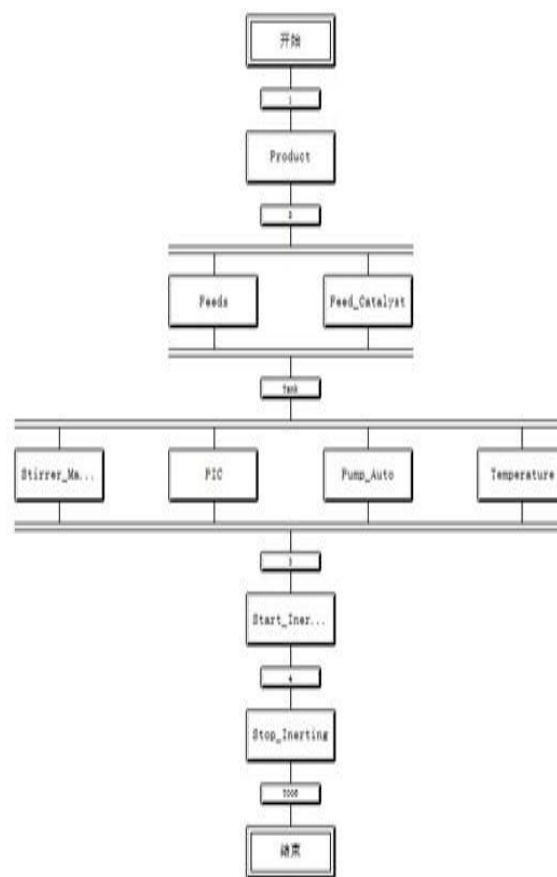
Each control loop enters the automatic control state according to the initial value, and after the implementation of the END step, the system will automatically enter the stable operation state, and the operation switch guide operator mode is fully controlled, that is, the operator can complete the automatic control according to the initial control target value, so that each control loop enters the automatic control state after the parameter initialization.


Figure 3-1 Simulating the SFC starting sequence

4. Design of Advanced Control Scheme for Simulation System of Chemical Reactor

The PID controller is used to control the reactor. The PID controller here uses the APL library of PCS7.

This topic has the feed part, the pressure part, the liquid level part and the temperature part.

The feed part is realized by a relatively simple ratio module, in which there are two modules, the master module and the slave module. The former controls the flow rate of the main reactant, the flow rate of the auxiliary reactant is controlled by the set value of the main module, the ratio controller provides two PID controls, and the latter controls the catalyst part of the reactant independently.

The pressure part is controlled by a separate PID module. To achieve this task, an initial setting value is set first. In actual simulation, if the running value exceeds our initial setting, the exhaust valve will be started; otherwise, if the running value is insufficient, the inert gas intake valve will be started until the process value each the set value. Then

the feedback control of the whole system is carried out by proportional integral and differential control method. In the liquid level part, a separate PID module is used to realize it.

In the temperature part, cascade control is used. The inner ring of cascade control adopts PID module to control the flow rate of hot and cold water valves to realize the control of jacket temperature [3]. The output MV of a PID module is adopted in the outer ring as the given value of the PID controller in the inner ring.

4.1. Liquid level control scheme

For the control of liquid level in the loop, a negative feedback closed-loop loop is used, as shown in Figure 4-1.
Figure 4-1 Pipes and devices

The value of the set value SP1 can be given by an external or internal PID controller whose parameters are tuned by the PID Tuner.

The liquid level control model, as shown in Figure 4-2 is built using the CFC block of PCS7.
Figure 4-2 Liquid level simulation objects

For these four parts, it is usually used in a user-defined closed-loop control system set by users, integrating the input values according to the ladder rule, and output the results.

Figure 4-3 shows the pipe diagram and function block of the liquid level control loop. A control loop is provided in the figure. The CFC block in Figure 4-4 is the liquid level control loop pipe.
Figure 4-3 Pipes and functional blocks of the

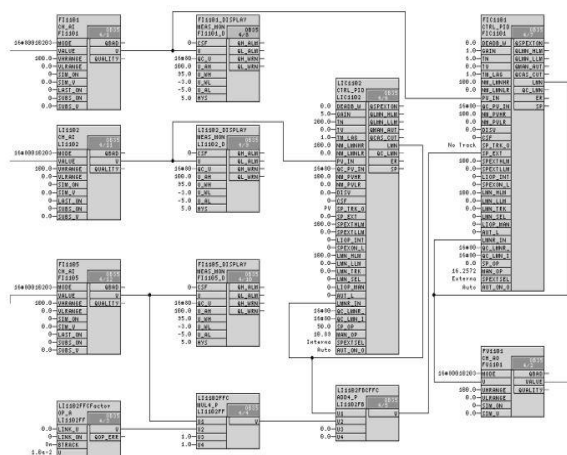
liquid level control loop


Figure 4-4 Connection structure of each CFC block in

the liquid level control loop

In addition, for the feed flow, pressure, temperature three parts, also to design the corresponding control scheme. Among them, the feed part is controlled by ratio, the pressure part is controlled by division, and the temperature is controlled by cascade.

4.2. Tuning of controller PID parameters

Using PID module to control the controlled object is very important for the parameters, and only appropriate parameters can meet our purpose. This topic only takes 4 control loops for example to study the liquid level control loop.

The PID Tuner tool is developed based on PCS7 software, and the data is collected and recorded through the background data block of PID function block, and the ideal data is obtained by simulation and applied in the controller. Different adjustment effects under various control modes can be achieved by setting. The tool

provides synchronous real-time data curve display of initial, median, and final values, and intuitive overall optimization functions are displayed.

Below, after proper PID tuning, the appropriate tuning pattern is obtained, which is shown in Figure 4-5.
Figure 4-5 Setting results of liquid level, flow rate, pressure, and temperature

Abstract

With the progressive exploration and application of formative assessment in university pedagogy, this evaluative method has become widely adopted for appraising students' everyday learning attitudes and conditions. Drawing upon pertinent data regarding classroom learning experiences of students at a specific university, this paper employs machine learning, K-means clustering, the TOPSIS evaluation model, and the entropy weighting method to investigate the relationship between formative assessment and the quality of university student learning, culminating in the creation of an evaluation model. This model allows us to pinpoint the key factors influencing student learning attitudes and offers support for formative assessment in the university context.

Keywords: University Process Assessment, attitude toward learning, machine learning, TOPSIS Evaluation model

1. Introduction

With the continuous deepening reform of education and teaching mechanism, the educational method of process assessment has been widely explored and applied by more and more universities. Compared with the outcome assessment, the process assessment can better evaluate the students' learning attitude and state [1].

In the process assessment, students' learning attitude is mainly affected by the objective environment and subjective initiative [2]. This paper will explore which factors have a greater impact on students' learning attitude, build a mathematical model that can reasonably evaluate the school's learning style and class style, and build an evaluation model that can reflect the level of students' learning enthusiasm.

The rest of this article is organized as follows. The second part analyzes the data and explores the factors that reflect students' learning attitude. The third part introduces the construction of evaluation model. The fourth part analyzes the evaluation model and the results obtained. The fifth part summarizes the main content of this paper.

2. Data Analysis

The data collected students' student number, college, class, course code, class code, teacher code, test name, test time, test full score, student score and normalized score. It should be noted that students choose different courses within the scope of core basic courses, some students choose multiple courses, some students choose only one course; Some students may have done work that was not posted by the class teacher; Some students don't take every test for some reason; Teachers in the same course don't publish pre-class tests the same often.

Yuhao Zhang, Ying Gong, Xuran Wang

In order to explore which factors have a greater impact on students' learning attitude, it is necessary to explore the control variables. The following will explore the influence of college factors, the number of courses selected by students, the attendance rate of students, and the factors of major, class, course, teacher and classroom on students' learning attitude.

2.1. College factor

By calculating the average scores of students in different colleges of the same course, and then summarizing all colleges, the average and variance of the scores of students in each college are obtained. The data are shown in Fig. 1.

Fig. 1 College factor visualization

The average score of students in different colleges is different, and the stability of grades is also different. Therefore, the learning atmosphere of different colleges is different, and students' learning attitude is also different. Therefore, students' learning attitude is affected by the factor of college.

2.2. The number of courses taken by students

We define the average of each student's normalized scores on several tests as the student's representative score. The number of courses selected by each student is 1, 2, and 1 of 3. The representative scores of students with 1, 2, and 3 courses selected respectively are calculated, and the corresponding scatter map is shown in Fig. 2.
Fig. 2 figure of the number of selected courses

As can be seen from Fig. 2, with the increase in the number of courses selected by students, the average scores of students are basically the same, and the overall scores of students are higher and more and more stable. It can be inferred that the more courses a student chooses, the higher the student's enthusiasm for the course and the better the attitude.

2.3. Student attendance

When the total number of tests for each course is taken as the number of the last measurement for this course, that is, the total number of tests organized by the teacher for this course, the attendance rate of each student is obtained. The scatter plot corresponding to the attendance rate of students and the representative score is shown in Fig. 3.
Fig. 3 Scatter plot of attendance

Count the number of people with scores greater than 80 in each attendance range and draw a bar chart, which is shown in Fig. 4.
Fig. 4 attendance and high score statistics chart

As can be seen from Fig. 3 and Fig. 4, when students' attendance rate is small (0-0.4), students' high scores are compared. With the increase of students' attendance rate, students' scores are generally higher, and with the increase of students' attendance rate, the number of students who get high scores is increasing. Therefore, students' attendance rate has a great impact on students' scores and can better reflect students' learning attitude.

2.4. Major, class, curriculum, teacher factor

Calculate the average grade and variance of grades for each major, each class, each course, and each classroom, as well as the average grade and variance of students taught by each teacher.

After analysis, the following conclusions are reached:

(1) Students' learning attitude is influenced by their major, but the influence is small. (2) On the whole, students' grades and the stability of grades are also different depending on the class they belong to. Therefore, students' learning attitude is affected by class factors. (3) The overall performance of students taught by some teachers is poor and unstable; The rest of the teachers taught students different overall grades, but the fluctuation is not large, can reflect the true level. Therefore, students' learning attitudes are influenced by their teachers and courses.

3. Construction of Evaluation Model

Data for all students in each college and class is aggregated to get an average of average test scores, average test participation rates, and number of courses taken by students in each college and class. This will result in a dataset consisting of the college (or class), average test score, average test participation rate, and number of courses taken. Since there are few indicators, TOPSIS method is adopted here [3].

3.1. Data standardization

Since attendance, grade point average, and average number of courses taken are all positive indicators, it is only necessary to standardize the dataset consisting of college (or class), average test score, average test participation rate, and number of courses taken.

3.2. Calculate index weight

To ensure the objectivity and scientificity of the index weights, entropy weight method and analytic hierarchy process are used to determine the index weights, and the weights are shown in Fig. 5.

	attendance rate	grade	Average number of courses selected
College weight	0.24935	0.3984	0.35225
Class weight	0.28405	0.3831	0.33285

Fig. 5 index weight

3.3. Calculating the score

Define the maximum value Z^+ as the maximum value of each column in the vector matrix and define the minimum value Z^- as the minimum value of each column in the vector matrix. Define the distance of the i $(i = 1,2,…,n)$ evaluation object to the maximum value as:

$$D_i^+ = \sqrt{\sum_{j=1}^m \omega_j \left(Z_j^+ - z_{ij}\right)^2} \qquad (1)$$

Define the distance of the i $(i = 1,2,…,n)$ evaluation object to the minimum value as:

$$D_i^- = \sqrt{\sum_{j=1}^m \omega_j \left(Z_j^- - z_{ij}\right)^2} \qquad (2)$$

Then, we can calculate the non-normalized score of the i $(i = 1,2,…,n)$ evaluation object as:

$$S_i = \frac{D_i^-}{D_i^+ + D_i^-} \qquad (3)$$

It is evident that $0 \le S_i \le 1$, and the larger S_i the smaller D_i^+, indicating closer proximity to the maximum value. By incorporating the obtained indicator weights into the calculation of sample distances, we obtain the score for each sample [3].

4. Introduction of Result

According to the above model construction, MATLAB is used to calculate, and the final answer is obtained.

4.1. Evaluation hierarchy

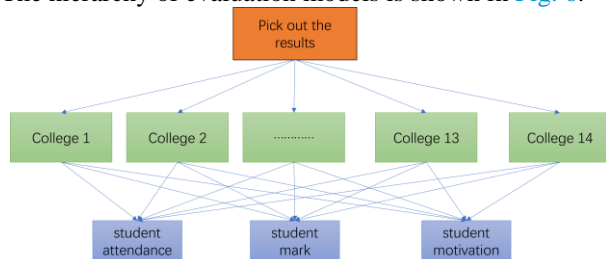
The hierarchy of evaluation models is shown in Fig. 6.


Fig. 6 evaluation hierarchy diagram

4.2. Personal evaluation model

Here, we want to find the best and worst people, and we first cluster them using K-Means into better and worse groups. Then, the two groups were evaluated by TOPSIS, and the evaluation index was the student attendance rate, the number of courses selected, and the individual performance [2].

5. Conclusion

Through the students' usual performance to construct the process evaluation model, get the factors that affect students' learning attitude, and can find the class, college, and students with better performance through the data.

This research will help colleges and universities to carry out process assessment better.

Abstract

This paper investigates the posture trajectories in human motion using pose recognition technology based on the deep learning framework MediaPipe. By detecting key points on the human body and plotting and calculating these trajectories in the temporal dimension, we further conduct comparative analysis of these trajectories with professional sports coaches' motion guidance to assist athletes in correcting their posture. Additionally, this technology has been deployed on Jetson Nano, enabling its practical application in mobile scenarios, and providing robust tools and methods for fields such as rehabilitation therapy, sports training, and animal behavior analysis. This study offers insights into the transfer applications of posture recognition.

Keywords: deep learning, MediaPipe, posture recognition, Jetson Nano

1. Introduction

With the continuous development of artificial intelligence, artificial intelligence technology has played a huge role in the development of the sports and fitness industry. Moreover, with the continuous development of economy and society and the continuous improvement of people's living standards, people are more and more willing to strengthen their health through physical exercise. The application of artificial intelligence technology in sports will inject vitality into the sports industry.

People in the usual self-training, because there is no manual coach guidance, which will make the athletes can not get timely feedback when improving skills. Through the use of the MediaPipe framework developed by Goole company to realize the identification of human bone key points, through the changes of bone points in continuous time to draw the human movement trajectory, and then analyze the movement Angle of each action [1]. This will provide a wealth of data for athletes to continuously optimize their level.

The posture analysis of athletes has been deployed on the Jetson Nano, so that athletes can be monitored by moving the jetson nano, whether they are exercising outdoors or indoors [2]. In addition, we added the camera to the steering gear, so that the camera can follow the movement in real time and accurately analyze the attitude data.

In addition, the continuous actions in the same period of time can be transferred to the movement of animals, such as octopus, snake and other animals, through deep learning to train a model to identify key points, and then analyze the movement behavior of animals, which will help us better understand animals [3].

The rest of this article is organized as follows. The second part introduces the hardware. The third part introduces the software part. The fourth part analyzes the captured motion changes. The fifth part summarizes the main content of this paper.

2. The Hardware Structure

The main hardware used in this research is jetson nano, steering gear and high-definition camera. The camera is moved through the steering gear to better capture people's posture information, and the powerful image processing capability of jetson nano is used for data analysis.

Yuhao Zhang, Mingyue Li, Jianhao Jiao

2.1. Jetson nano

Jetson Nano is an embedded computing platform based on NVIDIA Maxwell architecture with a 128-core NVIDIA Maxwell GPU and quad-core ARM Cortex-A57 CPU that delivers high-performance deep learning and computer vision capabilities. The board supports a variety of peripheral connections, including GPIO pins, I2C buses, UART serial ports, and more, making it an ideal platform for integrating a wide range of sensors and actuators [2]. Jetson Nano runs Ubuntu Linux with strong software support for deep learning and computer vision applications. The jetson nano used in this study is shown in Fig. 1.

Fig. 1 Jetson Nano

2.2. IMX415 HD camera

Sony's IMX415 HD camera is our choice. The camera features 8.46M effective pixels, a frame rate of up to 120fps, and a field of view Angle of 130 degrees, providing the system with clear, high-resolution images. To provide the system with clear, high-resolution images. The IMX415 is an advanced image sensor for applications that require high-quality image capture, such as our attitude recognition system. The IMX415 HD camera used in this study is shown in Fig. 2.

Fig. 2 IMX415 HD camera

2.3. DS3230 digital steering gear

Two DS3230 digital steering engines are used in this study. This steering gear provides precise Angle control, enabling the system to dynamically adjust the direction of the camera according to the movement of the target object, achieving a 360-degree rotation. Through the steering engine, we can realize the full range of the target object trajectory capture. The DS3230 digital steering gear used in this study is shown in Fig. 3.

Fig. 3 DS3230 digital steering gear

3. Software Distribution

In software development, this design is based on MediaPipe open-source framework development, and combined with OpenCV to achieve the complete code.

3.1. Introduction to MediaPipe

MediaPipe is an open-source computer vision library developed by Google to provide developers with a flexible and efficient set of tools to build visually aware applications. It is designed to simplify the development process of computer vision tasks by providing pre-trained models and easy-to-use Apis that make it easier for developers to implement a variety of visual tasks. The main performance is as follows:

(1) Real-time performance: MediaPipe focuses on real-time computing, enabling low latency and efficient real-time image processing on multiple hardware platforms.

(2) Multimodal input: Support a variety of input sources, including images, videos, camera streams, etc., making it suitable for a variety of scenes and devices.

(3) Rich pre-trained models: MediaPipe offers a range of pre-trained models covering many areas such as human pose estimation, hand tracking, face detection, etc., which can be used to quickly build various computer vision applications.

(4) Cross-platform support: MediaPipe supports multiple operating systems (including Linux, Windows, Android, iOS) and a variety of hardware accelerators (such as Gpus, Tpus), making it widely portable.

In this design, we chose the MediaPipe framework as the basis to realize the key function of attitude recognition. By combining OpenCV, we were able to flexibly process camera input and use the pre-trained model provided by MediaPipe to accurately capture key pose information of the target object. This combination allows us to quickly build a powerful computer vision system for monitoring and analyzing the movements of target objects.

3.2. Establishment of trajectory analysis model

Let's take the motion analysis of one arm as an example. Using the MediaPipe framework, call the poseLandmarkerResult function to generate the three-dimensional coordinates of the key points. In Fig. 4 below, A, B, and C represent the three nodes of the arm. The poseLandmarkerResult function can be used to return the three-dimensional coordinates of the node, and can draw the trajectory motion [1].
Fig. 4 Keypoint graph

Then according to the following formula, the angular distance change of the node relative to the previous state can be calculated.

$$\theta = arc\,cos\left(\frac{\overrightarrow{AB}*\overrightarrow{BC}}{|\overrightarrow{AB}|\cdot|\overrightarrow{BC}|}\right) \qquad (1)$$

4. Introduction of Result

Running the code on the jetson nano shows the trajectory on the screen and can calculate the Angle between the nodes.

4.1. Effect of display

As shown in Fig. 5 below, the trajectory of the key points of the arm in a period of time can be drawn, so that the movement posture of the professional athlete can be compared, and the change of the Angle of the joint can be accurately viewed to help the athlete find the correct movement posture.

Fig.5 effect display diagram

Through the object detection algorithm, the camera can capture objects such as tennis balls and ping-pong balls, which can better identify the position of people [2]. The display effect is shown in Fig. 6.
Fig. 6 object identification

4.2. Idea transfer application

It has far-reaching and multi-level significance to transfer human posture recognition technology to animals to realize key point detection and trajectory tracking. This not only provides new research avenues in the field of biology, deepening the understanding of animal ecology, behavior, and physiology, but also brings substantial contributions to wildlife conservation, livestock management and scientific education. Through the application of this technology, we can monitor the movement patterns, posture changes and behavior patterns of animals in real time, providing a scientific

basis for protecting endangered species, monitoring wildlife migration, and improving the efficiency of livestock production [3].

5. Conclusion

Through the movement posture analysis of human arm as an example, the trajectory of the athlete is successfully analyzed, which also reflects the key points of the whole body, and the movement posture analysis will help the athlete to correct the posture in a more three-dimensional way. And this model is deployed on the jetson nano, which will facilitate device movement. The transfer of posture analysis to animal movement behavior will greatly help the study of animals.

Abstract

In this paper, the functional safety evaluation of the safety protection system of gasoline hydrogenation unit was carried out using Petri net. Firstly, the principle and framework of the gasoline hydrogen refueling unit was described. Secondly, the safety integrity level was introduced, and the influencing factors of the safety integrity level were summarized. Thirdly, the Petri net model and the Markov model are compared and the Petri net model is used to verify its security integrity level. Finally, the calculation result demonstrated that the SIL did not reach the target level, and then reached the target level after improvement. This analysis method can provide reference for the safety integrity level evaluation of similar devices.

Keywords: Gasoline hydrogenation, Petri net, Functional safety assessment

1. Introduction

With the passage of time, modern science and technology continue to develop, the number of vehicles climbed. The sulfides produced by automobile exhaust have a great impact on air quality. Therefore, the production of clean gasoline is very important for environmental protection. In response to this problem, we have proposed the hydrogenation of gasoline. The purpose of gasoline hydrogenation is to desulfurize at a small octane loss. Gasoline hydrogenation equipment is a device used for filling the car fuel tank, which includes liquid level sensors, flowmeters, valves and other equipment. Because it is usually operated in high temperature, high pressure and hydrogen environment, there are safety risks, which requires us to do a good job of safety protection, equipped with safety instrument system. Safety instrument system is composed of sensor logic controller and actuator, it can perform one or more absolute safety control instrument functions. Petri networks, which can intuitively describe the relationship between system states and events, are widely applied in many fields. Therefore, the functional safety assessment of the safety protection system of the gasoline hydrogenation unit based on Petri network is a topic worth discussing.

The rest of this article is organized as follows. The second section introduces the research status at home and abroad about the gasoline hydrogenation technology and the safety analysis. In the third part, the gasoline hydrogenation unit is presented. In the fourth section, a example is given to analysis the risk of facility. In the fifth part verifies and improves the safety integrity level of gasoline hydrogenation unit. The sixth part summarizes the main content of this paper.

2. Research Status at Home and Abroad

2.1. Research status of gasoline hydrogenation technology

At present, most of the catalytic raw materials selected by the manufacturers in China have the problem of excessive metal content, as well as excessive sulfur content and non-hydrocarbon components. These problems will not only cause the decline of product quality in the gasoline production process, but also cause the problem of environmental pollution in view of the existence of many

sulfur and other elements in the production process. In the production process, using diolefin saturation treatment can effectively reduce the occurrence of olefin coking phenomenon; in addition, in the relatively mild reaction environment, the influence of impurities can be further reduced, so as to reduce the octane value factors and losses, and better meet the relevant national technical standards and production requirements.

2.2. Research status of safety analysis

The gasoline hydrogenation equipment of a chemical plant in China uses a set of independent safety instrument system (SIS) for safety control. Its process is complex, and the operating environment is high temperature and high pressure, involving flammable and explosive gases, which requires close monitoring. Since its launch, the application of SIS system has significantly improved the stability and reliability of the equipment, realized safe, stable and efficient operation, avoided the occurrence of equipment shutdown and failure problems, at the same time brought economic benefits to the enterprise, but also guaranteed the personal safety of workers.

2.3. Application of petri network in system security analysis

Petri was first proposed by Kal Adam Peri. Petri network represents the system model in the form of a mesh structure model. Petri network is a visual mathematical modeling tool that contains elements such as place, transition, arc and token, which can represent the static function and structure of the system. In addition, Petri networks combine data flow, control flow, and various logical relationships to support a more rich and complex system modeling, allowing for a better analysis of the dynamic behavior of a specific system.

3. Analysis of the Gasoline Hydrogenation Unit

The raw oil is introduced into the filter through an external device, and the purpose of the overall filtration is to separate the particles in the raw material. Among them, after the large particles are removed, they enter the selective hydrogenation feed equipment. The feed can be used as a way to select the hydrogenation reactor feed pump to control the flow rate to achieve a reasonable effect, and then use the supplementary hydrogen mixing mode to form a mixed feed. First, the mixture is sent to the selective hydrogenation reaction device, and the heat exchange is

carried out by means of the hydrodesulfurization reaction. The heating is stopped after the temperature is repeatedly raised to a suitable temperature. Next, the diene to olefin reaction is carried out to meet the requirements. In order to ensure the smooth progress of the whole reaction process, we introduce the catalyst under suitable catalytic conditions for the reaction. After the reaction is completed, we will use a tandem selective hydrogenation reactor to reprocess the product. Through the hydrogenation static desulfurization treatment, and the selective hydrogenation reaction redox reaction, the heat exchange is finally realized through the heat exchanger, and then after the treatment of the catalyst, the saturated state of the olefin product is successfully obtained.

During this process, the reactant is reinjected into the heat exchanger for heat exchange. When it reaches a certain extent, the subsequent reaction of the reactants can be continued. By adjusting the temperature and the interaction of the catalyst, they enter the second reactor for desulfurization treatment, and the catalyst can efficiently achieve the requirement of complete desulfurization. The product of hydrodesulfurization reaction enters the heat separation tank after heat exchange, and the gas phase is added to the product cold separation tank and circulating cleaning equipment after air cooling and cooling of the desulfurization reaction. After the treatment of desulfurization and hydrogenation reaction, the obtained product will be transported to the separation tank after gas phase cooling. In the separation tank, part of the oil phase material will be separated. After it is stable, the non-condensable gas will be transported to the liquid separation tank for further treatment. The separated liquid is discharged after condensation treatment through the condenser, and some of the gas is sent to the gas-liquid separator to mix with water vapor and return to the heat exchanger to continue heating. Then, the product after pressure stabilization treatment is transported to the absorption tower, and then processed again by the liquid separation equipment of the circulating hydrogen compressor. After the mixed hydrogen treatment, it meets the needs of desulfurization production.

4. Device Risk Analysis

4.1. Confirmation of the SIL level

Safety Integrity Level is a measure of the safety of safety instrument system and enterprise safety instrument system management level, its value represents the order of risk

reduction level. The three foundations for determining the level of security integrity are: structural constraints, system capabilities, and hardware security integrity. The safety integrity of hardware mainly depends on the reliability of hardware in the case of dangerous failure. The influence of these factors mainly includes the failure model, system structure, functional test cycle and component reliability level. In the IEC61508 standard, the safety integrity level is divided into four levels, and the operation mode of the system is divided into low requirement operation mode and high requirement operation mode. In the low requirement operation mode, the SIL level is based on the average failure probability, while in the high requirement or continuous operation mode, the SIL level is based on the average failure probability per hour. The requirements for SIL levels for different operating modes, which are shown in Table 1 and Table 2.

Table 1 The SIL level for the low-requirement operation mode

Low-required operation mode		
Safety integrity level	Average probability of failure on demand	Risk reduction factor
（SIL）	（PFD_{avg}）	（RRF）
4	$10^{-4}\sim10^{-5}$	10000~100000
3	$10^{-3}\sim10^{-4}$	1000~10000
2	$10^{-2}\sim10^{-3}$	100~1000
1	$10^{-1}\sim10^{-2}$	10~100

Table 2 The SIL level for the high requirement operation mode

The SIL level for the high requirement operation mode	
Safety Integrity Level	Meverage hourly failure probability
（SIL）	PFH_{avg}
4	$10^{-8}\sim10^{-9}$
3	$10^{-7}\sim10^{-8}$
2	$10^{-6}\sim10^{-7}$
1	$10^{-5}\sim10^{-6}$

The SIS system is more focused on monitoring whether there are risk conditions in the production process and reducing the possibility of risk occurrence. The scheme is a passive system, which is generally in a non-dynamic state. Only when necessary, it will play a role and will not actively participate in the normal operation of the basic process control system. The safety life cycle covers the entire period from the conceptual design of the project to

the discontinuation of SIF. Under certain time and conditions, the possibility of safety-related systems performing their prescribed safety functions can be called safety integrity level (SIL), which represents the level of reducing the risk of safety instrumented systems. It is very important to select the appropriate SIL level. If the selection is too high, it will cause cost waste, and if it is too low, it will bring unacceptable risks. According to the IEC61508 standard, SIL4 level is the highest and SIL1 level is the lowest.

4.2. Influencing factors of safety integrity level
- Failure mode
- Redundant structure
- Common cause failure
- Diagnostic coverage rate
- Periodic function test
- Maintenance mode

4.3. Safety integrity level verification

Hardware security integrity is a part of the overall security integrity of SIS, and its influencing factors include failure mode, component failure rate and detection cycle. When evaluating an interlocking circuit, it is necessary to determine its failure probability to determine its SIL level. Finally, the SIL verification results are compared with the grading analysis results to verify whether the circuit meets the requirements. In order to meet the requirements of SIL grading analysis, it is necessary to reset the layout structure, component selection, redundant design and maintenance plan of the interlocking loop. IEC standard provides a variety of methods to verify SIL level, including simple formula method, reliability block diagram method, fault tree analysis method and Markov model method.

For the transition of the system state, the Markov model is represented by a circle and an arrow, which represent the state of the system and the transition between states, respectively. The Markov model of the 1oo1 structure is shown in Fig. 1.
Fig.1. 1oo1 redundant structure Markov model

The state transition matrix of 1oo1 redundant structure is P [1].

$$P = \begin{bmatrix} 1-(\lambda_s + \lambda_D) & \lambda_{SD}+\lambda_{SU} & \lambda_{DD} & \lambda_{DU} \\ \mu_{SD} & 1-\mu_{SD} & 0 & 0 \\ \mu_0 & 0 & 1-\mu_0 & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix} \quad (1)$$

To calculate the mean time between failures, you can use the system state transition diagram, the system state transition diagram is shown in Fig. 2.

Fig.2 1oo1 structure Markov model (MTTFS)

The corresponding matrix is:

$$Q' = 1 - (\lambda_{SD} + \lambda_{SU}) \quad (2)$$

And because:

$$N = [I - Q']^{-1} \quad (3)$$

Therefore:

$$N = \frac{1}{\lambda_{SD} + \lambda_{SU}} \quad (4)$$

The sum of the elements of the N rows of the matrix is the result of MTTFS:

$$MTTF = \frac{1}{\lambda_{SD} + \lambda_{SU}} \quad (5)$$

The formula of system dangerous failure probability is:

$$PFS = S_0 P^{8760} \begin{bmatrix} 0 & 1 & 0 & 0 \end{bmatrix}^T \quad (6)$$

The formula of system safety failure probability is:

$$PFD = S_0 P^{8760} \begin{bmatrix} 0 & 0 & 1 & 1 \end{bmatrix}^T \quad (7)$$

Markov model is a model that can represent the dynamic behavior of the system. It can consider multiple reliability factors, and multiple reliability indexes can be obtained by one modeling. However, it will face problems such as space explosion. Especially when the complexity of the system increases, the difficulty of this method will increase greatly.

The stochastic Petri net is used to analyze the hardware failure probability, which solves the problem of Markov state explosion, reveals the dynamic characteristics of the system, and can evaluate the hardware safety integrity of the safety instrumented system.

5. Verification of safety integrity level of gasoline hydrogenation unit

In this section, SIL is evaluated for one of the dangerous scenarios SIF5 of the gasoline hydrogenation unit. The main fuel gas of the fractionator reboiler F9101 of SIF5 is selected to set low pressure and low PSLL6049 A / B / C (2oo3) interlock shutdown XV6011 as a representative. In this process, the components to be considered are as follows.

- SIF serial number:SIF5
- Accident scenario：The pressure of F9201 fuel gas in the hydrodesulfurization heating furnace is too low, which leads to the extinction of the main nozzle. If the fuel gas continues to enter the furnace, the furnace explosion accident may occur.
- Consequence description:The pressure of F9201 fuel gas in the hydrodesulfurization heating furnace is too low, which leads to the extinction of the main nozzle. If the fuel gas continues to enter the furnace, the furnace explosion accident may occur.
- SIF function description:F9101 main fuel gas setting pressure is low PSLL6049A / B / C (2oo3) interlock closed XV6011.
- SIL target: SIL2

In this process, the components to be considered include as shown in Table 3.

Table 3 Components to be considered for SIF5

Sensor Part Pressure Sensor	PSLL6049A / B / C (2oo3)
	Safety barrier (1oo2)
Logic controller part	PLC （2oo3）
	Relay 1 (1oo1)
Actuator	Emergency Shut-off Valve XV6011 (1oo1)
	Relay 2 (1oo1)

In order to evaluate random hardware failures, complete failure data of systems and components are required, considering functional test cycles and common cause failures. These factors will be included in the evaluation category in order to more accurately determine the random hardware failure probability of the system, and then evaluate its hardware security integrity level. The failure

probability of the system needs to meet the system requirements.

$$PFD_{avg} = PFD_{avg\ sensor} + PFD_{avg\ PLC} + PFD_{avg\ actuator} \quad (8)$$

The relay 1, relay 2, emergency cut-off valve and solenoid valve are all 1oo1 redundant structure, while the safety gate is 1oo2 redundant structure to ensure the stability and reliability of the system. Based on the Petri net model, the average failure probability of the emergency shut-off valve is calculated.

The state transition matrix Q is :

$$Q = \begin{bmatrix} -7.48\times10^{-6} & 2.34\times10^{-6} & 4.73\times10^{-6} & 4.13\times10^{-6} \\ 5.71\times10^{-5} & -5.71\times10^{-5} & & \\ 0.04167 & & -0.04167 & \\ 0.125 & & & -0.125 \end{bmatrix} \quad (9)$$

Equation solving:

$$\begin{cases} XQ = 0 \\ \sum_i Xi = 1, 1 \le i \le n \end{cases} \quad (10)$$

Solution:

$$PFD_{avg\ Cut\text{-}off\ valve} = 1.98\times10^{-2}$$
$$PFD_{avg\ Relay\ 1} = 2.455\times10^{-6}$$
$$PFD_{avg\ Solenoid\ valve} = 7.454\times10^{-4}$$
$$PFD_{avg\ Safety\ barrier} = 7.902\times10^{-4}$$
$$PFD_{avg\ Relay\ 2} = 2.5164\times10^{-6}$$

PLC,the system sensor is a 2oo3 redundant structure, and the reachability diagram of the 2oo3 structure Petri net is shown in Fig. 3.
Fig. 3 2oo3 structure reachable graph

The state matrix is:

$$Q = \begin{bmatrix} -0.125 & 4.38\times10^{-7} & 6.54\times10^{-7} & 1.75\times10^{-6} & 2.62\times10^{-6} & 1.81\times10^{-6} \\ 5.71\times10^{-5} & -5.71\times10^{-5} & 0 & 0 & 0 & 0 \\ 0.125 & 0 & -0.125 & 0 & 0 & 0 \\ 0 & 1.31\times10^{-6} & 1.97\times10^{-6} & -6.66\times10^{-6} & 0 & 0 \\ 0.125 & 0 & 3.28\times10^{-6} & 0 & -0.125 & 0 \\ 0 & 1.46\times10^{-7} & 2.18\times10^{-7} & 0 & 0 & -6.66\times10^{-6} \\ 0 & 0 & 1.82\times10^{-6} & 0 & 0 & 0 \\ 2.71\times10^{-6} & 1.46\times10^{-7} & 2.18\times10^{-7} & 0 & 0 & 0 \\ 0.0417 & 0 & 0 & 0 & 0 & 0 \\ 0.125 & 7.28\times10^{-7} & 1.08\times10^{-6} & 0 & 0 & 0 \\ 0 & 7.28\times10^{-7} & 1.08\times10^{-6} & 0 & 0 & 0 \\ 0 & 0 & 1.82\times10^{-6} & 0 & 0 & 0 \end{bmatrix}$$

$$\begin{bmatrix} 0.125 & 2.71\times10^{-6} & 1.13\times10^{-6} & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 1.80\times10^{-6} & 3.76\times10^{-6} & 1.20\times10^{-6} & 0 & 0 \\ 1.80\times10^{-6} & 0 & 3.76\times10^{-6} & 0 & 0 & 1.20\times10^{-6} \\ 0 & 0 & 3.38\times10^{-6} & 1.16\times10^{-6} & 0 & 1.75\times10^{-6} \\ -3.7\times10^{-6} & 0 & 1.88\times10^{-6} & 0 & 0 & 0 \\ 1.75\times10^{-6} & -9.37\times10^{-6} & 3.88\times10^{-6} & 0 & 1.16\times10^{-6} & 0 \\ 0 & 0 & -0.0417 & 0 & 0 & 0 \\ 0 & 0 & 1.88\times10^{-6} & -0.125 & 0 & 0 \\ 0 & 0 & 1.88\times10^{-6} & 0 & -3.69\times10^{-6} & 0 \\ 0 & 0 & 1.88\times10^{-6} & 0 & 0 & 3.7\times10^{-6} \end{bmatrix} \quad (11)$$

Equation solving:

$$\begin{cases} XQ = 0 \\ \sum_i Xi = 1, 1 \le i \le n \end{cases} \quad (12)$$

Solution:

$$PFD_{avgPLC} = 1.21\times10^{-6}$$
$$PFD_{avg\ sensor} = 2.3\times10^{-4}$$

Then $PFD_{SIS} = PFD_{avg\ cut\text{-}off\ valve} + PFD_{avg\ relay1} + PFD_{avg\ solenoid\ valve} + PFD_{avg\ relay2} + PFD_{avg\ safety\ barrier} + PFD_{avg\ PLC} + PFD_{avg\ sensor} = 2.15\times10^{-2}$, which does not meet the SIL2 requirements and needs to be adjusted. It can be seen from Table 3-10 that the shut-off valve has the greatest influence on the total PFD of the equipment is the shut-off valve,which is shown in Table 4.

Table 4 The contribution of subsystem to system PFD

Systematic name	Proportion of impact on PFD
Cut-off valve	90%
Solenoid valve	3%
Pressure sensor	4%
Safety barrier	3%

Therefore, we can take the transformation of the emergency shut-off valve and increase the emergency shut-off valve group to realize the transformation from the 1oo1 structure to the 1oo2 redundant structure. After the transformation, the $PFD_{avg\ shut\text{-}off\ valve'} = 4.36\times10^{-3}$. After the transformation, $PFD_{SIS} = PFD_{avg\ shut\text{-}off\ valve'} + PFD_{avg\ relay1} + PFD_{avg\ solenoid\ valve} + PFD_{avg\ relay2} + PFD_{avg\ safety\ barrier} + PFD_{avg}$

$_{PLC}$ + PFD$_{avg\ sensor}$ = 6.13×10^{-3}, which meets the SIL2 safety requirements.

6. Conclusion

In recent years, China has paid more and more attention to production safety, and the government has also issued relevant policies and regulations for industries with high risks. In this context, the automation level of China 's petrochemical enterprises has been continuously improved, which provides good conditions for ensuring production safety. Driven by the policy, with the superposition of new facilities and demand and the increase in the demand for facilities upgrading, SIS system will be more widely used and play a vital role in today 's society and the country. The main conclusion of this paper is that the security level of the system depends on many factors, among which structural constraints, system capability and hardware security integrity level are crucial factors. In order to ensure the safe operation of the system, it is necessary to make reasonable analysis and judgment on these factors. Explore a variety of factors that affect the functional safety of safety instrumented systems, and use Petri net models to model and optimize them, so as to improve the level of safety instrumented systems.

Abstract

This paper studied pedestrian attribute recognition based on deep learning, for its importance in the fields of smart city construction. Firstly, the research status of pedestrian attribute recognition and common deep learning models was introduced. Secondly, considering the accuracy decline problem and gradient problem of the neural network, the residual network was used as the main body of the neural network model. Thirdly, the model was trained to classify multiple person attributes through two data sets, Market-1501 and DukeMTMC-reID. Finally, the pedestrian attribute recognition model was tested, and good results were obtained.

Keywords: Neural networks, Pedestrian attributes, ResNet50

1. Introduction

The contribution of attribute recognition technology in medical, security, intelligent furniture and other fields has attracted more and more attention. After the introduction of deep learning algorithms in the computer field, the computer has realized the processing and application of massive information through continuous learning. The person attribute recognition based on deep learning extracts the feature information of a known pedestrian photo through the convolution and pooling network model, and classifies it to obtain several attributes about the person. The acquisition of these attributes brings important practical applications to the fields of smart city construction and military security.

In this paper, we first introduce the research background and current research status of pedestrian attribute recognition. In the second chapter, the theoretical basis of deep learning will be introduced, and the attribute recognition of pedestrians will be mainly studied and verified by relevant experiments. In the third chapter, the full text is summarized, discussed and analyzed.

2. Methods and results of pedestrian attribute recognition

In the field of computer vision, deep learning has become a basic tool. In this study, a large number of deep learning concepts will be used, and deep learning neural networks will be used to identify pedestrian attributes. Finally, results will be obtained in experiments..

2.1. The emergence of artificial neural networks

T Landahl et al. first proposed artificial neural network, which is a network model built by imitating the connection of nerve cells in the nervous system of animals. As shown in Fig. 1, each circle represents neurons and arrows represent the direction of signal transmission, which is similar to the synapses in nerve cells to transmit signals.
Fig. 1 Artificial neural network structure diagram

Peng Wang，Qikun Wang, Shengfeng Wang

As the basic part of the neural network model, the calculation formula of neurons is as follows:

$$y = f_{active}(\sum_{i=1}^{n} w_i * x_i + b) \quad (1)$$

Where, xi represents the ith input of the neuron, wi is the weight parameter of the input, which can be changed, n represents a total of n neuron inputs, and b is the bias value. Here is called the activation function, a neuron multiplies the input with a weight and then adds a bias value, which is output to the next layer through the activation function.

In the deep learning network, the weight value and bias value are the parameters that need to be learned. Through continuous learning, the gap between the output value and the real value becomes smaller and smaller.

2.2. Principle analysis of convolution layer

As shown in Fig. 2, the function of the convolution layer is to use multiple convolution operations to extract multi-channel eigenvalues from the output of the upper layer, and then send these eigenvalues as outputs to the next layer. The convolution layer reduces the parameters to be trained in the process of layer by layer extraction. In a given image, the local pixel information is converted to the corresponding information of the output image after weighted addition. The part of the convolution layer used for convolution is called the convolution kernel, its size can be defined, and the parameters in it are the parameters we want to train.

Other parameters we define in the convolution kernel determine the effect of image data extraction, including fill, number of output channels, number of input channels, and step size. The size of the convolution image is:

$$H_{out} = \left[\frac{H_{in}+2\times padding[0]-dilation[0]\times(ker\,nelsize[0]-1)-1}{stride[0]} + 1\right] \quad (2)$$

$$W_{out} = \left[\frac{W_{in}+2\times padding[1]-dilation[1]\times(ker\,nelsize[1]-1)-1}{stride[1]} + 1\right] \quad (3)$$
Fig. 2. Schematic diagram of convolution operation of 3*3 convolution kernel

2.3. Principles and advantages of ResNet network

With the more and more extensive application of deep learning in computer vision, the depth of neural network is also deepening. However, it is found that with the deepening of network depth, the results obtained are not getting better and better, and the problem of gradient disappearance is becoming more and more serious. Therefore, He et al proposed residual convolutional neural network. The residual block structure is added to the network structure, and the short circuit design is added next to the convolutional layer to solve the problem of the gradient disappearing and the accuracy of the training set.

ResNet is divided into 18, 34, 50, 101 and 152 layers, which differ in the number of layers with 4 groups of convolutional layers in the middle.

2.4. Meaning of loss function

The loss function is an operation function used to measure the difference between the predicted value f(x) of the model and the real value Y. It is a non-negative real value function, usually expressed by L(Y, f(x)). The smaller the loss function, the better the robustness of the model. We use is called the two-dimensional cross-entropy loss function. This function is a binary classification function, BCELoss is the binary loss function between the target value and the predicted value, the formula is:

$$l_n = -w_n * [y_n * log\,x_n + (1 - y_n) * log(1 - x_n)] \quad (4)$$

Where Wn represents the matrix of weights, Xn represents the prediction matrix of function output, and Yn represents the target matrix.

2.5. Introduction and application of data sets

In recent years, thanks to the exploration of many researchers on pedestrian attribute recognition, there are many open source data sets that can be used, and we will mainly use the following two data sets.

First, the first data set is Mark-1501 data set.

3-1(a)Picture under camera a

3-1(b)Pictures in other cameras
Fig. 3 Markrt-1501 data set

As shown in Fig. 3, the Mark-1501 dataset was originally used for gender reidentification research, and was filmed on the Tsinghua campus using six cameras with different viewing angles. Lin et al. [1]. annotated attributes for each person in this dataset. In this dataset, a total of 1501 pedestrians and 32,668 character rectangles are included, as shown in Table 1. In so many images, there are two parts: the training set and the test set.

Table 1 Labeling probabilities of some data attributes for Mark-1501

label	probability	label	probability
Young	0.0186	Adult	0.2130
Old	0.0107	Bag	0.2463
Handbag	0.1145	Downblue	0.1638
Downbrown	0.0919	Downgreen	0.0186
Downpink	0.0386	Downwhite	0.0772
Downyellow	0.0133	Upblue	0.0613
upgreen	0.0746	Uppurple	0.0399
upred	0.3901	Upyellow	0.3901
clothes	0.3901	Up	0.9481
hair	0.3262	gender	0.4261

Then, the second data set is DukeMTMC-reID.

In the training set, there were 12,936 images, including 751 pedestrians, with an average of 17.2 images per pedestrian. In the test set, there were 750 pedestrians with 19,732 images, an average of 26.3 images per person.

As shown in Fig. 4, the DukemtMC-Reid dataset is a subset of the DukeMTMC dataset. On the campus of Duke University, eight cameras were used to capture the video stored in the form of a pedestrian border box, each frame of which was manually marked by someone. In the video, images are captured every 120 frames, and the resulting images make up the data set. There were 1,404 pedestrians in the dataset, most of whom were captured by two or more cameras, and 36,411 images made up the DukeMTMC-reID dataset. In this data set, the training set consists of seven hundred and two images of people in rows randomly selected, and the remaining images are used as the test set. It is worth noting that there are 408 people caught by only one camera, and they are included as interference items in the data set. Lin et al. labeled a total of 23 attributes in this dataset, including gender, whether to wear boots, whether to wear a hat, whether to have a backpack, shoe color, seven lower body clothing colors and eight upper body clothing colors.

4-1(a)Picture under camera a

4-2(b)Pictures in other cameras
Fig.4.DukeMTMC-reID

2.6. Evaluation index design

The number of correct identifications for each semantic attribute and the number of all samples is calculated, and the quotient of these two numbers is evaluated as the accuracy of each attribute identification. The average accuracy of all attributes can indicate the extent of the model effect. The formula used is as follows:

$$acc_i = \frac{T_i}{N} \tag{5}$$

$$acc_{mean} = \frac{\sum_{i=1}^{c} acc_i}{c} \tag{6}$$

In addition, due to the great imbalance of pedestrian attribute sample data, the negative sample of a certain

attribute may occupy more than 90%. Therefore, a balanced indicator is also needed, and the average accuracy rate (AP) can balance the identification accuracy of positive and negative samples. The mAP of the average accuracy of each attribute can show the superiority of the algorithm on unbalanced data sets. For the ith attribute, TPi represents the number of positive samples correctly predicted, Pi is the total number of positive samples, TNi represents the number of negative samples correctly predicted, and Ni is the total number of negative samples, then:

$$AP_i = \frac{\frac{TP_i}{P_i} + \frac{TN_i}{N_i}}{2} \qquad (7)$$

$$mAP = \frac{\sum_{i=1}^{c} AP_i}{c} \qquad (8)$$

For the research of pedestrian attribute recognition, we should not only pay attention to the accuracy of individual attributes, but also pay attention to how many attributes in each image can be successfully recognized. This index mainly statistics the accuracy (acc.), accuracy (prec.), recall rate (Recc.) and F1 values of attribute recognition at the sample level.

Accuracy: In both positive and negative cases, the proportion of the predicted correct number to the total number is expressed by the formula:

$$ACC = \frac{TP+TN}{TP+FP+FN+TN} \qquad (9)$$

Precision is relative to the prediction results of positive examples. The accuracy of the predicted positive examples is evaluated by the proportion of the real positive examples in the predicted positive examples. The formula is as follows :

$$precision = \frac{TP}{TP+FP} \qquad (10)$$

The recall rate is judged according to the actual sample. Its main purpose is to judge the proportion of the predicted positive example in the actual positive example, and can be expressed by the formula :

$$recall = \frac{TP}{TP+FN} \qquad (11)$$

The F1 score is the harmonic mean of the correct rate and the recall rate, defined as :

$$F1 = \frac{2*precision*recall}{precision+recall} \qquad (12)$$

2.7. experimental result analysis

The conclusion on Mark-1501 is the average accuracy is 0.9631; the average F1 score is 0.6492. The following figures (Fig. 5 and Fig. 6) show the recognition results of some attributes.
Fig.5. Accuracy of some attributes
Fig.6. Precision of some attributes

On the DukeMTMC-reid dataset, we concluded that the average accuracy was 0.9152 and the average F1 score was 0.5739.The following figure (Fig.7 and Fig.8)shows the recognition results of some attributes.As shown in the figure, figure 7 shows partial accuracy, and figure 8 shows partial precision.

Fig. 7 Accuracy of some attribute

Fig. 8 Precision of some attributes

3. Conclusion
In this paper, nonlinear functions are introduced into a four-dimensional conservative chaotic system to generate multiple scrolls. After the introduction of nonlinear function, the equilibrium point of the system changes from a fixed point to a set of equilibrium points. The system carries out basic characteristic analysis, and discusses its divergence, equilibrium point and whether the energy is

conservative. The equilibrium points obtained by introducing one-dimensional nonlinear function are divided into two categories. For its Lyapunov exponent analysis, after introducing the sine function without multiple angles, The Lyapunov exponents of the system equations show similar periodic characteristics to the sine function, and the Lyapunov exponents obtained by changing the initial values are very different. With the change of initial value, the phase diagrams obtained are also different, and the number of vortex attractors formed is also different, which verifies the multi stability.

Then, the nonlinear function is extended, two nonlinear functions are introduced, and the system with two nonlinear functions is further analyzed. The obtained phase diagram changes from one-dimensional to two-dimensional scroll attractor, and the relationship between the number and arrangement of scroll and the threshold width is obtained. By changing the initial value, the phase diagram with different internal distribution but the same number of scroll is obtained.

Abstract

This paper analyzed the summer thermal environment of an office in Tianjin University of Science and Technology based on COMSOL software. Firstly, the principle of indoor thermal environment distribution was introduced. Secondly, according to the actual position of the furniture in the office, the mathematical model is constructed based on the basic theory of computational fluid dynamics. Thirdly, the COMSOL software was used for simulation and calculation, combining boundary conditions. Finally, the simulation results are analyzed through the simulated indoor three-dimensional velocity field and temperature field. The simulation results show that the air conditioning supply can well achieve indoor occupants' comfort.

Keywords: Temperature field, Wind speed field, Indoor thermal environment, CFD simulation, COMSOL

1. Introduction

Indoor temperature and velocity are one of the most important and frequently measured parameters in indoor environments, affecting personnel thermal comfort, energy balance and air flow [1]. Because the indoor temperature field and velocity field is a complex physical field, and there are many influencing factors. The change process of indoor temperature and velocity has the characteristics of large inertia, non-linearity, and easy to be affected by external environmental factors. Therefore, the indoor temperature distribution of most buildings is uneven, and the temperature data of different areas such as the corner, center, floor and ground of the room are very different. Therefore, it is necessary to use COMSOL fluid dynamics simulation software for indoor temperature and velocity simulation.

The first chapter introduces the necessity of simulating indoor temperature and velocity fields. The second chapter mainly introduces the construction of the indoor model, including the indoor objects, the heat transfer coefficient of the wall, the heat transfer coefficient of the window, etc. Meshing of indoor models. In Chapter 3, the simulated temperature and velocity fields are analyzed. In Chapter 4, simulation conclusions are drawn.

2. Indoor Physical Model Simulation

2.1. Model selection

The research object is an office on the fourth floor facing south. The north window and the corridor are adjacent. Due to the different functions of the room, the interior structure will also be different. In addition, the parameters of the office building walls, indoor personnel activities and room ventilation times and other factors, all greatly affect the office internal thermal environment. Since there are many objects in the office, not all objects can be considered, so the physical model only considers two types of objects, one is large objects such as desks, chairs and cabinets, and the other is hot objects such as computers, notebooks, human bodies and refrigerators. All objects are simplified to cuboids, which is conducive to grid division and calculation convergence.

This paper takes an office of Tianjin University of Science and Technology as the research object. The geometric size of the office is 6m×7.m×3.5m, and there is an air conditioner in the southwest corner of the room. The air supply port of the air conditioner is 1m×0.5m. The return air port is simulated as the return air port of the air conditioner, which is located below the air outlet. One of the Windows is located on the south wall with dimensions of 4m×2.3m and 1m above the ground. Suppose there is no

Peng Wang, Mengda Liu, Qikun Wang

turnover in the office，the number of people in the office is six. The physical model of the office is shown in Fig. 1 and Fig. 2.
Fig. 1 The exterior of the office physical mode
Fig. 2 The interior of the office physical model

2.2. Governing equation

Mass conservation equation is the embodiment of mass conservation law in fluid mechanics [2], as shown in Eq. (1), u,v,w--velocity component, unit m/s,ρ--Fluid density in kg/m³.

$$\frac{\partial(\rho)}{\partial t} + \frac{\partial(\rho u)}{\partial x} + \frac{\partial(\rho v)}{\partial y} + \frac{\partial(\rho w)}{\partial z} = 0 \qquad (1)$$

The hysical meaning of the energy conservation equation is that the increment of the total energy of the fluid controlled in the body per unit time is equal to the sum of the energy increment generated by the fluid capacity of the inflow control and the external action, which includes the energy increment generated by thermal radiation, heat conduction, work done by volume force, work done by pressure and work done by viscous force.as shown in Eq. (2).

$$\frac{\partial(\rho T)}{\partial t} + \frac{\partial(\rho uT)}{\partial x} + \frac{\partial(\rho vT)}{\partial y} + \frac{\partial(\rho wT)}{\partial z} =$$
$$\frac{\partial}{\partial x}\left(\frac{\mu}{pr}\frac{\partial T}{\partial x}\right) + \frac{\partial}{\partial y}\left(\frac{\mu}{pr}\frac{\partial \emptyset}{\partial y}\right) + \frac{\partial}{\partial x}\left(\frac{\mu}{pr}\frac{\partial \varphi}{\partial z}\right) + S_T \quad (2)$$

2.3. Mesh partition

COMSOL 6.0 software was used to model the office, the transient solver was used to solve the established model, and the dynamic simulation of the air conditioning supply situation of the office was carried out. The computed boundary conditions include the properties of the wall structural materials, the outdoor temperature of 30 degrees Celsius, the corridor temperature of 30 degrees Celsius, the air outlet speed of the air conditioner of 1m/s, and the air outlet temperature of the air conditioner of 20 degrees Celsius. Assuming that the indoor and ambient temperatures are the same at the beginning, the whole office is divided using a conventional grid to calculate laminar flow, solid and fluid heat transfer, and non-isothermal flows. The state of the office temperature field and velocity field within 6000s of air supply is simulated and calculated. The boundary conditions and heat sources are shown in Table 1 and Table 2.

Table 1 Boundary condition

Boundary	Heat transfer coefficient
Body of wall	5(W/(m2*K))
Windows	10(W/(m2*K))
Door	4(W/(m2*K))

Table 2 Source of heat

Source of heat	Flux of heat(W)
computer	100
people	50
80	80

3. Image Analysis

The temperature cloud image at room x=1, x=3, x=5m (as shown in Fig. 3, Fig. 4, Fig. 5) and velocity cloud image (as shown in Fig. 6, Fig. 7, Fig. 8) were captured respectively. The scale on the right of the temperature cloud image is the size of the temperature, corresponding to 20 to 30 degrees Celsius from blue to red, and the scale on the right of the velocity cloud image corresponds to the size of 0 to 2m/s. Fig. 3 shows the temperature cloud map at x=1m. The upper left corner is close to the air outlet of the air conditioner, where cold air blows into the room and the temperature is low. The temperature is about 20 degrees Celsius according to the scale. Fig. 4 and Fig. 5 are x=3m and x=5m respectively. The reason why the temperature in the lower left corner is relatively low is that the cold air from the air conditioner blows out and falls down due to gravity, and the cold air gathers to the ground on the left side, where the temperature is about 25 degrees Celsius. The combination of the three images shows that the temperature on the upper floor of the room is evenly distributed, about 27 degrees Celsius. However, the

position temperature of the air outlet is low, which is not conducive to the comfort of indoor personnel.
Fig. 3 The temperature field at x=1m
Fig. 4 The temperature field at x=3m
Fig. 5 The temperature field at x=5m

Fig. 6 shows the indoor velocity cloud map at x=1m. The reason for the large wind speed in the upper right corner is that it is located at the air conditioning outlet, and the wind speed is 2m/s. The reason for the large wind speed in Fig. 7 and Fig. 8 is that the wind speed in other places is evenly distributed due to the cold air blown by the air conditioner. The comprehensive wind speed cloud map shows that the wind speed in other places is evenly distributed except for the air conditioner outlet, and the indoor personnel are more comfortable.
Fig. 6 The velocity field at x=1m
Fig. 7 The velocity field at x=3m
Fig. 8 The velocity field at x=3m

The cross sections at y=1m and y=3.5m were intercepted, respectively, where Fig. 9 and Fig. 10 show the temperature cloud, and Fig. 11 and Fig. 12 show the velocity cloud. Fig. 9 shows the position of the air outlet of the air conditioner. It can be seen from the figure that after the air from the air conditioner blows out, it falls to the position of the table due to gravity, and the temperature is low. Fig. 10 shows that the temperature distribution in the upper and lower parts of the room is relatively uniform for the location located in the center of the room at y=3.5m.

Fig.9 The temperature field at y=1m

Peng Wang, Mengda Liu, Qikun Wang
Fig. 10 The temperature field at y=3.5m

Combined with Fig. 11 and Fig. 12, the comfort of indoor personnel is not high under the air conditioning, and the comfort of personnel is good in the middle position of the room.
Fig. 11 The velocity field at y=1m
Fig. 12 The velocity field at y=3.5m

Screenshots at z=0.2m and z=1.75m were taken, respectively, where Fig. 13 and Fig. 14 show the temperature cloud, and Fig. 15 and Fig. 16 show the velocity cloud. Combined with the above analysis, the upper temperature of the room is higher than the lower temperature, and with the height increase, the temperature also increases. The temperature distribution is uniform in the z plane.
Fig. 13 The temperature field at z=0.2m
Fig. 14 The temperature field at z=1.75m
Fig. 15 The velocity field at z=0.2m
Fig. 16 The velocity field at z=1.75m

Fig. 17 shows the 3D diagram of the room, where the green line represents the path of the wind sent by the air conditioner, and the red arrow represents the direction and magnitude of the wind speed. The figure shows that the air provided by the air conditioner can cover the whole room. In addition to the position of the air outlet of the air conditioner, the wind speed is also moderate, which can meet the comfort of indoor personnel.
Fig. 17 3D air supply path diagram

Mr. Qikun Wang
He graduated from Tianjin University of Science and Technology, is a senior engineer, research direction is HVAC, building technology.

4. Conclusion

Based on the above simulation analysis, the air provided by the air conditioner can cover the whole room, and the air supply by the air conditioner can meet the comfort of indoor personnel.

Abstract

As a new type of personal transportation, self-balancing unicycle has attracted wide attention with its unique design and advanced control system. We aim to study and optimize the self-balancing performance of the unicycle to improve its stability and maneuverability. Firstly, we gain an in-depth understanding of its operation principle. On this basis, an advanced control algorithm is proposed to realize real-time attitude adjustment. Second, for applications in complex environments, we propose an intelligent sensing system to enhance its environment sensing capability.

Keywords: Cascade PID, Angular feedback, MPU6050, Motor driver IC 33886.

1. Introduction

Since they all end up controlling the same control object (the motor of the car model), there is a coupling between them. For the sake of analysis, one of them is assumed to be stable with the other control objects. For example, when controlling the speed, the car model needs to be able to maintain upright control; When controlling the direction, the car model needs to be able to maintain balance and constant speed; Similarly, when it comes to balance control, speed and direction control are also required to be smooth. Of these three tasks, keeping the model balanced is key. Since the car model is affected by three controls at the same time, from the perspective of the car model balance control, the other two controls become its interference. Therefore, the control of the speed and direction of the car model should be kept as smooth as possible to reduce the interference of balance control. Taking speed adjustment as an example, it is necessary to change the inclination angle setting value of the car model in the balance control of the car model, so as to change the actual inclination angle of the car model. In order not to affect the balance control of the model, the change of the inclination of the model needs to be carried out very slowly. This will be discussed in more detail later in Speed Control.

The intuitive experience of controlling the balance of the car model comes from people's daily life experience. The average person can keep a straight wooden stick upright on the tip of a finger with simple practice. This requires two conditions: one is that the palm of the hand holding the wooden stick can be moved; The other is that the eye can observe the tilt angle and inclination tendency (angular velocity) of the stick. Counteract the angle and tendency of the stick by moving the palm of your hand, thus keeping the stick upright. These two conditions are indispensable, and in fact they are the negative feedback mechanism in the control [1], see Fig. 1.
Fig. 1 Feedback control to keep the stick upright

Balance control is also achieved through negative feedback, which is relatively simple compared to keeping the stick upright above. Because the model has two wheels on the ground, the body will only tilt in the direction of the wheels. Controlling the rotation of the wheels to counteract the tendency to tilt in one dimension keeps the car balanced. The gravitational field, which uses thin lines to suspend heavy objects, is simplified to form an idealized pendulum model. An upright model can be seen as an upside-down pendulum placed on a

platform that can be moved from side to side [2]. This is shown in Fig. 2.
Fig. 2 Simple pendulum

In the case of a small offset angle, the restoring force is proportional to the magnitude of the offset angle and is in opposite directions. Under the action of this restoring force, a single pendulum undergoes a periodic motion. A pendulum that moves in the air will eventually stop in a vertically balanced position due to the damping force of the air. The damping force of the air is directly proportional to the speed of the single pendulum motion and is in the opposite direction. The greater the damping force, the faster the pendulum will stabilize in the vertical position.

2. Hardware Usage Programme

2.1 Motor driver IC 33886

The DSC F8013 in Fig. 3 is a 3.3V device, and its IO output voltage is up to 3.3V, which does not meet the requirement that the 33886 must be greater than 3.5V, so a 5V power supply is specially designed in the circuit to pull the drive signal of the 33886 up to 5V. Since the IO port of the F8013 can tolerate 5V, the above circuit can make the 33886 drive signal voltage reach 5V.
Fig. 3 Dual-motor drive circuit

In order to improve the application efficiency of the power supply, the PWM waveform of the drive motor adopts a unipolar drive method. That is, the voltage applied to the motor is a voltage in a PWM cycle.

Therefore, in order for each motor to be able to achieve forward and reverse rotation, two PWM signals are required. The two motors require a total of 4 PWM signals. The drive circuit is shown in Fig. 4.
Fig. 4 Motor drive circuits

2.2 Surveillance camera

Each photocell outputs two pulsed signals, which have the same waveform, but are $90°$ out of phase. If the motor is forward, the second pulse is $90°$ behind, and if the motor is reversed, the second pulse is $90°$ ahead. This relationship can be used to determine whether the motor is rotating forward or reverse. In the actual circuit, only one pulse signal is detected, and the speed of the motor is measured by its frequency. The steering of the motor is judged by the positive or negative voltage applied to the motor. Although due to the inertia of the car model, it is possible that in the case of low motor speed, the direction of rotation of the motor and the voltage applied to it may be different, resulting in inaccurate measurement of motor speed. Due to the racing during the race, the motor is generally running at high speed, and the direction of the motor is consistent with the direction of the voltage. Experiments show that this method can effectively determine the rotation direction of the motor and control the speed.

2.3 Surveillance camera

In the article on the control principle of the car model, there are two ways to measure the angle and angular velocity of the car model, the first is through the gyroscope and the acceleration sensor, and the second is through two acceleration sensors. The angular velocity is integrated with feedback to obtain a smooth angle signal that is consistent with that of the accelerometer. This part of the signal processing can be done by the microcontroller software, or it can be realized by external op amp circuits. In order to verify the performance of this circuit, the ENC-03 measurement signal mounted on the model car was also acquired in Fig. 5.
Fig. 5 Measurement angle waveform plot

From the waveform, it can be seen that the angular velocity of the car model integrated by the accelerometer is the same as the waveform of the angular velocity measured by the gyroscope, which verifies the correctness of the method.

3. Innovative Design and Advantages

3.1. *Vehicle tuning*

The debugging of the car model is divided into various links such as debugging preparation, static parameter tuning, dynamic parameter tuning, mechanical adjustment of the car model and competition strategy formulation. There are many parameters and components involved in the whole commissioning, and these parameters are closely influenced by each other. If you don't have a clear understanding of the physical process and whether there are correct debugging steps, then all kinds of errors in the debugging process will cover up the correct cause, affect the entire debugging process, and even shake the confidence of the production.

3.2. *MCU program download and communication*

The DSC 56F8013 has on-the-system programming (ISP) capability. After the MCU came out, there was a bootloader program inside, and the user program could be downloaded through the UART serial port. If the program itself is bootstrapped for the first time, all future program downloads can be done through UART. For more information, please refer to the materials available on the Freescale website. UART can not only improve the download of the program, but also display the serial characters sent during the operation of the program with the assistance of the upper serial port monitor, which is convenient for debugging the program. It is

recommended that the Bootloader download function of F8013 and serial port monitoring be jointly developed into a host computer software, so that the development and debugging of the entire car model program can be completed through the serial port.

3.3. *Analog acquisition*

The F8013 has six channels of AD conversion. Five of these channels are applied in the reference design. Write an AD conversion program and send the collected values to the upper computer for display. By observing the collected values of each channel, the operating status of each sensor, the dynamic range of the signal, and the influence of noise on each channel are confirmed. It is best to display the values collected by each channel on a curve, so that you can intuitively observe the changes in the signal and the amplitude of the noise. The following is the acquisition waveform of the gyroscope and accelerometer displayed on the upper microcomputer.

Each analog quantity will have a different proportion of noise, and low-pass filtering is required for each acquisition. The simple way to do this is to average it over multiple acquisitions. The waveform data shown in Fig. 6 is averaged over 20 acquisitions [3].
Fig. 6 AD acquires the signal

4. Job Scenario Application.

4.1. *Personal travel*

The wheelwheel can be used as a lightweight, portable means of transportation for short distances in the city. The wheels are fast and flexible, they can shuttle between the flow of people, and they can control the direction and speed of the wheels by tilting their bodies, which is very convenient and fast.

Ziyue Xiao, Yumei Huang, Zhencheng Chang, Mingxuan Li

4. 2. *Industrial applications and military applications*

The wheels can also be applied to industrial scenarios, such as warehouses, factories, etc. The uniwheel can control the direction and speed of travel by tilting the body, making it suitable for transportation and handling work in narrow, crowded environments. The uniwheel is also used in military fields, such as reconnaissance, surveying, etc. The single wheel can carry out fast and maneuverable action and detection in severe environments through its lightness and flexibility. For example, on the battlefield, a single wheel can be used for quick patrols, monitoring the situation, gathering intelligence, etc.

5. Synthesis

The unicycle is a balanced vehicle based on the principle of an inverted pendulum, consisting of a body with only one wheel and a balance control system. The movement and control of the uniwheel is realized by the user's body tilt, which is lightweight, flexible and fast, and is suitable for a variety of application scenarios such as personal travel, toys and entertainment, industrial applications, and military fields.

Tianjin University of Science and Technology, Tianjin, China

*E-mail: *1418249500@qq.com*

Abstract

The team utilizes the second-order inverted pendulum cart based on LQR controller for steady pendulum control with light rods. First, the second-order inverted pendulum is used as a research object to obtain its set of dynamical equations, then, the set of dynamical equations is written in the form of state-space expressions, and finally, the second-order inverted pendulum system of a balanced trolley with a light rod is controlled by a stabilized pendulum using the LQR controller. The inverted pendulum is a typical nonlinear, underdriven and unstable system, which can realize the all-round wind resistance of the rod and occupy less space with high stability.

Keywords：LQR controller，Second-order handstand pendulum，Lagrangian mechanics.

1. Introduction

In real life, many structural systems need to be stable in a variety of environments, such as high-rise buildings, bridges, tower structures, etc. One of the important factors is the influence of climatic conditions, especially wind on the building structure. Due to the uncertainty and variability of wind forces, buildings and structural systems need to be designed to be stable enough to resist the effects of wind. In practical application, in order to ensure the stability of the structural system, it is usually necessary to take various resistance measures, such as adding dampers, support devices and traction devices to the structural system, This is shown in Fig. 1.

Fig. 1. Telephone poles in kind

For slender structures such as rods, due to their special morphological and material properties, the study of their stability under wind force is more complex and critical. Therefore, in order to ensure the wind resistance and stability of the rod, it is necessary to carry out relevant research and application.

To this end, it is possible to study the dynamic characteristics of the rod under the action of wind, etc., the morphological and material characteristics of the rod, and the structural design of the rod to explore how to achieve the stability of the rod. At the same time, some practical application devices can also be developed to help the rod stabilize under the action of wind and other forces, such as adding support, traction and adjustment devices [1].

However, these methods are too traditional and require the support of manpower and material resources, and when the device is damaged, it is not easy to repair, time-consuming and labor-intensive. Therefore, it is urgent to develop a new type of stable and non-falling rod device.

In view of the above shortcomings, our group proposed a second-order inverted pendulum system based on LQR controller to stabilize the pendulum control of the light bar. Our team first took the second-order inverted pendulum system of the balance trolley with light bar as the research object, analyzed its dynamics based on the Lagrangian mechanics

method, obtained its dynamic equations, and then wrote the dynamic equations into the form of state space expressions, and finally, after a brief overview of the LQR controller, the LQR controller was used to stabilize the second-order inverted pendulum system of the balance trolley with light bar. The inverted pendulum is a typical nonlinear, underdriven, and unstable system. Through the research and optimization of the inverted pendulum system, our team has obtained new control algorithms, which have application prospects in robot control, missile interception control, aviation docking control and general industry.

2. Hardware Usage Programme

2.1 Mpu6050

MPU6050 is a commonly used six-axis inertial measurement unit (IMU) consisting of a gyroscope and an accelerometer. It is capable of measuring changes in the rotation and acceleration of an object in three axes.

MPU6050 has a built-in 3-axis gyroscope and a 3-axis accelerometer that can communicate with the microcontroller via an I2C or SPI interface. It is widely used in robots, drones, game controllers, and other applications that require gesture perception or motion tracking [2].

With MPU6050, you can obtain the angular velocity and acceleration data of an object, which can be used to calculate the object's pose or perform motion tracking. This is shown in Fig. 2,
Fig, 2 MPU6050

2.2 STM32C8T6

STM32C8T6 is a 32-bit ARM Cortex-M3 core microcontroller from STMicroelectronics. It has high performance, low power consumption, a wide range of peripheral interfaces and rich development resources, and is one of the commonly used MCUs in embedded system development.

STM32C8T6 has expandable memory and peripheral interfaces, including high-speed USB, CAN bus, multiple serial communication interfaces, analog-to-digital converters and digital-to-analog converters, etc., and has a wide range of applications in industrial control, automotive electronics, home appliance control, medical equipment, smart home and other fields.

In addition, STM32C8T6 has a wealth of development resources, including development boards, online IDE tools, official documentation, and community support, which facilitate engineers to quickly develop and test embedded system applications.

3. System programming

3.1 LQR control

After the above qualitative description of the LQR controller, the simulation calculation was carried out by the relevant functions of Matlab (the mass of the body is 0.9 kg, the height is 0.126 m, the mass of the rod is 0.1 kg, and the length is 0.390 m [3], which is shown in Fig. 3.
Fig. 3 MATLAB simulation results

The device was then simulated with Simulink, and the results are shown in Fig. 4.
Fig. 4 Simulink simulation results

It can be seen from Fig. 2 that under the action of wind, the rotation angle of the wheel of the second-order inverted pendulum system with light rod reaches the maximum at 0.7s, and the rotation angle of the wheel reaches the maximum at 0.05s, and the second-order inverted pendulum system with light rod gradually tends to stabilize at 2s and basically achieves the stable effect at 3s [4].

3.2 Wind simulation

Wind Simulation We use Fluid Dynamics (CFD) simulation, which is a method of simulating fluid flow and force on objects through numerical calculations. When simulating the action of wind, the flow of the wind field can be simulated by establishing a mathematical horizontal shape, and the object to be tested can be added to the horizontal simulation, and the wind force on the object can be calculated through numerical calculation.

We perform a CFD simulation of a second-order inverted pendulum model with a light bar, and the results are shown in Fig. 5.
Fig, 5 CFD simulation

Wind power is the key to test the stability of the second-order inverted pendulum trolley with light bar, and the control variable method is used to test the wind power of the second-order inverted pendulum trolley with light bar. In physics, the method of controlling factors is often used to control multi-factor problems, turning multi-factor problems into multi-factor problems. Only one of the factors is changed at a time, and the remaining factors are controlled

unchanged, so as to study the influence of the changed factor on things, study them separately, and finally solve them comprehensively, this method is called the control variable method. It is an important method of thought in scientific inquiry, and is widely used in various scientific explorations and scientific experiments.

4. Introduction of Functional Module

4.1 Simulink emulation

For the test of the second-order inverted pendulum, a combination of simulation and reality is used. First, the system was simulated using Simulink to obtain the state data of the device. It is then combined with the real thing to verify the correctness of the simulation data. The controllable FS-75 industrial fan was used to perform wind tests on the second-order inverted pendulum system with light rods, and the device data was measured by changing the length, weight, and material of the rods. Through continuous simulation and testing, the efficiency of simulation testing is improved and the trial and error time is reduced. Extensive testing to ensure the correctness of the simulation and the ability to improve the simulated model in real time complement each other for continuous improvement.

4.2 FS-75 Industrial Fan Test

Experiments with a controllable FS-75 industrial fan and anemometer allow for better control of single variables for experimental measurements. After the experimental model is established, the system can be simulated and measured by Simulink rods of different lengths, weights, and materials, which greatly reduces the experimental time and improves the accuracy of the experimental data, which is shown in Fig. 6.

Fig. 6 FS-75

Ziyue Xiao, Zhencheng Chang, Mingxuan Li, Yumei Huang

5. Synthesis

In this experiment, the second-order inverted pendulum system was used to carry out the non-inverted experiment on the light rod, and the second-order inverted pendulum system with light rod was simulated by Simulink, and the system gradually stabilized in 2s. Then, the second-order inverted pendulum system with different rod lengths, different system states and different materials was simulated respectively, and the data state of the optimal second-order inverted pendulum system and device with light rod was obtained, and the influence of using different controllers on the stability of the device was discussed, and the time error was calculated to obtain the best controller. Then, combined with the real thing, the wind test of the second-order inverted pendulum system with light rod was carried out with the controllable FS-75 industrial fan and the stability test of the device was carried out by changing the length of the light rod, and it can be concluded that the experimental device has high stability, and the time to reach the stable state at the wind speed of $1 \sim 3$ m/s is 0.72s, 0.91s and 1.33s respectively, and the length of the rod is increased within a certain range, and the system can achieve stability, which meets the requirements of physical experiments [5].

In this experimental setup, the second-order inverted pendulum handstand model was studied, the optimal handstand state was discussed under different rod lengths and materials, the stability of the system was simulated under different external disturbances (wind speeds), and the influence of different controllers on the stability of the device and the time error were discussed. In the future, it is planned to change the length of the trolley (lower rod part) in the experimental device and simulate the measurement. Multiple fans were used to test the device to discuss whether the device could be more stable in more complex situations.

Design of Nanny's Abnormal Behavior Recognition Bracelet Based on Human Activity Recognition(HAR) Deep Learning Model

Dengpeng Wang*, Yingfan Zhu, Yande Xiang, Ziyue Xaio
Tianjin University of Science and Technology, Tianjin, China

Email: 3264418107@qq.com

Abstract

This article designs a nanny abnormal behavior recognition bracelet. The bracelet is equipped with multiple sensors and a powerful control board, forming a complete nanny abnormal behavior recognition system, which realizes nanny abnormal behavior recognition and alarm in various environments. It uses a gyroscope to collect the three-axis acceleration information of the nanny, and uses the HAR model to infer the nanny's real-time behavior. When the abnormal behavior of the nanny is inferred, STM32 sends the GPS collected positioning information to the employer through ESP32 for timely alarm.

Keywords: Behavior recognition, Nanny, HAR model, Alarm

1. Introduction

With the increasing aging situation in China and the gradual implementation of the two-child and three-child policy, the number of elderly and young people in China has soared, and more and more elderly and children need to be taken care of, and the market scale of the nanny industry has expanded year by year. However, it is difficult to regulate the behavior of nannies, and the incidents of nannies abusing the caretakers are frequent. At present, employers can only monitor nannies by installing surveillance cameras, but there are large dead corners where nannies can still commit violent acts against the caretakers.In particular to dynamics analysis with moving bodies, the selection of the numerical integration method is crucial for the realization of the actual dynamics occurring in the real world. It cannot be solved by a simple way to chip the time step of the integration in the explicit numerical method. In the implicit numerical integration, it will help to refine the time step adaptively.

A nanny's abnormal behavior recognition bracelet based on HAR deep learning model was studied to solve such pain points. The nanny needs to wear the bracelet anytime and anywhere, and the employer can check the nanny's behavior in real time through the mobile phone. When the nanny's behavior to the caregiver is identified, the location of the nanny is directly sent to the employer so that the employer can timely understand the situation and report to the police.

The rest of this paper is organized as follows: The second part introduces the construction and deployment of HAR model. The third part introduces the hardware selection. The fourth part introduces the software design of the system. The fifth part summarizes the main content of this paper.

2. Construction and deployment of HAR model

2.1. *HAR Model Introduction*

Activity recognition has recently gained attention as a research topic because of the increasing availability of accelerometers in consumer products, like cell phones, and because of the many potential applications [1]. HAR model is an efficient human behavior recognition model, which aims to accurately monitor complex human behavior with limited hardware resources. The model uses a convolutional neural network (CNN [2]) architecture, a deep learning architecture that has achieved remarkable success in the field of image recognition and is particularly suitable for processing multidimensional time series data.

The reasoning principle of the model is that when the human body performs different actions, the three-axis acceleration curves of Roll, Pitch and Yaw are significantly different. Fig. 1 and Fig. 2 show the three-axis acceleration curves of the human body while sitting and jogging respectively, and it can be seen that the two curves are significantly different. The model can judge the specific behavior of the human body by the triaxial acceleration when performing different actions.

Dengpeng Wang, Yingfan Zhu, Yande Xiang, Ziyue Xaio
Fig.1 Three axis acceleration curve of human body during sitting still.
Fig.2 Triaxial Acceleration Curve of the Human Body During Jogging.

2.2. *Construction of HAR model*

In the process of model construction, we fully consider the advantages of convolutional neural network in time series data processing. The convolutional layer can effectively capture local patterns in the data, while the maximum pooling layer helps to reduce the sensitivity of the model to the input data and improve the robustness of the model. The fully connected layer is responsible for integrating these local information to form a holistic understanding of different behaviors. This hierarchical structure allows the model to better learn and understand complex behavioral features. The overall structure is shown in Fig. 3.
Fig. 3 Overall Network Structure of HAR Model

In the design of the network structure, the parameter configuration of each layer is paid attention to to ensure that the model can effectively capture the key features in the timing data. First, by setting the number of

convolutional nuclei to 90, the size to 3*3, and the step size to 1, the local pattern of the input data is effectively extracted, which helps to capture subtle changes in the behavioral data. The activation function of the convolutional layer is ReLU [3] to introduce nonlinear characteristics and enhance the expressiveness of the model.

In the maximum pooling layer of the second layer, a 2*2 pooling kernel is adopted and its step size is set to 2 to reduce the spatial dimension of the data and the sensitivity of the model to the input data. This step helps to improve the generalization performance of the model so that it can better adapt to changes in different samples.

The design of the third convolutional layer continues to follow the above principles, the number of convolutional cores is 44, the size is 3*3, the step size is 1, the zero padding is 0, and the activation function is ReLU. The setting of this layer further deepens the feature extraction of time series data, and provides more informative input for the subsequent processing of the full connection layer.

The next three fully connected layers play a key role in the overall structure. The 5632 nodes of the fourth fully connected layer are responsible for integrating the local information extracted by the convolutional layer to form a holistic understanding of different behaviors. Two fully connected layers with a number of 64 nodes further improve the abstraction capability of the model, enabling it to better capture the abstract characteristics of the behavior.

The final output layer is a fully connected layer with six nodes, each corresponding to a behavior category (walking, jogging, going up, going down, standing, sitting, etc.). This design ensures that the model can accurately classify different behaviors, providing a reliable basis for real-time monitoring.

2.3. *Deployment of the HAR model*

In order to deploy the model on a small-capacity embedded device, we first upgraded the HAR model iteratively for several times, and successfully compressed the size of the HAR model from the initial 387.43KB to 19.75KB through operations such as pruning, quantization and optimization of the algorithm structure. The model size optimization effect is shown in Fig. 4.

b. After optimization

Fig. 4 Size comparison of HAR model before and after optimization

After lightweight and efficient processing, HAR model not only has a smaller storage footprint, but also can run on low-resource devices. In the training and design phase of the model, we employ a series of efficient algorithms and neural network structures, including advanced techniques such as convolutional neural networks (CNN) and recurrent neural networks (RNN [4]). These choices greatly reduce the training time and prediction time of the model to ensure both accuracy and timely reasoning in real-time applications. The improved model has achieved remarkable results in more than 100,000 test sets, and the accuracy rate of the model has increased from 85.19% to 89.22%, as shown in Fig. 5.

b. After optimization

Fig. 5 Comparison of accuracy before and after HAR model optimization

The deployment of the model is realized by STM32CubeMX tool, and the Cube AI component in the software can compress the model according to different magnifications and convert it into C language, so as to facilitate the deployment of the model to the embedded development equipment.

3. Hardware selection

3.1. *Main control chip*

The main control chip adopts STM32F407VET6 developed by ST Company. The chip adopts Cortex-M4 core, and the peripherals are mounted with multi-channel I2C, SPI, CAN and other communication interfaces. It has rich functions and its main frequency reaches

168MHz. With 512KB Flash and 192KB RAM, the powerful computing power and sufficient memory are enough to meet the real-time requirements of nanny abnormal behavior recognition bracelet behavior reasoning. The outline design of the chip is shown in Fig. 6.

Fig. 6 STM32F407VET6 chip shape design

3.2. *WIFI module*

This design uses ESP32-WROOM-32WIFI module, its appearance is shown in Fig. 7. The ESP32-WROOM-32 is a powerful universal Wi-Fi+BT+BLE MCU module with powerful features and a wide range of application areas. It can be used in low-power sensor networks and high-performance tasks such as speech coding, audio streaming, and MP3 decoding.

Fig. 7 WIFI module appearance diagram

The module combines high performance computing and low power consumption, which is very suitable for iot project development application scenarios. It uses asynchronous serial port to communicate with STM32 to receive data, acts as a Wi-Fi access point or client, accesses Aliyun iot platform to achieve wireless network connection, and supports wireless communication between iot devices.

3.3. *Gyroscope*

The gyroscope in this design uses MPU6050 attitude sensor, and its chip appearance is shown in Fig. 8. The MPU6050 is a 6-axis attitude sensor that integrates a 3-axis MEMS gyroscope, a 3-axis MEMS accelerometer, and a scalable Digital Motion Processor (DMP). The range of the accelerometer can reach ±16g, and there is a configurable digital low-pass filter inside, and the

configurable register can select the output data for low-pass filtering. The MPU6050 communicates with the STM32 via the IIC bus to transmit the nanny's three-axis acceleration.

Fig. 8 MPU6050 chip

3.4. *GPS Module*

The GPS module uses TAU1201 positioning module, and its module appearance is shown in Fig. 9. TAU1201 is a high-performance dual-band GNSS positioning module, equipped with BDA Beidou's CYNOSURE III GNSS SoC chip, the module supports the new generation of Beidou III signal system, and supports all civil navigation satellite systems in the world. These include BDS, GPS, GLONASS, Galileo, IRNSS, QZSS and SBAS (WAAS, EGNOS, GAGAN and MSAS). The TAU1201 integrates an efficient power management architecture to provide a high-precision, high-sensitivity, low-power solution for GNSS navigation applications.

Fig. 9 Appearance of the TAU1201 module

4. System software design

4.1. *Acquisition of triaxial acceleration*

The STM32 reads the contents of the relevant registers of the MPU6050 through the IIC communication protocol, a serial communication bus using a multi-master-slave architecture developed by Philips in the 1980s to allow motherboards, embedded systems, or mobile phones to connect low-speed peripherals. The IIC communication rate of STM32F407VET6 can reach up to 400KHz, which is enough to meet the requirements of HAR model inference.

Fig. 10 shows each meaning of the acceleration range register of the MPU6050 attitude sensor and the configuration guide. During configuration, the accelerometer range can be controlled by writing data to the register. Fig. 11 is an introduction of the acceleration read register of the MPU6050 attitude sensor. When the MPU6050 is used, the raw data of the three-axis acceleration is obtained through the 16-bit ADC value of the acceleration read register after the accelerometer RANGE is configured. The relationship between the three-axis acceleration (ACC) and the acceleration range (R) and the raw data (ADC) of the three-axis acceleration can be expressed as:

$$ACC = \frac{R * ADC}{32768} \tag{1}$$

Fig. 10 MPU6050 aceleration configuration register

Fig. 11 MPU6050 acceleration read register

4.2. *Nanny location acquisition*

The nanny location is obtained through the TAU1201 module. TAU1201 module can capture the signal of the satellite to be tested according to a certain height cutoff Angle of the satellite, track the operation of these satellites, transform, amplify and process the received GPS signal, so as to measure the propagation time of the GPS signal from the satellite to the receiver antenna, and interpret the navigation message sent by the GPS satellite. When the TAU1201 is finished interpreting, it communicates with STM32 through its own serial port to send the nanny location information to STM32.

4.3. *Behavioral inference data and location information upload*

Data upload is completed through the ESP32-Wroom-32wifi module. When the nanny's behavior is deduced on STM32, the HAR model inference result will be sent to ESP32 through STM32's own serial port. After the ESP32 makes the judgment of dangerous behavior, the judgment result will be sent to the employer's mobile phone server through MQTT protocol. When it is deduced that the nanny is in danger, the nanny's real-time location information is uploaded to the employer's mobile phone so that the employer can take the next step.

5. Conclusion

The nanny abnormal behavior recognition bracelet, to a large extent, solves the problems of traditional surveillance cameras, such as large monitoring dead Angle and not easy to carry, so that the nanny's behavior can be better supervised and standardized, has a good role in promoting the development of the nanny industry, and indirectly protects the life and property safety of the caretakers.

Abstract

Robot Operating System (ROS) is a software system framework used by many robot systems. Although ROS provides a good development environment and related frameworks, ROS is not suitable for public places such as restaurants because of the coming and going of people. Dynamic obstacle avoidance is often handled by stopping the robot, or when there are frequent environmental map changes or when sensors such as optical radar fail, the stop action is also used. However, this often causes path obstructions or delays in completing tasks. Therefore, this study attempts to use images, auxiliary sensors, and various path avoidance strategies to solve the problem of the robot stopping and waiting for the obstacles to disappear. The problem of rapid changes in map paths.

Keywords:Robot Operating System (ROS), Dynamic obstacle, Dynamic obstacle avoidance.

1. Introduction

Robot Operating System (ROS) [1] is a very commonly used development platform for developing and researching robot systems in recent years. Because this software uses open-source code and uses resources provided by many robot developers. Let this ROS system grow rapidly. Whether mobile robots can actually operate in actual environments is also a very important research topic for mobile robots. Because the mobile robot is in the actual environment, cannot avoidance dynamic or static obstacles. Or without the ability to re-plan the correct path, the mobile robot well cannot actually operate in a real environment. Of course, this also limits the application of mobile robots. Therefore, this study uses ROS as a research platform to focus on how mobile robots dodge dynamic obstacles in the environment. And re-chart the path to try to find a solution. This can reduce the chance of the mobile robot stopping when encountering obstacles and improve the efficiency of the mobile robot. It also enables mobile robots to be applied in real environments. In previous research, dynamic obstacle avoidance is an important research topic for many mobile robots. For example, CHEN, Chin S., et al. [2] use the ROS architecture to evaluate the path cost of autonomous mobile robots (AMR) for obstacles in the environment. Then choose the better path and let the mobile robot run. CHOI, Jaewan., et al. [3] use reinforcement learning to improve the reliability of dynamic window approach (DWA) [4] and timed elastic band (TEB) [5]. Make mobile robot obstacle avoidance more efficient.

It can be found from previous related research that many mobile robots mostly use small controllers such as Raspberry Pi [6] due to cost and volume. And it uses LiDAR Light Detection and Ranging (LiDAR) as the main sensor. Although such an architecture is lower in cost, it results in insufficient computing power. And because when detecting obstacles, lidar can only detect obstacles and measure distances on the plane that light or laser can scan. It often happens that when an obstacle is not in the LiDAR light scanning area, the obstacle is misjudged or cannot be detected. Therefore, the development and application of mobile robots are hindered. Therefore, this research will use the architecture of x86 computers. In addition to using LiDAR, it will also use imaging technology. Through this architecture, the mobile robot's computing power and obstacle detection can be faster and more accurate. Allowing mobile robots to truly overcome dynamic obstacles in the environment and enable practical applications.

2. System Architecture

The architecture diagram of the mobile robot is shown in Fig. 1. The robot is equipped with cameras, LiDAR and STM32 control boards, etc. It also has many various interfaces for expansion of different hardware. It can be widely used in actual or simulated various task development and applications. This robot architecture uses ROS as the

Yi-Wei Chen, Jr-Hung Guo, Kuo-Hsien Hsia

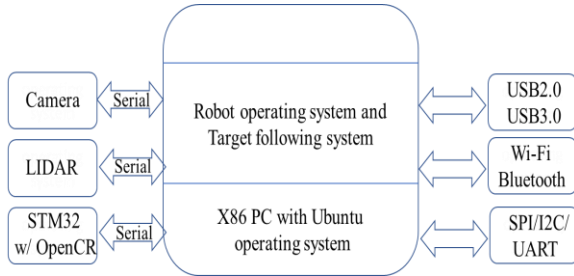
main core and adds modules such as targets following systems. The system can be adjusted according to different applications to provide a diverse robot development environment. At the same time, the development results can also be quickly transferred to different mobile robot platforms.


Fig.1 ROS mobile robot architecture block diagram.

In the ROS system, the sensors commonly used for object distance measurement are mainly LiDAR and imaging lenses. In order to consider the calculation amount and get the object distance, many robot platforms are based on LiDAR. However, general LiDAR is only 2D, that is, it can only measure one plane, and this also causes LiDAR to be unable to detect objects outside the 2D plane it scans. Therefore, in order to avoid obstacles that cannot be detected using LiDAR, this study uses images to detect obstacles and calculate distances.

There are two algorithms commonly used in ROS for object detection and distance calculation. One is KCF [7] (Kernelized Correlation Filter), which is a method to find the image features being tracked and then use this feature to track the object. Therefore, the operation speed of this method can be very fast. However, when obtaining object features and image tracking, this algorithm will lose the image data, making it impossible to perform accurate tracking. The other is DSST [8] (Discriminative Scale Space Tracker). DSST mainly improves the shortcomings of KCF that only uses gray scale to obtain object features and does not calculate the object scale. It makes the judgment of objects more accurate and enables distance estimation. The most important thing is that it will not have a big impact on the overall calculation amount. Although the above two algorithms are sufficient for tracking and following general mobile robots. However, because this research hopes to use images to process more complex, even more obstacles and more targets, the TLD [9] (Tracking-Learning-Detection) algorithm is also added. This algorithm can accurately identify the target, even when the object reappears after being obscured, it can still correctly identify the target. And if the target object rotates, TLD can also correctly identify it. Of course, the number of calculations required for this algorithm will be relatively large.

2.1 Research methods

In this study, in order to make ROS have a higher object recognition rate and calculate a more accurate object distance, we integrated KCF and DSST. As the main object

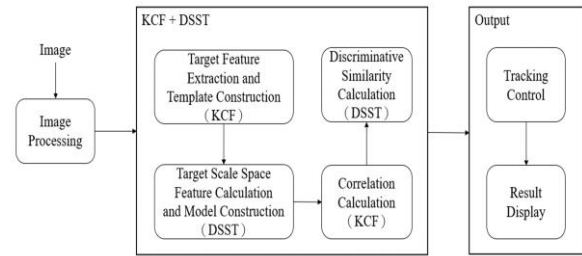
recognition and distance calculation core, the integrated operation structure diagram is shown in Fig. 2. In this processing block, KCF is mainly used to quickly identify targets and establish preliminary samples for subsequent identification. The main purpose is to identify possible obstacles or targets as quickly as possible, and then use DSST to further process the identification model and identification samples. Because KCF has a faster processing speed, it can first determine which objects may be closer to the mobile robot. Then, when necessary, it will be handed over to LiDAR and DSST for confirmation. Once a possible obstacle or path impact on the mobile robot is confirmed, it will continue to be tracked with KCF.


Fig.2 Block diagram of KCF+DSST target recognition system.

In the TLD algorithm part, because the preset requirements are relatively high for the computing power of the system, the calculation will only be performed when KCF+DSST determines that the object is closer to the mobile robot. Its block diagram is shown in Fig. 3. Moreover, the frequency of calculation can be set in the system, such as once per second, 10 times per second, etc. In addition, the maximum number of tracking can also be set. This prevents the CPU from consuming too much computing power in object tracking. Next, we will conduct experimental tests on the above methods.
Fig.3 TLD target identification system block diagram.

3. Experimental Results

We use an x86 computer as the main control core, and the specifications used are: CPU, Intel® Processor N-series

N100, 8GB DDR4 DRAM, 512GB SSD. And directly install Ubuntu, and then install Gazebo and ROS in the system. First, we first confirm the object detection capabilities of the KCF+DSST and TLD algorithms. Fig. 4 is our test results on ROS. We use the same obstacles to identify objects and calculate scale distances using the KCF+DSST and TLD algorithms. According to the experimental results, both algorithms can operate normally. The operation speed of KCF+DSST is about 20% faster than the TLD algorithm. The calculation results of the scale distance between the two are almost the same.
a. Objects move away from the robot.

b. Object approaches the robot
Fig.4 Object tracking and recognition results

But when we dynamically generate multiple objects with different sizes, distances, and positions. Although KCF+DSST can still find objects quickly. However, when objects are interlaced or have large displacement or rotation, KCF+DSST will lose the tracked object. As a result, the risk of collision of mobile robots becomes higher. When using TLD, this algorithm can quickly and correctly handle the interlacing of objects, as well as rapid displacement, rotation, etc., and can also correctly calculate the distance of objects. But when more than 150 objects appear, there will be a short pause based on the hardware we are using. Although it does not affect the operation of the system, there will be obvious pauses. KCF+DSST will only pause for a short time when there are about 300 objects.

4. Conclusions

This paper uses imaging technology to deal with the detection problem of multi-obstacle objects, and develops a mobile robot platform using an x86 CPU computer. The actual photo of this platform is shown in Fig. 5. We verified on ROS that KCF+DSST and the TLD method were used to verify the path re-planning that can be used to solve multi-dynamic obstacles. That is to say, obstacle avoidance can be performed when there are many dynamic obstacles in the environment. Of course, the current structure still cannot completely allow mobile robots to pause. However, based on the current experimental results, more than 90% of suspension situations can be avoided. The other 10% are almost all dynamic obstacles that completely block the path of the mobile robot. We will also try to solve this part in the future so that mobile robots can overcome the obstacles of dynamic emergence and movement in the environment and serve people in real environments.

Abstract

Mobile robots are playing an increasingly important role in both service and manufacturing industry. The management of multiple mobile robots is a very important issue on the research of mobile robotics. From a mathematical perspective, this paper discusses the problem of multiple robots on a two-dimensional plane reaching the designated positions in the shortest time to complete formation transformation. We improved the algorithm proposed by Hsia, Li and Su and proposed a new algorithm using a determinant and the Munkres assignment algorithm. Finally, the new algorithm is compared with the path distribution obtained by the Monte Carlo method under different numbers of robots and the excellence of the new algorithm has been verified.

Keywords: Multiple mobile robot, Pattern formation, Two-dimensional plane, Munkres assignment algorithm.

1. Introduction

In this society where time is money, saving time is an important factor that must be considered on task completion. How to complete tasks in the shortest time is what task assignment issues aim to achieve. Assignment problem [1] refers to the process of assigning specific work, tasks or responsibilities to specific people or teams. In an organization or team, assigning issues is a way of allocating work to ensure that matters are carried out efficiently and achieve desired goals. How to make an assignment that the tasks could be completed in the shortest time has always been the most important issue.

The shortest-path planning problem [2] is to find an assignment way for shortest-time running. Path planning refers to the movement path generated in order to enable one or more objects to complete a certain task in a designated area. In order to complete the task assignment problem in the shortest time, it is important to find a way to have the shortest path. The importance of the algorithm for this problem is that it can have the solution with higher efficiency, and the obtained result is repeatable.

This paper discusses the assignment problem of formation change of multiple robots. For a centralized robot system, there is a control center that makes decisions and assignments, while the other robots execute the received commands. In this paper, the multi-robot system is a centralized system and an algorithm is used to determine the destination that each robot is planning to move to. There are many types of formations in discussion, such as wild goose formation, front arrow formation, T-shaped formation, etc. The robots are asked to transfer their formation from one to another. The robots could only move laterally or vertically on a plane, so the robot is limited to a two-dimensional grid plane. In order to allow multiple robots to complete the formation in the shortest time, an algorithm can be used to find the assignment way that makes the formation transformation successfully in the shortest time.

2. Preliminary
2.1. *Problem description*

In the multi-robot formation transformation problem, there are n robots on a two-dimensional grid plane. The robots move horizontally or vertically from the starting positions to the target positions in the same speed. In order to find the fastest way to complete the formation change, we have to decide the target position for every robot and the robot with the longest distance will be assigned with a fastest way. This is a min-max problem.

Kuo-Hsien Hsia, Chun-Chi Lai, Yi-Ting Liu, Yu-Le Chen

2.2. *L1-norm between two points*

The L1-norm between two points is defined by the total distance of the projection of the line segment formed by each point on the axes on the Cartesian coordinate system, that is, the horizontal distance between the two points plus the longitudinal distance between them. Suppose the two points are at (x_1, y_1) and (x_2, y_2), their distance is $|x_1 - x_2| + |y_1 - y_2|$.

2.3. *Determinant*

To complete the assignment problem of *n* robots, each robot at his starting position will have a corresponding target point position. When all robots are assigned, their corresponding relationships will be presented in the distance matrix, and unassigned positions can be filled with 0. Under such circumstances, there will be *n* non-zero values in the distance matrix on different rows and columns, forming a square matrix of full rank. The fastest way to check for full rank is to check whether its determinant is 0 or not. Therefore, we use the determinant as a tool for checking the feasibility of formation transformation planning.

2.4. *Munkres assignment algorithm*

Munkres assignment algorithm [3] is an optimization algorithm for solving assignment problems. Given a cost or benefit matrix, it finds a set of assignments that minimize the total cost or maximize the total benefit, in which each row and column only can be assigned once.

2.5. *Monte Carlo method*

The Monte Carlo method is a numerical calculation method based on random sampling and statistical simulation [4]. When assigning tasks using the Monte Carlo method, one can randomly find an allocation way, and then find the maximum of the solution. One can get the number of steps for completing the tasks by using the Monte Carlo method one time. The more times of sampling, the more assignment ways there will be. By minimizing the maximum value of these, one can get a assignment way almost the most suitable.

3. Proposed new algorithm

3.1. *Deviation of the new algorithm*

We refer to the algorithm proposed by Hsia, Li and Su [5], but instead of finding the assignment way from the entries of the distance matrix, we find the minimum path from the positional relationship of the values in the matrix, and use the determinant to make the decision. The program searches sequentially from 0, and fills the searched position into another decision matrix. When a value is searched in the distance matrix, the

corresponding position in the decision matrix is filled with prime numbers from small to large, and the rest are not searched. The reached position is represented by 0 in the judgment matrix. When the search is completed, find the determinant of the judgement matrix. If the result is 0, add 1 to the search value and search again. Repeat the above steps until the determinant value is not 0, and then use the Munkres assignment algorithm to assign tasks.

3.2. *The algorithm*

Step 1: Calculate the L1-norm of all starting points to target points, and form the results into a matrix named distance matrix. The columns of the matrix correspond to the starting points, and the rows correspond to the target points.

Step 2: Initialize the judgement matrix of same dimension as distance matrix with all entries 0.

Step 3: Set the search value as 0.

Step 4: Fill in prime numbers in sequence to the corresponding position in the judgment matrix where the entry of the distance matrix is equal to the search value. The selection of prime numbers starts from 2, and each prime number filled in is the smallest prime number larger than the previous one.

Step 5: If the determinant of the decision matrix is not 0, jump to step 7.

Step 6: Increase the search value and back to step 4.

Step 7: Replace all positions of the distance matrix by a sufficiently large number, e.g. 999, if the corresponding position of the judgment matrix is 0.

Step 8: For a distance matrix, subtract the minimum value of that row from each row and subtract the minimum value of that column from each column. Thus at least one element in each row and each column will be zero.

Step 9: Use the least straight line to pass through all 0s, so that each 0 has at least one line passing through it.

Step 10: When the number of lines equals the number of robots, the position of 0 in the matrix can be used for task assignment. Starting from the row with the fewest 0s, only one 0 can be circled in each row and column. If the number of circles is equal to the number of robots, the assignment of the task is completed. If not, go to the next step.

Step 11: Subtract the minimum value in the undrawn row /column, and add the minimum value to the intersection position of the lines. After completion, back to step 9.

4. Comparison to Monte Carlo method

This comparison was performed on Matlab 2021, simulating the formation transformation situations of 10,

30, 50, 100, 500 and 1000 robots respectively. The starting and target points of the robots are randomly generated each time. Then the proposed algorithm and the Monte Carlo method are used for task assignment. The Monte Carlo method takes the best allocation method out of 10,000 times as the representative value. After comparison, the smaller one is the better assignment in the simulation. For each number of robots, we have 1000 simulations for both methods. This comparison index is to count the number of simulations that the proposed algorithm's result is not greater than the Monte Carlo method's result in 1000 simulations with different numbers of robots. The simulation results are summarized in Table 1. It is clear from Table 1 that the proposed algorithm can always have the same or better assignment way. Hence the proposed algorithm is better than Monte Carlo method for the formation transformation problem.

Table 1. Comparison results.

Number of robots	10	30	50	100	500	1000
Number of the results of proposed algorithm not worse than Monte Carlo method	1000	1000	1000	1000	1000	1000

5. Illustrated Examples

This paper takes three formation transformations as examples, namely the flying goose formation, the front vector formation and the T-shaped formation, and MATLAB is used for simulation. The robot is located on a 7x7 grid plane. The configuration of each formation is shown in Fig. 1. For the flying goose formation (V shape), the robots are at (4, 1), (4, 7), (5, 2), (5, 6), (6, 3), (6, 5), and (7, 4). For the front vector formation (Q shape), the robots are at (2, 4), (3, 4), (4, 4), (5, 4), (6, 3), (6, 5), and (7, 4). For the T-shaped formation (T shape), the robots are at (2, 1), (2, 2), (2, 3), (2, 4), (2, 5), (3, 3), and (4, 3).

The 7 robots form the flying goose formation initially. We would like to make the robots changed to the front vector formation, and then changed to the T-shaped formation. The assignment results are summarized in Table 2, and the routes for the robots are shown in Fig. 2.

Table 2. The assignment results.

Pts of V-shape	(4, 1)	(4, 7)	(5, 2)	(5, 6)	(6, 3)	(6, 5)	(7, 4)
Pts of Q-shape	(2, 4)	(4, 4)	(3, 4)	(5, 4)	(6, 3)	(6, 5)	(7, 4)
Distance for #1	5	3	4	2	0	0	0
Pts of T-shape	(2, 1)	(2, 2)	(2, 3)	(2, 4)	(3, 3)	(2, 5)	(4, 3)
Distance for #2	3	4	2	3	3	4	4
Pts of V-shape	(4, 1)	(5, 2)	(6, 3)	(4, 7)	(5, 6)	(6, 5)	(7, 4)
Distance for #3	2	3	4	5	5	4	4

6. Conclusion

This paper proposed a new algorithm to solve the task assignment problem for a multi-robot system on formation transformation. Each mobile robot is limited to horizontal and vertical movement and starts at the same time. We'd like the transformation to be completed in the shortest time. The proposed algorithm can be used to systematically find out how to assign the target points of each robot so that the robot's formation can be transformed in the shortest time. Unlike previous works, we use determinant of a matrix to find out the shortest time required to complete the formation change, and use the Munkres assignment algorithm to obtain the shortest time. This work can ensure the best assignment result.

Abstract

In this paper, we present a system based on a microcontroller unit (MCU) for measuring the utilization rate of traditional, non-networked machinery. This equipment is designed for use with older machines equipped with andon lights. It employs optocoupler circuits to capture the status of these lights and current transformers to measure their operating and standby currents. Data is transmitted to the server using the Hypertext Transfer Protocol (HTTP) in JavaScript Object Notation (JSON) format. On the server side, a Hypertext Preprocessor (PHP) interprets the data, connects to a Structured Query Language (SQL) database, and stores the data using SQL commands. Users can access graphical data through a web-based interface, using it to refine production processes, reduce production costs, and minimize carbon emissions.

Keywords: Utilization, Non-networked machinery, Andon lights, Current transformers.

1. Introduction

With the widespread adoption of Industry 4.0 concepts and the concurrent advancement of relevant technologies such as networking and microchips, the Internet of Things (IoT) has emerged as a globally esteemed paradigm. The internet of machines refers to the ability of machines and devices to interact with the internet without human intervention. Information from devices, including operational progress, work duration, production history, and more, is transmitted via the Internet to servers for recording and analysis. The data facilitates analyses such as production process and utilization rate, allowing enterprises to adjust production processes based on this data. However, these actions are typically limited to new generations of IoT-enabled devices, as traditional machinery lacks such capabilities.

On the other hand, environmental protection has become a topic of global concern in recent years. Nations worldwide recognize the severity of greenhouse gas emissions and the importance of reducing carbon footprints. Governments have initiated carbon fees and tax policies, with the European Union passing a Carbon Border Tax set to take effect in 2026 [1]. This policy targets high carbon-emitting industries, imposing restrictions and charges. For enterprises, maintaining or reducing carbon emissions has become a matter of heightened concern. The determination of product carbon footprints and the subsequent implementation of carbon reduction labels are tasks to be addressed in the future.

This paper aims to assist factories in recording changes in andon light signals and corresponding time-related variations in electrical currents without intrusively altering traditional machinery's existing hardware and software. This is achieved by incorporating IoT devices to facilitate the documentation of machine operating states, thereby reducing downtime and enhancing overall operational efficiency. In addition, it also provides relevant information on the product's carbon footprint, aligning with the demands of Industry 4.0 and the implementation of carbon taxes.

2. Related Work
2.1. *Utilization*

The production or manufacturing process involves transforming raw materials or components into finished products. In the industrial context, production lines can be categorized into three types: automated production lines, semi-automated production lines, and manual production lines. The nature of a production line depends on the complexity of the finished product, production qunatity, and costs. Enterprises can plan and lay out production lines based on their requirements [2].

As highlighted by both [2], [3], inefficient working hours on the production line primarily stem from machine waiting times for personnel handling, waiting for material changes, troubleshooting, and maintenance. The efficiency metric used is referred to as "utilization rate." The utilization rate indicates the percentage of the total working hours where the machine is under load during effective working hours. Effective personnel management plays a crucial role in improving the factory's utilization rate.

2.2. *Industry 4.0 and the Internet of Things (IoT)*

The term Industry 4.0 emerged in Germany in 2011, referring to the technology used in the manufacturing process to monitor processes and employ data-based techniques for predicting, correcting, and adaptively adjusting production strategies [4]. Its objective is to integrate various data, tools, and processes to analyze and reduce costs, mitigate risks, and enhance efficiency [5], [6], [7]. Unlike previous industrial revolutions, Industry 4.0 is not based on a single technology. Instead, it is a convergence of modern technologies such as Big Data, the Internet of Things (IoT), Cloud Computing, and Artificial Intelligence (AI) [5].

The Internet of Things (IoT) applications have deeply penetrated our lives, with interconnected IoT devices sharing vast amounts of information without human intervention. According to [8], global IoT devices online in 2020 totaled 9.76 billion, with application areas illustrated in Fig. 1. Of these, 22% were applied in the industrial sector, 15% in transportation, and 14% in energy. By 2026, the number of online devices is projected to reach 21.09 billion; by 2030, it is estimated to approach nearly 30 billion devices.
Fig. 1 The top 10 IoT application areas in 2020 [9]

This project aims to transform traditional machinery by further integrating it into the framework of Industry 4.0 to enhance machine utilization rates and production line efficiency. The referenced Internet of Machine Architecture model, as established in [10], [11], comprises five layers: the physical layer, sensor layer, connectivity layer, data layer, and application layer. The machinery transformation in line with Industry 4.0 primarily focuses on configuring the sensor, connectivity, and data layers. In the sensor layer, determining required machine states is crucial, involving establishing corresponding sensors and utilizing the production

information provided by the machine. The connectivity layer deals with how the collected information is transmitted to the server for processing. The data layer emphasizes planning the format of machine data and storing it in a database for subsequent applications and analysis.

2.3. *Carbon credit issues*

With global industrialization and increased energy consumption, there is a significant increase in carbon dioxide emissions, contributing to climate challenges. Addressing these issues requires international cooperation to reduce and control carbon emissions. The European Parliament has taken legislative action this year, entering a transitional phase from October. They are implementing the European Union Carbon Border Adjustment Mechanism (CBAM), which restricts the import of high-carbon products such as steel, cement, and electricity. It will be mandatory for imported products falling into supervised categories to purchase CBAM certificates [1] after 2026.

3. System Architecture

In this project, the collaborating partners are concerned about the machinery's operational status and energy consumption. However, due to the large number of machines, totaling 27 units with over ten different models, some of the actual machine appearances are depicted in Fig. 2. Embedded systems, coupled with sensors, will be utilized to extract information on machine status and energy consumption. This data will be wirelessly transmitted to a server for storage, facilitating subsequent analysis and processing.

Fig. 2 The actual appearance of the machinery

As illustrated in Fig. 3, the network architecture primarily consists of an MCU and a server. When the sensor reads values and transmits data to the MCU, the MCU packages the data in a predefined format. Subsequently, using the built-in Wi-Fi module, the data is transmitted to the server. Specific PHP (Hypertext Preprocessor) programs perform data analysis within the server and upload it to the MySQL database. Upon

completion of the upload, users can view all the data as of a webpage or export the data into reports through
Fig. 3 The network architecture diagram

additional programming.

4. System Development
4.1. *Andon light status detection*

The core component of the Andon light status detection circuit is component U1 in Fig. 4, which is a optocoupler element. A optocoupler element is a device that uses light (such as visible light or infrared) as a medium to transmit electrical signals [12]. As previously mentioned, different machine models on the production line may use different electrical configurations for warning lights, distinguishing between AC and DC. Therefore, the PC814 bidirectional photocoupling element manufactured by Sharp, a Japanese electronics company, has been selected for development for this project. The main difference lies in the internal structure of the PC814, which includes a pair of light-emitting diodes — one forward and one reverse — enabling it to function in both directions of current flow. It elegantly resolved the compatibility issue between alternating current and direct current.
Fig. 4 Andon light status detection circuit diagram (detection part)

4.2. *Current Measurement*

This project utilized the SCT013 split-core current transformer manufactured by YHDC to avoid damaging the original power wiring. The circuit structure employed is illustrated in Fig. 5 with the calculation method for the burden resistor according to Eq. (1).

$$\text{Burden Resistor}(\Omega) = \frac{V_{AREF} * CT\ TURNS}{2\sqrt{2} * I_{pm}} \qquad (1)$$

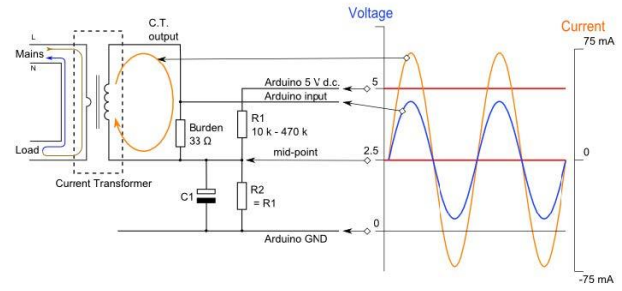
Where V_{AREF} denotes analog reference voltage, CT TURNS represents the current transformer turns ratio,


Fig. 5 Current measurement circuit diagram (measurement part) [13]

and I_{pm} denotes the maximum current on the primary side. By generating a voltage across the burden resistor through the secondary side current, the capacitor in Fig. 5 can accurately represent the direction and magnitude of the current. This information is acquired through the MCU's Analog-to-Digital Converter (ADC).

4.3. *Data format and transmission*

Upon receiving the status and data from peripheral devices, the MCU must analyze and upload the information to the server. The transmitted data should include details such as machine ID, data type, and timestamp. JSON (JavaScript Object Notation) can be employed as the data packaging format. JSON is a lightweight data interchange format supported by most programming languages, often with additional libraries for convenient packaging and parsing. The specific packaging format for this project is illustrated in Fig. 6.

Fig. 6 Data format

The data, transmitted through HTTP request by the MCU with Wi-Fi functionality, undergoes analysis on the server side using PHP. PHP also responds to the HTTP request and uploads the data to the database for storage. The server-side data transfer path is illustrated in Fig. 7.
Fig. 7 The server-side data transfer path

5. Result

This paper uses the ESP32 series MCU, which Espressif Systems developed as the core for edge-side development. Its advantages lie in its cost-effectiveness and the integration of network modules with basic microprocessors. This MCU is commonly employed in the development of IoT applications.

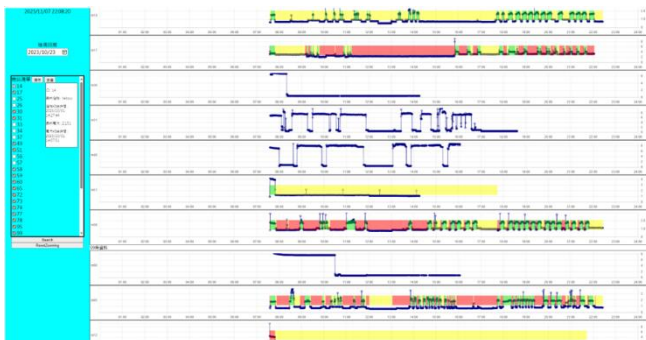
After collecting data, present it to users in a graphical format for more straightforward interpretation and analysis. The system is developed as a Web App to avoid the need for different applications on various devices and the authentication thresholds of mobile applications. The advantages of a Web App lie in its accessibility—any internet-connected device with basic browser functionality can use it. The web page is coded using HTML (Hypertext Markup Language) for interface design. JavaScript is employed for real-time content updates and user interaction. PHP serves as an intermediary between JavaScript and the database for data requests.


Fig. 8 Web App

Fig. 8 shows the interface displayed in the web app, divided into two main sections. Users can choose the machine number and time of interest on the left-hand side in the blue area. After selection, the data for the chosen machine will be displayed on the right-hand side in the white area. Each row in the chart on the right represents the data for a single machine on a given day. The various colored blocks represent the machine's status (indicator lights) during specific time intervals, while the lines depict the machine's current consumption. Analyzing this data assists factories in power consumption statistics, emission calculations, and formulating strategies for emission reduction. Aligns with national and international carbon policies, helping to minimize carbon-related costs and reduce unnecessary energy consumption during idle times.

6. Conclusion

This article utilizes a microcontroller with wireless connectivity, sensors, and electronic components to create a non-invasive device. Combined with a web app, factory administrators can swiftly gather production information to analyze and adjust production strategies.

Abstract

An edge computing system based on micro control unit (MCU) for liquid level measurement is proposed in this paper. The system includes a solenoid electromagnet for bottle hit and a microphone to capture sound waves. The signals are converted from time domain to frequency domain by Fast Fourier Transform (FFT), employing an artificial intelligence (AI) model to predict the water level. Artificial Neural Network (ANN) model is applied for classification on the MCU. When optimizing hyperparameters, the accuracy of each parameter combinations should be considered. Ensure the model size suits the limited MCU memory and computing capabilities. The experimental results can be up to 99% accurate under multiple tests.

Keywords: Artificial Neural Network, Hyperparameters, Edge Computing, Audio Process

1. Introduction

As artificial intelligence (AI) is more popular, there are many applications to be proposed no matter for the consumer or industrial market. Moreover, it is crucial to tackle the emerging challenges associated with edge computing [1], a topic of great significance and current prominence. The utilization of endpoints for model computation has attracted considerable attention, given its potential to reduce network latency and lower costs [2], [3]. Furthermore, the exploration of alternative AI models for measurement becomes pivotal in situations where sensor availability is constrained or cost prohibitive. When a container, such as bottle, experiences physical impact, it produces distinct tones depending on the liquid's varying levels inside, owing to vibration frequencies. Determining the water level through sound analysis, as presented in [4], relies on specific vessel geometries. However, employing an AI model or sound-based water level measurement becomes a viable option. Furthermore, given the limited resources of the endpoint platform, careful consideration of AI model selection and hyperparameter optimization for edge computing is crucial. Artificial neural networks (ANN) model, is simple yet effective for classification tasks, represent a viable candidate for this study [5], [6]. Moreover, Bayesian optimization emerges as a popular method for efficient hyperparameter optimization, offering convenient and efficient.

A micro control unit (MCU) based edge computing system for liquid level measurement is proposed in this paper, and all calculation and control including data acquisition are performed by a consumer MCU, Artery AT32F415 [7]. The proposed AI model utilizes one-dimensional sound information for classification, resulting in reduced memory requirements.

During the training stage, the proposed system offers a data sampling function, where the gathered information is transmitted to a personal computer (PC). The hyperparameters optimization and model training processes are conducted on the PC. Once completed, the trained model will be installed onto the MCU, enabling edge computing for measurement tasks performed by this MCU.

2. Methodology
2.1. SYSTEM STRUCTURE

The proposed system structure is shown in Fig. 1. Two micro switches are used to trigger procedure, which includes knocking, sampling, and edge computing. Moreover, these two switches also could make sure that the hitting situation, such as position and distance. MCU is the center of the system, and controls the full procedure, as mentioned previously, which also provide the edge computing. The UART (Universal Asynchronous Receiver/Transmitter) protocol is adopted for communication with PC, the sound sampling is sent to PC for training from MCU.
Fig. 1 The system diagram

A capacitive microphone is applied to convert sound to voltage, which amplitude is amplified and offset is shift by operational amplifier (OPA) [8] circuit for the input range of the Analog to Digital Converter (ADC), which is a built peripheral function of MCU. The knock component, a solenoid electromagnet, is driven by H-Bridge [9] to eject and attract.

2.2. DATA ANALYSIS AND REPROPCESSING

Before algorithm development, the data analysis is necessary. As mentioned previously, the converted sampling data are sent to PC for analysis and training via UART. The audio voltage is sampled at 10k Hz, and the number of sampling points is 2048 per trigger. The time domain waveforms of the different water levels are shown in Fig. 2 and there is not any saturation and truncation, it means that the sampling rate and length are suitable for this application. To develop the algorithm, the Fourier transform converts waveform data in the time domain into the frequency domain as shown in Fig. 3. Note, the frequency of the first spike, which decreases with increasing water volume, this phenomenon is consistent with the sound heard. Frequency information only from 83Hz to 1464.8Hz is adopted to identify water level. Furthermore, the frequency domain differences between different water levels are obvious, and the classification function could be performed by the artificial neural networks (ANN) model, which is simple and efficient for categorization. Compared to most other AI models, ANN requires less memory and calculation resource, in other words, it is suitable to be adopted into the simple edge-computing platform, MCU. So, Fourier transform (FFT) is selected for pre-processing, and ANN is applied to classify the water level.
Fig. 2 Audio signals at different water level

In order to prevent the data from being affected by abnormal waveforms and to enhance the features, the system adopts Min-Max Normalization for each data. The Normalization finds the maximum and minimum values of the sound frequency, and then converts the maximum value is set to 1, and the minimum value is adjusted to 0. Finally, all audio data are scaled to the range between 0 and 1. The calculation formula is as (1) :

$$X_{nom} = \frac{X - X_{min}}{X_{max} - X_{min}} \qquad (1)$$

Here, X is the original data, Xmin and Xmax are the minimum and maximum value of the frequency domain data, and X_nom indicates the normalized data in frequency domain. The waveforms after data pre-processing are shown in the Fig. 3.
Fig. 3 Audio signals at different water level

2.3. HYPERPARAMETER OPTIMIZATION

Hyperparameter [10] is an important issue in deep learning algorithm as it determines the size and accuracy of AI model by selecting the number of hidden layers, the number of nodes and activation function in each layer. Typically, the hyperparameter combination that achieve the highest accuracy will be chosen to be implemented in the MCU. However, in this system, the implementation of edge computing is also a crucial consideration. Therefore, while ensuring the accuracy requirements are met, it is necessary to select a parameter combination that is suitable for the resource constraints.
Bayesian optimization [11] is a modelling method based on surrogate function that is used to optimizing the hyperparameter in the proposed system. It employs Gaussian process to model and updates the acquisition function based on the model's results, continually exploring the uncertain regions. As the number of searching increases, the surrogate function will be closer to the distribution of real function. Table 1 displays the results by hyperparameter search, sorted by the model size, number of hidden layers, number of nodes in each layer, and the corresponding model size and the accuracy rate Considering the memory limitation of the MCU, the first model which satisfies the accuracy requirements

while also relatively small memory requirements is selected as the training parameters for this system.

Table 1. HYPERPARAMETER BY BAYESIAN OPTIMIZATION RESULTS

Hidden Layer(s)	Node 1	Node 2	Node 3	Node 4	Size (kB)	acc
2	5	5	0	0	49.75	0.99
2	5	7	0	0	49.77	0.98
2	5	16	0	0	50.75	0.99
3	5	8	8	0	57.53	0.99
4	32	32	5	8	172.50	0.99
4	32	32	5	16	174.50	0.80

After confirming the hyperparameters, the collected data and hyperparameters are utilized to train the AI model. The MCU code includes a knocking driver, ADC sampling, and pre-processing functions. Subsequently, the execution program is installed on the MCU. The execution time of the program, as shown in Table 2 is only 0.71 seconds for the entire process, including data sampling, pre-processing, and prediction, as illustrated in Fig. 4. Regarding MCU memory usage, the proposed system requires only 125.8 KB of read-only memory (ROM) and 28.8 KB of random-access memory (RAM). This system can be implemented in most of the memory management systems available in the market.

Table 2. PROGRAM EXECUTION TIME

	Sampling	Pre-processing	Prediction	All

3. Results and Discussion

The edge-computing platform proposed in this paper, which is include MCU, microphone, and solenoid electromagnet is shown in Fig. 5. In the picture, the micro switches on both sides of the solenoid valve ensure that the former can knock the middle of the bottle correctly
Fig. 5 Edge-computing platform

After installing the model into the MCU, the liquid level can be predicted. The performance of the AI model is often assessed using the confusion matrix, which categorizes predicted results into four classes: true positive (TP), false positive (FP), true negative (TN), and false negative (FN). These metrics are used to calculate various performance indicators, including accuracy as defined in formula (5), true positive rate (TPR), false positive rate (FPR), true negative rate (TNR), and false negative rate (FNR).

In this paper, a multicategory model is proposed as the basis of analysis. Fig. 6 illustrates the index calculation for the '100ml' category when there are five output categories. If the predicted result matches the true label ('100ml'), it is labeled as $C\_1,1$ (TP). Here, the symbol C represents a case, and C_(i,j) denotes the case in the i-th row and j-th column of a confusion matrix. Therefore, $C\_1,1$ represents the case in the 1st row (true label: '100ml') and 1st column (predicted label: '100ml') of a confusion matrix. TPR represents the probability that a positive sample is correctly identified as positive, while FPR is the probability that a negative sample is incorrectly classified as positive. TNR is the probability that an actual negative sample is correctly identified as negative, and FNR is the probability that a positive sample is incorrectly identified as negative. A complete list of formulas is provided in the following sections (2) to (6).

Fig. 6 Categories of Confusion matrix

$$Accuracy = \frac{TP + TN}{TP + FN + FP + TN} \tag{2}$$

$$TPR = \frac{TP}{TP + FN} = \frac{C_{100,100}}{C_{100,100} + \sum_{k=200}^{500} C_{100,k}} \tag{3}$$

$$FPR = \frac{FP}{FP + TN}$$
$$= \frac{\sum_{k=200}^{500} C_{k,100}}{\sum_{k=200}^{500} C_{k,100} + \sum_{i=200}^{500}(\sum_{j=200}^{500} C_{i,j})} \tag{4}$$

$$TNR = \frac{TN}{FP + TN}$$
$$= \frac{\sum_{i=200}^{500}(\sum_{j=200}^{500} C_{i,j})}{\sum_{k=200}^{500} C_{k,100} + \sum_{i=200}^{500}(\sum_{j=200}^{500} C_{i,j})} \tag{5}$$

$$FNR = \frac{FN}{TP + FN} = \frac{\sum_{k=200}^{500} C_{100,k}}{C_{100,100} + \sum_{k=200}^{500} C_{100,k}} \tag{6}$$

Chung-Wen Hung, Chun-Liang Liu, Tai-Hsuan Wu, Chau-Chung Song

The Fig. 7 confusion matrix summarizes the actual and predicted classifications of online testing, and the confidence values of each liquid level are in line with expectations. As a result, 95% accuracy when calculating the true negative value of each water level, and 99% accuracy rate when calculating the full water levels.

The results of this study can be used to verify the feasibility of the proposed system as well as the discussed artificial intelligence model.
Fig. 7 Confusion matrix of the model

4. Conclusion

The paper proposes a MCU-based edge computing platform for liquid level measurement. This includes not only a knocking block, an audio signal preprocessing circuit, and MCU. but contains a detailed explanation of the development process, such as the optimization of hyperparameters, conversion of the model and installation for MCU. The utilization of glass bottles in the experiment led to more pronounced variations in the energy of the knocking sound. The experimental results can be up to 99% accurate under multiple tests. Experimental results indicate that the system is feasible and measurement accuracy is acceptable.

Abstract

For a rapid area coverage multiple UAVs are often used simultaneously. However, a path planning for a UAVs group during an area coverage task is computationally challenging. In practice, heuristic algorithms are applied to solve this problem. This paper overviews approaches to an area coverage problem with a group of UAVs using genetic algorithms. The article explores modifications that may be useful for a genetic algorithm for solving the coverage problem as well as representation methods for chromosomes that reflect a path of multi-UAV. Additionally, UAV group collision avoidance strategies during area coverage are considered.

Keywords: Genetic algorithms, Coverage path, multi-UAV coverage

1. Introduction

A current rapid progress in robotics drives robotic systems into many areas of a human life including autonomous driving [1], manufacturing [2], search and rescue activities [3], agriculture [4], [5], and medical services [6]. In modern industrial applications of Industry 4.0 [7] a human–robot interaction in a shared workspace is emphasized [8], [9]. Service robotics [10] is a promising area for robots' integration covering multiple applications from education [11] and medicine [12] to entertainment [13] and advertisement [14]. A task of area coverage using mobile robots often arises in various practical applications of mobile robotics. Together with a proper scheduling, a determining of an optimal route for a mobile robot to ensure coverage of all points in a certain area while avoiding collisions with obstacles plays an important role [15].

Unmanned Aerial Vehicles (UAVs) provide an efficient solution for automating coverage and monitoring of large areas. UAVs are not constrained by obstacles on the ground and can quickly navigate through hard-to-reach areas while reducing human labor costs [16]. The use of UAVs for area coverage can be a key element in solving complex problems such as security [17], mapping [18], forest fire monitoring [19], search operations [20]. The task of covering an area with a group of UAVs attempts finding a path for each UAV such that the UAVs observe all locations of a given area without colliding with each other [21]. This task may have constraints, such as a time limit for an entire mission, safety constraints related to a minimum distance between UAVs, flight range constraints due to a battery capacity, and others.

The coverage path problem for a mobile robot is NP-hard [22] due to a need of analyzing an entire set of possible solutions, a number of which grows exponentially with increasing a complexity and a size of an area to be covered. In practice, heuristic algorithms are often employed for this task as they allow to get close to the optimal solution rather quickly, yet do not find a guaranteed optimal solution.

Genetic algorithms are popular heuristic algorithms that have a relatively simple implementation and could be easily parallelized, which is especially important when working with large solution spaces. Genetic algorithms can deal with multiple optimization criteria, which is often the case in practice. They provide a method for

exploring an entire solution space to find a global optimum, which is useful in problems with many local extrema. All these turn genetic algorithms into an effective solution of the multiagent coverage problem.

2. Genetic algorithms

Genetic algorithms are based on principles of biological evolution and often are applied to search problems [23]. They model a process of natural selection to find optimal solutions. These algorithms interact with a population of potential solutions, each called an *individual*. By successively evaluating a set of solutions a new generation is created. The best solutions have a higher chance of passing on their characteristics to a next generation. Over time, solutions within the population become better adapted to a particular task.

First a genetic algorithm creates an initial population, which in typically contains random *chromosomes*. Each chromosome is a possible solution of a problem and a fitness function assigns each chromosome a numerical value that reflects its effectiveness in solving the problem. To create a next generation, individuals are selected from the population in a fixed manner. Individuals with a higher fitness for an environment have a better chance of surviving and passing their traits on to the next generation. This leads to an improvement in the population over time. A crossover operation is performed to create new offspring chromosomes. This allows new individuals to inherit the best characteristics from their parents, thus preserving them for future generations. Mutations are random changes in chromosomes of individuals that maintain a genetic diversity and periodically contribute to significant leaps in a population development. After a crossover, there is a certain probability that a mutation occurs. This mutation slightly alters chromosomes of an offspring.

3. Features of genetic operators' application in area coverage

In the area coverage problem for UAVs, it is necessary to find an optimal trajectory employed by a UAV to visit all given points of an area. Each chromosome encodes a trajectory of a UAV and the population is a set of possible UAV trajectories. In practice, chromosomes are usually sequences of integers, yet a user decides on a way of trajectory encoding within a chromosome [24].

An important feature of applying a genetic algorithm to the coverage problem is that after crossover or mutation operations, a chromosome must encode some trajectory for a UAV. Therefore, crossover and mutation operations are subjects to certain constraints.

Fig. 1 shows a two-point classical crossover operation that produces two offspring. A chromosome represents an order of visiting obstacle-free cells while covering a

UAV's assigned area. If parents represent acceptable chromosomes, the offspring could contain the same genes and do not represent solutions of the coverage problem. For example, child A contains genes 2, 4, and 5, and according to the chromosome, the UAV trajectory passes through these regions twice, but it does not visit regions 1, 3, and 8.
Fig. 1. An example of a crossover operation where an offspring no longer reflects a proper UAV trajectory

One solution is to modify the crossover operation. For example, using a two-point crossover from a single parent. With this method of the crossover from a single parent many children are formed and then two with a highest value of the fitness function are selected (Fig.2). In this case, each offspring reflects a proper UAV trajectory. In [25] the authors reported a four times computation acceleration of a genetic algorithm simulation using the proposed crossover method.
Fig. 2. An example of a crossover from one parent producing three offspring

4. Single UAV and group of UAV coverage tasks

In practice, using a group of UAVs for an area coverage increases a speed and a reliability of the procedure. Each UAV acts as a moving obstacle for other UAVs, and its route cannot be planned in isolation from the rest of the group [26]. Therefore, the genetic algorithm must consider routes of all UAVs together. A multiagent coverage problem solution is a path for each UAV in

which they cover a given area together and do not collide with each other, i.e., the solution combines paths of all UAVs into a single chromosome (Fig. 3) [27].
Fig. 3. A chromosome combines paths of four UAVs

5. UAV group collision avoidance strategies during area coverage

While using a group of UAVs reduces a time to complete the task, it also introduces potential risks of UAV collisions during the mission. Two strategies of UAVs' collision avoidance are discussed in this section in the context of genetic algorithms: assigning UAVs a different coverage areas and introducing a penalty for approaching other UAVs.

In the first approach, to prevent UAVs from colliding in the air, the area could be divided into equal subareas and each UAV is assigned a different subarea to cover [28]. This method allows a computation paralleling for each UAV with a genetic algorithm (as their trajectories are independent, (Fig. 4) and keeps a genetic algorithm simple. Disadvantages of this strategy include a high dependence of a resulting coverage effectiveness on a quality of an area distribution between UAVs, collision avoidance considerations while distributing UAVs (that takeoff in a common area) for the assigned subareas, and complicated splitting into subareas for a case of different survey priorities of the subareas.

In the second approach, a penalty function can be introduced to reduce a fitness function value if UAVs fly too close to each other at a coverage time [29]. This strategy is a flexible way to influence the genetic algorithm and allows using different penalty functions depending on task goals. Yet, it requires a pairwise
Fig. 4. Example of division of area to be covered into separate areas for each UAV

comparison of a minimum distance between each pair of UAVs and as a number of UAVs increases, a complexity increases exponentially.

6. Conclusions

Classical genetic algorithms require a task dependent adaptation in order to be employed for the problem of covering a known territory with a group of UAVs as the use of standard genetic algorithm operators in this context may destruct a chromosome that represents a trajectory of a UAVs' group. Genetic algorithms should optimize methods of representation and decomposition of a surveyed area and incorporate dynamic obstacles' collision avoidance strategies to increase the efficiency of their usage.

Abstract

The functionality of industrial robots is provided primarily by the capabilities of their end effectors. The limited capabilities of robotic grippers determined the transition to the creation of anthropomorphic grippers. The number of degrees of freedom (DOF) of the end effector in the form of an anthropomorphic hand ensuring reliable grasping and holding the object should be at least nine, preferably twelve. The implementation of such a design is possible only when switching to the principle of construction of an underactuated grippers system. This paper presents the concept of constructing a group drive, which ensures the implementation of the movement of the output links of two or more executive groups from one motor. Technical solutions are based on the development of methods for analyzing complex mechanical systems using functional circuits.

Keywords: Anthropomorphic gripper, underactuated grippers, end effector, robotic grasp

1. Introduction

Today, robotic manipulators are actively used in industrial production [1]. They improve working conditions of employees and reduce enterprise costs ensuring a continuous production. Typical applications include assembly, casting, stamping, cutting, machine loading/unloading, welding and material handling [2]. Generally, a robotic arm functionality is determined by design and properties of an end effector. The most applied end tool is a robotic gripper. The choice of a grip depends on many characteristics, including weight, shape of an object, motion speed, permissible compression force, and a point of contact [3]. Values of each characteristics are often taken into account at a design stage of a robotic arm. Thus, problems arise with an inefficient operation of a robot in case of miscalculations in the design or/and an inability to adjust the arm to a new task. One of the solutions is to unify the hand [4].

The most widely used are universal vacuum suction grippers and multi-fingered hands [5]. The first one is a single mass of granular material that flows around a target object and takes its shape upon applying a pressure on the object. The disadvantage of this approach is a need to return to a neutral state after each grasping. Multi-fingered hands usually possess many independently actuated joints. This design of the end effector has sufficient softness and rigidity for a reliable and stable grip of an object [6]. [7]. MCU Based Edge Computing. The main difficulty of the approach is related to a computational complexity of tactile sensing and computer vision based algorithms [8]. Our research is aimed at developing a concept of a multi-fingered hand using both active and passive joints. Such design allows

Evgeny Dudorov, Ivan Zhidenko, Alexander Permyakov, Julia Zhdanova, Vladimir Moshkin, Alexander Eryomin, Evgeni Magid

the hand to envelop an object without complex calculations.

The most common anthropomorphic grippers are structure diagrams of grippers with three [9] or four parallel executive groups of links [10]. Each executive group includes, as a rule, three output links [11]. Collectively, the gripper has nine or more degrees of freedom (DOF). There are two typical layout schemes for installing individual drives for each link. In accordance with the first one, the motors are placed at the output links [10]. In the second case, the motors are located within a single link of the manipulator [12], [13].

Typically, dimensions of output links do not allow internal installation of motors with a sufficient power [14]. Consequently, forces generated at endpoints of the output links do not exceed 1.5 N [10]. Installing motors in a single link involves a significant complication of a design. For instance, a gripper by DLR [15] has 65 pulleys for laying flexible rods on a manipulator link and 38 pulleys directly on the gripper. At the same time, it is also impossible to provide a significant effort at the output link. In a modified DLR version, the maximum force is 9 N [16]. The use of individual drives complicates a control system. In this case, a number of controllers for drives equals to a number of output links.

A group drive solves the abovementioned problems of controllability and complexity of individual drives. In the ASIMO grippers [17] and JPL‐Nautilus Gripper [18] a single motor provides a movement of three output links in each executive group. An object is grasped according to the principle of kinematically dependent movements of the links. Thus, the manipulator reliably grips objects of only a certain size with all three links.

2. Related Work

A qualitative change in operational characteristics of a system with a group drive is achieved by using a principle of underactuated grippers. It is based on an implementation of additional passive elements into a structure of each executive group. These can be compression springs [19], [20] or tension springs [21], [22]. At the same time, an adaptive motion control is implemented by output links in the executive group. Links move sequentially, from a proximal link to a distal link. A change of a control object (an output link) is achieved when external conditions change, and a moving link stops after reaching an external object.

A further reduction of anthropomorphic gripper mass is possible by ensuring a motion of output links of adjacent executive groups from a single motor. Using the principle of underactuated grippers, flexible elements should be placed into a group drive system for an entire gripper. Similarly, for the executive group, this will ensure independent motion of the executive groups of links from

a single motor. Thus, inspired by [23] we designed a modifiable structure of an anthropomorphic gripper, which is presented in this paper.

3. A gripper design

The proposed design is based on an anthropomorphic gripper with two parallel executive groups of links (Fig. 1). From motor 1 that is installed at the basis of the gripper, the movement is transmitted by two parallel streams to two executive groups. A flexible twisting spring is integrated into a kinematic scheme of each stream, connecting coaxial shafts *a* and *b*. Links 2 and 3 transmit movement through transmission systems to the output links using the shafts. The installation of flexible elements adds a relative rotation of the coaxial shafts to a motion transmission system.
Fig. 1. Structure diagram of an anthropomorphic gripper with two parallel executive groups of the output links.
Fig. 2. Structure diagram of an anthropomorphic gripper with two opposite executive groups of the output links.

Fig. 2 shows a structure diagram of the anthropomorphic gripper with opposite executive groups of links 4, 5 and a lever system for motion transmitting [24]. The movement is transmitted from motor 1 in two parallel streams to driving links 2 and 3 involving twisting springs *a* and *b*. Then links 2 and 3 set into motion lever mechanisms 6 and 7. Executive groups 4 and 5 are constructed using the principle of underactuated grippers. Compression springs *d* and *c* are installed between the links of the motion transmission system and the driving links.

Executive groups 4 and 5 move from initial position synchronously in a direction of an object located between them, which should be grasped. A grasp can shift towards one of the executive groups, depending on a shape of the object. As the object is gripped by link 8, a rotational movement of leading link 2 decreases and spring *a* gets partially deformed. After grasping the object with all links 8-10, the transmission of rotation through spring *a* stops and the spring gets twisted. The movement of executive group 5 is maintained until its links completely encircle the object. The rotation of the motor stops after reaching a preset torque value. Deformed springs *a* and *b* retain a force corresponding to an end of the grasping process. This provides a given force effect on the object.

Fig. 3. The constructed anthropomorphic gripper with three executive groups of links.

Fig. 3 shows the constructed anthropomorphic gripper with three executive groups of links. The single motor provides the movement of the output links. The distal link possesses 10.5 N force for the entire length of the executive group links of 100 mm.

4. Conclusion

The paper proposed a new design an anthropomorphic hand with an underactuated gripper. A movement of output links of several executive groups of the gripper is performed using a single motor. A number of implemented flexible links equals to a number of executive groups. A shape of an object to be grasped determines a resulting motion of executive group links and a sequence of their motion. Experimental validation confirmed feasibility of the proposed construction of the anthropomorphic gripper.

Abstract

As drones navigate through shared airspace, they often encounter other drones, wireless devices, and communication systems. This coexistence creates potential sources of interference that can degrade the signal-to-noise ratio (SNR). To maintain reliable communication in drone systems, it is crucial to effectively manage and mitigate interference from other drones and wireless devices operating on the same frequency bands. By addressing these challenges, we can ensure a stable and dependable SNR for seamless communication among drones. This paper sheds light on the history of applications and challenges of utilizing flying base stations for wireless networks and analyzes different factors that affect signal-to-noise ratio (SNR) to enhance the performance of drone communication.

Keywords: SNR, UAV, drone, Matlab, IoT

1. Introduction

Unmanned aerial vehicles (UAVs) are set to play a crucial role in the next generation of wireless networks, offering a promising solution to meet the ever-increasing user demands. Their mobility, flexibility, improved line-of-sight capabilities, and ability to reach inaccessible areas make them ideal candidates to act as aerial base stations. Researchers are actively exploring various aspects of deploying, analyzing performance, managing resources, optimizing trajectories, and modeling channels in such networks. This survey article focuses on different applications and the algorithms involved in implementing aerial base stations, providing a comprehensive review of each research area. In summary, this article highlights the key applications, challenges, and technology employed in the design and analysis of UAVs as base stations.

In recent years, the widespread adoption of drones across various industries and applications has been remarkable. From capturing stunning aerial photographs to delivering packages, drones have become increasingly prevalent. One crucial factor that significantly influences the performance and efficiency of drone networks is the signal-to-noise ratio. The signal-to-noise ratio represents the ratio between the desired signal and unwanted noise in a communication system. A high signal-to-noise ratio is paramount for clear and reliable communication between drones and ground control stations, as well as for

accurate data transmission [1]. However, achieving a high signal-to-noise ratio in drone networks presents several challenges [2]. The use of multiple drones operating in close proximity can result in interference and signal degradation, affecting the overall quality of communication. Moreover, the noise generated by the drones themselves, commonly referred to as ego-noise, can further impact the signal-to-noise ratio. These challenges necessitate careful consideration and innovative solutions to optimize the signal-to-noise ratio in drone networks, ensuring efficient and reliable communication between drones and ground control stations [3]. The interference experienced by each drone at a particular location can be measured by its signal-to-noise ratio (SNR). The SNR is influenced by multiple factors, including the transmission power levels, antenna properties, drone altitude, path loss, and the power spectral density of the surrounding noise. These variables collectively contribute to the observed interference levels and play a crucial role in determining the quality of communication in drone networks [4]. The altitude at which drones fly significantly impacts the signal-to-noise ratio in their networks. Higher altitudes result in larger distances between the transmitter and receiver, leading to a decrease in signal quality. Atmospheric attenuation further contributes to signal loss as altitude increases. Transmission power levels and antenna characteristics of drones also play a vital role in determining signal strength. Optimal power levels ensure overcoming noise and interference, while antenna properties affect signal

Gershom Phiri, Mastaneh Mokayef, MHD Amen Summakieh, M. K. A Ahamed Khan, Sew Sun Tiang, Wei Hong Lim, Abdul Qayyum

coverage and directionality. Lastly, the noise power spectral density, originating from various sources, introduces background noise that affects the overall signal-to-noise ratio. Careful consideration of these factors is crucial for maintaining reliable communication in drone networks [5], [6], [7]. In [8], they delve into the realm of drone-assisted backscatter communication within an Internet of Things (IoT) sensor network. Their work focuses on developing a framework to evaluate the likelihood of ground-based sensor nodes being covered. Raja's study in 2021 explores how communication propagates between drones and base stations in indoor environments, taking into account factors like diffraction, frequency, and atmospheric attenuation [9]. While paper [10] proposes an innovative multi-UAV communication model that prioritizes security. This model employs a wireless mesh network and cryptographic techniques to ensure efficient and protected communication among multiple drones. The study underscores the significance of establishing reliable data communication security between drones and servers. Collectively, these papers offer valuable insights into coverage probability assessment, propagation mechanisms, multi-UAV coordination, and security measures within the realm of drone communication. To aid in understanding the communication requirements of UAVs, Table 1 concisely presents a summary of these requirements. This reference table offers a clear and accessible overview of the key aspects involved in UAV communication, making it easier for readers to grasp the necessary information.

Table 1: Essential Communication Requirements for UAV Systems

	Data Type	Data Rate
DL	Synchronization (PSS/SSS)	N/A
	Radio control (PDCCH)	
	Command and control (C&C)	60-100 kbps
UL	Command and Control (C &C)	60-100 kbps
	Application data	Up to 50 Mbps

A Comparative Study of the distinctive features of drone types are presented in [9], [10], [11] and the summary of these results is tabulated in Table 2.

Table 2: Distinctive Features of Drone Types [11], [12]

	Micro (weight6100g)	Very Small (100g<weight<2kg)	Small (2kg6weight<25kg)	Medium (25kg6weight6150kg)	Large (weight>150kg)
Model	Kogan nano drone	Parrot Disco	DJI Spreading Wings S900	Scout B-330 UAV helicopter	Predator B
Illustration	A 16g N/A Multi-rotor	B 750g N/A Fixed-wing	C 3.3kg 4.9 kg Multi-rotor	D 90kg 50kg Multi-rotor	E 2223kg 1700kg 1700kg Multi-rotor
Weight	16g	750g	3.3kg	90kg	2223gg
Payload	N/A	N/A	4.9kg	50kg	1700kg
Flying mechanism	Multi-rotor	Fixed-wing	Multi-rotor	Multi-rotor	Multi-rotor
Range	50-80 m	2km	N/A	N/A	1852km
Altitude	N/A	N/A	N/A	3km	15km
Flight time	6-8 min	45min	18min	180min	1800min
Speed	N/A	80 km/h	57.6 km/h	100km/h (horizontal)	482km/h
Power supply	3.7V/160mAh Li-battery	2700mAh/25A 3-cell LiPo Battery	LiPo Battery (6S, 10000mAh_15000mAh, 15C(Min))	Gasoline	950-shaft-horsepower Turboprop Engine

2. Methodology
2.1. Performance evaluation Through SNR strength

Unmanned aerial vehicles (UAVs) have gained significant popularity, due to their autonomous features, versatility, and wide range of applications. In this section, we will delve into a detailed evaluation of drone performance. Our main focus will revolve around analyzing a key metric of the SNR. This metric will be used to thoroughly assess and scrutinize the effectiveness of drone operations, providing valuable insights into their overall efficacy. SNR is commonly expressed in decibels and represents the ratio of signal power to noise power. An SNR greater than 1:1 (greater than 0 dB) indicates that the signal is stronger than the noise. When information is transmitted wirelessly from one point to another, it is

referred to as a data link. In the context of unmanned aviation, this wireless transmission is known as a radio link or radio modem. The data link enables the exchange of information between the aircraft's autopilot and the Ground Control Station (GCS). This communication involves two distinct links: the uplink, which transmits information from the GCS to the aircraft, and the downlink, which transmits information from the aircraft to the GCS. Eq. (1) is used to calculate the SNR level.

$$SNR\ (dB) = P_{signal}\ (dB) - P_{noise}\ (dB) \quad (1)$$

Where P is the power. The power levels can be expressed in decibels per dBm. The range at which a drone can fly in relation to a base station is determined by the minimum SNR required for the specific application. It is important to establish the maximum distance that can be achieved while maintaining the desired SNR. During flight, the SNR changes as the drone moves through different distances, adapting to meet the target SNR. To illustrate this relationship, Fig. 1 depicts a simulation graph created using MATLAB, showing how the SNR is influenced by the distance traveled by the drone.

a.

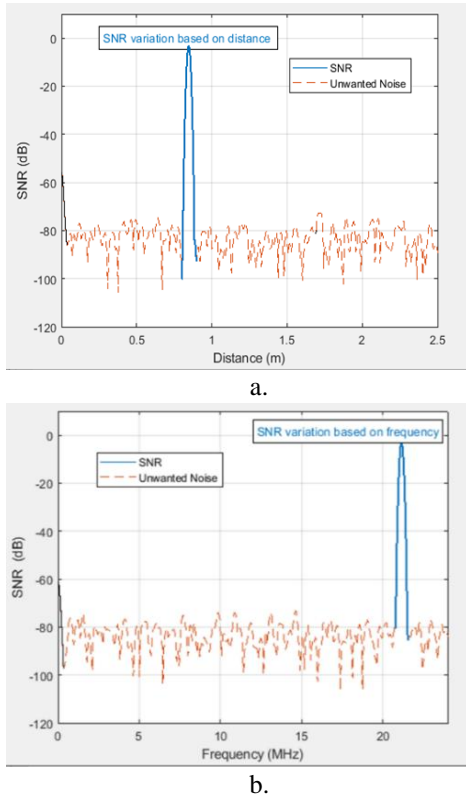
b.


Fig. 1 SNR as a function of (a) distance traveled by drone, and (b) frequency of operation [13]

2.2. *SNR enhancement methods*

The analysis presented in Fig. 1 provides valuable insights into the significance of the signal-to-noise ratio (SNR) in determining the quality of output. The observed threshold value for SNR is -10 dB; however, to achieve

optimal output quality, it is recommended to have an SNR higher than -20 dB. The graph illustrates a gradual decline in signal quality as the range increases, with the highest signal quality observed in close proximity to the transmitter. Considering the fixed parameters of a frequency threshold of 2.4 GHz, a power threshold of 1W, and a specific distance, it becomes evident that a stronger signal is required at a distance of 1m and a frequency of 10 MHz, with a transmit power of 1W [11]. This is due to the reduced interference from various sources such as remote controls, phones, Bluetooth devices, plants, and buildings, which tend to degrade the signal quality. As the distance between the transmitter and receiver increases, the SNR decreases, indicating weaker signal quality at longer ranges.

3. SNR enhancement by Array Gain for Line-of-Sight Propagation

SNR enhancement by array gain is a technique used to improve the quality and reliability of wireless communication in line-of sight propagation scenarios. Modern wireless communication systems often implement large-scale antenna arrays to take advantage of the benefits offered by array gain [14]. To improve the SNR level and consequently wireless communication, we proposed the use of an array antenna instead of the single antenna into the drone side [15], [16]. The SNR is calculated and compared for both SISO and SIMO cases using Eq. (2) and Eq. (3) respectively.

$$SNR_{siso} = \frac{P_t G_t G_r \lambda^2}{4\pi d^2 N_0} \quad (2)$$

Where P_t, G_t, G_r, and λ are transmitted power, Transmitted gain, Received gain and wavelength of transmitted signal respectively. The d and N_0 also stands for distance between transmitter-receiver, and the noise power.

$$SNR_{siso} = \frac{P_t G_t \sum G_{ri} \lambda^2}{4\pi d^2 N_0} \quad (3)$$

Where G_{ri} is the gain of the i-th receiving antenna.

The result of these calculations has been presented in a comparison way showing the energy per bit to noise power spectral density ratio. This technique is commonly used as a metric to quantify the quality of a communication system in terms of the received signal power and the noise power affecting the transmission.
Fig. 2 Energy per Bit to Noise Power Spectral Density Ratio (E/N) Comparison for SISO and SIMO Systems

Due to the LOS communications, the transmitter and receiver are in direct communication. For the ease of calculation, a four-element Uniform Linear Array (ULA) with half-wavelength spacing, is considered in our simulations. The SISO and SIMO channel BER and the energy per bit to noise power spectral density ratio is depicted in Fig. 2. In a SIMO system, the BER curve demonstrates a notable improvement of 6 dB when a receive array is utilized. This gain is primarily attributed to the coherent nature of the received signals that interact with the components of the receive array. As a result, the receive array can be strategically oriented towards the transmitter, leading to an enhanced Signal-to-Noise Ratio (SNR). This phenomenon indicates that the receiver has knowledge of the incoming signal path, allowing for improved performance in terms of signal quality and error rate. The observed gain can be explained by the fact that the received signals around the receive array components exhibit coherence. This coherence arises due to the spatial diversity provided by multiple antennas in the receive array. Each antenna captures multiple instances of the transmitted signal, with slight variations in phase and amplitude. When these signals are combined, they undergo constructive interference, leading to an increase in the overall received signal power. This phenomenon highlights the advantage of utilizing a receive array with multiple antennas, as it enables the system to effectively capture and utilize the coherent signals, resulting in improved signal strength.

4. Conclusion

In summary, this research paper emphasizes the significant role of Unmanned Aerial Vehicles (UAVs) in wireless networks, offering a wide range of applications such as aerial base stations, wireless network user services, and mobile relays in flying ad-hoc networks. Deploying UAV base stations can greatly enhance wireless network coverage and power, enabling communication in various scenarios, including those where the dissemination of public safety information is critical. Furthermore, UAVs show promise in supporting secure and energy-efficient millimeter-wave communications and Internet of Things (IoT) communications. When equipped with cellular links, drones require secure and low-latency communication with ground base stations. The coherent nature of received signals through the Single-Input Multiple-Output (SIMO) receive array presents an opportunity to direct the array towards the transmitter, thereby increasing the Signal-to-Noise Ratio (SNR). Analysis of the Bit Error Rate (BER) curve reveals a gain of 6 dB achieved through the utilization of the receive array. This gain indicates that the receiver has knowledge of the incoming signal path. These findings highlight the advantages of incorporating UAVs into wireless networks, showcasing their potential to enhance coverage, power, and communication capabilities. The ability to steer the receive array towards the transmitter, coupled with the coherent nature of received signals, contributes to improved SNR and overall system performance. Future research can focus on optimizing UAV deployments, refining beamforming techniques, and exploring additional applications where UAVs can be effectively utilized in wireless networks. By harnessing the capabilities of UAVs in these contexts, advancements can be made towards more secure, reliable, and efficient wireless communication systems.

Authors Introduction

Dr. Mastaneh Mokayef

She has received her PhD from Wireless Communication Centre Faculty of Electrical Engineering in University Technology Malaysia (UTM) in 2014. She has also obtained her master's degree from the faculty of engineering in 2009 from the University Technology Malaysia. She has been working in UCSI University, Malaysia, since 2015 in which she currently serves as an Assistant Professor in the Faculty of Engineering and Built Environment. Her research interests include: Wireless communications, spectrum sharing method, spectrum management, etc.

Mr. MHD Amen Summakieh

He received the B.Eng. degree (Hons.) in communication and electronics engineering from UCSI University, Malaysia, in 2016, and the M.Eng.Sc. degree from Multimedia University, Malaysia, in 2020. His research interests include heterogeneous LTE-advanced cellular networks, user association, metaheuristic algorithms, and antennas design.

Dr. M. KA. Ahamed Khan

He completed his undergraduate degree in Electronics and Communication Engineering and postgraduate degree in Electronics and Control Engineering in India. Additionally, he obtained an advanced diploma in Power Electronics and Drives from Lucas-Nuelle in Germany in 2002, and a Diploma in Drives and Controls from Woo Sun in Korea in 2014. He pursued a PhD in Robotics, Power Electronics, and Controls in the United States and holds certifications. He is a Senior member of the IEEE in the USA and a member of MIET in the UK.

Dr. Sew Sun Tiang

She is an Assistant Professor in Faculty of Engineering at UCSI University in Malaysia. She received her PhD in Electrical and Electronic Engineering from Universiti Sains Malaysia in 2014. Her research interests are optimization and antenna design.

Dr. Wei Hong Lim

He is an Assistant Professor in Faculty of Engineering at UCSI University in Malaysia. He received his PhD in Computational Intelligence from Universiti Sains Malaysia in 2014. His research interests are optimization and artificial intelligence.

Dr. Abdul Qayyum

He received his PhD in Electrical and Electronic Engineering from Universiti Teknologi Petronas, Malaysia, in 2018. He developed the totype. Previously, he completed his bachelor's degree in computer engineering and master's degree in electronic engineering from Pakistan. He is a postdoctoral researcher at the University of Burgundy, France, where he studies cardiac MRI images using deep learning approaches. He is currently affiliated with the National Heart and Lung Institute at Imperial College London, UK.

Empowering Elderly Individuals through the Intelligent Shopping Trolley

Abstract

In this research, we have developed a prototype that aims to improve the weekly shopping experience for senior citizens. Our system tracks the movements of elderly individuals, eliminating the need for them to exert physical force in pushing or pulling the shopping trolley. To achieve this, we utilize a combination of sensors, including a gyroscope and magnetometer, to estimate the user's walking distance and direction. Additionally, we employ WiFi fingerprinting to accurately determine the user's position. Our experiments have yielded satisfactory results in terms of tracking accuracy and the overall functionality of the system. By addressing the specific challenges faced by senior citizens during the routine and essential process of grocery shopping, our smart shopping trolley concept seeks to enhance their experience. Through the integration of tracking technology and sensor-based solutions, we aim to make shopping more convenient and comfortable for elderly individuals. The positive outcomes observed in our experiments validate the effectiveness and feasibility of this approach.

Keywords: smart shopping trolley, elderly citizen, smart phone, UML

1. Introduction

Senior citizens often encounter challenges when it comes to shopping, particularly in the case of grocery shopping. While there are options available such as helpers or online shopping, many elderly individuals prefer to do their own shopping but still require assistance in carrying their bags back home. The advancement of technology has sparked interest in integrating different systems, resulting in the rise of the Internet of Things (IoT) and its widespread use in wireless communication.

The term "smart" has become increasingly common in various electronic devices and technologies, such as smartphones, smart cars, smartwatches, and even smart homes. In line with this trend, the concepts of "smart shopping" and "smart trolleys" have emerged to provide valuable support to senior citizens. Smart trolleys often incorporate Radio Frequency Identification (RFID) technology, enabling products to be scanned as they are placed in the trolley. By utilizing ZIGBEE communication, the collected data can be transmitted to the counter, reducing the time spent waiting in queues. Moreover, the use of RFID technology in smart trolleys can enhance security by facilitating cashless transactions.

Additionally, the successful integration of purchased items, payment systems, and data collection relies on the implementation of IoT standards. This ensures smooth connectivity and compatibility among the various components involved in the shopping process. The Internet of Things (IoT) field is experiencing rapid growth in the world of wireless telecommunications [1]. Its purpose is to enable computers to interact with their surroundings and access information about devices and objects without the need for direct human involvement [2]. According to a report [3], IoT is characterized by moderate data transmission rates, affordability, and operates within the frequency range of 100MHz to 5.8GHz. This advancement in wireless technology offers users a flexible and cost-effective means of communication. A recent report [4], [5] suggests that by the year 2020, around 50 billion devices will be

Mastaneh Mokayef, Muzaiyanah Binti Hidayab, MHD Amen Summakieh, M.K.A Ahamed Khan, Kim Soon Chong, Chin Hong Wong, Chua Huang Shen, Abdul Qayyum.

connected to the internet, opening up a plethora of functionalities. There is a rising demand for technology and a growing need for convenient shopping experiences, which has spurred increased research efforts in the development of smart shopping concepts. These trolleys are equipped with core functionalities such as following the user, navigating through the shopping paths, and avoiding collisions with obstacles. This technology aims to eliminate the physical strain and difficulties that elderly individuals often face while shopping, resulting in a more comfortable and enjoyable experience. Advancements in autonomous navigation have been a key focus in the development of smart shopping trolleys. Researchers have been exploring various approaches to enable autonomous navigation for smart shopping trolleys. For example, a new automated smart cart system for modern shopping centers was presented, along with Android application-controlled approaches [1]. These advancements in autonomous navigation provide the trolleys with the ability to move independently, allowing elderly individuals to navigate the store without physical exertion. The implementation of smart shopping trolleys for elderly care holds several key advancements and benefits. Other recent reports in [6], [7] describe a smart trolley system for mega malls that uses a microcontroller. It allows customers to automatically scan products with a barcode scanner and see running totals on an LCD display, without needing to queue for checkout.

In this paper, the novel smart shopping trolley has been introduced. The proposed smart trolley is designed to avoid the pushing the typical shopping trolley. It is also designed to follow the user to ease of the controlling process for the user.

2. Hardware Interfaces

The smart shopping trolley designed specifically for elderly care integrates various essential components to improve its functionality and user-friendliness. These components are crucial in creating a smooth and convenient shopping experience for elderly individuals. The following are the components utilized in this project:

2.1. *Micro Controller Unit (NodeMCU)*

The NodeMCU micro-controller is used in this project as the main controller which has the integrated WiFi module. NodeMCU is an open source Lua based firmware for the ESP8266 WiFi SOC from Espressif and uses an on-module flash-based SPIFFS file system. NodeMCU is implemented in C that ease the use of this component in IoT based projects.

2.2. *DC motor*

A utilized DC motor would have only two terminals. Since these terminals are connected together only through a coil, they do not have a polarity. Revering the connection will only reverse the direction of the motor.

2.3. *Inertial gyro sensor*

In our proposed design, we have included a special sensor called a gyroscope to help us keep track of how something is rotating. This sensor is pretty clever because it also has a built-in accelerometer, which measures how fast something is moving in a straight line. So, while the accelerometer tells us about the linear movement of the user, the gyroscope tells us about the angular rotation. By combining these two sets of information, we can accurately detect and understand how the user is moving. Another great thing about this sensor is that it's small and doesn't cost too much, which makes it a perfect fit for our project. We wanted to make sure we chose components that are both effective and affordable.

2.4. *H-Bridge dual motor controller L298N*

In order to control the rotation direction of the motor, the current flow through the motor must be inverted. The most common method of doing that is by using an H-Bridge circuit. An H-Bridge circuit contains four switching elements, transistors or MOSFETs, with the motor at the center forming an H-like configuration. By activating two switches at the same time, the direction of the current flow and as a result the rotation direction of the motor will be changed. In this project, the L298N is used as a dual H-Bridge motor driver which allows speed and direction control of two DC motors at the same time.

3. Design and fabrication

In the world of shopping trolleys, we've seen various types introduced over the years. However, our project takes things a step further with the development of a smart shopping trolley that brings convenience to a whole new level. Imagine being able to control your shopping trolley using your smartphone, thanks to Wi-Fi technology. Through a real-time Wi-Fi connection between the trolley's micro-controller and your smartphone, you can effortlessly guide the trolley to your desired destination. All it takes is a few taps on a dedicated app installed on your smartphone to send commands to the micro-controller via the Wi-Fi signal. It's like having a personal assistant for your shopping needs.

But convenience isn't the only thing we focused on. We also wanted to ensure the safety of both the user and the trolley. That's why we integrated an ultrasonic sensor right at the front of the trolley. This little hero plays a crucial role in preventing accidents and damage caused by sudden stops or collisions. It works by emitting sound waves and then listening for the echoes that bounce back. By analyzing the time it takes for the sound waves to travel and return, the ultrasonic sensor can accurately

measure the distance between the trolley and any obstacles in its path. This allows the trolley to adjust its movement and avoid potential collisions by utilizing the signals it sends and receives. So, in a nutshell, our smart shopping trolley combines the convenience of smartphone-controlled Wi-Fi technology with the added peace of mind provided by the ultrasonic sensor. With this integration, we aim to enhance your shopping experience by giving you seamless control and ensuring a safe journey through the store, effortlessly avoiding obstacles along the way. It's like having a reliable shopping companion right by your side. The operation of ultrasonic sensor has been shown in Fig. 1.
Fig.1 Obstacle detection via ultrasonic sensor

To establish the necessary connections for the ultrasonic sensor in the trolley, we connect the VCC (power supply) and GND (ground) pins to a 5V power source. Additionally, the trigger input (Trig) pin is linked to a digital output, while the echo (Echo) pin is connected to a digital input on the trolley's microcontroller.

To accurately measure the distance between the trolley and an obstacle, we employ a technique that involves pulsing the trigger pin to a high level for approximately 10 microseconds. After that, we wait for a high-level signal on the echo pin. The duration of this high-level signal corresponds to the time it takes for the ultrasonic sound to travel to the obstacle and back. By analyzing the response time and duration, we can determine the proximity of the trolley to the obstacle. This allows for precise distance measurement and enables the trolley to effectively detect and avoid obstacles. The distance can be calculated as follows:

$$\text{Distance}= \text{Time}\times\text{Speed}=\text{time}\times0.034\text{cm/µs} \quad (1)$$

As sound travels at approximately 340 meters per second. This corresponds to about 29.41 µs.

The circuit design has been shown in Fig. 2. As shown in this figure, the MCU, ultrasonic sensor, two motors and motor controller are connected together as the main components of our proposed design.
Fig.2 Circuit design for the proposed trolley

The Node MCU, known for its energy efficiency and 16-bit RSIC, is utilized as a controller because of its integrated ESP-12 and convenient WiFi module, which streamline the control process. The ESP-12 incorporates a CPU clock speed of 80MHz, with the ability to reach a maximum value of 160MHz. The L298N motor controller is employed to connect the DC motors to the microcontroller. Both the microcontroller and L298N motor controller are powered by a 9V battery in parallel. The controller has been programmed to define the movements of the trolley, as outlined in Table 1.

Table 1. The motor movement instruction

Movement	Left motor forward	Left motor backward	Right motor forward	Right motor backward
Forward	High	Low	High	Off
Backward	Low	High	Low	High
Left	-	-	High	Low
Right	High	Low	-	-

The controlling instructions are sent to the microcontroller through the app created by MIT app inventor. The block function of the created app is shown in Fig. 3.

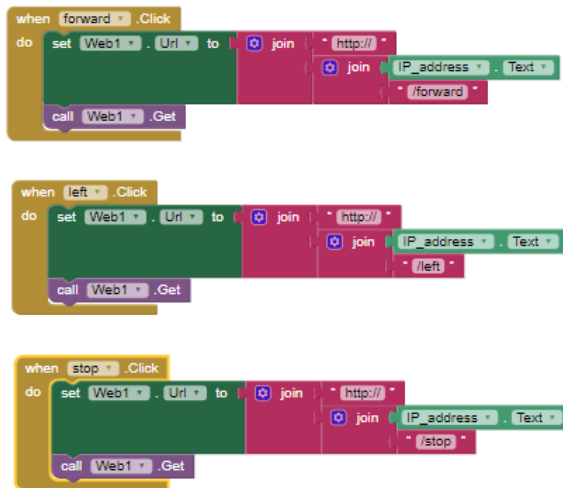
Mastaneh Mokayef, Muzaiyanah Binti Hidayab, MHD Amen Summakieh, M.K.A Ahamed Khan, Kim Soon Chong, Chin Hong Wong, Chua Huang Shen, Abdul Qayyum.


Fig.3 The controlling function block of the app

The fabrication of our proposed prototype is shown in Fig. 4.
Fig.4 The fabricated prototype

4. Conclusion and Future Work

In conclusion, we have successfully designed, fabricated, and tested a smart shopping trolley specifically tailored for elderly care. The results have been highly satisfactory, indicating the effectiveness of our proposed solution. By implementing advanced technology, our smart trolley is designed to recognize the movement patterns of elderly users and autonomously follow them. This eliminates the need for users to exert physical effort in pushing or pulling the trolley, providing a more convenient and comfortable shopping experience. Looking ahead, there is potential for further improvement and expansion of our smart shopping trolley. One possible avenue for future work is the integration of GPS technology. By incorporating GPS, the trolley can accurately determine its indoor and outdoor location,

allowing users to easily navigate and even return the trolley to its designated location rather than being limited to indoor use only. This enhancement would offer even greater convenience and flexibility to the users, making their shopping trips more efficient and enjoyable. In summary, our smart shopping trolley for elderly care has shown promising results, offering a user-friendly and assistance-driven approach to shopping. The inclusion of GPS technology in future iterations has the potential to further enhance the functionality and versatility of the trolley, providing an improved and seamless shopping experience for elderly individuals.

Authors Introduction

Dr. Mastaneh Mokayef

She has received her PhD from Wireless Communication Centre Faculty of Electrical Engineering in University Technology Malaysia (UTM) in 2014. She has also obtained her master's degree from the faculty of engineering in 2009 from the University Technology Malaysia. She has been working in UCSI University, Malaysia, since 2015 in which she currently serves as an Assistant Professor in the Faculty of Engineering and Built Environment. Her research interests include: Wireless communications, spectrum sharing method, etc

Mr. MHD Amen Summakieh

He received the B.Eng. degree (Hons.) in communication and electronics engineering from UCSI University, Malaysia, in 2016, and the M.Eng.Sc. degree from Multimedia University, Malaysia, in 2020. His research interests include heterogeneous LTE-advanced cellular networks, user association, metaheuristic algorithms, and antennas design.

Dr. M. KA. Ahamed Khan

He completed his undergraduate degree in Electronics and Communication Engineering and postgraduate degree in Electronics and Control Engineering in India. Additionally, he obtained an advanced diploma in Power Electronics and Drives from Lucas-Nuelle in Germany in 2002, and a Diploma in Drives and Controls from Woo Sun in Korea in 2014. He pursued a PhD in Robotics, Power Electronics, and Controls in the United States and holds certifications. He is a Senior member of the IEEE in the USA and a member of MIET in the UK.

Dr. Kim Soon Chong

He obtained his B.Eng., M.S., and Ph.D. degrees in electrical and electronic engineering from Universiti Kebangsaan Malaysia in 2012, 2015, and 2019, respectively. He currently serves as an Assistant Professor in the Department of Computer Engineering (Artificial Intelligence) within the Faculty of Engineering Technology and Built Environment at UCSI Kuala Lumpur. His research focuses on areas such as medical signal processing and instrumentation.

Dr. Chin Hong Wong

He is a Lecturer in Maynooth International Engineering College at Fuzhou University in China. He received his PhD in Electrical and Electronic Engineering from Universiti Sains Malaysia in 2017. His research interests are Energy harvesting and control system.

Mr. Chua Huang Shen (Mason)

He holds the position of Senior Lecturer at UOW Malaysia KDU. He received a Master of Science degree from the University of Belfast in 2004 and a Bachelor of Science degree (Hons) in Electronic Control Systems from the Moore School of Liverpool University in 2002. - Earned a bachelor's degree in engineering from Rahman University (UTAR). He is currently working on his Ph.D.

Dr. Abdul Qayyum

He received his PhD in Electrical and Electronic Engineering from Universiti Teknologi Petronas, Malaysia, in 2018. He developed the totype. Previously, he completed his bachelor's degree in computer engineering and master's degree in electronic engineering from Pakistan. He is a postdoctoral researcher at the University of Burgundy, France, where he studies cardiac MRI images using deep learning approaches. He is currently affiliated with the National Heart and Lung Institute at Imperial College London, UK.

Optimized Microstrip Slot UWB Patch Antenna for Medical Imaging

Abstract

This research work presents the development of an Ultra-Wideband (UWB) microstrip patch antenna (MPA) with the specific purpose of tissue characterization. The antenna was carefully designed and simulated to operate within a frequency range of 4.8 to 6.9 GHz, optimized for its intended application. To ensure the best performance, a series of simulations and comparisons were conducted using CST Microwave Studio. Various antenna shapes were tested and evaluated to determine the most effective design. The results of these simulations were highly promising, as they revealed a simulated return loss (S_{11}) of -33dB. This indicates excellent performance and demonstrates the suitability and acceptability of the proposed antenna for medical imaging such as breast imaging, tumor detection, or monitoring physiological changes.

Keywords: Microstrip antenna, medical imaging, UWB, CST

1. Introduction

In recent years, the use of microstrip antennas in medical imaging has attracted significant attention. These antennas have demonstrated immense potential in delivering high-resolution images and precise measurements in various medical imaging techniques like magnetic resonance imaging and positron emission tomography. According to Shimu et al., microstrip patch antennas have found wide-ranging applications in the medical field, as well as in other industries [1]. Microstrip antennas offer several advantages that make them well-suited for medical imaging applications. Firstly, microstrip antennas have a small size and low profile, which makes them ideal for integration into medical devices and equipment. Their lightweight nature allows for easy customization to meet specific requirements. Additionally, microstrip antennas can be designed with wide bandwidths, enabling the transmission and reception of diverse frequencies. Microstrip patch antennas also provide high gain and low return loss, ensuring efficient signal transmission and reception [1, 2]. Another advantage of microstrip patch antennas in medical imaging lies in their robust design and fabrication. These antennas are known for their durability and reliability, which are crucial factors in medical imaging where accuracy and consistency are of paramount importance. Furthermore, microstrip antennas exhibit excellent radiation characteristics, including low cross-polarization and high directivity. These characteristics are particularly valuable in medical imaging, as they contribute to clearer and more accurate imaging results. With these advantages, microstrip antennas have the potential to revolutionize medical imaging by providing high-quality images with improved resolution and accuracy. However, it is important to address the limitations associated with microstrip antennas in order to fully harness their potential in medical imaging.

One limitation of microstrip antennas is their narrow bandwidth, which restricts the range of frequencies that can be transmitted or received. Researchers are actively exploring different techniques, such as adding additional resonant elements or using multiband designs, to increase the bandwidth of microstrip antennas. Additionally, microstrip antennas often have relatively low gain compared to other types of antennas [3]. To address this, researchers are investigating techniques such as designing stacked or array configurations to enhance the gain of microstrip antennas. Impedance matching is another issue that microstrip antennas face, leading to signal degradation. Researchers are focusing on improving the manufacturing process and developing advanced impedance-matching techniques, such as using matching networks or adding dielectric layers, to optimize impedance matching and improve overall performance. Furthermore, efforts are being made to enhance the polarization characteristics of microstrip antennas, as certain imaging techniques require specific

polarization orientations for optimal image quality. Researchers are exploring various polarization techniques, such as circularly polarized microstrip antennas or the use of metasurfaces, to control the polarization of the antenna [4]. The study in [1] presents the design, fabrication, and analysis of a compact microstrip patch antenna operating in the Industrial, Scientific, and Medical (ISM) frequency range of 2.4-2.5 GHz for medical applications. To investigate the performance of this antenna structure through simulations, the high-frequency structure simulator (ANSYS HFSS) and Advanced Design System (ADS) has been used. Moreover, to measure the level of electromagnetic waves absorbed by the human head model the specific absorption rate (SAR) is simulated at different positions. A 2.45 GHz Rectangular Patch Microstrip Antenna (RMSA) was designed and analyzed for breast cancer detection in [5], using an insect feed technique for impedance matching. Simulations showed the RMSA had a VSWR<2 bandwidth of 70 MHz (2.8% of operating frequency), resonating at 2.45 GHz. Results indicate the RMSA outperforms existing designs, making it a promising option for improved breast tumor detection. While in [7, 8] a low-cost microstrip patch antenna was developed specifically for microwave imaging (MWI) applications across a wideband frequency range. The antenna design incorporates an artificial magnetic conductor (AMC) to enhance its performance. Computer simulations using CST demonstrated that the presence of the AMC significantly improved the frequency selectivity at 8.6 GHz, resulting in a peak realized gain of 9.90443 dBi (simulated) and 10.61 dBi (measured). To validate the simulation results, the proposed microstrip antenna was fabricated and experimentally tested.

2. Antenna Structure

In this paper, we introduce a newly proposed Ultra-Wideband microstrip antenna and provide an overview of its structure. The decision to utilize an FR-4 substrate is driven by its cost-effectiveness and wide accessibility in the market. The simplicity and convenience of implementing FR-4 as a substrate make it an ideal choice for the design of our antenna. In the upcoming sections, we will delve into the fabrication process and design specifics of the microstrip antenna, emphasizing its potential for Ultra-Wideband applications.

As depicted in Fig. 1, the antenna is mounted on the FR-4 substrate including the main and sub-fluidline for the impedance matching purpose. The detailed dimensions of the design can be found in Table 1.
Fig.1 Front View of the Proposed Antenna

Table 1. Antenna Dimensions

Area	Parameter	Dimensions (mm)
PATCH (copper)	Width	10
	Length	13
	a	2
	b	9
	c	0.5
	d	5
	Thickness	0.035
FEED LINE (FL) (copper)	Width	0.6
	Length	8
	Thickness	0.035
MAIN LINE (ML) (copper)	Width	2
	Length	4
	Thickness	0.035
SUBSTRATE (FR-4)	Width	28
	Length	29
	Thickness	1.6
GROUND (copper)	Width	28
	Length	10.5
	Thickness	0.035

3. Results and Discussion

3.1. *Accuracy of numerical integration*

As defined in [4], the UWB has a bandwidth of greater than 500MHz and an operating frequency of between 3.1GHz and 10.6GHz. The return loss threshold of -10dB has been defined in [5]. A simulation of return loss S_{11} is shown in Fig. 2.
Fig.2 Return Loss of the Proposed Antenna

The simulation and expected results match well. The threshold is pointed at -10dB, so the bandwidth is 2.1GHz, in agreement with the 500MHz minimum required by UWB. Furthermore, the resonance frequency is 5.8GHz. This one is great, the signal propagation characteristics at 5.8GHz in free space are similar in rainy conditions. This issue is important to consider in tropical climates such as Malaysia [6]. The radiation pattern of the proposed antenna is illustrated in Fig. 3.
Fig. 3 Antenna's radiation pattern

As shown in Fig. 3, the main lobe magnitude is 1.68 dBi and the main lobe direction of 179 deg has been obtained. The Angular width (3dB) of 94.8 degrees and the side lobe level of-1.7 dB has been obtained. Finally, the results of the VSWR simulation are given in Fig. 4.
Fig. 4. Simulation of VSWR

The acceptable range of Voltage Standing Wave Radio (VSWR) is under 2V. So the acceptable frequency of between 4.7 and 7 GHz are the acceptable range which matches well with the previous results obtained in the operating frequency from 4.8 to 6.9 GHz.

4. Conclusion

In conclusion, this project successfully proposed an Ultra-wideband (UWB) microstrip patch antenna (MPA) using an FR-4 substrate. The achieved return loss of -33dB at a resonance frequency of 5.8GHz demonstrates the effectiveness of the antenna design. With dimensions of 29×28mm, this antenna offers a cost-effective, user-friendly, and portable solution for various applications, particularly in breast cancer detection. Through meticulous design and simulation using CST Microwave Studio, the antenna was optimized to operate within the desired frequency range of 4.8 to 6.9 GHz. The extensive simulations and comparisons performed confirmed the superior performance of the proposed design. The obtained results, including the impressive return loss of -33dB, highlight the antenna's suitability for medical imaging, such as breast imaging, tumor detection, or monitoring physiological changes.

Dr. Mastaneh Mokayef

She has received her PhD from Wireless Communication Centre Faculty of Electrical Engineering in University Technology Malaysia (UTM) in 2014. She has also obtained her master's degree from the faculty of engineering in 2009 from the University Technology Malaysia. She is a member of Board of Engineers Malaysia (BEM) since 2017, She has been working in UCSI University, Malaysia, since 2015 in which she currently serves as an Assistant Professor in the Faculty of Engineering and Built Environment (FETBE). Her research interests include: Wireless communications, spectrum sharing method, spectrum management, cellular communication systems and Antenna design. To date, he has been awarded with the qualifications of a Chartered Engineer (C.Eng.) from U.K. Engineering Council.

Mr. MHD Amen Summakieh

He received the B.Eng. degree (Hons.) in communication and electronics engineering from UCSI University, Malaysia, in 2016, and the M.Eng.Sc. degree from Multimedia University, Malaysia, in 2020. His research interests include heterogeneous LTE-advanced cellular networks, user association, metaheuristic algorithms, and antennas design.

Dr. M. KA. Ahamed Khan

He completed his undergraduate degree in Electronics and Communication Engineering and postgraduate degree in Electronics and Control Engineering in India. Additionally, he obtained an advanced diploma in Power Electronics and Drives from Lucas-Nuelle in Germany in 2002, and a Diploma in Drives and Controls from Woo Sun in Korea in 2014. He pursued a PhD in Robotics, Power Electronics, and Controls in the United States and holds certifications as a Professional Engineer (PEng) in the USA and a Chartered Engineer (CEng) in the UK. He is a Senior member of the IEEE in the USA and a member of MIET in the UK.

Dr. Sew Sun Tiang

She is an Assistant Professor in Faculty of Engineering at UCSI University in Malaysia. She received her PhD in Electrical and Electronic Engineering from Universiti Sains Malaysia in 2014. Her research interests are optimization and antenna design.

Dr. Wei Hong Lim

He is an Assistant Professor in Faculty of Engineering at UCSI University in Malaysia. He received his PhD in Computational Intelligence from Universiti Sains Malaysia in 2014. His research interests are optimization and artificial intelligence.

Dr. Abdul Qayyum

He did his PhD in Electrical and Electronics Engineering from Universiti Teknologi PETRONAS, Malaysia 2018. He developed deep learning based algorithms for depth estimation of vegetation, trees near power lines for Tenaga Nasional Berhad (TNB) and Sabah Electric Supply Berhad (SESB) under the ministry of Green , Water and Technology (KeTTHA) Malaysia. He also developed a prototype for Vital signs (heart rate, breathing rate, Sp02) estimation and assessment of stroke and Arterial fibrillation (AF) using face video analytic based on deep leaning models. Earlier, he had completed his bachelor's in computer engineering and Master in Electronic Engineering from Pakistan. Besides, he gained one-year industrial experience while working as a BSS engineer for Huawei, Pakistan. He had also taught several courses under electrical, specifically, signal processing domain for 7 years in various public and private universities in Pakistan. He was working as a research scientist in CISIR, UTP for less than one year and was developed deep learning algorithms for brain signal (EEG) classification and reconstruction, remote sensing image segmentation and biomedical image analysis. He is associated with burgundy university France as a Post Doc researcher and working on the cardiac MRI images using deep learning approach. He is also working as a consultant in various projects involving deep learning models in Big Data, Vital Sign Estimation, IoT and BCI applications. Currently he is associated with National Heart and Lung Institute, Imperial College London, UK.

Development of an Innovative Undergraduate Industrial Automation and Robotics Degree Program

Abstract

In recent years, the need for integrated engineering courses has increased. Due to its multidisciplinary nature, Industrial Automation and Robotics degree course is an ideal example of curriculum integration. This paper discusses several issues such as course offerings, topical content, student profile, student performance and other pertinent matters related to the recent development of an Industrial Automation and Robotics undergraduate degree programme at the University of Kuala Lumpur, Malaysia.

Keywords: Industrial Automation, Robotics, Curriculum Development, Undergraduate

1. Introduction

Industrial Automation and Robotics is a multidisciplinary science that encompasses the areas of computer science, mathematics, physics, mechanical engineering, industrial engineering, electrical engineering, computer engineering, materials science, and manufacturing engineering among others. It provides an opportunity to break the barriers between all these disciplines in a single course and it offers an excellent example of multidisciplinary integration for engineering students. In recent years, several institutions, following the lead of the robot-building course at the Massachusetts Institute of Technology [1], now offer robot building classes and laboratories. Some graduate level courses in Artificial Intelligence also rely on robot building techniques to illustrate general concepts of decision-making and machine intelligence [2], [3].

In Malaysia colleges, public and private universities offer many programs which lead to the degree of Bachelor of Engineering and Bachelor of Engineering Technology. These programmes range in topics from Electrical, Mechanical, Chemical, etc. With increasing frequency, employers are requiring employees in their engineering or technical staff to have multi-skills. Naturally, aspiring employees want to take-up inter-disciplinary courses to enhance their marketability. To help meet these desires, a new degree was developed by University Kuala Lumpur with the first batch of students enrolled in July 2002.

2. Planning Process

A number of authors have considered the broad issues associated with current and future trends in multidisciplinary engineering education [4], [5]. It is clear that there is no one correct curricula or approach to treating multidisciplinary engineering education. Rather, one must take into careful consideration the regional employment demands, as well as the preparation necessary for graduate study. It is necessary to practice careful discernment regarding the rapid technological fluctuations that are prevalent today. Specifically, industry can be expected to make regular demands of undergraduate preparation to meet their perceived needs [6], [7], [8]. Sometimes these expectations will provide valuable insights into changing career paths, and at other times the demands will be inappropriate, and best understood as related to the "tools and toys" of the trade. Engineering students must have a fundamental concept base which allows agility and flexibility, for if a program is too specialised, the range of opportunities available for graduates will be compromised. In the course of investigating the content and structure of a new program to address the design and development of the 'industrial automation and robotics' programme, it became clear that close ties to the fundamental disciplines associated with electrical engineering was critical. The wide variety of distributed sensors, their associated electronic interfaces, the large-scale control systems, and the extreme environments within which they operate require careful treatment of analog and digital electronic circuit design, communication and control theory, mathematics, and physics. These topics traditionally constitute the core of the electrical engineering discipline [9], [10].

A curriculum planning process is necessary to investigate the individual program topics, their relationships, and the pedagogy necessary to present them in an integrated fashion at an undergraduate level. We utilised two methods of inquiry to meet these goals. The first method of inquiry was based on a series of

formal meetings (both group and individual) with representatives drawn from our industrial partners and industrial advisory board. This varied group of people has been asked to consider their educational needs (industrial automation and robotics) based on the large and clearly identified trends in their industries. The second method involved the exploration of the substantial educational literature available including such publications as the IEEE Transactions on Education and the Journal of Engineering Education. At the end of the planning period, the following outcomes were generated:

- a compilation of the topical content for courses, particularly for topics that are new in the sense

curriculum so that appropriate acquisition of laboratory equipment could be addressed and the attendant facilities set up; and
- a time-bound roadmap for introducing the new curriculum

3. The Development of Bachelor of Engineering Technology Programme

The development of Bachelor of Engineering Technology Programme in Industrial Automation and Robotics Technology (IART) will discussed in the following paras. Once admitted into IART degree programme, the student takes a minimum of 120 semester

Table 1: Subject Distribution of IART

NO	CATEOGORY	SUBJECTS	CH	%	TCH	%
1	General	LAN	9	7.31	25	20.32

	TOTAL CREDITS HOURS		123		123	100%

that they address emerging technologies and hence are non-traditional;
- a prioritisation of the topics since covering everything may not be feasible;
- a list of courses and their appropriate hierarchy in the curriculum;
- an identification of the necessary technologies that would be needed to offer this new

From Table 1, it can also be seen that the general studies is composed of 20.32%, management 12.19%, technical 62.61% and INTRA 4.88%. The total credits hours is 123. It is important to note that the department responsible for the technical concentration areas have specified the courses for each IART core area. Since concentration areas are attached to individual academic departments such department of automation, electrical and mechanical, this allows the individual departments a great deal of flexibility. There are currently 3 different technical concentrations available for the IART student, i.e., automation, electrical and mechanical.

Various subjects are offered in the 8 semesters. As an example, some of the subjects offered in semester 1 is shown in Table 2.

credit hours of coursework (over 8 semesters) divided among four general categories of classes. The four areas are general studies, management, technical and industri training (INTRA) as shown in Table 1, where CH is the credit hours and TCH is the total credit hours.

Table 2: Subjects of 1st Semester

No	Code	Subjects	Credit Hours	No. of Hrs Per Week	LEC	TD	P	No of Hrs Per Sem
1	AUT 3412	Introduction to Automation	2	3	1		2	54
2	FDE 3012	Engg. Drawing	2	3	2			54
3	ELE 3112	Electrical Fundamental	2	3	1		2	54
4	INM 3012	Safety Management	2	2	2			36
5	LAN 1002	Bahasa Malaysia	3	3	3			54
6	LAN 1004	Islamic (or Moral) Studies	3	3	3			54
7	MAT 3112	Mathematics 1	2	3	1	1.5		45
8	MAA 3012	Static and Dynamics	2	2.5	1	1.5		45
			18	22	14	3	4	396

From Table 2, it can seen that the subjects offered in semester 1 are 'Introduction to Automation', Engineering Drawing, Electrical Fundamental, Safety Management, Bahasa Malaysia, Islamic (Moral) Studies', 'Mathematics I' and 'Statics and Dynamics'. As an example, looking at 'Introduction to Automation', it can noted that it is 2 credits hours subject where the number of contact hours between the lecturers and students are 3 hours which is divided as 1 hour for lecture and 2 hours for practical. In one semester, 54 hours is allocated for this subject. A total of 396 'contact hours' takes place between the lecturers and students.

To look at the topical contents of the subjects offered, an example of a typical higher level subject is discussed below. The title of the subject title is known as 'Robotics I'. It is offered as a 3 credit hour core subject. Its main objective is to provide senior undergraduate students with broad knowledge on robots. The class consists of two and a half hours of lecture and tutorial, and a three-hour laboratory session weekly. The lecture and tutorial portion is used to teach fundamentals of robotics while the laboratory portion teaches 'hands on' robot programming techniques. The course is concerned with "classical" Robotics, which covers geometric models of robot manipulators, kinematics, dynamics, control, and path planning. Many excellent textbooks in this area are available. The authors have used and particularly recommends the texts by John J. Craig [6] or P. J. McKerrow [7].

The course contents are listed below:
- Review of Mathematical concepts. This part is a review and an introduction to trigonometric functions, vectors and matrices, and geometric transforms such as translations and rotations of objects in space. The use of Matlab in solving numerical problems is examined through lecture examples and homework assignments.
- Kinematics of robot manipulators. The use of the Denavit-Hartenberg model for robot manipulators is introduced and the study of direct and inverse kinematics is presented.
- Robot path planning and generation. Student are taught to use cubic splines to determine a path for the robot between two end points.

- Dynamics and Control of a Two-link robot. The students are introduced to the concepts of Newton-Euler dynamics only in the case of a two-link robot. Classical joint-position and velocity control is also examined without delving too deeply into this subject.
- Robot Manipulator Programming. A six-axis industrial robot, ABB and Staubli provides students with a test bed for robot manipulator programming. As a laboratory exercise, students program the ABB and Staubli, for a pick and place task or a simple assembly task.

4. Student Data

This section is divided into three sections, i.e., student profile in first section which encompasses the student intake and graduation, whilst the second section covers the student performance and the third section discusses about student employment.

4.1 Student Profile

The student profile which encompasses the student intake and graduation is given in Table 3.

Table 3: Student Profile

Intake	M	F	TOTAL
Batch July 2002	40	18	58
Batch July 2003	19	4	23

Final Semester	M	F	TOTAL
Batch July 2002	31	13	44
Batch July 2003	12	3	15

Graduate	M	F	TOTAL
Batch July 2002	30	11	41
Batch July 2003	12	3	15

Fail to Graduate	M	F	TOTAL
Batch July 2002	1	2	3
Batch July 2003	0	0	0

It can be seen from the Table 3, for the batch July 2002 out of 44 students, 41 manage to get the graduation and 3 fail to graduate. For the batch July 2003 all 15 students graduated.

The age group of batch July 2002 and batch July 2003 is shown in Table 4.

Table 4: Age Group

Age	28	27	26	25	24	23	22	21	Total
Batch July 2002	1	2	3	1	6	8	11	26	58
Batch July 2003			1			4	6	12	23

From Table 4, it can be seen that the age of the students enrolled in first semester varies from 21 to 28 years. The first and second batches had initial enrolment of 58 and 23 students. The higher age group is an evidence of candidates enrolement with some Industrial experience.

4.2   Student Performance

The final semester results for the batch July 2002 and July 2003 is shown in Table 5.

Table 5: Final Semester Results

Category	DL	KB	Total
Batch July 2002	3	38	41
Batch July 2003	4	11	15

DL	>3.5
KB	2.00-3.49
KP1	<2.00 1st time
KP2	<2.00 2nd time
GB	<1.00 or <2.00 3rd time
INC	Incomplete semester

From Table 5, it can be seen that in batch July 2002, 3 students fall under the category of DL and 38 students comes under the category of KB. Total number of students passed is 41.

In batch July 2003, 4 students fall under the category of DL and 11 students come under KB. Total number of students passed is 15.

The final CGPA results for the batch July 2002 and batch July 2003 is shown in the Table 6.

Table 6: Final Semester Results

CGPA	<2.00	2.00-2.50	2.50-3.00	3.0-3.50	>3.5	Total
Batch July 2002		3	26	9	3	41
Batch July 2003			10	5		15

From Table 6, it can be seen that in batch July 2002, 3 students have got final CGPA ranging from 2.00 to 2.50, 26 students have got CGPA ranging from 2.50 to 3.00, 9 students have got CGPA ranging from 3.00 to 3.50 and finally 3 students rated above 3.5 CGPA. Total passed is 41.

In batch July 2003, 10 students have got CGPA ranging from 2.50 to 3.00 and 5 students have got CGPA ranging from 3.00 to 3.50.Total passed is 15.

The trend of GPA for the batch July 2003 is shown in the Table 7.

Table 7: Trend of GPA

	KB	KP1	GB	INC	Total
Sem 2003/2	17		2	3	22
Sem 2004/1	13	3			16
Sem 2004/2	15				15
Sem 2005/1	15				15
Sem 2005/2	15				15
Sem 2006/1	15				15

The trend of GPA is shown in Table 7, it can be seen that for the batch July 2003 [Sem 2003/2] out of total 22 students, 17 got KB, 2 got GB and 3 doesn't complete the semester. In Sem 2004/1, 13 students come under KB and 3 come under KP1. In Sem 2004/2, 15 come under KB.In Sem 2005/1, 15 come under KB.In Sem 2005/2, 15 come under KB. In Sem 2006/1, 15 come under KB.

4.3 Student Employment

The majority of the students enrolled in the IART degree program are currently employed. In the first batch, 60-70% of students were able to find employment within 6 months of their graduation whereas 50-60% of the students were employed from the second batch which graduated in July 2006. They are employed in multinationals and as well as locally owned small and medium enterprises. Amongst the companies that there are attached with are Texas Instruments, Solectron, GlaxoSmith Kline, B Braun, Hicom, to name a few. At the time of writing this paper, it is already four months since the graduation of the second batch. As mentioned above, although 60% of them have found employment

within this period, it is expected that over time, the majority of graduates will find employment.

5.0 Conclusion

This paper has discussed the development of an multidisciplinary course in industrial automation and robotics for undergraduate engineering students. The IART degree offers a student with a completed diploma the opportunity to complete a bachelor's degree in a timely fashion, with little lose in transfer credits. The average CGPA of IART students are competitive, and employers recognise the degree and employ the graduates because of the academic content and the graduates' ability to perform, both academically and professionally.

Abstract

As people get older their shopping experience gets harder, as they have to keep pushing a trolley that is made of steel, as well as they keep on adding items through their shopping journey the trolley gets heavier. As a result, this project aims to help these senior citizens by providing a robotic trolley that follows them during their journey (through face detection) without the need of any physical interrreference, in addition to calculating the walking distance providing the property of showing how many meters they have walked. The trolley has been fabricated with the walking distance estimation feature that has been accomplished by the ultrasonic sensor after the camera detects the user and tracks him. This strategy is achieved by using an OpenCV library that is particularly could be used in Python programming language. The results have shown a great improvement in the elderly individuals' lives, as it supports them by giving more comfort and extra liberty to the shopping experience.

Keywords: Smart following trolley, OpenCV, Face detection, Walking distance estimation

1. Introduction

As we live in a time where technology is advancing daily, people occasionally come up with contemporary ideas to update or develop specific technologies as elaborated by Ng [1]. One of these technologies is the shopping trolleys which are available in all supermarkets to make it easier for customers to choose and store products. Customers need to drop the products they want to purchase and then proceed to checkout. Currently, when entering the shopping mall or a grocery store the customer has to choose a shopping cart (trolley), select the items they want to buy, and then put them in the shopping trolley which is very challenging this to do for senior citizens.

To get a robot to move and follow you, a brain of the prototype is in order, a brain will move everything in sequence and give orders to all the components chosen by the engineer (designer), and change this sequence if needed to and all of this is accomplished by the algorithm which is the software used to put everything in to place, the software means the language we people choose to communicate with device in this case an automated trolley we are creating as explained by Li [2].

The brain will keep reading the messages from the sensors the engineer chose to use as ultrasonic sensors which is very good when it comes to objects detection as demonstrated by Sanghavi [3], an infrared sensor is efficient to use for people detection even at night because it follows the temperature mapping technique as analyzed by Nagarajan [4], as well as the proximity sensor can be used for the reasons as the ultrasonic sensors used for however with better efficiency, on account of the proximity's higher efficiency it is used for accidents or collision prevention, which is why it's a perfectly suitable option as elaborated by Lee [5].

In order to get the trolley moving automatically, the presence of a motor is a must, as it will receive a signal from the brain (microcontroller) to move, however to get the motors to move in different directions forward, backward, right, and left motor controllers are needed, many motors can be used to get a robot to move it depends on the speed required, the place the robot will be used in, as DC motors or a servo motor.

Before the microcontroller sends a message to the motors to move in any direction first the microcontroller should locate the person who is supposed to follow and then send the message, and that is accomplished by adding a camera to the trolley that would track the person

Dina Koushek, Mastaneh Mokayef, MHD Amen Summakieh, M. K. A Ahamed Khan, Abdul Qayyum, Sivajothi A/L Paramasivam.

based on his/her features, or even the camera could follow something that the trolley user is holding on to, or even by using a transceiver

2. Methodology and Experimental Setup

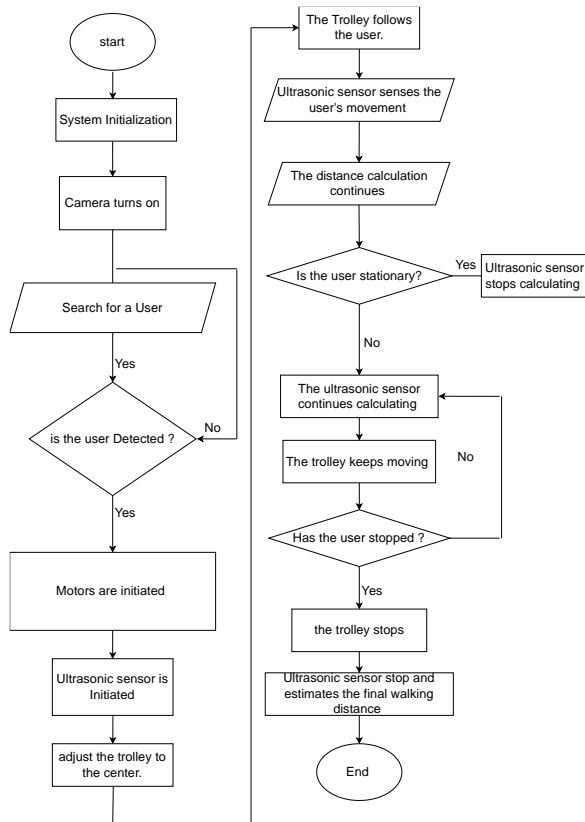
In this chapter, the methodology applied for this project is described, as well as the mathematical approaches and correlations related to the smart follower trolley and the components selection shall be mentioned in Fig. 1.


Fig. 1. Project flow chart

In this proposed project the methodology thesis will be implemented into three parts. To begin with, how will the detection and tracking of the user's movements will be implemented, following on from that, walking distance besides the user's directions estimation, finally the whole project's (the smart follower trolley) fabrication specification in terms of connecting all the components chosen due to their quality and cost.

The components used to bring this project's idea to life are a raspberry pi 4 model B as the main system core (brain of the system), a permanent magnet DC motor, an Arduino UNO is used to control these motors while being connected to the Raspberry pi 4 model B through an USB as a communication interface, the sensors chosen are the ultrasonic sensor used for obstacle detection and avoidance, as for the user's detection the infrared sensor is used along with a camera settled on the trolley.

2.1. *Hardware of the trolley*

Raspberry pi 4 Model B

The most recent model of the Raspberry Pi computer line is the Raspberry Pi 4 Model B. Comparing it to the Raspberry Pi 3 Model B+ of the previous generation, it provides revolutionary improvements in processing speed, multimedia performance, memory, and connection while maintaining backward compatibility and a similar level of power consumption. Performance on the desktop is comparable to that of entry-level x86 PC systems for the end-user on the Raspberry Pi 4 Model B as denoted by Raspberry Pi [6].

This fourth-generation raspberry pi model is chosen for in project as the main system core in other words the brain of the robot, due to its high-performance 64-bit quad-core processor, a dual display support at a resolution up to 4K (Kilo) through the micro-HDMI (High Definition Multimedia Interface) ports as modular compliance certification for Bluetooth and dual-band wireless LAN (Local Area Network) enables the board to be integrated into finalized devices with a great reduction in compliance testing, reducing cost and speeding up time to market, as well as the raspberry pi 4 model B contains a higher memory (2/4/8GB RAM option), its connectivity is better than the other raspberry pi computer types, as it has 2.4 GHz and 5.0 GHz, the data transfer is done at a very high rate as it contains 2 USB 3.0 ports 2 USB 2.0 ports. It has 40 GPIO pins.

Arduino UNO

An ATmega328P-based microcontroller board is the Arduino UNO. It contains 6 analogue inputs, a 16 MHz ceramic resonator, a USB port, a power jack, an ICSP(In Circuit Serial Programming) header, and a reset button. It also has 14 digital input/output pins, six of which can be used as PWM outputs. It comes with everything required to support the microcontroller; to get started, just use a USB cable to connect it to a computer, or an AC-to-DC adapter or battery to power it. You can experiment with your UNO without being very concerned about making a mistake as demonstrated by Arduino memory guide [7].

An ATmega328P-based microcontroller board is the Arduino UNO. It contains 6 analogue inputs, a 16 MHz ceramic resonator, a USB port, a power jack, an ICSP header, and a reset button. It also has 14 digital input/output pins, six of which can be used as PWM outputs. It comes with everything required to support the microcontroller; to get started, just use a USB cable to connect it to a computer, or an AC-to-DC adapter or battery to power it. You can experiment with your UNO without being very concerned about making a mistake as demonstrated by Arduino Memory Guide [7].

Using an Arduino UNO to control the PMDC motors is very effective and why is that, due to its simplicity, the Arduino UNO is designed in a way to work efficiently with real-time projects, as well as the Arduino UNO can work easily with motor drivers as an L293D motor driver, L298N motor driver, in addition to it way to work effectively with components that consume low power, as well as changing the speed of a DC motor is fairly simple. The speed of a DC motor can change when PWM is applied to the analogue output pin of an Arduino. Therefore, it is a straightforward task. Unlike the raspberry pi 4 model B, it works efficiently with components that have high power consumption, it will work with the PMDC motor, but not as effectively as the Arduino UNO as explained by DC motor speed [8].

High precision ultrasonic sensor range finder

Three ultrasonic sensors will be used, each one of them will be directly connected to the raspberry pi 4 model B (brain), they will be used for obstacle avoidance, ultrasonic sensor ESP32 is chosen as its better than the ultrasonic sensor ESP8266 in terms of performance as well as it provides BLE.

PMDC motor

A PMDC motor is chosen for this project dues to its high torque and low power consumption, the kind of PMDC motor is chosen based on its torque speed, and this parameter is chosen after choosing the trolley itself and deciding which size is preferred to bring this idea to life.

43A H-Bridge driver

If any motor would work on its own it would work in only one direction (forward), however in order for us to control how the motor we are using, in this case, a PMDC motor needs a driver to make the motor move forward or backward, this driver will be receiving the orders from the main system core (raspberry pi 4) to tell what should be the motor's next move, in addition to what velocity should it move with, as well as the direction it should be headed to upon the logic added to this core.

LM2596 3A Buck module with display

A converter is in order as its very important when it comes to prototyping, as different components are chosen for this project and each work at a very specific level of voltage, so the converter's job is to step down the voltage in order not to ruin the components.

2.2. *Software*

The most important library used for this project is OpenCV python has the option of image processing that is chosen in this project to use in the software part for user's detection. Processing a video means executing operations frame-by-frame to the video. Frames are nothing more than a single discrete instance of the video at a given point in time. Even in one second, there could be several frames. It is possible to treat frames similarly to an image. Therefore, we can execute all actions on frames that we can on images precisely explained by [9].

3. Results and Discussion

In order for the brain to do its job which is to control all other components it needs to be connected to a power source which in this case is the laptop, after the connection is settled the set-up is made by VNC viewer which is a way to access and control the raspberry pi (any kind) desktop remotely from another computer, using a USB C-type cable to activate the brain itself, for this minicomputer to work it needs internet to function based on this the raspberry pi 4 model B has the feature to connect it to the internet without using an ethernet cable. In this project the raspberry pi has a wireless connection with internet.

The connection between the Raspberry Pi and the Arduino UNO is done using a USB B type cable, this is only done for energizing it and it's the way in which the Arduino UNO will take the orders from the raspberry pi, as for the connections between the Arduino UNO and the PMDC motor, first the motor works at a 250 watts, and it needs to be stepped down this is the main reason why a converter is used. The motors are designed in a way that when it works it works only in one direction to make this motor move in all directions a motor driver is used. The connections are made as follows starting with connecting the Arduino UNO to the motor driver ENA pins and IN1, afterward connecting the motor driver to the PMDC motor through positive and negative terminals, and the step-down converter as well in the same way. This converter will be connected to the power supply. And all of the components are connected to the same ground on the used breadboard.

For connecting the ultrasonic sensor with the raspberry pi to achieve the second objective, first the ultrasonic sensor is set at the front of the trolley to be able to detect the person and calculate his walked distance, there are four main wires for this connection, one from the VCC (ultrasonic sensor) to the positive railway, ground wire to the negative railway on breadboard. As for the raspberry pi the GPIO pin 5 volts which is pin number two connected to the positive railway of the breadboard, as well as pin number six is connected to the negative railway where I plugged in the ultrasonic sensor. Then connecting the trig connection of ultrasonic sensor to GPIO 23 which is pin number 16 through a blank rail on the breadboard, and finally connecting ECHO in the ultrasonic sensor with GPIO 24 which is pin number eighteen through blank rail on the breadboard. Fig. 2

shows the primary fabrication of the proposed smart trolley.

Fig. 2 Automated Trolley

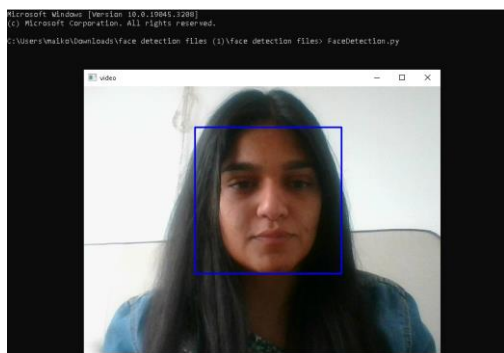
3.1. *Software Results*


Fig. 3. Face Detection

The performance or real-time face detection is one of the goals of this project first the numpy and OpenCV libraries were added to the code, and then adding the XML file that contains all of the important knowledge for accomplishing the face detection for us to enable the camera to recognize the person in front of it, afterward a video of size 640 cm x 480 cm starts that its only functionality is to keep capturing images, then a while loop is created for the continuous photo capturing. Inside the while loop, the photos (frames) captured will be turned into a grayscale for a better quality formation. The next step for all the faces detected in each frame is a blue box will appear marking all of them that will keep appearing even if the people move around in the camera's region the system will wait for the person using the trolley to press the "ESC" button if they would like to end the shopping journey. If the person presses this button all data will be destroyed, and the system will be ready for the next customer. The result of face detection is illustrated in Fig. 3.

Supported Sustainable Development Goals

The Sustainable Development Goals ("SDGs") are intended to direct international development efforts during the ensuing fifteen years, from 2015 to 2030. They are planned to be endorsed by the United Nations General Assembly (UNGA) in 2015 as part of its development agenda. The Millennium Development Goals ("MDGs"), which were in effect from 2000 to 2015, have been replaced. The sustainable development means to make the world a better place without destroying the possibilities for the next generations keeping three life aspects in mind which are social progress, economic development and climate and environment. The smart follower trolley for elderly care project supports as explained by Pogge [10].

4. Conclusion

The fabrication of a smart assistive trolley specifically designed for elderly care has brought about a remarkable advancement in enhancing the shopping experience for senior citizens. The incorporation of face detection technology and walking distance estimation capabilities in this robotic trolley has resulted in increased comfort, convenience, and a greater sense of independence for the elderly. These improvements ultimately contribute to enhancing the overall quality of life for older individuals, making their shopping experiences more enjoyable and empowering.

Authors Introduction

Ms. Dina Ashraf Mohamed Talaat Koushek

She is currently pursuing a Bachelor's degree in Electronics Engineering (Communication) with Honors at UCSI University Malaysia.

Dr. Mastaneh Mokayef

She has received her PhD from Wireless Communication Centre Faculty of Electrical Engineering in University Technology Malaysia (UTM) in 2014. She has also obtained her master's degree from the faculty of engineering in 2009 from the University Technology Malaysia. She has been working in UCSI University, Malaysia, since 2015 in which she currently serves as an Assistant Professor in the Faculty of Engineering and Built Environment. Her research interests include: Wireless communications, spectrum sharing method, spectrum management, etc.

Mr. MHD Amen Summakieh

He received the B.Eng. degree (Hons.) in communication and electronics engineering from UCSI University, Malaysia, in 2016, and the M.Eng.Sc. degree from Multimedia University, Malaysia, in 2020. His research interests include heterogeneous LTE-advanced cellular networks, user association, metaheuristic algorithms, and antennas design.

Dr. M. KA. Ahamed Khan

He completed his undergraduate degree in Electronics and Communication Engineering and postgraduate degree in Electronics and Control Engineering in India. Additionally, he obtained an advanced diploma in Power Electronics and Drives from Lucas-Nuelle in Germany in 2002, and a Diploma in Drives and Controls from Woo Sun in Korea in 2014. He pursued a PhD in Robotics, Power Electronics, and Controls in the United States and holds certifications. He is a Senior member of the IEEE in the USA and a member of MIET in the UK.

Dr. Abdul Qayyum

He received his PhD in Electrical and Electronic Engineering from Universiti Teknologi Petronas, Malaysia, in 2018. He developed the totype. Previously, he completed his bachelor's degree in computer engineering and master's degree in electronic engineering from Pakistan. He is a postdoctoral researcher at the University of Burgundy, France, where he studies cardiac MRI images using deep learning approaches. He is currently affiliated with the National Heart and Lung Institute at Imperial College London, UK.

Dr. Sivajothi A/L Paramasivam

He completed MEng in Manufacturing Management at the University of South Australia and then received his PhD in Mechanical Engineering from University of Northumbria, Newcastle, UK. He is a Senior Lecturer, currently Head of Department for school of Engineering in the same university. He is interested in discipline-based and pedagogic research related to teaching and its associated framework, etc.

Parallel Cross Window Attention Transformer and CNN Model for Segmentation of Instrument during Surgery

Abstract

Precise segmentation of surgical instruments is a fundamental component in the development of computer-aided surgery systems by assisting the surgeons to navigate the patient's body aiming to enhance the surgical precision and patient safety. Though real-time tracking of surgical instruments is critically important in invasive computer-assisted surgeries, it is challenging to achieve a highly sensitive and accurate system in complex surgical environment. Recently, synthetic data for instrument segmentation in surgery (Syn-ISS) challenge using synthetic datasets is organized to develop high performance methods for instrument segmentation. In this work, we present encoder and decoder-based hybrid parallel cross window attention-based transformer during the feature extraction, which consists of the multi-scale channel attention, convolutional layers, and Transformer layers, forming a unified block. Syn-ISS challenge dataset comprised of two tasks. In first task1, they need to develop deep learning-based method for binary instrument segmentation and in second task multiclass instrument segmentation is required. Experiments conducted on Syn-ISS dataset achieved 0.993 F-score for task 1 and 0.993, 0.975, and 0.951 F-score for shaft, wrist, and jaw segmentation respectively for Task 2.

Keywords: Deep Learning, Parallel Cross Window Attention, Transformer, 2D Instrument Surgery segmentation, Dense Net.

1. Introduction

Minimally invasive segmentation using optical imaging systems have gained popularity in modern healthcare due to their advantages, including reduced patient recovery time and lower mortality rates. Optical imaging has enabled the use of robotic platforms such as the da Vinci surgical system by Intuitive Surgery for complex minimally invasive surgeries [1]. Nevertheless, during endoscopic surgical suturing procedures, the presence of surgical instruments can impede surgeons' dexterity due to the confined working space and limited visual field-of-view. These visual obstructions elevate the risk of tissue scars and tears. Therefore, the crucial task is to transparently remove or mask the surgical instruments from the background and subsequently fill the masked region with appropriate background content. Automated segmentation of surgical instruments in MIS is currently a focal point of research due to its significant practical applications [2].

Abdul Qayyum, M. K. A. Ahamed Khan, Moona Mazher, Imran Razzak, Mastaneh Mokayef, C. S. Hassan, Ridzuan, A

The challenges associated with surgical instrument segmentation are diverse and contingent upon factors such as the source of dataset acquisition, the type of surgical procedure, the specific instruments or tools in use, image resolution, dataset scale, tool characteristics, and challenging conditions like occlusions, rapid appearance alterations, specular reflections, smoke, blur, and blood spatter. Segmentation of surgical instruments has been formulated using both instance segmentation [2] and semantic and segmentation [2].

Recently, Syn- ISS (synthetic data for instrument segmentation in surgery) challenge using synthetic datasets is organized to develop high performance methods for instrument segmentation [3]. Recently, there is a different method has been proposed using medical imaging and signals [4], [5], [6], [7], [8] for classification and segmentation. Based on our previous work on segmentation [6], [7], [8], [9]. We presented encoder-decoder based hybrid transformer and CNN model for instrument segmentation with parallel cross window attention-based transformer block in encoder and 2D Dense Net layer CNN blocks in decoder. The main contribution in this work is:

i. Developed Parallel Cross Window Attention Transformer encoder block for 2D segmentation task.
ii. Proposed 2D Dense Net block at decoder side of proposed model using transformer-based encoder features.
iii. Compare performance on synthetic data for instrument segmentation in surgery for binary and multiclass surgery instrument segmentation.

2. Methodology
2.1. Parallel Cross Window Attention Transformer and CNN model for instrument segmentation

Due to the intrinsic locality of convolution, which is incapable of modelling long-range dependencies. In addition, Transformer generates single scale features with only token wise attention, and it ignores the relationship among channels, thus subpar to tackle situations such as segmenting multi scale lesion regions in medical images. Considering these issues, we introduce the hybrid Transformer block during the feature extraction, which consists of the multi-scale channel attention, convolutional layers, and Transformer layers, forming a unified block. Our proposed model is based on encoder and decoder layers, and we have proposed a hybrid transformer and CNN model for instrument segmentation. Our proposed model consisted of Parallel Cross window attention-based transformer block on the encoder side and 2D Dense Net layer CNN blocks on the decoder side. We have used Dense Net 201 based layers on the decoder side. The proposed model is shown in Figure 1 (a) and Figure 1 (b).

2.2. Parallel Cross Window Attention Transformer Block:

An efficient hybrid segmentation framework consisting of integration of convolutional neural network and learnable global attention heads using Efficient Parallel-Cross Attention module. We use the depth-wise separable convolution as an efficient version of convolution implemented by depth wise conv and pointwise conv, where the depth wise convolution gathers the spatial information while the pointwise convolution gathers along the channel dimension. Furthermore, we have concatenated features from multi-window transformer block with depth wise convolutional layer. In encoder side, we have used transformer-based block aided with cross attention window-based mechanism, however, we have used normal 2DCNN based module at decoder-side. The features are concatenated from window area partition and window partition and further these features are concatenated with depth wise convolutional layer features and then pass these features to next layer of the encoder block.

Unlike the vision transformer (ViT) that computes relationship between tokens at each step of self-attention module, swin transformer is based on computation of attention within partition of non-overlapping local windows of lower resolution feature map and original image. In contrast to the original swin transformer that uses patch merging layer to empower it for pixel level tasks, we used rectangular-paralleled-piped windows to accommodate non-square images using Parallel-Cross Attention approach (window area partition and window partition). To extract different feature maps from each convolutional block with parallel window-based transformer in encoder, each block consists of Parallel Cross Window Attention Transformer block, patch merging and depth wise [7] convolutional layer. The proposed block is shown in Figure 1 (b).

2.3 Convolutional Neural Network (CNN) block:

To better encode spatial location information and inject strong inductive bias, we adopt convolutional block to extract local spatial features. Specifically, given an input feature F_(i-1), we adopt the convolutional block to model local spatial features, which are shown as follows:

$$F_c^i = ConvBlocks_i(F_{i-1}), i \in \{1,2,3,4\} \qquad (1)$$

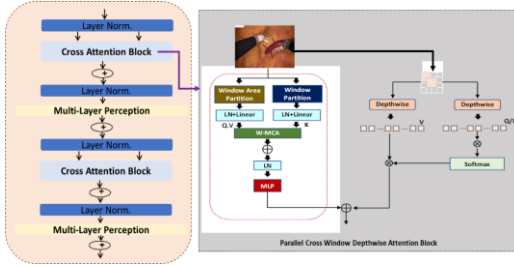
$where\ F_c^i \in R^{\frac{H}{2^{i+1}} \times \frac{W}{2^{i+1}} \times C_i}$ is the local features, which contains 2D spatial location information, making it possible to encode position information. The convolutional blocks in each decoder stage consisted of DensNet-201 based architecture is shown in Figure 1 (a).
Fig. 1 (a) The proposed model based on hybrid transformer and Dense Net CNN for instrument and instruments parts segmentation


Fig. 1 (b) The proposed Transformer block based on parallel cross window depth wise attention module

In the encoder block, the spatial input size has been reduced with an increasing number of feature maps and on the decoder side, the input image spatial size has been increased using a 2D Conv-Transpose layer. The input features' maps that are obtained from every encoder block are concatenated with every decoder block feature map to reconstruct the semantic information. The spatial size doubled at every encoder block and feature maps are halved at each decoder stage of the proposed model. The feature concatenation has been done at every encoder and decoder block except the last 1x1 convolutional layer. The three-level deep-supervision techniques are applied to get the aggregated loss between ground truth and prediction.

3.0 Experiment
3.1 Dataset

Recently, Syn-ISS challenge [3] is introduce in MICCAI-2023 to develop high performance methods for instrument segmentation. Syn-ISS dataset is synthetic instrument segmentation datasets consist of two main tasks. The task-1 is a binary segmentation to annotate all pixels that contain an instrument and consist of 1200 instances of simulated scene along with computer generated corresponding masks. Task-2 further focuses on segmentation of pixels belonging to different parts of the instrument and consists of 1800 instances.

3.2 Network Setting

We adopted data augmentation of horizontal flips, vertical flips, and random rescales. The network is trained for 200 epochs using the Adam optimizer and the weight decay is 0.0001. We have used binary cross-entropy and dice loss used for training and optimization [10], [11]. [12]. The dataset has different spatial size, hence, we resized each image and label sample to 512x512, whereas we resized each sample to original input 2D image size by bilinear interpolation during inference time. The 25-batch size is used during training. The model is training on A6000 GPU machine with 4 GPUs and all model codes are developed from scratch using Pytorch Library.

4.0 Result

The training dataset has been divided into 80 percent training and 20 percent validation. We have trained and validated our proposed model using 5-fold cross validation and based on the best validation score, the proposed model has been submitted for task 1 binary segmentation and task 2 multiclass segmentation. We have evaluated the performance using IOU, F-Score, Recall, Precision, and HD. The best score produced by our proposed model based on validation dataset is shown in Table.1 for Task 1 and Task 2.

Table 1. The performance analysis of proposed solution for Task1 and Task2.

Algorithms	Tasks	classes	IOU	F-Score	Recall	Precision	HD
Proposed model 1	Task 2	shaft	0.9868	0.9930	0.9923	0.9920	14.23
		wrist	0.9497	0.9753	0.9753	0.9695	10.67
		jaw	0.9086	0.9506	0.9523	0.9357	12.88
Proposed model 1	Task 1	instrument	0.9868	0.9933	0.9934	0.9909	0

The visualization of validation input image for binary and multiclass segmentation is shown in Figure 2. Our proposed produced similar prediction masks as compared to ground-truth segmentation masks.

Fig. 2 The input, ground-truth, and predicted segmentation masks. shaft, wrist, and jaws are shown using a yellow, red, and green segmentation mask.

5.0 Conclusion

Ideally, surgical instrument segmentation is used in real time, to identify tools being used as a surgery is being performed. The integration of surgical instrument segmentation into computer-aided surgery systems offers numerous benefits, including real-time guidance, instrument tracking, and improved surgical outcomes. In this work, we presented an encoder and decoder-based hybrid parallel cross window attention-based transformer which consists of the multi-scale channel attention, convolutional layers, and Transformer layers. Experiments conducted on Syn-ISS challenge dataset achieved 0.993 F-score for task-1 and 0.993, 0.975, and 0.951 F-score for shaft, wrist, and jaw segmentation respectively for Task 2.

Abstract

The human brain is a complex and heterogeneous organ composed of distinct compartments such as cerebral cortex, the cerebellum, the brainstem, and the subcortical regions. To analyze the chemical composition of tissues in brain, in vivo magnetic resonance spectroscopy allows non-invasive measurements of neurochemicals in either single voxel or multiple voxels. The reconstruction spectra using 1/3rd of original data than current Edited-MRS scans will not only result in four times faster edited-MRS scans but also extensively reduction in radiations. In this work, we present a deep depth-wise channel attention module (DCAM) based fine-tuned network for magnetic resonance spectroscopy image reconstruction. Besides, we have used channel-wise convolutions and average pooling without dimensionality reduction. We have trained the initial network from scratch on track-1 simulated dataset, however due to the limited dataset, we finetune the network on track-2 and track-3. Experiments are conducted on Edited-MRS-Rec-Challenge dataset1 that showed significantly better performance.

Keywords: Deep Learning, Magnetic Resonance Spectroscopy, Style Transfer, depth-wise channel attention, Reconstruction, Huber loss.

1. Introduction

The brain is a highly complex and heterogeneous organ that consists of many different types of cells, including neurons, glial cells, and endothelial cells. These cells interact with each other in complex ways to perform a wide range of functions, including perception, thought, movement, and emotion. Due to its complexity and heterogeneity, studying the brain is a challenging task that requires a wide range of techniques and approaches. These include anatomical imaging techniques, such as magnetic resonance imaging (MRI), magnetic resonance spectroscopy (MRS) and computed tomography (CT), functional MRI (fMRI) and positron emission tomography (PET). The biochemical processes that occur in the brain are highly complex and dynamic, and involve the activity of numerous neurotransmitters, enzymes, receptors, and other signaling molecules. Magnetic Resonance Spectroscopy (MRS) is a non-invasive imaging technique identical with nuclear magnetic resonance (NMR) spectroscopy. It uses magnetic fields and radio waves to analyze the chemical composition of tissues in the human body such as quantification of Gamma Aminobutyric Acid (GABA), which is overlapped by creatine and glutamate.

MRS provides information about the concentrations of various metabolites within tissues, which can be used to diagnose and monitor diseases. Besides, it can also be

Abdul Qayyum, Steven Niederer, M. K. A. Ahamed Khan, Moona Mazher, Imran Razzak, Mastaneh Mokayef, C. S. Hassan, M. Ridzuan, A

used to detect tissue changes in stroke and epilepsy. MRS data is acquired as a series of spectra, each representing the concentration of a different metabolite [2], [3]. The spectra are typically acquired in a 3D volume, with each voxel (3D pixel) in the volume containing a spectrum and can provide estimates of GABA levels in the brain, however, it has limitations and may not always be precise or accurate. Figure 1 shows the different chemical peaks of a suspected brain tumor. Besides, its high-quality data is needed to efficiently estimate GABA which requires long scan times. Hence, Edited-MRS reconstruction challenge is organized to investigate the machine learning models for spectra reconstruct using 1/3rd of data than current Edited-MRS scans, which will not only result in to four times faster edited-MRS scans but also extensively reduction in radiations. In this work, we present a deep depth-wise channel attention module (DCAM) for magnetic resonance spectroscopy image reconstruction. Besides, we have used channel-wise convolutions and average pooling without dimensionality reduction.
Fig. 1 MRS graph shows the different chemical peaks of a suspected brain tumor [1]

Recently deep learning models have been used in medical image analysis for segmentation, classification, and object recognition [4], [5], [6], [7]. The 2D and 3D segmentation models have been proposed for segmentation of medical imaging [8], [9], [10].

2. Methodology
2.1. Proposed Depth-Wise Edited-Mrs Reconstruction

In this work, we presented UNet based model for MSR reconstruction tasks. Figure 2 and Figure 3 show the proposed reconstruction framework that consists of convolutional blocks, Max-Pooling blocks, Up-Sampling blocks, 1x1 Conv, depth wise channel attention module (DCAM) blocks (see figure 4. The DCAM block is introduced in each encoder block after the convolutional layer block. The convolutional block consists of convolutional layers with Batch-Normalization and ReLU activation function to extract the different feature maps from each block in the encoder side. The 2D max-pooling layer has been used to reduce the input spectral size. The 1x1 convolutional layer with SoftMax function

has been used at the end of the proposed model. Spectral input size is reduced with increasing the number of layers in the encoder block and the spectral input size is recovered via a 2D up sampling layer using a bilinear up sampling method in the decoder side. The DCAM block handles the input feature maps extracted from each convolutional block in the encoder side and further passes these feature maps into the decoder block. The output of each encoder block is fed into the proposed DCAM. Later, the outputs of DCAMs are concatenating them with the corresponding decoder blocks. The output of the last encoder block is passed to the DCAM, and the resulting feature maps are directly concatenated with the corresponding decoder block. Each max-pooling layer receives the output from DCAM. In addition to DCAM, we have implemented different other modules such as channel attention module (CAM), spatial attention module (SAM), channel spatial attention Module (CSAM). As we have larger dataset available for task 1, we trained the proposed model from scratch on track 1. However, there are only few samples available for track 2 and track 3, thus we have developed the style-transfer based framework by finetuning the pre-trained model and freezing the parameters of the encoder and decoder layers except the bottom and last two layers where the weights or parameters are finetuned using vivo dataset for track-2 and track-3. Figure 3 shows the block diagram of finetune network for track-2 and track-3.
Fig. 2 The proposed model used for track1 simulated dataset
Fig. 3 The proposed model used for track2 and track3 vivo dataset
Fig. 4 Diagram of the proposed depth-wise channel attention module (DCAM)

Figure 4 is proposed depth-wise channel attention module (DCAM) used in encoder side of the proposed model. In this experiment, we have used two loss functions: Mean Squared Error (MSE) and Dynamic Huber loss (LHuber). MSE is sensitive towards outliers whereas L Huber is less sensitive to outliers than MSE loss. For N predictions, MSE loss function is defined by;

$$L_{MSE} = \frac{1}{N}\sum_i^N (X_i - \breve{X}_i)^2 \qquad (1)$$

N and $X = (x_1, x_2, \ldots, x_N)$ are the ground truth MRI spectrum and $\breve{X} = (\widetilde{x_1}, \widetilde{x_2}, \ldots, \widetilde{x_N})$ are their corresponding estimated MRI spectrum. The huber loss function is defined;

$$L_{Huber} = \frac{1}{N}\sum_i^N z_i \qquad (2)$$

Where N is the batch size and z_i is defined by;

$$z_i = \begin{cases} 0.5(x_i - \breve{x}_i)^2, & if \; |x_i - \breve{x}_i| \le \beta \\ \beta|x_i - \breve{x}_i| - 0.5\beta^2 & otherwise \end{cases} \qquad (3)$$

Where β is controlling hyperparameter. In our experiment, β decreases from 15 to 1 during the training for each epoch.

2.2. *Simulation Results*

In this section, we briefly first describe the dataset, followed by evaluation parameters, experimental setting, and evaluation. We have used preprocessing step provided by challenge organizer to convert dataset into Frequency domain spectra and added some noises (random Gaussian amplitude, random Gaussian frequency and random Gaussian phase noise, combined).

2.3 Dataset and Evaluation Matrix

The test set may differ in traditional features, such as by vendor and echo time and it will be lower quality data i.e., lower main SNR or larger frequency and phase shifts.

The dataset consists of 5500 spectra (5000 ground-truth spectra and 500 corrupted spectra). The evaluation of the proposed model is performed on an evaluation set which has similar features to that of train set. To evaluate the performance, we have used mean squared error (MSE), signal to noise ratio (SNR), linewidth (FWHM), peak shapes GABA, GLX (PS). Evaluation of model is based on task (simulated, in vivo homogeneous, in vivo heterogeneous) and each metric is ranked individually and well as combined (MSE, SNR, FWHM, PS with ratio of 40%,20%,2 0%, 20%, 20% respectively).

2.4 Parameter Setting

In this work, we β decreases from 15 to 1 during the training for each epoch. We have trained proposed models using Adam optimizer and dynamics Huber loss function using 0.0001 learning rate and 200 epochs. The dataset is normalized using clip [0,1] window. All models use PyTorch and trained on Tesla V100 GPU machine [11], [12]. We have converted all dataset time series into frequency spectrum. The challenge organizers provided simulated and in vivo data training sets representing GABA-edited MEGA-PRESS scans composed of two sub spectra (ON and OFF).

3. Results

We have used scripts provided by organizers to add varying noise, frequency, and phase shifts, that were used for data augmentation purposes. We have developed different variations of proposed framework (depth-wise channel attention module (DCAM), channel attention module (CAM), spatial attention module (SAM), channel spatial attention Module (CSAM)) and compared the performance. The frequency spectrum has been used as input to train our proposed model for task 1, 2 and 3. We have trained proposed model parameters from scratch using 80 percent simulated data in frequency domain and validated using 20 percent of the frequency spectra of simulated dataset. In task two, vivo data (i.e., single-vendor data) in frequency domain has been used to fine-tune the trained model that was trained using simulated dataset. Similarly, for task3, the heterogeneous in vivo data with different frequency spectra has been used to train the proposed model and later fine-tuned the proposed model using different number of epochs. We have used dynamic Huber and Dynamic Tukey loss function for training and optimizing the parameters of our proposed model. The combined loss (Huber and Tukey) loss function provided better performance on validation dataset. Figure 5 shows the comparative analysis. Table 1 describes the evaluation results of proposed edited magnetic resonance spectroscopy reconstruction framework. We can notice that our proposed framework achieved significantly better mean squared error (8.89e-03), signal to noise ratio (4.61e+01), linewidth (9.17e-02) and peak shapes score (9.44e-01) respectively in comparison to baseline method and other methods.

4. Conclusion

In this paper, we presented deep depth-wise channel attention module (DCAM) based fine-tuned UNet architecture for magnetic resonance spectroscopy image reconstruction. Due to the availability of large dataset for task 1, we have trained network from scratch on track-1 simulated dataset followed by finetuning the network on track-2 and track-3. Experiments are conducted on Edited-MRS-Rec-Challenge dataset that showed significantly better performance for all parameters i.e. mean squared error (8.89e-03), signal to noise ratio (4.61e+01), linewidth (9.17e-02) and peak shapes score (9.44e-01) respectively in comparison to baseline method and other methods.

Abstract

Federated learning is an emerging approach that enables large-scale decentralized learning without the need to share data among different data owners. This approach is particularly valuable in addressing data privacy concerns in medical image analysis. However, existing methods often impose a strict requirement for label consistency across clients, which significantly limits its applicability. Various clinical sites may only provide annotations for specific organs of interest, and there may be limited or no overlap in the labeled data among different sites. The human brain receives nutrients and oxygen through blood vessels in the brain. The pathology of small vessels, i.e. mesoscopic scale, is a vulnerable component of the cerebral blood supply and can result in major complications such as Cerebral Small Vessel Diseases (CSVD). In this paper, we propose a hybrid architecture for medical image segmentation to produce efficient representations from global and local features and adaptively aggregate them, aiming to fully exploit their strengths to obtain better segmentation performance in federated learning. Furthermore, we propose a multi-scale feature extraction module embedded at the bottom of the proposed model, which can efficiently extract hidden multi-scale contextual information and aggregate multi-scale features. Experiments on segmentation over three-dimensional rotational angiography of internal Carotid Artery with aneurysm (SHINY-ICARUS) challenge dataset show the effectiveness of the proposed multiscale framework.

Keywords: Federated Learning, Deep Learning, Medical Image Analysis, 3D volume Segmentation, Cerebral Small Vessel Diseases, Brain angiography.

1. Introduction

Distributed big data and digital healthcare technologies hold immense potential for advancing medical services. However, challenges arise when attempting to develop predictive models from diverse and intricate e-health datasets. Federated learning (FL) [1] has emerged as a decentralized learning paradigm that enables multiple data owners to collectively train deep learning (DL) models without sharing the raw data. Previous studies [1], [2] have showcased the viability of FL, particularly the federated averaging (Fe-dAvg) algorithm in the context of medical image segmentation. Federated Learning (FL), as a collaborative machine learning technique, aims to tackle these challenges by creating a joint predictive model across clients at multiple sites, especially within distributed medical institutions or hospitals. FL allows

for the collective training of deep learning models using distinct patient data from various hospitals for various clinical applications, including medical image segmentation. Given the non-convex nature of the training objective in deep neural networks, averaging locally trained models can result in suboptimal solutions within the parameter space, potentially leading to performance degradation [1]. However, a significant issue with FL is the performance degradation it may experience when dealing with data that are not independently and identically distributed (non-iid), a situation commonly encountered in medical image datasets. Recent publications by various authors [2], [3], [4], [5] have focused on federated deep learning, especially for segmentation and classification tasks. Wicaksana et al. [3] introduced "FedMix: Mixed Supervised Federated Learning for Medical Image Segmentation," while Xu et al. [4] presented "Federated Cross Learning for Medical Image Segmentation." Additionally, Qiu et al. [5] proposed "Federated Semi-Supervised Learning for Medical Image Segmentation via Pseudo-Label Denoising."

As the expert knowledge usually required for annotating medical images is much more demanding and difficult to obtain, various medical institutions have very limited strong pixel-level annotated images and most available images are unlabeled or weakly annotated. Therefore, a realistic clinical mechanism that utilizes every available supervision for cross-institutional collaboration without data sharing is highly desirable. We propose to develop a label-agnostic Mixed Supervised Federated Learning approach that efficiently uses data labeled in any form for medical image segmentation. Specifically, in the absence of pixel-level labels, it will effectively utilize unlabeled images as well as useful information contained in the weakly labeled for producing and selecting high-quality pseudo labels. We will devise an effective adaptive weight assignment across clients, where each client can learn an aggregation weight. Adaptive weight assignment is essential to handle inter-client variations in supervision availability. Recently, the SHINY-ICARUS challenge was organized to analyze vascular morphology and topology efficiently to provide a platform and benchmark for brain vascular segmentation [6]. Recent advancements in deep learning and imaging technology have enabled the development of advanced deep learning models and large-scale datasets [6], [7], [8]. Recently a lot of work proposed deep learning-based segmentation methods for medical imaging and signals [8], [9], [10], [11], [12]. In this work, we present an efficient hybrid attention and multi-scale feature aggregation 3D deep learning framework for automatic brain vascular segmentation. Experiments are conducted on the SHINY-ICARUS challenge which shows the effectiveness of the proposed framework.

The key contributions of this work are:

1. Present a 3D UNet-based segmentation framework aided with hybrid attention and multi-scale features for automatic brain vascular segmentation in the federated learning environment.
2. The attention-guided feature fusion module exploits the most useful features (both high-level features and low-level features) between two adjacent layers and the multiscale feature module assists the model in extracting precise features at different scales and training on each client and communicating with the server model using the weighting aggregation approach.
3. Extensive experiments were conducted on the SHINY-ICARUS challenge dataset which showed efficient segmentation of brain vascular.

2. Methodology

3D angiographies of brain vasculature segmentation especially segmentation of visible vasculature connected to one or more of the main feeding arteries of the brain is a challenging problem due to its complex nature. To effectively analyze the vascular morphology and topology, we present an efficient hybrid attention and multi-scale feature aggregation 3D deep learning framework for automatic brain vascular segmentation. In the following section, we first present the overall framework followed by details of each component. The proposed vascular segmentation architecture is based on a classical U-shape encoder–decoder structure [13], [14], [15]. Besides, we have also integrated two core modules (hybrid spatial and channel attention module, multi-scale feature extractor module) subtly and seamlessly which helps to select important multiscale contextual spatial information and semantic information adaptively. The hybrid spatial and channel attention module (HSCA) suppresses the low-level background noise and retains local semantic information of vessel structure, whereas the multiscale feature extractor module (MSFE) assists in the effective extraction of concealed multi-scale contextual information as well as aggregating multi-scale features. As a results, it helps to enhance the capability of the network to deal with complex cases where vascular heavily varies in shape and size, and many are intertwined. Figure 1 illustrates the proposed framework. To extract different feature maps from each convolutional block in the encoder, each block consists of 3D convolutional layers with batch-normalization and ReLU activation functions. We have used the 3D max-pooling layer to reduce the input spatial size of the image. Notice that we have reduced the size of spatial input with the increase in several layers and we have recovered the spatial resolution in the decoder. To recover the spatial resolution in the decoder, we have applied 3D up-sampling using bi-linear up-sampling. In this experiment, we have used $3 \times 3 \times 3$ kernel size in both the encoder and decoder and the number of feature map numbers to 16, 32, 64, 128, and 256 for each encoder. To down-sample the spatial resolution. we have set the kernel size to $2 \times 2 \times 2$ for the 3D-MaxPool layer on encoder side.

Finally, we have used a transpose3D convolutional layer with stride 2 and $2 \times 2 \times 2$ kernel size for up-sampling the size of each decoder. At the end, we have concatenated the output of each encoder block to the corresponding

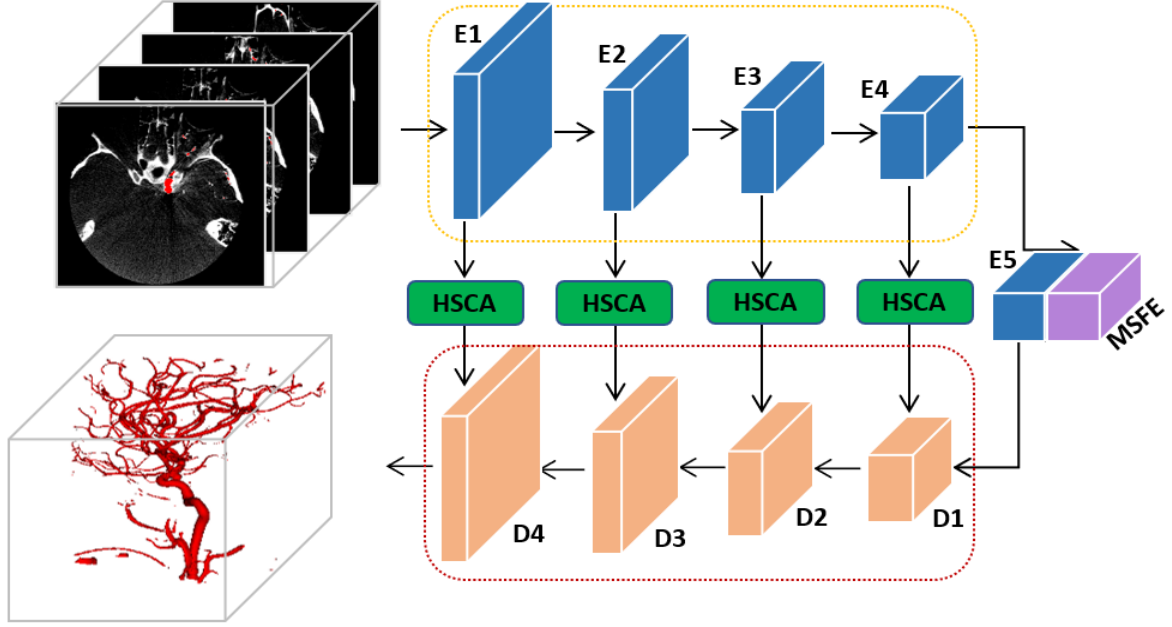
decoder block. To generate the final output segmentation map, we have used a 1×1 convolutional layer with softmax function.


Fig. 1. Proposed Multi-scale Feature extraction Module (MSFE) and hybrid spatial and Channel attention module (HSCA) aided brain vascular segmentation framework. E1, E2, E3, E4 are encoders blocks and D1, D2, D3 and D4 are decoders blocks respectively.

Our approach follows the structure of the FedAvg [1] algorithm, a widely recognized benchmark in the field of Federated Learning (FL). This approach involves a central server node and K client nodes. The central server's main role is to manage the communication and computation processes among the various client nodes. Meanwhile, the client nodes are primarily responsible for training the model using their local data and computing devices. With a universal label set encompassing M organs, each client node possesses a local dataset D_k, which is labeled with a subset of $N_k (\leq M)$ organs. Our objective is to develop a segmentation network F(.,θ) for all M organs by leveraging the labeled datasets $\{D_k\}_{k=1}^{K}$, which are distributed across distinct client nodes and cannot be joined or centralized for training purposes. The training process within the Federated Learning (FL) framework is comprised of Tcommunication rounds between the server and client nodes. In each communication round, denoted as the t_{th} round, each client node k initially downloads the parameters of the current segmentation network, represented as $F(.,\theta^t)$ from the server (referred to as the global model). This process results in a local copy of the model, denoted as the local model.

Subsequently, the client node proceeds to train its local model using its local dataset, Dk, for a specified number of E epochs. Following the local training, the server collects the trained local models, $F(.,\theta_k^t)$, from all Kclient nodes and combines them into a new global model through a parameter-wise averaging process.

$$\theta^{t+1} = \sum_{k}^{K} \frac{|D_k|}{\sum_{j}^{K}|D_j|} \cdot \theta_t \qquad (1)$$

Since the local models are trained separately on the client nodes, the server node is only required to transmit the model parameters, as opposed to the raw data, from the clients. This approach allows the Federated Learning (FL) model to gain insights from distinct client datasets without compromising data privacy. Figure 2 showed the process of federated learning environment for brain tumor segmentation.

As labels for regions in brain vascular are sparse, hence, we have used binary cross-entropy and weighted binary cross-entropy loss [14] which can adjust the learning bias between vessels and background. Besides, we also used dice similarity coefficient loss [15] to ensure the

segmentation of small vessels. Finally, we define the 3D optimization loss function.

$$L = BCE + \alpha WBCE + (1 - \alpha)LDSC \qquad (2)$$

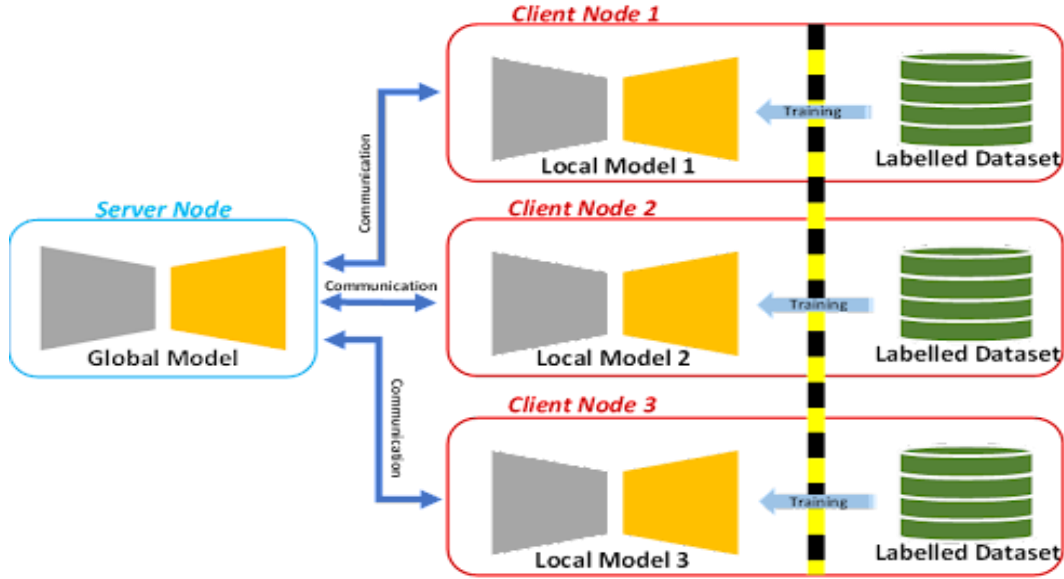
where α is the weight balance parameter between weighted binary cross entropy (WBCE) and LDSC (Dice loss). We have empirically set $\alpha = 0.6$.


Fig. 2 Federated Learning environment for brain tumor segmentation

3. Results and Discussion

In this section, we first present details of the dataset followed by the experiment and results. We have evaluated and compared the performance using the Dice, Jaccard index, volumetric similarity coefficient, and balanced average Hausdorff distance (HD). SHINY-ICARUS challenge evaluation is based on two overlapping matrices such as clDice5 and Dice. ClDices measure the similarity while favoring both connectivity and topology. Both clDice5 and Dice carry the same weight for the evaluation.

3.1. Dataset

SHINY-ICARUS dataset consists of manually segmented cerebral arteries NIfTI volumes with 16-bit representation. The images (resolution $0.227 \times 0.227 \times 0.227$mm) are acquired by interventional neuroradiologists from patients presenting intracranial aneurysms, using a GE INNOVA 3D. The dataset consists of contract images of most of the patient's head. In this experiment, we have divided the dataset into five-fold cross-validation based on the best validation score, the proposed model uploaded in a docker container. The challenge organized provided 35 volumes for training the proposed model. A detailed description of the dataset can be found [6]. A sample dataset with manual annotation is shown in Figure 3.

(a) image   (b) mask
Fig. 3 A sample dataset was used in our proposed model.

3.2. Experimental Results

For evaluation purposes, the SHINY-ICARUS challenge provides two test sets (primary and secret). We have trained the proposed model using patches of input volume due to the limitation of memory. We have found $160 \times 160 \times 160$ the best patch for training. We have generated 10 random patches with a single epoch during training and optimization. In this experiment, we used Adam optimizer, batch size 2, and set the learning rate to 0.0001 and epoch to 1000. We have used a combined loss functions function between the prediction mask and the ground truth. We have used early stopping criteria and training was ended after 20 epochs on similar validation dice. We have used NVIDIA GTX 3070 GPU having a 24GB memory machine and developed the model in PyTorch library and trained from scratch. Figure 4 illustrates the visualization of the validation set. Table 1 shows the results of the proposed model using the validation dataset.

Figure 4 shows the predicted and ground truth segmentation for subject1 and subject2 validation datasets. The proposed model produced a similar segmentation mask as compared to ground truth segmentation. Our proposed model produced overestimated some branches and we can remove these extra segmentation branches using connected components.

4. Conclusion

In this paper, we presented an efficient brain vascular segmentation deep framework aided with hybrid attention and multi-scale feature aggregation modules. Experiments are conducted on the SHINY-ICARUS challenge which shows that our model is ranked 2nd on the secret test and 3rd on the combo test that validates the effectiveness of the proposed framework. We have divided the dataset into five-fold cross-validation and based on the best validation score, the proposed model was uploaded in a docker container. Experiment results showed efficient (dice and clDice5) segmentation of brain vascular.

Abstract

Quantum machines enhance the capabilities of classical counterparts across various domains, notably in addressing real-world challenges. The classification of brain MR images for tumor detection is a crucial diagnostic process in the analysis of brain images. Traditional approaches, such as classical machine learning techniques and conventional deep learning structures like convolutional neural networks, are frequently employed for image classification. However, as the network size increases, training these models becomes increasingly arduous. Quantum algorithms offer advantages by optimizing the performance of classical algorithms through the incorporation of the intrinsic properties of quantum bits. In this paper, we proposed a hybrid classical and quantum convolutional neural network for Alzheimer's disease (AD) classification. The proposed model was further validated on the brain tumor classification task. The fundamental concept involves encoding data into quantum states, facilitating quicker information extraction, and subsequently utilizing this information to discern the data class. The proposed model results underscore the reliability and robustness and demonstrated by optimal performance accuracies across various datasets, the proposed model substantiates its efficacy in detecting and classifying AD disease and brain tumors.

Keywords: Quantum machine learning, Deep learning, Classification, Alzheimer's disease, Brain Tumour, Hybrid Quantum technique in medical imaging.

1. Introduction

Alzheimer's disease (AD) is the most common reason of dementia worldwide [1]. Dementia belongs to assess abnormal changes in the brain and commonly interrupts the communication between the brain cells [1]. Disrupted communication between cells can lead to impairments in an individual's cognitive functions, including memory loss, emotional regulation, reasoning and decision-making, behavior, and language proficiency [1]. In recent years, substantial progress has been achieved in the advancement of cerebrospinal fluid (CSF) biomarkers [2] and cutting-edge imaging techniques like amyloid and tau positron emission tomography (PET) [2]. Although there have been significant advancements, numerous emerging diagnostic and treatment approaches are still primarily confined to research settings. As a result, the primary means of diagnosis before death continues to rely on traditional clinical evaluation, neuropsychological testing [10] and magnetic resonance imaging (MRI) [11]. Mild cognitive impairment (MCI), which serves as an early precursor to dementia, can also represent a subtle initial manifestation of Alzheimer's disease (AD). Diagnosing MCI as an early sign of AD demands a high level of clinical expertise from skilled specialists. Alzheimer's disease (AD) is a neurological disorder that can be detected through brain imaging, and numerous

Moona Mazher, Abdul Qayyum, M. K. A. Ahamed Khan, Steven Niederer, Mastaneh Mokayef, C. S. Hassan, M. Ridzuan, A.

studies have concentrated on using machine learning or deep learning methods to classify AD based on brain images [3].

Recently, various studies proposed deep learning models for AD classifications [3], [4]. They proposed traditional deep learning classification models, in this study we investigate a hybrid model based on classical deep learning and quantum machine learning. Recently Quantum machine learning research has gained success in the medical community.

Few studies proposed quantum machine learning for brain tumor classification [5]. We have proposed hybrid deep learning and quantum layers for the classification of AD and compared the performance with state-of-the-art methods using a hybrid proposed approach. We proposed first-time hybrid classical deep learning and quantum machine learning models for AD classification. We have compared performance using the brain tumor dataset using our proposed technique.

2. Methodology

Our proposed approach combines a classical network with a quantum network to harness the strengths of both worlds, creating a model that can effectively identify AD

abnormalities using MRI analysis. The architecture primarily emphasizes the utilization of classical algorithms for enhanced detection, thereby expediting the diagnosis and treatment processes. The substructure integrated into constructing a quantum layer aims to transform classical data points into quantum states, facilitating faster information extraction and improving the efficiency of feature detection and pattern recognition.

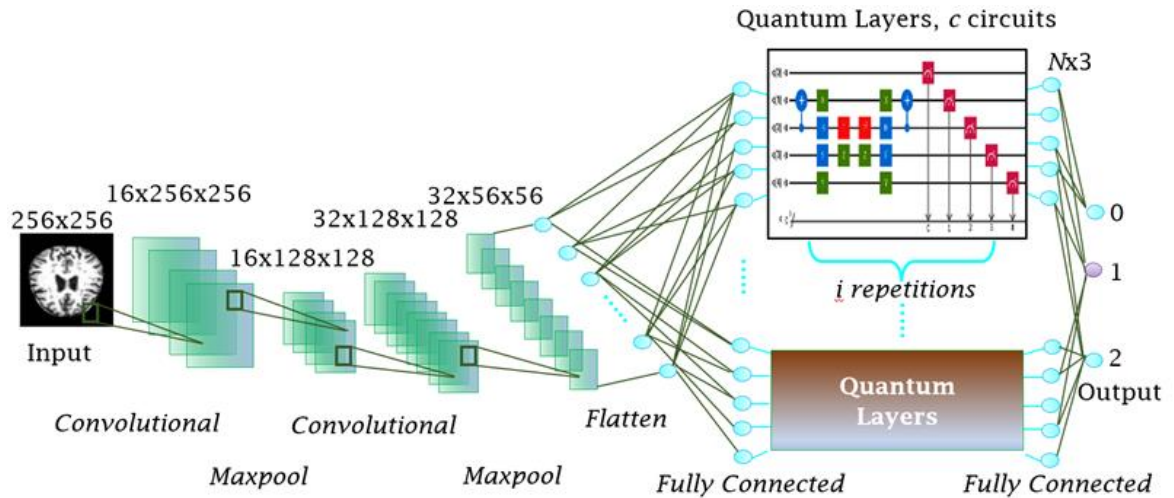
The Convolutional Neural Network (CNN) is a widely employed architecture for a range of processing tasks, such as image recognition, segmentation, and classification [6], [7], [8], [9], [10], [11], [12]. It is composed of three basic layers: Convolution, pooling, and fully connected layers. The convolution and pooling layers are involved in feature extraction from input images, while the fully connected layer extracts features to the output, facilitating classification based on the identified features. A typical CNN structure comprises multiple blocks that integrate convolution, pooling, and fully connected layers. We have proposed three blocks of conv layers. Each block consisted of 2D Conv, 2D MaxPool, and 2D Normalization layers [13], [14], [15]. We have used one fully connected (FC) layer and one hybrid quantum layer for AD and brain tumor classification. The structure of the proposed model is shown in Figure 1.


Fig. 1 The structure of the proposed classical and Quantum deep learning network.

3. Quantum Layers

Quantum supremacy manifests when solving intricate problems more effectively than traditional classical methods [5]. Quantum mechanics provides the fundamental framework for the operation of quantum machines. In a quantum computer, the fundamental unit of information processing is a quantum bit, or qubit, akin to the role played by classical bits in conventional computers. A standard quantum computer utilizes the

unique features of a quantum bit, primarily superposition and quantum entanglement, to process data and information. Unlike a classical bit, a qubit's superposition property enables it to simultaneously exist in multiple states, including zero and one. In essence, qubits can be described as state vectors within Hilbert space. The hybrid layer has been proposed with classical deep learning models for AD classification and further compared on the brain tumor classification dataset.

Figure 2 shows the complete block architecture of the quantum layers.
Fig. 2 Block of the quantum layer.

4. Dataset

We have used an Alzheimer's Disease Neuroimaging Initiative (ADNI) dataset, consisting of 1,821 participants based on magnetic resonance imaging (MRI) scans. After rigorous inclusion criteria were applied, the dataset comprised a total of 8,916 participants. Subjects were labeled according to the clinical diagnoses provided by the ADNI study cohort. For any subjects with documented dementia and a primary diagnosis of Alzheimer's disease dementia, an AD label was assigned regardless of the presence of additional dementing comorbidities. We compared the performance of our proposed method using a brain tumor dataset. All algorithms undergo training and performance validation using the Kaggle Brain Tumor MRI dataset. The Kaggle Brain dataset comprises 7,023 human brain MRI scan images in DICOM format, categorized into four distinct classes, namely glioma, meningioma, no tumor, and pituitary [5].

5. Results and Discussion

In this study, a series of tests have been performed to assess the benefits of employing quantum circuits in AD disease and brain cancer classification. These tests specifically compared the performance of a traditional CNN with quantum circuits used for feature extraction, with a focus on highlighting the advantages of quantum circuits. The proposed approach with Quantum layers produced comparable performance using both datasets as shown in Table 1.

Table 1 Classification performance of brain tumor using classical and quantum deep learning models

Table 2 shows the performance of the proposed model using classical and hybrid deep learning models. The quantum-based hybrid deep learning model produced optimal performance on brain tumor and AD disease classification tasks.

Furthermore, the results found have the capacity of the hybrid quantum model to enhance the efficiency of medical image classification and diagnosis. However, additional research is necessary to evaluate its performance in classifying different types of data. This research offers valuable insights into the benefits of integrating quantum circuitry into CNN models for the analysis of medical images, opening possibilities for quantum-enhanced machine learning within this field.

6. Conclusion

The proposed study introduces an efficient Hybrid Quantum deep learning model for the classification and diagnosis of AD disease and Kaggle brain tumors medical image datasets. The proposed model attains a comparable performance accuracy as compared to the conventional CNN's performance. The validation accuracy results provide additional evidence of this superior performance. Future research efforts will be directed towards assessing the resilience of hybrid quantum-based models against adversarial attacks. The research on quantum with classical deep learning models will continue to enrich the body of knowledge in quantum computing and its potential applications in medical imaging research, ultimately driving progress in precise diagnosis and enhanced patient care.

Abstract

This paper investigates the discontinuous state feedback control for stabilizing a class of nonholonomic integrators with drift terms. The control design relies on constraining state trajectory in an invariant set. To this end, we apply constant controls to drive the states moving into the invariant set and then switch to a continuous control law with suitable gain selections. It is proven in the Lyapunov sense that the proposed control scheme achieves global exponential stabilization of the states, and the control switch would only occur at most once. Numerical simulations are carried out to validate the proposed control law.

Keywords: Nonholonomic integrators, Discontinuous feedback, Nonlinear control

1. Introduction

Nonholonomic integrators refer to one kind of control systems that obstruct Brockett's necessary condition for the existence of static time-invariant stabilizers [1]. They have attracted much attention in the control community because various robotic systems can be converted into nonholonomic integrators [2].

Due to non-integrable properties, only discontinuous, time-varying, or hybrid control laws are applicable to stabilize the nonholonomic integrators [3], [4], [5], [6]. Via forcing the state trajectories to move on a sliding mode surface, a stabilization and a tracking control law were developed in [3] for nonholonomic integrators, achieving global asymptotical convergence of the states. In [4], a novel logic-based hybrid control law with the switching mechanism that achieved global exponential stabilization was reported. Using virtual control and variable structure design, the control scheme in [5] stabilized the states of nonholonomic integrators to zero exponentially from any initial states. An alternative with the control Lyapunov function approach for stabilizing the nonholonomic integrators can be found in [6]. The leading results in [3], [4], [5], [6] are helpful in understanding the structural properties and solution trajectory of nonholonomic integrators. Yet, the drift terms that play affect on the dynamic performance of the

system are not considered in the literature mentioned above.

It is necessary to consider drift terms for utilizing the results developed for pure nonholonomic integrators on practical robotic systems. In [2], an adaptive leader-following formation control scheme of multiple wheeled mobile robots was developed by applying techniques associated with nonholonomic integrators, regulating formation errors globally convergent to the neighborhood of the origin. After converting the kinematic model of unicycles into the form of nonholonomic integrators with drift terms, a control law capable of rendezvous and tracking of networked unicycles was proposed in [7], which, however, only consider the case that the error states are initialized inside an invariant set.

Motivated by the discussions above, this paper makes further endeavors on the control design of nonholonomic integrators. The concerned nonholonomic integrators can be viewed as an augmented version of that in [1] by adding a drift term. The control design involves a state feedback control law and a constant control law, which achieves asymptotical convergence of the states in an invariant set and forces the state trajectory to move into the invariant set, respectively. A simple switch would occur if the initial states are outside the invariant set. Lyapunov stability theory is utilized to prove the obtained theoretical results.

The rest is organized as follows. Section 2 formulates the control problem and presents the control design.

Numerical simulations are carried out in Section 3. Section 4 concludes the work briefly.

2. Main results
2.1. Problem formulation

The concerned nonholonomic integrator with a drift term in this work holds the form below,

$$
\begin{cases}
\dot{z}_1 = u_1 \\
\dot{z}_2 = u_2 \\
\dot{z}_3 = z_2 u_1 - z_1 u_2 + f(z_1, z_2)
\end{cases} \tag{1}
$$

where $z_1, z_2, z_3, u_1, u_2 \in \Box, f : \Box \times \Box \mapsto \Box$, and there is a positive number κ_1 such that $|f(z_1, z_2)| \leq \kappa_1 \|[z_1, z_2]\|$. The nonholonomic dynamic (1) obstructs the famous Brockett's necessary condition for the existence of full-state time-invariant static stabilizer. To this end, we plan to find a discontinuous control law for (1) so that

$$
\lim_{t \to \infty} z_1 = 0, \lim_{t \to \infty} z_2 = 0, \lim_{t \to \infty} z_3 = 0 \tag{2}
$$

from any initial states.

Remark 1. Either kinematic or dynamic models of various nonholonomic systems, including nonholonomic unicycles and underactuated hovercrafts [7], can be converted into the form of (1). Thus, the addressed nonholonomic integrator (1) has general property though its form is simple.

2.2. Control design

The discontinuous control design includes two steps. First, we design a state feedback control law so that the state trajectory is convergent to zero in an invariant set. Second, we propose a constant control to force the states to move into the invariant set. The design process above is depicted in Fig. 1.

$$
C \triangleq \left\{ Z = [z_1, z_2, z_3]^T \in \mathbb{R}^3 \middle| z_1^2 + z_2^2 > |z_3| \right\}
$$
Fig. 1. The invariant set and switching mechanism.

Design the following control law,

$$
\begin{aligned}
u_1 &= -k_1 \tanh z_1 - \frac{z_2}{z_1^2 + z_2^2}(f + g + k_2 z_3) \\
u_2 &= -k_1 \tanh z_2 + \frac{z_1}{z_1^2 + z_2^2}(f + g + k_2 z_3)
\end{aligned} \tag{3}
$$

where $g \Box -k_1 z_2 \tanh z_1 + k_1 z_1 \tanh z_2, k_2 > 2k_1 > 0$. The effectiveness of the control law (3) is summarized in the lemma below.

LEMMA 1. *The application of (3) on (1) achieves that $z_1 \to 0, z_2 \to 0, z_3 \to 0$ as $t \to +\infty$ and $u_1, u_2 \in L_\infty$, if $k_2 > 2k_1 > 0$ and $Z(0) \in C \Box \left\{ Z \in \Box^3 \middle| z_1^2 + z_2^2 > |z_3| \right\}$.*

Proof. Substituting (3) into (1) results in,

$$
\begin{aligned}
\dot{z}_1 &= -k_1 \tanh z_1 - \frac{z_2}{z_1^2 + z_2^2}(f + g + k_2 z_3) \\
\dot{z}_2 &= -k_1 \tanh z_2 + \frac{z_2}{z_1^2 + z_2^2}(f + g + k_2 z_3) \\
\dot{z}_3 &= -k_2 z_3
\end{aligned} \tag{4}
$$

Obviously, one has $z_3(t) = z_3(0)e^{-k_2 t}$ and obtains that z_3 would converge to zero exponentially. Choose a positive function,

$$
V = 0.5(z_1^2 + z_2^2) \tag{5}
$$

The time derivative of V along with the solution trajectory of (4) can be calculated as,

$$
\dot{V} = -k_1 z_1 \tanh z_1 - k_1 z_2 \tanh z_2 \leq 0 \tag{6}
$$

which implies that the states z_1 and z_2 converge to zero asymptotically. Next, we prove the boundedness of the control inputs and invariant properties of the set C. Due to the forms of f and g, it is direct to obtain

$$
\begin{aligned}
|f| &\leq \kappa_1 \sqrt{z_2^2 + z_2^2} \\
|g| &\leq k_1 |z_1| + k_1 |z_2| \leq 2k_1 \sqrt{z_2^2 + z_2^2}
\end{aligned} \tag{7}
$$

which, together with (3), demonstrates that

$$
\begin{aligned}
|u_1| &\leq k_1 + \frac{|f| + |g|}{\sqrt{z_1^2 + z_2^2}} + \frac{k_2 |z_3|}{\sqrt{z_1^2 + z_2^2}} \\
&\leq 3k_1 + \kappa_1 + \frac{k_2 |z_3|}{\sqrt{z_1^2 + z_2^2}}
\end{aligned} \tag{8}
$$

According to $|x| \geq |\tanh x|, \forall x \in \Box$, we derive that

$$
\dot{V} \geq -k_1(z_1^2 + z_2^2) = -2k_1 V \tag{9}
$$

Using the comparison principle then yields [8],

$$
V(t) \geq e^{-2k_1 t} V(0) \tag{10}
$$

Therefore, one has

$$
\|[z_1(t), z_2(t)]\| \geq \|[z_1(0), z_2(0)]\| e^{-k_1 t} \tag{11}
$$

and

$$
\frac{|z_3|}{\sqrt{z_1^2 + z_2^2}} \leq \frac{|z_3(0)|}{\sqrt{z_1^2(0) + z_2^2(0)}} \tag{12}
$$

Combining (8) and (12), we find out that

$$
|u_1| \leq U \Box 3k_1 + \kappa_1 + k_2 \frac{|z_3(0)|}{\sqrt{z_1^2(0) + z_2^2(0)}} \tag{13}
$$

and u_1 is bounded. Following the same routine above, we can also prove the boundedness $|u_2| \leq U$. Additionally, the inequality (11) and the fact $z_3(t) = z_3(0)e^{-k_2 t}$ imply that $z_1^2 + z_2^2 > |z_3|, \forall t \geq 0$ as $k_2 > 2k_1$ and $Z(0) \in C$.

Therefore, the set C is invariant. This completes the proof. □

The Lemma 1 shows that the state trajectory would converge to zero asymptotically in the invariant set C. In what follows, we would like to use constant controls to drive the state trajectory moving into the set C if the states are not initialized therein.

Without losing generality, the initial states are assumed to be outside the invariant set C, i.e., $Z(0) \in \Box^3 - C$. Consider the constant control inputs,

$$u_1 \equiv u_{1c}, u_2 \equiv u_{2c} \qquad (14)$$

Using (14) and integrating (1) with respect to time then lead to,

$$z_1(t) = z_1(0) + u_{1c}t$$
$$z_2(t) = z_2(0) + u_{2c}t$$
$$z_3(t) = z_3(0) + [z_2(0)u_{1c} - z_1(0)u_{2c}]t \qquad (15)$$
$$+ \int_0^t f(z_1(\tau), z_2(\tau))d\tau$$

The term $\int_0^t f(z_1(\tau), z_2(\tau))d\tau$ satisfies,

$$\int_0^t f(z_1(\tau), z_2(\tau))d\tau \le \kappa_1 \int_0^t (|z_1(0)| + |z_2(0)|)d\tau$$
$$+ \kappa_1 \int_0^t (|u_{1c}| + |u_{2c}|)\tau d\tau \qquad (16)$$
$$= c_1 t + c_2 t^2$$

where $c_1 = \kappa_1(|z_1(0)| + |z_2(0)|), c_2 = 0.5\kappa_1(|u_{1c}| + |u_{2c}|)$.

Let $c_0 = |z_3(0)|, c_3 = \kappa_1(|z_1(0)| + |z_2(0)|) + [z_2(0)u_{1c} - z_1(0)u_{2c}]$, the estimation for $z_3(t)$ can be given by,

$$z_3(t) \le c_0 + c_3 t + c_2 t^2 \qquad (17)$$

It hence follows that,

$$z_1^2(t) + z_2^2(t) - |z_3(t)| \ge (z_1(0) + u_{1c}t)^2 + (z_2(0) + u_{2c}t)^2$$
$$- c_0 - c_3 t - c_2 t^2 \qquad (18)$$
$$= b_2 t^2 + b_1 t + b_0$$

with

$$b_2 \Box u_{1c}^2 + u_{2c}^2 - c_2,$$
$$b_1 \Box 2z_1(0)u_{1c} + 2z_2(0)u_{2c} - c_3 \qquad (19)$$
$$b_0 \Box z_1^2(0) + z_2^2(0) - c_0 < 0$$

Observing (19), if u_{1c}, u_{2c} are chosen satisfying $u_{1c}^2 + u_{2c}^2 > c_2$, then we conclude from $b_2 > 0$ and $b_0 < 0$ that there exists a finite time instant $t_1 > 0$ so that,

$$z_1^2(t_1) + z_2^2(t_1) - |z_3(t_1)| = 0$$
$$z_1^2(t) + z_2^2(t) - |z_3(t)| > 0, \forall t > t_1 \qquad (20)$$

Such a t_1 can be estimated as,

$$0 < t_1 \le t_2 \Box \frac{-b_1 + \sqrt{b_1^2 - 4b_2 b_0}}{2b_2} \qquad (21)$$

The derivations above are gathered together in the following lemma.

LEMMA 2. *Given the constant control inputs $[u_{1c}, u_{2c}]$ in (14) satisfying $u_{1c}^2 + u_{2c}^2 > c_2$ and $Z(0) \in \Box^3 - C$, there is a finite time instant t_1 given by (21) so that $Z(t_1) \in C$.*
Proof. The proof is direct via following the derivations (14)-(21), and hence omitted. □

According to Lemmas 1-2, the discontinuous control law can be constructed as

$$u_1 = \begin{cases} -k_1 \tanh z_1 - \frac{z_2}{z_1^2 + z_2^2}(f + g + k_2 z_3), & \text{if } Z \in C \\ u_{1c}, & \text{if } Z \in \Box^3 - C \end{cases}$$
$$u_2 = \begin{cases} -k_1 \tanh z_2 + \frac{z_1}{z_1^2 + z_2^2}(f + g + k_2 z_3), & \text{if } Z \in C \\ u_{2c}, & \text{if } Z \in \Box^3 - C \end{cases} \qquad (22)$$

THEOREM 1. *Given the discontinuous control law (22), the system (1) is globally asymptotically stable if $k_2 > 2k_1 > 0$ and $u_{1c}^2 + u_{2c}^2 > c_2$.*
Proof. According to Lemma 1, the states would converge to zero asymptotically in the invariant set C by the control law (22). Moreover, the states would be driven moving into the set C in finite time if they are initialized outside the invariant set. Thus, the discontinuous scheme (22) would always ensure the asymptotic convergence to zero of the states. The claims in the theorem are established immediately. □

Remark 2. *Note that the time instant t_1 is not necessarily known for control switch in (22). We introduce the estimation on t_1 to prove that the state trajectory would move into the invariant set C in finite time.*

Remark 3. *Due to the invariant property of C, the switch of the control law (22) would only occur once at most.*

2.3. Application to the tracking control of a unicycle robot

This subsection illustrates the application of (22) on the trajectory tracking of a unicycle robot. The kinematic model of a unicycle robot can be given by

$$\dot{x} = v\cos\theta, \dot{y} = v\sin\theta, \dot{\theta} = \omega \qquad (23)$$

where $[x, y]^T$ denotes the Cartesian position, θ is the orientation angle, u represents linear velocity and ω stands for the angular velocity. Let $[x_r, y_r, \theta_r]^T$ denote the reference trajectory generated by

$$\dot{x}_r = v_r \cos\theta_r, \dot{y}_r = v_r \sin\theta_r, \dot{\theta}_r = \omega_r \qquad (24)$$

where the reference velocities v_r and ω_r are bounded. Define the following tracking errors,

$$z_1 = (x - x_r)\cos\theta + (y - y_r)\sin\theta$$
$$z_2 = \theta - \theta_r \qquad (25)$$
$$z_3 = -2(x - x_r)\sin\theta + 2(y - y_r)\cos\theta + z_1 z_2$$

The time derivative of (25) can be calculated as

$$\dot{z}_1 = v + 0.5\omega(z_3 - z_1 z_2) - v_r \cos z_2$$
$$\dot{z}_2 = \omega - \omega_r \qquad (26)$$
$$\dot{z}_3 = z_2 \dot{z}_1 - z_1 \dot{z}_2 + 2(v_r \sin z_2 - \omega_r z_1)$$

Obviously, the error dynamics (26) features the same structure as (1) if we define

$$u_1 = v + 0.5\omega(z_3 - z_1 z_2) - v_r \cos z_2$$
$$u_2 = \omega - \omega_r$$
$$f = 2(v_r \sin z_2 - \omega_r z_1) \qquad (27)$$
$$\kappa_1 = 2\sqrt{v_r^2 + \omega_r^2}$$

Therefore, applying the control law (22) on (26) would steer the error (25) to zero globally asymptotically. As the state transformation (25) is globally invertible, the original tracking errors $x - x_r$, $y - y_r$ and $\theta - \theta_r$ would converge to zero asymptotically from any initial states.

3. Numerical Simulations

This section validates the proposed control law (22) by numerical simulations. To this end, we initialize the nonholonomic integrator (1) by $Z(0) = [-1, 1, -4]^T$ and set the control coefficients as $k_1 = 0.25, k_2 = 0.55$. The drift term is $f = 0.2(z_1 + z_2)$. The constant control inputs are $u_{1c} = 0.2, u_{2c} = 0.2$. We depict the results in Figs 2-3.
Fig. 2. The state trajectories.

As can be seen from Fig. 2. the initial states are outside the invariant set, and the control inputs are constant in this phase. The control is automatically switched into state feedback control law as soon as the switching condition $z_1^2(t) + z_2^2(t) > |z_3(t)|$ is satisfied, which can be drawn from the turnings in Fig. 2. Then, the states are constrained in the invariant set and converge to zero asymptotically. In addition, the control inputs are always bounded, which can be concluded from Fig. 3.
Fig. 3. The control inputs.

To validate the control law on solving the trajectory tracking control problem of a unicycle robot, we set the

reference signal by $v_r = 0.2, \omega_r = 0.1$ with initial condition $x_r(0) = 0, y_r(0) = -2, \theta_r(0) = 0$. The initial pose of the unicycle is chosen as $x(0) = -2, y(0) = -2.5, \theta(0) = \pi$. Meanwhile, the control coefficients k_1, k_2, u_{1c} and u_{2c} are set the same as previous case. We depict the position trajectory and errors in Fig. 4 and Fig. 5, respectively.

As can be seen, the Fig. 4-5 illustrate the success of applying discontinuous control law (22) on the trajectory tracking control of a typical unicycle robot. The pose tracking errors are convergent to zero asymptotically.
Fig. 4. The position trajectory(*:starting point).
Fig. 5. The tracking errors.

4. Conclusion

This brief introduces a discontinuous global stabilizer for a class of nonholonomic integrators with drift terms. The proposed control scheme includes a state feedback controller and a constant control law, fusing with a simple criterion for control switching. It is proven in the Lyapunov sense that the system states converge to zero globally asymptotically, with the control switching occurring at most once. In the future, the authors will generalize the current control scheme to solve global stabilization problems of other nonholonomic systems.

Abstract

Optimal design of vibration absorbers has been extensively investigated. Most of the design methods are approached by optimizing certain performance indices, resulting in a set of optimal parameters that are independent of exogenous forcing frequencies. In practical designs, however, it is often desirable to know the performance limits over a frequency band of interest. This problem is tackled in the present paper where both lower and upper bounds are obtained. Numerical examples are given to validate the corresponding designs.

Keywords: Vibration absorbers, optimal design, performance limit

1. Introduction

Tuned mass dampers (TMD) are widely used for vibration attenuation either at a frequency or over a frequency range. Many configurations have been proposed [1], [2], [3] while one typical TMD consists of a secondary mass-damper-spring system, attached to a vibrating primary system. The secondary system is also called an absorber whose parameters are to be designed. Besides the classical "equal height" methods, many approaches have been proposed for optimal design of TMD parameters. Most of the developments are preceded with formulating optimization problems by optimizing a properly chosen performance index. For example, H2/H∞ forms of performance indices can be optimized where even analytical solution can be found for optimal parameter selections [4], [5]. A comparison between different optimization criteria is given in [6], while more elaborated examples can be found in [7]. As a result of the optimization, optimal parameters can be obtained which is usually represented as optimal damping and frequency ratios as a function of the mass ratio.

In review of the available results in the literature, it is seen that the optimization of performance indices leads to the results that only optimize the pre-designated indices, yet performance limits, particularly the frequency-dependence performance bounding information cannot be obtained. This frequency-dependence performance limit of vibration absorbers is considered in the paper. It is organized as follows: section 2 formulates the problem to be considered. Section 3 proceeds to develop the lower and upper bounds. Numerical examples are also provided before a conclusion in section 4.

2. Problem Formulation

The model can be represented as:

$$m_1 \ddot{x}_1 + (c_1 + c_2)\dot{x}_1 - c_2 \dot{x}_2 + (k_1 + k_2)x_1 - k_2 x_2 = d$$
$$m_2 \ddot{x}_2 - c_2 \dot{x}_1 + c_2 \dot{x}_2 - k_2 x_1 + k_2 x_2 = 0 \qquad (1)$$
$$F = c_1 \dot{x}_1 + k_1 x_1$$

where the dependence on time has been omitted for easy reference. The frequency response property for the transmission force can then be written down:

$$\frac{F(j\omega)}{D(j\omega)} = \frac{(k_1 + jc_1\omega)(-m_2\omega^2 + k_2 + jc_2\omega)}{[-m_1\omega^2 + k_1 + k_2 + j(c_1+c_2)\omega](-m_2\omega^2 + k_2 + jc_2\omega) - (k_2 + jc_2\omega)^2}$$
(2)

where $F(j\omega)$ and $D(j\omega)$ are the Fourier transforms of $F(t)$ and $d(t)$, respectively.

The aim of the TMD design is to design the absorber parameters m_2, c_2, and k_2 in such a way, so that certain appropriate performance indices such as energy/magnitude defined by H2/H∞ norms are optimized. Although the optimization "routines" exist for obtaining feasible solutions to the corresponding optimization problems, it is still of great significance and interest to seek the boundary or limit of performance. As the limits will dictate the achievable performance, on the one hand, *they are not to be conquered by any form of performance index to be optimized; on the other hand, they will actually provide guidance to the designers* if a choice of performance index is suitable by knowing its "distance" to the limits. Henceforth, performance limits should be treated as a benchmarking that any design through any optimization method with any performance index must compare with. These issues are treated in the following sections.

3. Performance Limit: Lower & Upper Bounds

From equation (1), it is known that the following frequency responses relationship holds:

$$F(j\omega) = (k_1 + j\omega c_1)X_1(j\omega)$$
(3)

For any particular configuration, the primary system parameters c_1 and k_1 are known, hence optimizing $F(j\omega)/D(j\omega)$ is equivalent to optimizing $X_1(j\omega)/D(j\omega)$. From equation (2), it is known:

$$\frac{X_1(j\omega)}{D(j\omega)} = \frac{(-m_2\omega^2 + k_2 + jc_2\omega)}{[-m_1\omega^2 + k_1 + k_2 + j(c_1+c_2)\omega](-m_2\omega^2 + k_2 + jc_2\omega) - (k_2 + jc_2\omega)^2}$$
(4)

Thus the objective of TMD design can be re-stated to reduce the transmission magnitude $|X_1(j\omega)/D(j\omega)|$ through the optimal selection of the absorber parameters m_2, c_2, and k_2. In the following, the performance bounds for attenuation of the magnitude of $X_1(j\omega)/D(j\omega)$ through the to-be-designed parameters of m_2, c_2, and k_2 will be sought. This is preceded by boldly stating the results.

Theorem 1 (Lower Bound): The performance of $|X_1(j\omega)/D(j\omega)|$ is bounded from below by:

$$\left|\frac{X_1(j\omega)}{D(j\omega)}\right| > \frac{1}{\sqrt{(k_1 - m_1\omega^2)^2 + c_1^2\omega^2} + \omega\sqrt{\frac{m_2(k_2^2 + c_2^2\omega^2)}{2}}}$$
, $\forall \omega$
(5)

The relationship is strictly "greater than" implying that the lower bound is absolute and never to be attained.

Theorem 2: The performance of $|X_1(j\omega)/D(j\omega)|$ is bounded from above by:

$$\left|\frac{X_1(j\omega)}{D(j\omega)}\right| < \frac{\sqrt{K^2 + M^2\omega^4 + C^2\omega^2}}{h(\omega)}, \quad \forall \omega$$
(6)

where: $h(\omega)$ is a positive function dependent on frequency.

From the above result, a series of observations follow:

(1) While the minimum lower bound is attained at natural frequency of the primary system $\omega_1 = \sqrt{k_1/m_1}$, the minimum upper bound is achieved at the natural frequency of the absorber $\omega_2 = \sqrt{k_2/m_2}$.

(2) As the lower bound, the upper bound is also inversely proportional to the natural frequency ω_2 —to increase the bound, ω_2 needs to be decreased!

(3) Yet one of the most important applications for upper bound is the assertion that the performance $|X_1(j\omega)/D(j\omega)|$ will always be attenuated over the frequency bands where the upper bound is less than unity. This can be developed into a very useful and powerful design methodology.

For example, assume c_1 and m_2 are unities, then the bound becomes:

$$\frac{1}{\omega + \dfrac{c_2\omega^5}{(k_2 - \omega^2)^2 + c_2^2\omega^2}}$$
(7)

Then a calculation for cubic unities of k_2, c_2, and ω with a grid of $10 \times 10 \times 10$ shows that a set of solutions exist for satisfying (7). This is shown in Figure1.
Figure 1: feasible choices of parameters k_2, c_2, and ω within a $10\times10\times10$ cubic unity grid

4. Conclusion

Frequency-dependent performance limits of tuned mass dampers have been considered. It has been demonstrated that the performance is not only bounded from below, but also bounded from above. The existence of the lower bound is very useful providing guidance upon best performance to be expected. Combining with the concept of attenuation by bounding from above, it has been shown that this can lead to design methods with such features as guaranteed performance.

Abstract

In this paper, an adaptive iterative learning algorithm is proposed to solve the optimal tracking control problem (OTCP). Unlike the existing method, we select the finite-time horizon cost function to measure tracking performance. Our method doesn't require an accurate system dynamic and the concurrent learning (CL) technique is utilized to learn the system identification model. Based on identification model, we present our concurrent iterative learning algorithm under the Pontryagin's framework to learn the solution for OTCP. The proposed algorithm overcomes the limitation of Adaptive Dynamic Programming (ADP) methods when dealing with time-varying systems or situations involving state inequality constraints. The algorithm's effectiveness is demonstrated through a numerical simulation.

Keywords: Optimal tracking control, Concurrent learning, State inequality constraints, Adaptive iterative algorithm

1. Introduction

Optimal tracking control [1], [2] is a comprehensive problem to find an optimal control input to minimize the tracking cost function to ensure that the system follows the prescribed trajectory. Due to the complexity of the nonlinear systems, it is difficult to obtain analytical solutions for OTCP. This paper aims to design an iterative algorithm to realize the tracking control without the accurate system information.

Many researchers apply Reinforcement learning (RL) technique [3], [4], [5], [6] to solve the above problems. The advantage of reinforcement learning is that it does not require a precise prior knowledge of system dynamics. Most of the methods use the ADP technique to solve the tracking Hamilton–Jacobi–Bellman (HJB) equation. Approximation methods like neural networks (NNs) are widely used in ADP literature for value function approximation. Although ADP is effective, it still has inherent technical obstacles. The HJB equation reduced to the form of an ODE under an infinite-horizon cost function and an affine nonlinear system. It is easier to learn solutions compared to PDE.

Another important problem for the OTCP is the is the existence of constraints. For control input constraints, a nonquadratic performance function [7], [8] is used in the optimal regulation problem. As for the state constraints problem, the explicit expression between optimal control and value function no longer holds in affine nonlinear systems. Therefore, within the ADP framework, the problem of state constraints for OTCP remains unresolved.

This paper aims to develop a new adaptive iterative algorithm to solve the OTCP with finite-horizon cost function and state constraints. CL technique [9] is used to learn the system identification model. Based on Pontryagin's framework and the identification model, we design a new adaptive iterative method to learn the optimal control input which minimize the tacking cost function in prescribed time interval without the exact system dynamic. Moreover, the system trajectory not only tracks the predetermined trajectory, but also satisfies the state constraints.

2. Problem statement

We consider the following nonlinear dynamic system:

$$\dot{x} = f(x, u, t), \quad x(t_0) = x_0 \quad (1)$$

where $x \in \mathbb{R}^n$ is the system state with initial state x_0, and $u \in \mathbb{R}^m$ is the control input. The unknown map $f: \mathbb{R}^n \times \mathbb{R}^m \times \mathbb{R} \to \mathbb{R}^n$ is Lipschitz continuous. It is assumed that the state must be limited to satisfy the following inequality constraints:

$$s(x, t) \leq 0 \quad (2)$$

where $s = (s_1, s_2, \ldots, s_z)^T \in \mathbb{R}^n \times \mathbb{R} \to \mathbb{R}^z$ is a z-dimensional column vector function. Let $x_d(t) \in \mathbb{R}^n$ is a prescribed trajectory with initial state x_{d0}, the dynamic of tracking error and the constraints can be expressed as:

$$\begin{cases} \dot{e} = F(e, u, t) & (3) \\ S(e, t) \leq 0 & (4) \end{cases}$$

where $e = x - x_d$ is the tracking error, $F(e, u, t) = f(e + x_d, u, t) - \dot{x}_d$ and $S(e, t) = s(e + x_d, t)$. We define the following finite-horizon cost function for tracking performance:

$$J(e, u) = \int_{t_0}^{t_f} L(e, u) dt \qquad (5)$$

where $L(e, u) = e^T Q e + u^T R u$, $Q \in \mathbb{R}^{n \times n}$ and $R \in \mathbb{R}^{m \times m}$ are positive definite symmetric matrices. The optimal tracking control problem in this paper aims to find an optimal control input $u^*(t), t \in [t_0, t_f]$ to minimize the cost function (5) subject to system (3) and inequality constraints (4).

It is proved [10] that the above state constraints optimal control problem can be reduced to solve a sequence of unconstrained problem by minimizing the following Kelley-Bryson penalty cost function as $k \to \infty$:

$$J(e, u, r^k) = \int_{t_0}^{t_f} L(e, u) + r^k \sum_{j=1}^{z} h(S_j) S_j^2(e, t) \, dt \quad (6)$$

where $\lim_{k \to \infty} r^k = \infty$ and $h(\sigma) = \begin{cases} 1, \sigma > 0 \\ 0, \sigma \leq 0. \end{cases}$

The necessary condition for each optimal control problem associated with $J(e, u, r^k)$ is concluded by:

$$\begin{cases} \dot{\lambda} = -H_e - 2r^k \sum_{j=1}^{z} h(S_j) S_j S_{je} \\ u = \underset{u}{\operatorname{argmin}} H(e, u, \lambda, t) \end{cases} \qquad (7)$$

where $H(e, u, \lambda, t) = L(e, u) + \lambda^T F(e, u, t)$.

3. Concurrent learning iterative algorithm

3.1. *System identification*

First, we suppose that the unknown error dynamic (3) can be represented through a finite set of basis functions:

$$F(e, u) = \Theta^T(t) \Phi(e, u) + \varepsilon \qquad (8)$$

where $\Phi(e, u): \mathbb{R}^n \times \mathbb{R}^m \to \mathbb{R}^N$ is the vector of basis functions. $\Theta: \mathbb{R} \to \mathbb{R}^{N \times n}$ is the unknown time-varying weight matrix. ε is the vector of approximation errors. According to the Weierstrass approximation theorem, ε can be reduced to zero with arbitrarily high precision as $N \to \infty$. We define the estimate of weight matrix and tracking error as $\widehat{\Theta}$ and $\hat{e}$, respectively.

For error dynamic system (3), we define the historical data stack as $\left\{ \mathbb{E}_j(t), \mathbb{U}_j(t), \dot{\mathbb{E}}_j(t), \ t \in [t_0, t_f] \right\}_{j=1}^{W}$, which stores the tracking error, the control input, and the derivative of the tracking error. We have the following assumption for history trajectory stack:

Assumption 1. Let $\Pi^t = \sum_{j=1}^{W} \Phi^T(\mathbb{E}_j^t, \mathbb{U}_j^t) \Phi(\mathbb{E}_j^t, \mathbb{U}_j^t)$. It is assumed that there exist positive constants $\overline{\mu} > \underline{\mu} > 0$, for $\forall t[t_0, t_f]$, we have $\underline{\mu}I < \Pi^t < \overline{\mu}I$.

We design the following adaptive updating law of the i-th estimates for tracking error $\hat{e}^i$ and weight matrix $\widehat{\Theta}^i$:

$$\begin{cases} \dot{\hat{e}}^i = (\widehat{\Theta}^i(t))^T \Phi(e, u) + \omega \tilde{e}^i, \ \hat{e}^i(t_0) = x_0 - x_{d0} \ (9) \\ \widehat{\Theta}^i(t) = \widehat{\Theta}^{i-1}(t) + (I - \mu \Pi^t)^2 \Phi(e, u)(\tilde{e}^i)^T \\ \quad + \mu \sum_{j=1}^{W} \Phi(\mathbb{E}_j^t, \mathbb{U}_j^t) \left(\dot{\mathbb{E}}_j^t - (\widehat{\Theta}^{i-1}(t))^T (\Phi(\mathbb{E}_j^t, \mathbb{U}_j^t)) \right)^T \\ = \widehat{\Theta}^{i-1}(t) + (I - \mu \Pi^t)^2 \Phi(e, u)(\tilde{e}^i)^T + \mu \Pi^t \widetilde{\Theta}^{i-1}(t) \\ \hspace{8cm} (10) \end{cases}$$

where $0 < \mu < \frac{1}{\overline{\mu}}$ is a positive constant. $\tilde{e}^i = e - \hat{e}^i$ and $\widetilde{\Theta}^i(t) = \Theta(t) - \widehat{\Theta}^i(t)$ are i-th estimation errors of the tracking error and the weight matrix, respectively. Under Assumption 1, the adaptive updating law (10) guarantees that the weight matrix $\widehat{\Theta}^i$ converges to its true values.

3.2. *Iterative learning algorithm*

In this subsection, we will provide our iterative learning algorithm to solve the optimal tracking problem. To start with, we define:

$$\begin{cases} P(e, u, r, t) = L(e, u) + r^k \sum_{j=1}^{z} h(S_j) S_j^2(e, t) \\ Q(e, u, r, t, \lambda, \Theta) = P(e, u, r, t) + \lambda^T \Theta^T(\text{t}) \Phi(e, u) \end{cases} \quad (11)$$

Algorithm 1. Iterative learning algorithm for optimal tracking problem

Step 1: Initialize parameters $r^0 > 0$, $a^0 > 0$, $b^0 > 0$, $\widehat{\Theta}^0(t)$, $t \in [t_0, t_f]$, convergence error $\epsilon_1 > 0$, $\epsilon_2 > 0$, $\epsilon_3 > 0$. Select the initial control input $\text{u}^0(t)$, $t \in [t_0, t_f]$. Update the initial estimation of tracking error by solving:

$$\dot{e}^0 = (\widehat{\Theta}^0(t))^T \Phi(e, u) + \omega \tilde{e}^0, \quad \hat{e}^0(t_0) = x_0 - x_{d0} \quad (12)$$

Calculate the initial tracking cost function:

$$J(e^0, u^0, r^0) = \int_{t_0}^{t_f} P(e^0, u^0, r^0, t)dt \quad (13)$$

Let $i = 0$ and $k = 0$.

Step 2: Calculate u^{i+1} and λ^i by following equation:

$$\begin{cases} \dot{\lambda}^i = -Q_e(e^i, u^{i+1}, r^k, t, \lambda^i, \widehat{\Theta}^i), \quad \lambda^i(t_f) = 0 \\ u^{i+1} = \underset{u}{argmin} \, Q(e^i, u, r^k, t, \lambda^i, \widehat{\Theta}^i) \\ \qquad + a^i \|u - u^i\|_1 + \frac{1}{2} b^i \|u - u^i\|_2^2 \end{cases} \quad (14)$$

Step 3: Calculate $\hat{e}^i$ and $\widehat{\Theta}^i$ by following equation:

$$\begin{cases} \dot{\hat{e}}^i = (\widehat{\Theta}^i(t))^T \Phi(e, u) + \omega \tilde{e}^i, \quad \hat{e}^i(t_0) = x_0 - x_{d0} \\ \widehat{\Theta}^i(t) = \widehat{\Theta}^{i-1}(t) + (I - \mu \Pi^t)^2 \Phi(e, u)(\tilde{e}^i)^T \\ \qquad + \mu \Pi^t \widetilde{\Theta}^{i-1}(t) \end{cases} \quad (15)$$

Step 4: Calculate the tracking cost function:

$$J(e^{i+1}, u^{i+1}, r^k) = \int_{t_0}^{t_f} P(e^{i+1}, u^{i+1}, r^k, t)dt \quad (16)$$

If $J(e^{i+1}, u^{i+1}, r^k) > J(e^i, u^i, r^k)$, let $a^i \leftarrow a^i + d_a$ and $b^i \leftarrow b^i + d_b$, where d_a and d_b are positive step size, then go to Step 2. Else go to Step 5.

Step 5: If $\|u^{i+1} - u^i\| \leq \epsilon_1$, go to Step 6. Else let $i \leftarrow i + 1$, $a^i \leftarrow a^0$, $b^i \leftarrow b^0$, go to Step 2.

Step 6: If $\|\widehat{\Theta}^{i+1} - \widehat{\Theta}^i\| \leq \epsilon_2$, go to Step 7. Else let $i \leftarrow i + 1$, $a^i \leftarrow a^0$, $b^i \leftarrow b^0$, go to Step 2.

Step 7: If $S(e^{i+1}, t) \leq \epsilon_3$, go to Step 8. Else let $i \leftarrow i + 1$, $a^i \leftarrow a^0$, $b^i \leftarrow b^0$, $r^k \leftarrow r^k + d_r$ where d_r is the positive step size, then go to Step 2.

4. Simulation

In this section, we provide a nonlinear dual motor servo system with backlash to validate the efficiency of our algorithm. The system can be modeled as:

$$\begin{cases} J_i \ddot{\theta}_i + b_i \dot{\theta}_i = u_i - \tau_i \\ J_m \dot{\theta}_m + b_m \dot{\theta}_m = \sum_{i=1}^{2} \tau_i \end{cases}$$

where θ_i and θ_m represent the angles of motors and the load, J_i and J_m are the moment of inertia for the motor and the load, b_i and b_m are the resistance coefficients of the motor and load, respectively. u_i is the input torque of the motor, τ_i is the torque transmitted when the driving motor and load come into contact, which can be expressed as the following dead zone function:

$$\tau_i = \begin{cases} k(z_i + \alpha), & z_i \leq \alpha \\ 0, & |z_i| < \alpha \\ k(z_i - \alpha), & z_i \geq \alpha \end{cases}$$

where k is the torque torsion coefficient, $z_i = \theta_i - \gamma \theta_m$ is the angular error between the motor and the load, γ is transmission ratio, 2α is the backlash width. Due to the non differentiability of the dead zone function, it is generally approximated by the following smooth continuous differentiable functions:

$$\tau_i = k\left(z_i - \alpha\left(\frac{2}{1 + e^{-rz_i}} - 1\right)\right) = k(z_i - \alpha g_i)$$

Assuming two motors have the same parameters, the transmission ratio γ is selected as 1, the parameter r in the approximation function is selected as 10, and the parameters of the system are selected as Table 1.

Table 1. The system parameters.

Parameter	Value	Units
J_m	0.185	$kg \cdot m^2$
b_m	1.2	$N \cdot m \cdot s/rad$
J_i	0.028	$kg \cdot m^2$
b_i	1.3	$N \cdot m \cdot s/rad$
k	56	$N \cdot m/rad$
α	0.2	rad

Let $x = (\theta_m, \dot{\theta}_m, \theta_1, \dot{\theta}_1, \theta_2, \dot{\theta}_2)^T$. The target is selected as $x_d(t) = [1\ 0\ 1\ 0\ 1\ 0]^T$, we choose cost function:

$$J(e, u) = \int_0^{20} \frac{1}{2}\left(\sum_{i=1}^{6} e_i^2 + \sum_{j=1}^{2} u_j^2\right)dt$$

the state constraints are assumed to be $|x_2| \leq 0.4 rad/s$, $|x_4| \leq 0.4 rad/s$, $|x_6| \leq 0.4 rad/s$, which can be rewritten as: $s_1 = e_2 - 0.4$, $s_2 = -e_2 - 0.4$, $s_3 = e_4 - 0.4$, $s_4 = -e_4 - 0.4$, $s_5 = e_6 - 0.4$, $s_6 = -e_6 - 0.4$. The basis function is selected as $\Phi(e, u) = (e_1, e_2, e_3, e_4, e_5, e_6, g_1(e_1, e_3), g_2(e_1, e_5), u_1, u_2)^T$. The initial state is $x_0 = (1.5\ 0\ 1.6\ -0.1\ 1.5\ 0.1)^T$. The initial parameters are set to be $r_0 = c_0 = d_0 = 1$, $\widehat{\Theta}_0^0 = rand(6,10)^T$, $\epsilon_1 = \epsilon_2 = \epsilon_3 = 0.001$.

Yuqi Zhang, Bin Zhang

Fig. 1 and Fig. 2 are visual representations of the results. We can see that compared with the initial trajectory, the angles of load and motor have stabilized around the predetermined values.
Fig. 1. Comparisons of the tracking angles.
Fig. 2. Comparisons of the tracking angular velocities.

5. Conclusion

In this paper, we present a novel concurrent iterative learning algorithm. The tracking cost function is selected as a finite-horizon form. Our method does not require precise dynamic information and can handle with the time-varying systems. Moreover, state constraints are considered in the process of solving OTCP.

Abstract

This paper investigates privacy-preserving mean-square consensus in distributed heterogeneous multi-agent systems with communication noise on fixed undirected graphs. To mitigate the impact of communication noise, we introduce a stochastic approximation step rule in the control protocol. Utilizing graph theory, stochastic analysis, and Lyapunov theory, consensus conditions are derived. Subsequently, a cryptographic cryptosystem encrypts the designed protocol, safeguarding against eavesdropping and information privacy loss between agents during consensus. Numerical simulations confirm the efficacy of the proposed consensus protocol and privacy protection algorithm.

Keywords: Distributed, Heterogeneous multi-agent systems (HMAS), Consensus, Privacy preserving

1. Introduction

In recent years, research on multi-agent systems has profoundly impacted the development of engineering technology [1]. Consensus control stands out as a key issue in multi-agent system studies, aiming for the convergence of state and output values of each agent through a control protocol [2]. Extensive research results exist for consensus control in multi-agent systems comprising first or second-order agents [3]. However, the focus is expanding to include Heterogeneous Multi-Agent Systems (HMAS) consisting of both first-order and second-order agents. HMAS demonstrates superior load and task configuration capabilities, making it suitable for more complex environments [4].

In the above research, the consensus control protocol relies on the interaction of state information between adjacent nodes to achieve consensus. For instance, a group of agents aiming to converge at a specific location may wish to keep their initial locations confidential. In recent years, various privacy protection schemes have been explored. A commonly used method is differential privacy, where random noise is introduced to the interaction state to obscure the true state [5]. However, this approach is susceptible to eavesdropping, as the added noise compromises accuracy [6], [7]. Another approach involves a state decomposition mechanism introduced in literature. To address privacy concerns without sacrificing accuracy, the study delves into the homomorphic encryption scheme and extends the average consensus of first-order agent systems to second-order agent systems [7], [8]. Nevertheless, practical networks often operate in uncertain communication environments with random perturbations. Consequently, instead of assuming a deterministic form, literature considers the mean square consensus of communication noise [9], [10]. However, it overlooks privacy protection in the presence of communication noise, leaving the challenge of achieving privacy-preserving consensus for Heterogeneous Multi-Agent Systems (HMAS) with communication noises unresolved. This paper presents a distributed consensus algorithm for HMAS based on cryptography. The main contributions of this paper are as follows:

Tongqing Yang, Lipo Mo, Yingmin Jia.

1) We propose a privacy consensus algorithm for HMAS with communication noises based on partial homomorphic cryptography;

2) The privacy protection for the initial state of the agent is analyzed in detail. In particular, compared with the existing approach in [7], [8], our algorithm can achieve higher privacy when there exists an agent connected with only one neighbor;

3) The effectiveness of our method is verified by simulation.

2. Preliminaries and problem description

The network of HAMS consisting of n agents is represented by an undirected connected graph G. For HMAS with first-order and second-order agents, the Laplacian matrix of the graph G can be described as

$$L = \begin{bmatrix} L_s + D_{sf} & -A_{sf} \\ -A_{fs} & L_f + D_{fs} \end{bmatrix},$$

where L_s and L_f represent the Laplacian matrices of the graph comprising the second-order agents and first-order agents, respectively. A_{sf} and A_{fs} denote the adjacency matrix between the second-order agents (first-order agents) and first-order agents (second-order agents) respectively, D_{sf} and D_{fs} denote their row sums.

Paillier Cryptosystem: The Pailler crypto-system has key generation, encryption and decryption functions. The encryption operator E and the decryption operator D are usually used in the encryption and decryption process. Now, we introduce the additive homomorphism property of the Paillier cryptosystem:

$$E(z)^k = \prod_{i=1}^{k} E(z) = E(\sum_{i=1}^{k} z) = E(kz).$$

We assume that there are n agents in the HMAS, and the first group has m second-order agents, labeled $V_m = \{1, 2, \cdots, m\}$, while the rest are first-order agents, labeled $V_{n-m} = \{m+1, m+2, \cdots, n\}$. The dynamic equation of the composed HMAS is as follows:

$$\begin{cases} x_i(k+1) = x_i(k) + v_i(t)T \\ v_i(k+1) = v_i(k) + u_i(t)T, & i \in V_m, \\ x_i(k+1) = x_i(k) + u_i(t)T, & i \in V_{n-m}. \end{cases} \quad (1)$$

where $x_i(k) \in \Box$, $v_i(k) \in \Box$ and $u_i(k) \in \Box$ are the position, velocity and control input of agent i, respectively. The sample time is $0 < T < 1$. All results can obtained exist in $\Box^n$ by using the Kronecker product.

Definition 1. The HMAS consisted of (1) is said to achieve mean-square consensus if for any initial condition, we have

$$\lim_{k \to \infty} E\Box x_j(k) - x_i(k)\Box^2 = 0 \quad i, j = 1, 2, \cdots, n$$

$$\lim_{k \to \infty} E\Box v_i(k)\Box^2 = 0 \quad i, j = 1, 2, \cdots, m$$

Lemma 1. Let $\{\tau(k)\}, \{\beta(k)\}$ and $\{q(k)\}, k = 0, 1, \cdots$, be real sequences, satisfying $0 < q(k) \leq 1, \tau(k) \geq 0$, $\beta(k) \geq 0$, $\sum_{k=0}^{\infty} q(k) = \infty, \frac{\beta(k)}{q(k)} \to 0, k \to \infty$, and $\tau(k+1) \leq (1 - q(k))\tau(k) + \beta(k)$, then $\tau(k) \to 0, k \to \infty$.

3. Main contents

3.1. *Mean-square Consensus in Heterogeneous Multi-agent Systems*

We propose the following consensus protocol:

$$\begin{cases} u_i(k) = \alpha(k)\sum_{j=1}^{n} a_{ij}(x_j(k) + w_{ji}(k) - x_i(k)) - k_1 v_i(k), & i \in V_m, \\ u_i(k) = \alpha(k)\sum_{j=1}^{n} a_{ij}(x_j(k) + w_{ji}(k) - x_i(k)), & i \in V_{n-m}. \end{cases} \quad (2)$$

where $\alpha(k)$ and k_1 are the control gains, $\{w_{ji}(k), k \geq 0\}$ are communication noise sequences.

Let $y_i(k) = x_i(k) + v_i(k)$, $i \in V_m$, then derived from (1)
$$x_i(k+1) = (1-T)x_i(k) + Ty_i(k).$$

Define $\xi(k) = [x_1(k), \cdots, x_m(k), y_1(k), \cdots, y_m(k), x_{m+1}(k), \cdots, x_n(k)]$, $W(k) = [W_1^T(k), \cdots, W_m^T(k), W_1^T(k), \cdots, W_n^T(k)]^T$, $\Lambda = diag\{0, \cdots, 0, \Lambda_1, \cdots, \Lambda_n\}, \Lambda_i = [a_{i1}, a_{i2}, \cdots, a_{in}]$, $W_i(k) = [w_{1i}(k), \cdots, w_{ni}(k)]^T$. Then the HMAS (1) can be rewritten as

$$\xi(k+1) = [I_{m+n} - \alpha(k)T\Psi_1 - (1 - \alpha(k))T\Psi_2]\xi(k) + \alpha(k)T\Lambda W(k) \quad (3)$$

where

$$\Psi_1 = \begin{bmatrix} I_m & -I_m & 0 \\ (1-k_1)I_m + (L_s + D_{sf}) & (k_1-1)I_m & -A_{sf}T \\ -A_{fs}T & 0 & (L_f + D_{fs})T \end{bmatrix}$$

$$\Psi_2 = \begin{bmatrix} I_m & -I_m & 0 \\ (1-k_1)I_m & (k_1-1)I_m & 0 \\ 0 & 0 & 0 \end{bmatrix}.$$

It is clear that $\theta = [(k_1 - 1)\mathbf{1}_m^{\sharp}, \mathbf{1}_m, \mathbf{1}_{n-m}]$ and $\mathbf{1}_{n+m}$ are the left eigenvector and right eigenvector associated with zero eigenvalue of $\alpha(k)T\Psi_1 + (1 - \alpha(k))T\Psi_2$, respectively.

Assumption 1. The additive independent noise $\{w_{ji}(k), k \geq 0\}$, $E(w_{ji}(k)) = 0$, $Var(\{w_{ji}(k)\}) = \sigma_W$.

Assumption 2. Suppose that the control gains satisfy the following conditions

$$1)\sum_{k=0}^{\infty}a(k)=\infty, 0<a(k)<1, a(k+1)\le a(k), 2)\sum_{k=0}^{\infty}a^2(k)<\infty.$$

Lemma 2. If Assumptions 1-2 hold, $0<T\le\min\{\max_{\lambda_i\neq 0}$

$\frac{1}{\sqrt{\text{Re}^2(\lambda_i)+\text{Im}^2(\lambda_i)}}, \max_{\eta_i\neq 0}\frac{1}{\sqrt{\text{Re}^2(\eta_i)+\text{Im}^2(\eta_i)}}\}$ and $k_1\ge 1+\max l_{ii}$, l_{ii},

$1,2,\cdots,n$, then $0<\alpha(k)T\rho_1<1$, $0<(1-\alpha(k))T\rho_2<1$,

where $\lambda_i, i=1,2,\cdots,n+m$ and $\eta_i, i=1,2,\cdots,n+m$ are the eigenvalues of Ψ_1 and Ψ_2 , ρ_1 and ρ_2 are the spectral radius of Ψ_2 and Ψ_2 , respectively. l_{ii} is the diagonal element of the Laplacian matrix.

Theorem 1. If Assumptions 1-2 hold, $0<T\le\min\{\max_{\lambda_i\neq 0}$

$\frac{1}{\sqrt{\text{Re}^2(\lambda_i)+\text{Im}^2(\lambda_i)}}, \max_{\eta_i\neq 0}\frac{1}{\sqrt{\text{Re}^2(\eta_i)+\text{Im}^2(\eta_i)}}\}$ and $k_1\ge 1+\max l_{ii}$, l_{ii}, i

$=1,2,\cdots,n$, then the HMAS (3) reach mean-square consensus.

3.2. *Privacy protection*

In this paper, honest-but-curious and eavesdropper were considered.

Algorithm 1 Encrypted information exchange

Initialization: Each agent i initializes its state $x_i(0)$, the public key pk_i and private key sk_i are generated, and broadcasts pk_i to its neighbor(s) while keeps sk_i private. Each time a message is sent, a independent random variable $w_{j\to i}(k), \forall i,j\in\mathbb{V}_m, k=\ 0,1,\cdots$ is added.

Input: $x_i(k), k_1$; **Output:** $u_i(k)$.

1: Agent i encrypts $x_i(k)$ with its public key pk_i :
$$-x_i(k)\to\text{E}_i(-x_i(k))$$
then sends $\text{E}_i(-x_i(k))$ to each neighbor $j\in N_i$, the equivalent of sending $\text{E}_i(-x_i(k)+w_{i\to j}(k))$.

2: Each agent j encrypts $x_j(k)$, and $v_j(k)$ with its public key pk_i :
$$x_j(k)\to\text{E}_i(x_j(k))$$

3: Each agent i generates the number $a_i(k)$ and agent $j\in N_i$ generates the number $a_j(k)$.

4: Each agent $j\in N_i$ computes the encrypted differences based on property of the Paillier cryptosystem:

$\text{E}_i(x_j(k))\text{E}_i(-x_i(k)+w_{i\to j}(k))=\text{E}_i(x_j(k)-x_i(k)$

$+w_{i\to j}(k))\to(\text{E}_i(x_j(k)-x_i(k)+w_{i\to j}(k)))^{a_j(k)}$

$=\text{E}_i(a_j(k)(x_j(k)-x_i(k)+w_{i\to j}(k)))$

then sends encrypted differences back to agent i .

5: Agent i decrypts the received ciphertexts with private key sk_i and computes weighted differences:

$\text{E}_i(a_j(k)(x_j(k)-x_i(k)+w_{i\to j}(k)+w_{j\to i}(k)))$

$\to a_j(k)(x_j(k)-x_i(k)+w_{ji}(k))$

$\xrightarrow{\times a_i(k)}a_{ij}(x_j(k)-x_i(k)+w_{ji}(k))$

6: The values calculated in step 5 are taken into protocol (2) to update $x_i(k)$ and $v_i(k)$.

7: Set $k\leftarrow k+1$.

Definition 2 [7]: For a connected network of n nodes, the privacy of the initial value $x_i(0)$ of node i is preserved if an honest-but-curious adversary cannot estimate $x_i(0)$ with any accuracy.

Similar to [7], the fixed coupling weight can be decomposed, $a_{ij}=a_{ij}=a_i(k)a_j(k)>0$, where $a_i(k)$ is generated when agent i transmits information and only known by itself. Similarly, we split the noise delivered by a communication link, i.e., $w_{ji}(k)=w_{i\to j}(k)+w_{j\to i}(k)$ in (2).

Theorem 2: In a connected network of nodes with system dynamics given by (1), each agent adheres to the consensus protocol (2) and Algorithm 1 for state updates. An honest-but-curious node, Eve, capable of receiving messages from a neighboring node, Alice, cannot ascertain Alice's initial state if Alice is also connected to another legitimate node, Bob. Furthermore, Alice's privacy remains undisclosed to external eavesdroppers.

Theorem 3: In a connected network of nodes governed by system dynamics as described in (1), each agent adheres to the consensus protocol (2) and Algorithm 1 for state updates. If a node, Alice, is solely connected to the rest of the network through an honest-but-curious node (or a colluding group of such nodes) Eve, and the noise introduced by the communication link is symmetrical, Eve can asymptotically deduce Alice's initial state. Conversely, in the case of asymmetric noise, while Eve can receive messages from its neighbor Alice, it lacks the means to ascertain Alice's initial state.

4. Numerical simulation

Consider the HMAS with eight agents, where nodes 1-4 represent first-order agents with input saturation and nodes 5-8 represent second-order agents. The network of the eight agents between communication topology shown

Tongqing Yang, Lipo Mo, Yingmin Jia.

in Fig. 1 (a). We assume $k_1 = 5$, given the initial value $x(0) = [1,2,3,4,5,6,7,8]^{\sharp}, v(0) = [1,2,3,4]$. Fig. 1 (b) represents the case where the state of the agent converges to 0. Fig. 1 (c) is the comparison between the real value of the input of agent 1 and the encrypted ciphertext.

a. Network   b. Convergence   c. Control input
Fig.1. Numerical simulation picture
5. Conclusion

This paper explores privacy-preserving consensus in distributed heterogeneous multi-agent systems with first-order and second-order agents, addressing communication noise using graph theory, stochastic analysis, Lyapunov theory, and cryptography. It proves that the closed-loop system attains consensus. The designed protocol is encrypted to prevent eavesdropping and information privacy loss. However, there are limitations when a secure agent connects with an adversary alone. Numerical simulations validate the consensus protocol's effectiveness and the privacy protection algorithm's ability to safeguard agent privacy.

Abstract

The event-triggered consensus problem for singular multi-agent systems with Lipschitz nonlinearity under directed topology is investigated in this paper. A sampled-data-based event-triggered mechanism is constructed to decide when the current data-packet should be broadcast. The objective is to design an event-triggered protocol such that the considered multi-agent system can achieve admissible consensus. Based on graph theory and singular system theory, sufficient conditions of consensus of nonlinear singular multi-agent systems are derived. Finally, a numerical example shows the effectiveness of our proposed approach.

Keywords: Singular multi-agent systems, Event-triggered scheme, Consensus control, Lipschitz nonlinearity

1. Introduction

In recent decades, the distributed coordinated control of multi-agent systems has attracted tremendous attention due to its wide adoption in various fields, such as robot formation [1], [2], [3], sensor network [4], [5], [6], neural network [7], [8], target tracking control [9] and so on. Consensus is the basis problem of the coordinated control of multi-agent systems. In practical, each agent may be equipped by the embedded microprocessor, which is with limited computing and communication capabilities. How to utilize these limited resources to operate system efficiently becomes a concerned issue. Therefore, event-triggered consensus has attracted much attention and achieved some results [10], [11], [12]. Singular systems, can provide convenient and accurate description in economic systems, power systems and aircraft modeling from practical considerations. Some literatures have studied the event-triggered for singular systems [13], [14], [15]. However, to the best of our knowledge, there are few works regarding to the event-triggered consensus for singular multi-agent systems (SMAS), which motivates the current study.

In the present study, we focus on the event-triggered consensus control for a class of SMAS with Lipschitz nonlinearity under directed topology. An even-triggered mechanism excluding Zeno behavior is proposed, and an artificial transition time-delay is introduced to design the event-trigged consensus control protocol. Sufficient conditions that can guarantee the consensus of the considered SMAS are obtained. Throughout this paper, $P > 0$ $(P \geq 0)$ means that P is positive definite (positive semi-define). I_N is the $N \times N$ identity matrix. $\otimes$ and $\|\cdot\|$ are used to represent Kronecker product and Euclidean norm of a vector or a matrix, respectively. In a symmetric matrix, * denotes the matrix entries implied by symmetry. **diag**$\{\cdots\}$ stands for a block-diagonal matrix.

2. Problem formulation and preliminaries
2.1. Graph theory

A directed graph $\mathcal{G}(\mathcal{V}, \mathcal{E}, \mathcal{A})$ is considered in this paper, in which $\mathcal{V} = \{v_1, v_2, \cdots v_N\}$ is the node set, $\mathcal{E}$ is the edge set, and $\mathcal{A} = [a_{ij}]_{N \times N}$ is the adjacency matrix, $a_{ij} > 0$ if v_i can receive the information from $v_j (i, j = 1,2,\cdots N)$, otherwise $a_{ij} = 0$. The set of neighbors of the v_i is denotes as $\mathcal{N}_i$. Let $d_i = \sum_{j=1}^{j=N} a_{ij}$ be the in-degree of node v_i and $D = \text{diag}(d_1, \cdots, d_N)$. The Laplacian matrix of $\mathcal{G}$ can be defined as $\mathcal{L} = D - \mathcal{A}$. Suppose the graph $\mathcal{G}$ has a directed spanning tree.

2.2. Problem formulation

Consider a group of N agents, and the dynamic of ith agent is described by

$$E\dot{x}_i(t) = Ax_i(t) + Bu_i(t) + f(x_i(t)), i = 1,2\cdots, N \quad (1)$$

where $x_i(t) \in \mathbb{R}^n$, $u_i(t) \in \mathbb{R}^m$ denote the state and the input, respectively. E, A and B are constant with $rank(E) = r < n$. The nonlinear function $f(x_i(t))$ satisfies $\|f(\varsigma_1) - f(\varsigma_2)\| \leq \mu \|\varsigma_1 - \varsigma_2\|$, $\forall \varsigma_1, \varsigma_1 \in \mathbb{R}^n$ with $\mu > 0$ is the Lipschitz constant.

Definition 1: The SMAS (1) is said to achieve admissible consensus if it is regular, impulse free while satisfying

$$\lim_{t \to \infty} \| x_i(t) - x_j(t) \| = 0, \forall i, j = 1, 2 \cdots N.$$

In this paper, we assume that the state of the multi-agent system (1) is periodically sampled at a constant sampling period $h > 0$. The sampling sequence is described by the set $\mathbb{S}_1 = \{0, h, 2h, \cdots, kh, \cdots\}$. The transmission event is determined by an event-triggered scheme. The transmission sequence of agent i is described by the set $\mathbb{S}_2 = \{0, t_1^i h, t_2^i h, \cdots, t_k^i h, \cdots\}$.

The event detector is described as follows

$$\begin{cases} t_{k+1}^i h = \inf\{kh|kh > t_k^i h, \psi_i(kh) \geq 0\} \\ \psi_i(kh) = \chi_i^T(t_k^i h + l_i h)\Phi\chi_i(t_k^i h + l_i h) - \\ \qquad \delta_i\lambda_i^T(t_k^i h + l_i h)\Phi\lambda_i(t_k^i h + l_i h)\} \end{cases} \quad (2)$$

where $kh = t_k^i h + l_i h$, $l_i \in \mathbb{N}$, $\delta_i > 0$ is the threshold parameter, Φ is a positive definite matrix, and

$$\begin{cases} \chi_i(t_k^i h + l_i h) = x_i(t_k^i h + l_i h) - x_i(t_k^i h) \\ \lambda_i(t_k^i h + l_i h) = \sum_{j \in \mathcal{N}_i} a_{ij}(x_i(t_k^i h) - x_j(t_{k_j'}^j h)) \end{cases}$$

with $k_j' = argmin_p\{t_k^i + l_i - t_p^j | t_k^i + l_i > t_p^j, p \in \mathbb{N}\}$.

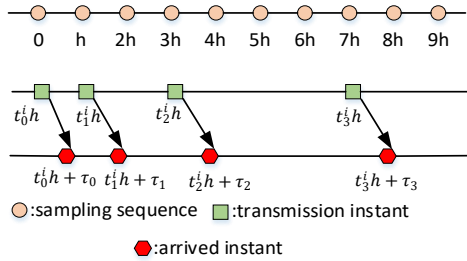
Under the event-triggered scheme (2), $t_{k+1}^i h - t_k^i h$ denotes the transmission period of the Event generators. Let τ_k^i denote the signal transmission delay of ith agent. Suppose τ_k^i is bound, that is, $\tau_k^i \in (0, \tau_M]$, where τ_M is a positive integer. In view of the effect of signal transmission delay, the released states $x_i(t_k^i h)$ will reach the controller at the time instants $t_k^i h + \tau_k^i$. Obviously, $t_k^i h + \tau_k^i < t_{k+1}^i h + \tau_{k+1}^i (k = 1, 2 \cdots)$. Figure 1 shows the above-mentioned event-triggered transmission scheme.


Figure 1. Example of time evolution of the sampling and transmission series of agent i

In system (1), based on the event-triggered mechanism (2), consider the following control protocol

$$u_i(t) = -K \sum_{j \in \mathcal{N}_i} a_{ij}\left(x_i(t_k^i h) - x_j\left(t_{k_j'}^j h\right)\right) \quad (3)$$

where $t \in \left[t_k^i h + \tau_k^i, t_{k+1}^i h + \tau_{k+1}^i\right)$, $i = 1, 2 \cdots N$, and K is the control gain matrix to be determined.

Define the function $\tau_i(t)$ as

$$\tau_i(t) = \begin{cases} t - t_k^i h, & t \in [t_k^i h + \tau_k^i, t_k^i h + h + \tau_M) \\ t - t_k^i h - \Delta h, & t \in [t_k^i h + \Delta h + \tau_M, t_k^i h + \Delta h + h + \tau_M) \\ t - t_k^i h - dh, & t \in [t_k^i h + dh + \tau_M, t_{k+1}^i h + \tau_{k+1}^i) \end{cases}$$

where $\tau_M = \max\{\tau_k^i\}$, Δ is a positive integer satisfying $\Delta \geq 1$. It is easy to see that

$$e_i(t_k^i h + \Delta h) = 0, \ t \in [t_k^i h + \tau_k^i, t_k^i h + h + \tau_M),$$
$$e_i(t_k^i h + \Delta h) = x_i(t_k^i h + \Delta h) - x_i(t_k^i h),$$
$$t \in [t_k^i h + \Delta h + \tau_M, t_k^i h + \Delta h + h + \tau_M)$$
$$e_i(t_k^i h + \Delta h) = x_i(t_k^i h + dh) - x_i(t_k^i h),$$
$$t \in [t_k^i h + dh + \tau_M, t_{k+1}^i h + \tau_{k+1}^i)$$

Then, we get
$$x_i(t_k^i h) = x_i(t - \tau_i(t) - e_i(t_k^i h + \Delta h))$$

Then, the event-triggered scheme (2) can be rewritten as

$$\chi_i^T(t_k^i h + l_i h)\Phi\chi_i(t_k^i h + l_i h) < \delta_i\left[\sum_{j \in \mathcal{N}_i} a_{ij}(x_i(t_k^i h) - x_j(t_{k_j'}^j h))\right]^T \Phi\left[\sum_{j \in \mathcal{N}_i} a_{ij}(x_i(t_k^i h) - x_j(t_{k_j'}^j h))\right]$$

Substituting (3) into the system (1) yields
$$(I_N \otimes E)\dot{x}(t) = (I_N \otimes A)x(t) - (\mathcal{L} \otimes BK)x(t - \tau(t)) + (\mathcal{L} \otimes BK)e(kh) + F(x(t))$$

Let $z_i(t) = x_1(t) - x_{i+1}(t)$, $\varepsilon_i(kh) = e_1(kh) - e_{i+1}(kh)$, $z(t) = [z_1^T(t), z_2^T(t), \cdots, z_{N-1}^T(t)]^T = (T_1 \otimes I_n)x(t)$, $\varepsilon(kh) = [\varepsilon_1^T(kh), \varepsilon_1^T(kh), \cdots, \varepsilon_{N-1}^T(kh)] = (T_2 \otimes I_n)e(kh)$, $T_1 = [1, -I_{N-1}] \in \mathbb{R}^{(N-1) \times N}$, $T_2 = [0, -I_{N-1}]^T \in \mathbb{R}^{N \times (N-1)}$. The following system is immediate

$$(I_{N-1} \otimes E)\dot{z}(t) = (I_{N-1} \otimes A)z(t) - (T_1 \mathcal{L} T_2 \otimes BK)z(t - \tau(t)) + (T_1 \mathcal{L} T_2 \otimes BK)\varepsilon(kh) + (T_1 \otimes I_n)F(x(t))$$

$$(4)$$

Now, the consensus problem of SMAS (1) is transformed to the admissible of system (4).

3. Main results

Theorem 1: Given h, τ_m, $\bar{\tau}_M$, and μ, the SMAS (1) achieves admissible consensus if there exist real matrices P, positive definite matrices Q, R_1, R_2, Z_1, Z_2 such that the following matrix inequalities hold

$$\bar{E}^T P \bar{E} \geq 0 \quad (5)$$

$$\Omega_1 = \begin{bmatrix} \Psi_0 + \Upsilon + \Upsilon^T & \sqrt{\tau_m}\Psi_1 & \sqrt{\tau_{Mm}}\Psi_2 & \sqrt{\tau_m}L & \sqrt{\tau_{Mm}}M \\ * & Z_1 & 0 & 0 & 0 \\ * & * & Z_2 & 0 & 0 \\ * & * & * & Z_1 & 0 \\ * & * & * & * & Z_2 \end{bmatrix} < 0 \quad (6)$$

$$\Omega_2 = \begin{bmatrix} \Psi_0 + \Upsilon + \Upsilon^T & \sqrt{\tau_m}\Psi_1 & \sqrt{\tau_{Mm}}\Psi_2 & \sqrt{\tau_m}L & \sqrt{\tau_{Mm}}N \\ * & Z_1 & 0 & 0 & 0 \\ * & * & Z_2 & 0 & 0 \\ * & * & * & Z_1 & 0 \\ * & * & * & * & Z_2 \end{bmatrix} < 0 \quad (7)$$

where

$$\varphi_0 = \bar{A}^T \mathbb{P}^T + \mathbb{P}\bar{A} + R_1 + R_2 + \mu^2 I,$$

$$\varphi_1 = -Q + \lambda(T_2^T L^T \Lambda L T_2) \otimes \Phi,$$

$$\varphi_2 = -\lambda(T_2^T L^T \Lambda L T_2) \otimes \Phi,$$

$$\varphi_3 = -(I_{N-1} \otimes \Phi) + \lambda(T_2^T L^T \Lambda L T_2) \otimes \Phi,$$

$\Upsilon = [L\bar{E} \quad 0 \quad (N-M)\bar{E} \quad (M-N)\bar{E} \quad -N\bar{E} \quad 0],$

$\Psi_1 = [Z_1\bar{A} \quad 0 \quad Z_1\bar{L} \quad 0 \quad 0 \quad -Z_1\bar{L}]^T,$

$\Psi_2 = [Z_2\bar{A} \quad 0 \quad Z_2\bar{L} \quad 0 \quad 0 \quad -Z_2\bar{L}]^T,$

$\mathbb{P} = I_{N-1} \otimes (E^T P + TS^T).$

$$\Psi_0 = \begin{bmatrix} \varphi_0 & \mathbb{P} & -\mathbb{P}\bar{L} & 0 & 0 & \mathbb{P}\bar{L} \\ * & -I & 0 & 0 & 0 & 0 \\ * & * & \varphi_1 & 0 & 0 & \varphi_2 \\ * & * & * & -R_1 & 0 & 0 \\ * & * & * & * & -R_2 & 0 \\ * & * & * & * & * & \varphi_3 \end{bmatrix}$$

Proof: Firstly, similar to the analysis in [14], it can be proved that LMIs (6) and LMIs (7) can guarantee that system (4) is regular and impulse-free.

Next, we will prove that the system (4) is asymptotically stable. Construct the Lyapunov functional

$V(t) = V_1(t) + V_2(t) + V_3(t)$

$V_1(t) = z^T(t)\bar{E}^T P\bar{E}z(t) + (\bar{\tau}_M - \tau(t))z^T(t-\tau(t))Qz(t-\tau(t))$

$V_2(t) = \int_{t-\tau_m}^t z^T(\alpha)ER_1z(\alpha)d\alpha + \int_{t-\bar{\tau}_M}^t z^T(\alpha)R_2z(\alpha)d\alpha$

$V_3(t) = \int_{t-\tau_m}^t \int_{t+\beta}^t \dot{z}^T(\alpha)\bar{E}^T Z_1\bar{E}\dot{z}(\alpha)d\alpha d\beta$
$$+ \int_{t-\bar{\tau}_M}^{t-\tau_m} \int_{t+\beta}^t \dot{z}^T(\alpha)\bar{E}^T Z_2\bar{E}\dot{z}(\alpha)d\alpha d\beta$$

From $\tau_m \leq \tau(t) \leq \bar{\tau}_M$. And taking the derivative of $V(t)$ with respect to t along the solution of (4) yields

$\dot{V}(t) = \dot{z}^T(t)\bar{E}^T(I_{N-1}\otimes P)\bar{E}z(t) + z^T(t)\bar{E}^T(I_{N-1}\otimes P)\bar{E}\dot{z}(t) - z^T(t-\tau(t))Qz(t-\tau(t)) + z^T(R_1+R_2)z(t) - z^T(t-\tau_m)R_1z(t-\tau_m) - z^T(t-\bar{\tau}_M)R_2z(t-\bar{\tau}_M) + \tau_m\dot{z}^T(t)\bar{E}^T Z_1\bar{E}\dot{z}(t) + (\bar{\tau}_M - \tau_m)z^T(t)\bar{E}^T Z_2\bar{E}\dot{z}(t) - \int_{t-\tau_m}^t \dot{z}^T(\alpha)\bar{E}^T Z_1\bar{E}\dot{z}(\alpha)d\alpha - \int_{t-\bar{\tau}_M}^{t-\tau_m} \dot{z}^T(\alpha)\bar{E}^T Z_2\bar{E}\dot{z}(\alpha)d\alpha.$

For any free-weighting matrices *L*, *M* and *N*, we have

$2\eta^T(t)L\left[\bar{E}z(t) - \bar{E}z(t-\tau_m) - \int_{t-\tau_m}^t \bar{E}\dot{z}(\alpha)d\alpha\right] = 0$

$2\eta^T(t)M\left[\bar{E}z(t-\tau_m) - \bar{E}z(t-\tau(t)) - \int_{t-\tau(t)}^{t-\tau_m}\bar{E}\dot{z}(\alpha)d\alpha\right] = 0$

$2\eta^T(t)N\left[\bar{E}z(t-\tau(t)) - \bar{E}z(t-\bar{\tau}_M) - \int_{t-\bar{\tau}_M}^{t-\tau(t)}\bar{E}\dot{z}(\alpha)\right] = 0$

where $\eta(t) = [z^T(t), F^T(z(t)), z^T(t-\tau(t)), z^T(t-\tau_m), z(t-\bar{\tau}_M), \varepsilon^T(kh)]^T$. Then, we have

$-2\eta^T(t)L\int_{t-\tau_m}^t \bar{E}\dot{z}(\alpha)d\alpha \leq \tau_m\eta^T(t)LZ^{-1}L^T\eta(t)$
$$+ \int_{t-\tau_m}^t \dot{z}^T\bar{E}^T Z_1\bar{E}\dot{z}(\alpha)d\alpha$$

$-2\eta^T(t)M\int_{t-\tau(t)}^{t-\tau_m}\bar{E}\dot{z}(\alpha)d\alpha \leq (\tau(t)-\tau_m)\eta^T(t)$

$MZ_1^{-1}M^T\eta(t) + \int_{t-\tau(t)}^{t-\tau_m}\dot{z}^T\bar{E}^T Z_2\bar{E}z(\alpha)d\alpha$

$-2\eta^T(t)N\int_{t-\bar{\tau}_M}^{t-\tau(t)}\bar{E}\dot{z}(\alpha)d\alpha \leq (\tau_M - \tau(t))\eta^T(t)$

$NZ^{-1}N^T\eta(t) + \int_{t-\bar{\tau}_M}^{t-\tau(t)}\dot{z}^T(\alpha)\bar{E}^T Z_2\bar{E}z(\alpha)d\alpha$

By using the Kronecker product, the event-triggered scheme can be written in the compact form as follows:

$\varepsilon^T(kh)(I_{N-1} \otimes \Phi_1)\varepsilon(kh)$
$$= e^T(kh)(T_1^T I_{N-1}T_1 \otimes \Phi_1)e(kh).$$

It is obviously that

$\varepsilon^T(kh)(I_{N-1} \otimes \Phi_1)\varepsilon(kh) \leq \lambda e^T(kh)(I_N \otimes \Phi_1)e(kh)$

$\leq \lambda[z(kh) - \varepsilon(kh)]^T[(T_2^T L^T \Lambda LT_2) \otimes \Phi_2][z(kh) - \varepsilon(kh)]$

where λ is the largest eigenvalue of $T_1^T T_1$. $\Lambda = \text{diag}\{\delta_1, \delta_2, \cdots \delta_N\}$.

Since $\|f(x_i(t)) - f(x_j(t))\| \leq \mu\|x_i(t) - x_j(t)\|$, Then, $F^T(z(t))F(z(t)) \leq \mu^2 z^T(t)(I_{N-1} \otimes I_n)z(t)$. To sum up, we can get

$\dot{V}(t) \leq \eta^T(t)\Omega\eta(t)$

where
$\Omega = \Psi + \Upsilon + \Upsilon^T + \tau_m\Psi_1 Z_1^{-1}\Psi_1^T + (\bar{\tau}_M - \tau_m)\Psi_2 Z_1^{-1}\Psi_2^T + \tau_m L Z_1^{-1}L^T + (\tau(t) - \tau_m)MZ_1^{-1}M^T + ((\bar{\tau}_M - \tau(t))NZ_1^{-1}N^T.$

The inequalities (6) and (7) are equivalent to $\Omega < 0$, that is $\dot{V}(t) < 0$, which implies system (4) is asymptotically stable. Hence, system (4) is admissible. From Definition 1, the multi-agent system (1) achieves admissible consensus. This completes the proof.

4. Simulation example

Consider a SMAS with six agents shown in Figure 2. There is a directed spanning tree in this graph.
Figure 2. The interaction topology of agents

The dynamics of each agent described by (1) with $f(x_i(t)) = [0 \quad 0 \quad -\mu\sin(x_{i1})]^T$, and

$$E = \begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 0 \end{bmatrix}, A = \begin{bmatrix} -2 & 1 & 0.5 \\ 0 & 0 & -1 \\ 2 & 1 & -1 \end{bmatrix}, B = \begin{bmatrix} 1 \\ 1 \\ 0 \end{bmatrix}$$

Let $h = 0.05, \tau_m = 0.02, \bar{\tau}_M = 0.07, \mu = 0.5$ and $x_i = [x_{i1}, x_{i2}, x_{i3}, x_{i4}, x_{i5}, x_{i6}]^T$. The initial state is selected as

$$[x_1(0) \quad x_2(0) \quad x_3(0) \quad x_4(0) \quad x_5(0) \quad x_6(0)]$$
$$= \begin{bmatrix} 1.5 & -1 & 1 & 1.5 & -1.5 & 0.5 \\ 1 & -1.5 & 1.5 & 1 & -1 & -1.5 \\ -1.5 & 0.5 & -1 & 1.5 & 1 & -0.5 \end{bmatrix}$$

Solve the matrix inequalities (5), (6), (7), we can obtain
$K = [0.0445 \quad -0.2153 \quad 0.1489]$, and

$$\Phi = \begin{bmatrix} 29.4174 & 9.0284 & 9.4232 \\ 9.0284 & 43.4806 & 32.8987 \\ 9.4232 & 32.8987 & 48.9758 \end{bmatrix}$$

The state trajectories of system (1) are shown in Figure 3, 4, 5. One can clearly see that all agent's states can indeed reach consensus.
Figure 3. State trajectories $x_{i1,}(i = 1, 2 \cdots 6)$
Figure 4. State trajectories $x_{i2,}(i = 1, 2 \cdots 6)$
Figure 5. State trajectories $x_{i3,}(i = 1, 2 \cdots 6)$

The transmission instants and release intervals are illustrated in Figure 6, which shows that the number of the sampled-data transmission is significantly decreased.
Figure 6. Transmission instants and release interval of agent $i(i = 1, 2)$

5. Conclusion

Event-triggered consensus problem of nonlinear SMAS with directed topologies has been investigated in this paper. The conditions of achieving event-triggered consensus were obtained, while consensus control gain matrix is designed. The effectiveness of the proposed method was verified by a numerical example. It would be important and more practical to study consensus for SMAS with leaders or under switching topologies, which will be our further analysis.

Abstract

Formal software models based on EPNAT (Extended Place/transition Net with Attributed Tokens) can be converted to VDM++ specifications that enable simulation of abstract software behavior before implementation processes. However, the conversion technique has two problems, that is, (1) extracting all properties to be checked from the VDM++ specifications requires time and effort, and (2) the structure of the VDM++ specifications has less readability and maintainability. In this study, we improve the conversion technique by (1) adding features to extract an abstract current state of software, and (2) dividing into classes that correspond to subnets of EPNAT models. This paper shows a new conversion rule, a new structure of VDM++ specifications, a simple example, and the discussion about their effectiveness.

Keywords: Software model, Place/transition net, Vienna development method, Conversion technique

1. Introduction

Formal software models are useful to define specifications and designs clearly, and to find failures early in software development. EPNAT (Extended Place/transition Net with Attributed Tokens), which is based on place/transition nets and VDM++, has been proposed as a formal software modeling language especially for concurrent and distributed software that is composed of multiple subsystems (and/or systems) [1]. In an EPNAT model (that is, a formal software model that is defined by using EPNAT), the behavior of each subsystem is defined as a subnet, and the interactions between the subsystems are defined as glue transitions. EPNAT models can be converted to VDM++ specifications, and enable simulation of abstract software behavior before implementation processes [2].

However, the conversion technique has two problems. One is that extracting all properties (that is, data to be checked in the simulation) from the VDM++ specifications requires time and effort. In the simulation, a common VDM++ interpreter [3] is used to execute the VDM++ specifications, and moreover, a particular feature of our support tool to manage its original EPNAT model needs to be used to process and obtain some properties. Another is that the structure of the VDM++ specifications has less readability and maintainability. The structure is not appropriately divided into modules that correspond to the elements of its original EPNAT model.

To tackle the above problems, we propose an improved conversion technique from EPNAT models to VDM++ specifications. In this technique, features to extract an abstract current state of software are added to the VDM++ specifications in order to tackle the first problem. Additionally, the structure of the VDM++ specifications is divided into classes that correspond to subnets of EPNAT models in order to tackle the second problems. In general, the important things in the conversion of

Sho Matsumoto, Ryoichi Ishigami, Tetsuro Katayama, Tomohiko Takagi

software models are correctness and automation [4], and thus we try to keep or improve them in this study. This paper shows a new conversion rule, a new structure of VDM++ specifications, and a simple example in section 2. The discussion about their effectiveness is given in section 3, and then conclusion and future work are shown in section 4.

2. Conversion Technique

The improvement of the previous technique to convert from EPNAT models to VDM++ specifications consists of introducing the features to obtain marking data (discussed in section 2.1) and the basic class structure of the VDM++ specifications (discussed in section 2.2). The former is proposed for tackling the first problem, and the latter is proposed for tackling the second problem.

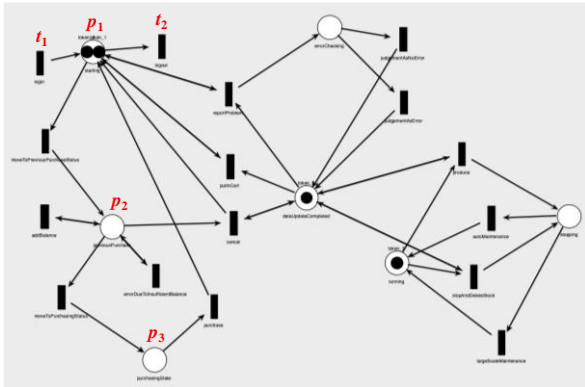
For the discussion in this study, we have constructed an experimental EPNAT model of BSS (imaginary Business Support Software) that is composed of a purchase subsystem, a production subsystem, and a stock management subsystem. Its overview is shown in Fig. 1.


Fig. 1. Overview of an experimental EPNAT model.

2.1. *Features to obtain marking data*

The features to extract an abstract current state of software should be added to the VDM++ specifications. In EPNAT models, the abstract states are expressed as the distributions of attributed tokens, that is, markings. Therefore, in this technique, the features to obtain original markings and partitioned markings are added to the VDM++ specifications. The idea of the partitioned markings has been derived from equivalence partitioning testing and coverability trees [5].

An original marking is the list of the numbers of attributed tokens in every place. For example, the original marking in the purchase subsystem of BSS (Fig. 1) is expressed as $[p_1, p_2, p_3] = [2, 0, 0]$. In general, there is a huge number of original markings in an EPNAT model, and it is not so easy to cover all of them in the simulation. In partitioned markings, the ranges of the numbers of attributed tokens in which software seems to have the

same behavior are expressed as symbols (the ranges are defined by engineers). A symbol represents all the numbers of attributed tokens in a corresponding range, and therefore the number of markings to be covered can be reasonably reduced. For example, in the purchase subsystem of BSS (Fig. 1), an execution path by using original markings $[1, 0, 0]$->t_1->$[2, 0, 0]$->t_1->$[3, 0, 0]$->t_2->$[2, 0, 0]$->t_2->$[1, 0, 0]$ can be converted into an execution path by using partitioned markings $[1, 0, 0]$->t_1->$[w, 0, 0]$->t_1->$[w, 0, 0]$->t_2->$[w, 0, 0]$->t_2->$[1, 0, 0]$, when the number of attributed tokens in p_1 in the range of two or more is represented as a symbol w. In this example, the original markings $[2, 0, 0]$ and $[3, 0, 0]$ are replaced with the partitioned marking $[w, 0, 0]$.

In the simulation, if possible, a search algorithm should avoid to revisit the same partitioned markings to improve its efficiency. The features to obtain marking data will be frequently used in the simulation, since the marking data is important properties to capture the abstract software behavior. The way of adding the features to VDM++ specifications is discussed in the next section.

2.2. *Basic class structure of VDM++ specifications*

The structure of VDM++ specifications should be divided into modules that correspond to the elements of its original EPNAT model. Therefore, the basic class structure of VDM++ specifications is constructed in this study.

The basic class structure is shown in Fig. 2. It is composed of five kinds of classes, that is, "Software", "Subsystem", "AttributedToken", "Places", and "Marking". "Subsystem" and "AttributedToken" are the sets of classes for specifying each subsystem. In each of the sets, there are N classes (N expresses the number of subsystems), and one class peculiar to each subsystem needs to be defined in the VDM++ specifications. The others are classes for managing the data of all of the subsystems. In the VDM++ specifications, they need to be defined as one class, respectively.

"Subsystem" is a part of "Software", and corresponds to the subnets of the original EPNAT model. There are relations between "Subsystem$_i$" and "AttributedToken$_i$", and also there are relations between "AttributedToken$_i$" and "Places" ($1 \leq i \leq N$; *ClassName$_i$* expresses the *i*-th class in the set *ClassName*). They mean that each subsystem keeps corresponding attributed tokens in its own places. There are relations between "Marking" and "Subsystem$_i$", which means that original markings and partitioned markings are derived from the places of subsystems. The operations that correspond to glue transitions are defined in "Software", since they have a role in the interaction between different subsystems. The other transitions (hereinafter, referred to as normal transitions) are peculiar to each subsystem, and thus the operations that correspond to normal transitions are

defined in corresponding "Subsystem*ᵢ*". Executing the operations of the transitions changes the current marking, which corresponds to arcs. Therefore, the VDM++ specifications have no explicit elements that correspond to arcs.

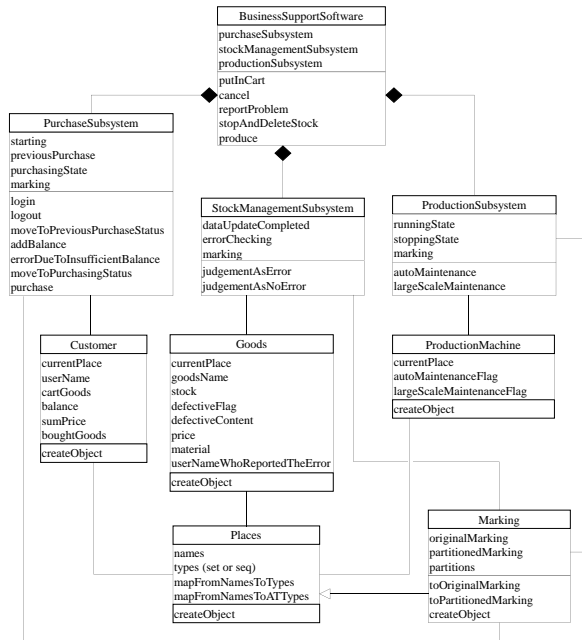
Fig. 3 shows the overview of the VDM++ specifications of the experimental EPNAT model that are based on the basic class structure. The classes "PurchaseSubsystem", "StockManagementSubsystem", and "ProductionSubsystem" correspond to "Subsystem" of the basic class structure. The classes "Customer", "Goods", and "ProductionMachine" correspond to "AttributedToken" of the basic class structure.
Fig. 2. Overview of the basic class structure.


Fig. 3. Overview of VDM++ specifications
of the experimental EPNAT model
based on the basic class structure.

3. Discussion

This section gives the discussion about the effectiveness of this technique. We have manually converted the experimental EPNAT model to VDM++

specifications by using this technique. Also, we have converted the experimental EPNAT model to VDM++ specifications by using the previous technique. Hereinafter, the former is referred to as improved specifications, and the latter is referred to as previous specifications. We have compared the improved specifications and the previous specifications, and have found the followings.

- The improved specifications can additionally provide marking data (original markings and partitioned markings). Also, the improved specifications can provide the information about individual attributed tokens by subsystems, and variables by subsystems. These will be useful to search the VDM++ specifications for the failures of software in the simulation.
- The elements of EPNAT models correspond to the elements of the improved specifications. There is traceability between EPNAT models and the improved specifications to some extent. Additionally, the improved technique can avoid the errors that the actions of normal transitions of a subsystem try to access the elements of other subsystems, since subsystems are separately defined as classes in the improved specifications.
- The improved specifications and the previous specifications consist of about 440 and 280 lines of code in VDM++, respectively. The previous specifications do not have the features to obtain marking data discussed in section 2.1, and the improved specifications excluding the features consist of about 340 lines of code. In any case, the improved specifications are larger than the previous specifications.

4. Conclusion and Future Work

In this paper, we have proposed an improved conversion technique from EPNAT models to VDM++ specifications for the simulation of abstract software behavior. The improvement consists of (1) introducing the features to obtain marking data and (2) introducing the basic class structure of the VDM++ specifications. Regarding (1), the features will be frequently used in the simulation, since the marking data is important properties to capture the abstract software behavior. We have concentrated on obtaining marking data, but other properties also need to be collected to be efficiently checked in the simulation. The features to collect other properties will be considered in future work. Regarding (2), the basic class structure establishes traceability between EPNAT models and VDM++ specifications to some extent, and avoids a certain kind of errors. However, VDM++ specifications by the improved conversion technique are larger than VDM++ specifications by the previous conversion technique. The basic class structure

Sho Matsumoto, Ryoichi Ishigami, Tetsuro Katayama, Tomohiko Takagi

may need to be refined further to improve the readability and maintainability in future work.

Abstract

It is difficult to understand the structure of large and complex mobile applications. To support iOS app development, we proposed SwiftDiagram, a visualization of the static structure of Swift source code and confirmed its high usefulness. However, manually drawing SwiftDiagram is labor-intensive. This paper implemented a prototype of RAGESS (Real-time Automatic Generation of SwiftDiagram System), a tool that automatically generates SwiftDiagram by performing static analysis on Swift source code every time an iOS app build is successful.

Keywords: Software visualization, Mobile application, Swift

1. Introduction

The smartphone and tablet application market is expanding every year [1]. As a result, mobile applications are becoming larger and more complex. The following problems exist for developers of increasingly complex mobile applications.

- Difficult to understand the overall structure of the application
- Difficult to keep track of where changes to the source code may have an impact

To solve the above problems through software visualization, we have proposed SwiftDiagram. SwiftDiagram is a diagram that visualizes the static structure and impact scope of source code written in Swift, a programming language used to develop iOS applications. However, manually drawing a SwiftDiagram takes time and effort. Therefore, this paper implements RAGESS (Real-time Automatic Generation of SwiftDiagram System) to support the development of iOS applications in Swift. RAGESS is a tool that performs a static analysis of the Swift source code and automatically draws the corresponding SwiftDiagram when it detects that the target application builds successfully.

2. SwiftDiagram

SwiftDiagram is a diagram that targets source code written in the Swift programming language and supports

the design and maintenance of iOS applications by visualizing the following:

- Static structure of type
- Affected scope when making changes to the type

In addition, SwiftDiagram is composed of the following four types of parts and one type of arrow. The appearance of each part and arrow is shown in Fig. 1.

- **Header Part**
  Shows a type identifier, such as type categories and name
- **Details Part**
  Shows type components such as properties, methods, protocol conformance, and so on
- **Extension Part**
  Shows a type extension
- **Nest Part**
  Shows a type that is declared nested inside another type
- **Affected scope (arrow)**
  Shows that changes made to the type at the root of the arrow may affect the component of the type pointed to by the arrow tip

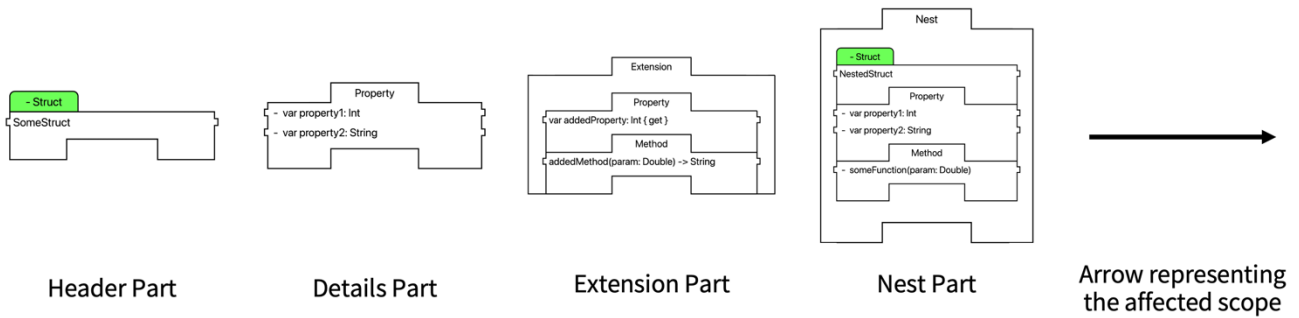
Haruki Onaga, Tetsuro Katayama, Yoshihiro Kita, Hisaaki Yamaba, Kentaro Aburada, Naonobu Okazaki


Fig. 1 Component parts of SwiftDiagram
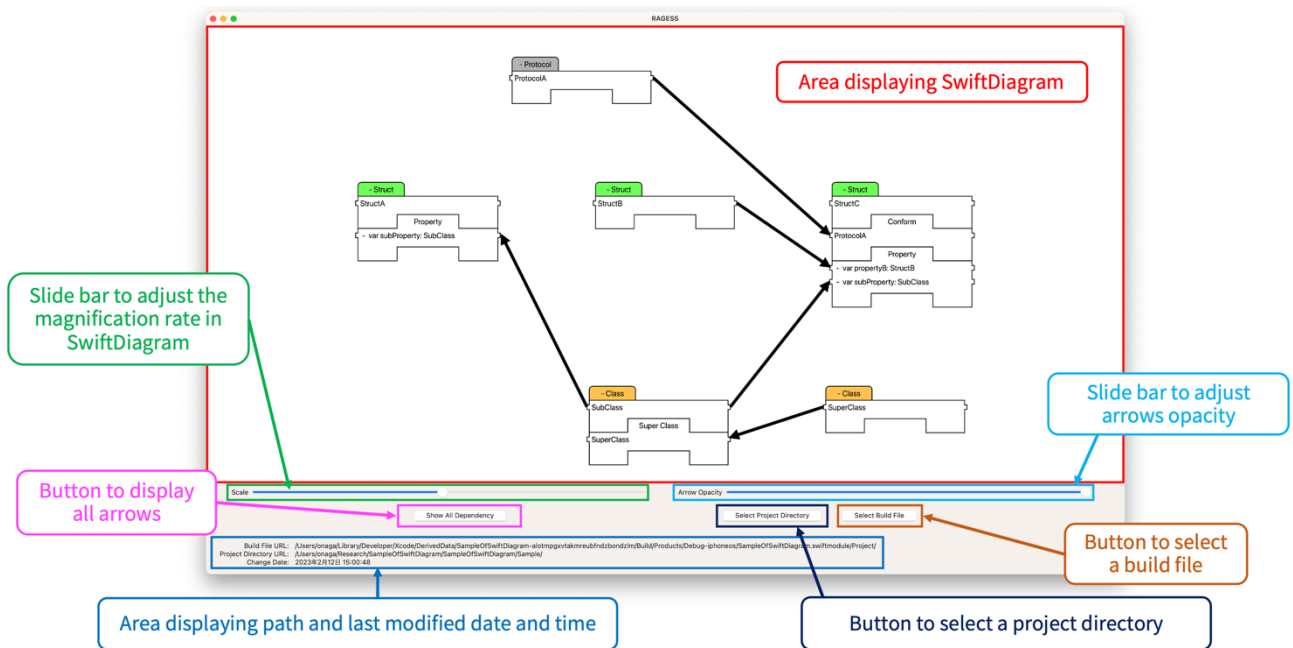

Fig. 2 Overview of RAGESS

3. RAGESS

We implement RAGESS as a macOS application in Swift. After launching RAGESS, the user can use RAGESS functions by selecting the path to the project and its build file for which the user wants to draw SwiftDiagram. This chapter describes the overview and functions of RAGESS.

3.1. *Overview of RAGESS*

Fig. 2 shows the overview of RAGESS implemented in this paper. RAGESS consists of two areas, two slide bars, and three buttons as shown below.

- Area displaying SwiftDiagram
- Area displaying path and last modified date and time
- Slide bar to adjust the magnification rate in SwiftDiagram
- Slide bar to adjust arrows opacity
- Button to display all arrows
- Button to select a project directory
- Button to select a build file

3.2. *Functions of RAGESS*

RAGESS has the following two functions.

- Automatic real-time drawing of SwiftDiagram corresponding the latest source code
- Narrowing down the affected scope

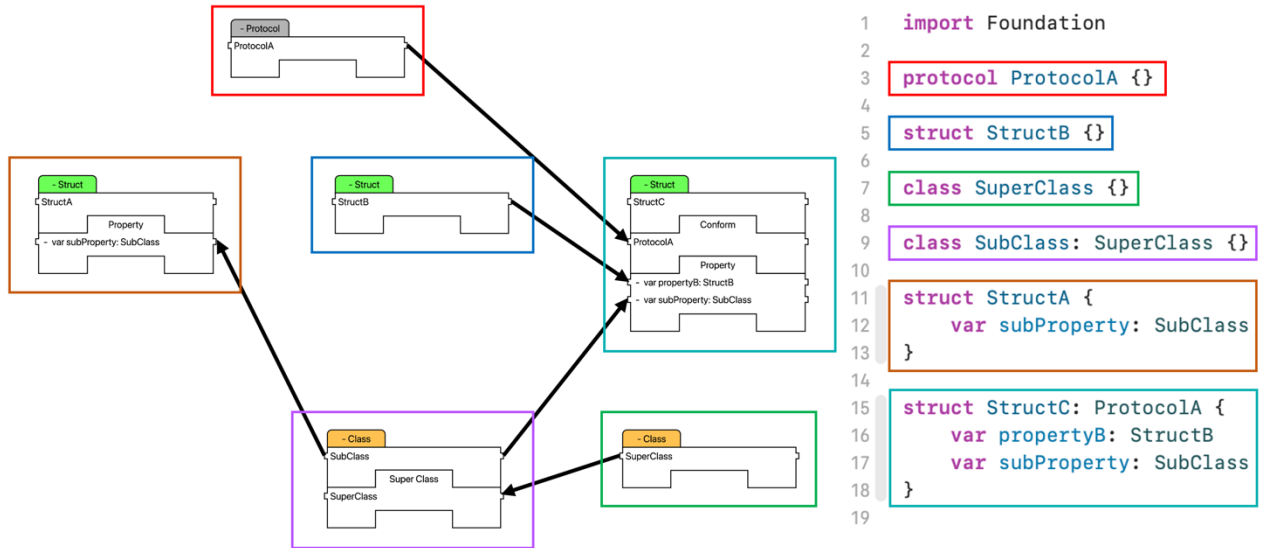
RAGESS monitors the build file of the target project. RAGESS statically analyzes the project's Swift source code every time it detects a change in the build file and automatically draws the corresponding SwiftDiagram. This saves the user from the trouble of updating the SwiftDiagram and means that the source code represented by the SwiftDiagram doesn't contain any syntax errors. Static analysis of Swift source code is


Fig. 3 Correspondence between SwiftDiagram and Swift source code in the sample project

performed by using SwiftSyntax [2], which is open source by Apple. The user can scale the drawn SwiftDiagram by operating the slide bar.

Representing the overall structure of a project in SwiftDiagram could complicate the arrows representing the affected scope and make it difficult for the user to understand the structure. When the user selects a header part, RAGESS narrows down the display to only those arrows that represent the affected scope of the changes made to the type. The user can also operate the slide bar to adjust the opacity of the arrows representing the affected scope. The button to display all arrows, returns the state of the narrowed down affected scope and the opacity of the arrows to their initial state, and displays all the arrows that represent the affected scope for the entire project.

4. Application Example

By using an application example, we verify that the RAGESS functionality works correctly for Swift source code that defines multiple types. Fig. 3 shows the correspondence between the SwiftDiagram drawn by RAGESS and the Swift source code in the example. Here, Fig. 2 shows a screen shot of RAGESS monitoring the build file of the project containing the Swift source code in the example, and when the build is successful.

By looking at the StructA of the SwiftDiagram and the Swift source code in Fig. 3, the structure name and properties of the structure in the SwiftDiagram correspond to the structure name and properties of the structure in the Swift source code, respectively. Similarly, looking at StructC, the structure name, properties, and dependencies by protocol conformance in the

SwiftDiagram correspond to the structure name, properties, and dependencies by protocol conformance in the Swift source code, respectively.

Also, ProtocolA, SuperClass, SubClass, and StructB in the SwiftDiagram extend arrows toward components of the type that may be affected by changes made to the type.

Hence, it is clear that RAGESS can statically analyze Swift source code and draw the corresponding SwiftDiagram.

5. Related work

Emerge [3] is a tool for visualizing Swift source code. It is a browser-based tool that visualizes codebase and dependencies for multiple programming languages like Swift, Kotlin, and TypeScript. Because it visualizes the source code in a graph structure composed of nodes and edges, the user can explore and analyze it visually.

Emerge analyzes source files under the source directory that are written in a language set by the user and generates files for displaying graphs in a Web browser. The user can load the file with a Web browser to analyze the dependencies. However, Emerge cannot reflect changes made to the target source code after analysis in the graph displayed in the Web browser. Also, because it takes types and files as nodes, the user cannot analyze the dependencies of the type components. On the other hand, RAGESS automatically draws SwiftDiagram every time the target application builds successfully. In addition, because arrows representing the dependencies are connected to type components such as properties and methods, the user can understand the dependencies in more detail.

Haruki Onaga, Tetsuro Katayama, Yoshihiro Kita, Hisaaki Yamaba, Kentaro Aburada, Naonobu Okazaki

And another tool for visualizing Swift source code is Swiftcity [4], [5]. Swiftcity adapts the city metaphor, which has been studied for Java, C++, and other languages, to unique type extensions, structures, and more of Swift to map and visualize source code into cities and buildings. The height of the building represents the number of lines of code (LOC) of the type, while the width and depth of the building represent the number of methods of the type. The user can use Swiftcity by uploading a project file to the user's Web browser.

Swiftcity is useful for getting an overview of the application. For example, yellow buildings represent type extension, so if a city has many yellow buildings, it means that type extension are frequently used in its source code. The variety of building colors also means the use of all the standard features provided by Swift. However, Swiftcity visualizes type categories and the number of methods, but doesn't visualize elements such as properties and enumerated type cases, nor the dependencies such as function calls and protocol conformance. Therefore, use of Swiftcity is limited to understanding and analyzing an overview of the application in the maintenance process. On the other hand, RAGESS can visualize the size of a type by the height of the SwiftDiagram that combines each part and also components and dependencies of the type.

Therefore, RAGESS provides a more detailed visualization of the structure of applications than the other two tools that visualize Swift source code. In addition, it updates the SwiftDiagram in real-time every time the application builds successfully, thus reducing the time the user needs to modify the deliverables.

6. Conclusion

In this paper, we have implemented RAGESS, a tool statically analyzes the project's Swift source code every time it detects a change in the build file and automatically draws the corresponding SwiftDiagram, in order to support the development of iOS applications in the Swift programming language.

We have applied RAGESS to Swift source code and confirmed that it can draw the corresponding SwiftDiagram. We also have confirmed that RAGESS can visualize the structure of the application in more detail and in real-time compared to other tools that visualize Swift source code.

Consequently, RAGESS is expected to support the development of iOS applications in the Swift programming language.

Future works are as follows:

- **Evaluation of usefulness by subject experimentation**

RAGESS cannot coexist with the current Swift and SwiftSyntax versions and is not buildable. Therefore, in this paper, we couldn't evaluate the usefulness of RAGESS through experimentation in which subjects actually use RAGESS. We need to implement RAGESS to adapt it to current Swift and SwiftSyntax versions and conduct subject experimentation to confirm its usefulness.

- **Implementation of SwiftDiagram editing function**

We enable SwiftDiagram to edit in the area displaying SwiftDiagrams of RAGESS and reflect the edits in the source code. This function could assist the user in designing new developments or adding new function. We need to implement it because we believe it feature will further increase the usefulness of SwiftDiagram and RAGESS.

- **Implementation of search function**

In the current RAGESS, the user must visually search for the target type in the area displaying SwiftDiagram to understand the structure of the application. We believe that implementing the function to search by type name or component will further reduce the user's time and effort.

- **Extension of supported syntax**

RAGESS does not support type inference and can only extract properties whose types are explicitly indicated by type annotations. Since type inference is used in much Swift source code, we believe that supporting type inference would further increase the usefulness of RAGESS. And even if there are more nested types within nested declared types, RAGESS cannot extract that information. It is also not yet compatible with Swift Macros released with Swift 5.9. We plan to make RAGESS compatible with them.

Abstract

Generating test cases from the formal specification description VDM++, which is a method for disambiguating specifications, is time-consuming and labor intensive. Therefore, our laboratory has developed BWDM, a tool that automatically generates test cases from VDM++ specifications. However, existing BWDM has problems that it only supports integer types and cannot generate test cases for operation and function definitions including recursive structure. Therefore, in order to improve the usefulness of BWDM, this paper extends BWDM to solve the above problems. Consequently, it has confirmed that the use of extended BWDM can reduce the test case generation time compared to manual test case generation.

Keywords: software testing, formal methods, VDM++, automatic generation, test cases

1. Introduction

Today, our lives are supported by a lot of software. As a result, software has become larger and more complex, and software bugs have a greater impact on society. One of the causes of bugs in software is the use of natural language in the upstream stage of software development. This is because natural language contains ambiguity. One method to solve this problem is to design software using formal methods. VDM is one of the most common formal methods used for this purpose, and VDM++ is a formal specification description language used in VDM for object-oriented modeling [1].

On the other hand, software design using VDM++ requires software testing. However, it is time-consuming and labor-intensive to manually generate test cases from specifications written in VDM++. In addition, manual test case generation may cause leakage in testing. Therefore, our laboratory has developed BWDM [2], [3], an automatic test case generation tool for VDM++ specifications. However, existing BWDM has the problem that it only supports integer types and cannot generate test cases for operation and function definitions with recursive structure.

Therefore, to improve the usefulness of BWDM, it is extended as follows.

- Addition of a function to generate test cases for enumerated type
- Addition of a function to generate test cases for operations/functions with recursive structure

In this paper, Chapter 2 describes the existing BWDM, Chapter 3 describes the extended BWDM, Chapter 4 shows application examples, and Chapter 5 discusses and confirms the usefulness of BWDM. Chapter 6 is the conclusion.

2. BWDM

BWDM is a tool that automatically generates test cases using the VDM++ specification as input. As examples, Fig. 1 shows the VDM++ specification and Fig.2 shows the test cases generated from it by BWDM, respectively.

3. The Extended BWDM

This chapter describes the details of the extension of BWDM. Fig. 3 shows the structure of the extended BWDM.

judgeLeapYear(year) ==
  if(year mod 4 = 0 and ((year mod 100 = 0) =>
    (year mod 400 = 0))) then
  "Leap Year"
  else "Normal Year "
end calendar
```

Fig. 1 Example of VDM++ specification

3.1. *Addition of a Function to Generate Test Cases for Enumerated Type*

To solve the problem of the existing BWDM only supporting specific types, we extend Syntax Analyzer and Symbolic Executor. Concretely, we extend BWDM to generate test cases for enumerated type consisting of a set of unique identifiers.

In the extended Syntax Analyzer, if a type definition of an enumerated type exists in the abstract syntax tree analyzing process, the corresponding type declaration is replaced with a list consisting of the declared name and values. If the substituted list exists in the syntax tree in the Symbolic Executor, JavaAPI [4] which generates enumerated type is used to generate constraints to be registered with the SMT solver [5] used in the propositional analyzer section. This additional process can generate input data for enumerated type by symbolic execution.

3.2. *Addition of a Function to Generate Test Cases for Operations/Functions with Recursive Structure*

To solve the problem of existing BWDM's inability to generate test cases for operation and function definitions with recursive structure, we extend Syntax Analyzer and Test Suite Generator.

In existing BWDM, when there is an operation/function call in test suite generation, test cases cannot be generated unless the parsing of the called operation/function is completed. This is the cause that the parsing of the operation/function including recursive calls is not completed and the abstract syntax tree cannot be generated.

Therefore, when there is an operation or function that has self-recursive calls, an upper limit is set on the number of recursive calls, and the abstract parse tree analysis process is modified so that it is executed after the parse tree analysis for all definitions is completed. This allows the test data generation to be performed after the parsing of the VDM++ specification given as input is completed. Additionally, a function is added that terminates the process if self-recursive calls are performed more than a limited number of times when

```
Function Name : judgeLeapYear
Argument Type : current_year : nat
Return Type : seq of (char)
Number of Test Cases : 17 cases(BVA:13 /SE:4)

Boundary Values for Each Argument
current_year : 4294967295 4294967294 0 -1 3 4
5 99 100 101 399 400 401

Test Cases for Boundary Value Analysis
No.1 : 4294967295 -> Undefined Action
No.2 : 4294967294 -> "Normal year"
No.3 : 0 -> "Leap year"
No.4 : -1 -> Undefined Action
No.5 : 3 -> "Normal year"
No.6 : 4 -> "Leap year"
No.7 : 5 -> "Normal year"

recursively generating output data in the output data generation section in Test Suite Generator.

4. Application Examples

This chapter shows application examples to confirm that the extended BWDM works correctly.

4.1. *Confirmation that Test Cases can be Generated for Enumerated Type*

Fig. 4, shows the VDM++ specification using enumerated type used for verification, and Fig.5 shows the results of applying it to the extended BWDM, respectively.

From Fig. 4, it can see that in the "judgeLightColor" function, "public TraficLight = <BLUE>|<YELLOW>|<RED>;" is defined as the type. As output, Fig.5 shows that test cases can be generated for the definition using the enumerated type.

4.2. *Confirmation that Test Cases can be Generated for Definitions with Recursive Structure*

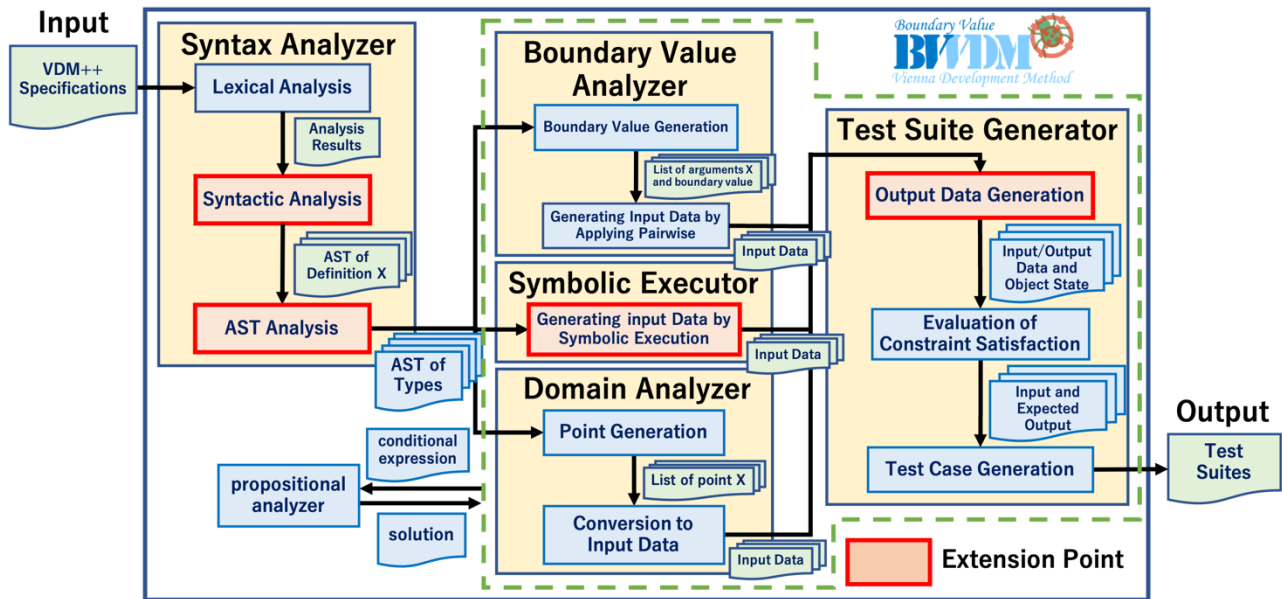
Fig. 6 shows the VDM++ specification using a definition with recursive structure used for verification, and Fig 7


Fig. 3 The structure of the extended BWDM

```
Class judgeLightColor

Types
public TrafficLight = <BLUE> | <YELLOW> | <RED>;
functions
  judgeLightColor: TrafficLight ==> seq of char
    judgeLightCoulor (color) ==
      if color = <BLUE >
        "The color is blue. "
      if color = <YELLOW>
        "The color is yellow"
      if color = <RED>
        "The color is red."

end judgeLightColor
```

No.2 : <YELLOW> -> "The color is yellow"
No.3 : <RED> -> "The clolor is red"
```

Fig. 5 Output when Fig.4 is applied to
the extended BWDM

shows the results of applying it to the extended BWDM, respectively.

From Fig. 6, it can see that in the "calcSum" function is defined with recursive structure. As output, Fig.7 shows that test cases can be generated for definition with recursive structure.

5. Discussion

5.1. *Evaluation of Test Cases Generation for Definitions using Enum Type*

As shown in Section 4.1, we have confirmed that the extended BWDM can generate test cases from definitions using enumerated type in the VDM++ specification of Fig. 4. Therefore, it can be said that this extension enables BWDM to generate test cases from definitions using

enumerated type. Thus, the usefulness of BWDM has been improved.

5.2. *Evaluation of Test Case Generation for Definitions with Recursive Structure*

As shown in Section 4.2, we have confirmed that the extended BWDM can generate test cases from definition with recursive structure in the VDM++ specification of Fig. 6. Therefore, it can be said that this extension enables BWDM to generate test cases from definitions with recursive structure. Thus, the usefulness of BWDM has been improved.

5.3. *Comparison with Manual Test Case Generation Time*

Using the extended BWDM, we evaluate the test case generation time for the VDM++ specifications which include definitions with enumerated type and recursive structure, by comparing it to the human case. Two VDM++ specifications, Fig. 4 and Fig. 6, are used in the

No.1 : 4294967295 −> Undefined Action
No.2 : 4294967294 −> Undefined Action
No.3 : 0 −> 0
No.4 : −1 −> Undefined Action
```

Fig. 7 Output when Fig.6 is applied to
the extended BWDM

experiment. The manual verification is performed by a total of five people, two graduate students and three fourth-year undergraduates in our laboratory. We measure the time required to generate sufficient test cases from the VDM++ specification, which are no leakage. The time measurement is terminated when the subjects have generated the correct test cases, and when the manually test cases includes any incorrect test cases, the mistakes are pointed out. The comparison results are shown in Table.1.

Table 1 shows that about 14 minutes are saved when using the extended BWDM to generate test cases compared to manual test case creation. In addition, human error has been observed in the manual test case creation.

In this research, we have confirmed that an extended BWDM that adds a test case generation function for definitions using enumerated type and recursive structure can reduce the time and human errors required for test case generation. Therefore, it can be said that the usefulness of BWDM has been improved.

Table.1 Comparison of test case generation time

	Time
Average of 10 subjects	14m29s
BWDM	2.6s

6. Conclusion

In order to improve the usefulness of BWDM, an automatic test case generation tool for the VDM++ specification, two extensions have been made to the existing BWDM to solve the problems that only supports integer types and that it cannot generate test cases for operation and function definitions with recursive structure.

The application examples of the extended BWDM are shown, and the test case generation function for definitions using enumerated type and definitions with recursive structure for expanding the range of supported types is confirmed. We have confirmed that the extended BWDM can reduce test case generation time by about 14 minutes compared to manually generating test cases from VDM++ specifications. In addition, we have confirmed that the extended BWDM can eliminate human errors.

Therefore, it can be said that the usefulness of BWDM has been improved by the extensions in this paper.

The future issues are the following.

- Support for types other than integer and enumerated type
- Test case generation for input values with more recursive calls
- Test case generation for mutually recursive functions

Abstract

This paper proposes a prototype of ASLA, segmentation and labeling tool for document images based on deep learning, to reduce the time required for region segmentation and label generation. To evaluate the usefulness of ASLA, we have compared the time required for region segmentation and label generation using ASLA and by hand, and then confirmed the reduction in time. We also have confirmed that the rule-based region redividing method achieves a high recall and precision.

Keywords: Region segmentation, Labeling, Document image, Rule-based region redividing

1. Introduction

Because storage space is needed to store paper documents, maintaining and managing their condition are costly. Electronic documents are used to solve this problem [1]. The use of electronic documents enables the reduction of paper and the cost of the maintenance and management. Therefore, the use of electronic documents is becoming more widespread.

The current situation of the electronic documents is only a substitute for paper. As a new way to utilize electronic documents, we focus on dividing electronic documents into regions by their elements and generating keywords and sentences as labels from the contents of the elements. In addition, the movement of the reader's line of sight when they read the electronic document is recorded as coordinate information. By realizing these features, it is possible to improve the efficiency of sales activities by capturing the level of interest and concern of customers, and to strengthen compliance by checking whether important matters are properly explained to subscribers of products or services.

To achieve the above, the following two tasks are required.

- Region segmentation that divides the components of an electronic document into some regions.
- Label generation that analyzes the contents of a region and then generates labels according to the contents of the region.

However, these tasks are time-consuming and labor-intensive in the manual. This paper proposes a prototype of ASLA (Automatic Segmentation and Labeling tool using AI), segmentation and labeling tool for document images based on deep learning, to reduce the time required for region segmentation and label generation.

2. ASLA

2.1. *Functions*

ASLA takes a single column or two columns Japanese document image as input. ASLA outputs segmentation image and class identification on the input image. Table 1 shows the definitions of class and region in ASLA. The output is a segmentation image and an analysis result file. The segmentation image is a JPEG format image. Each region of the image is color-coded and visualized as red for the text class region, blue for the figure class region, and green for the table class region. The analysis result file is a CSV (Comma Separated Value) format file. In that file, the top-left x-coordinate, top-left y-coordinate, bottom-right x-coordinate, bottom-right y-coordinate, class name, and label pair in each region are recorded per line.

Kanta Kakinoki, Tetsuro Katayama, Yoshihiro Kita, Hisaaki Yamaba, Kentaro Aburada, Naonobu Okazaki

Table 1 Definition of classes and regions in ASLA.

Class Name	Target	Definition of regions
Text	Text and title, etc.	Smallest rectangle surrounding each element
Figure	Figure	Smallest rectangle surrounding the figure
Table	Table	Smallest rectangle surrounding the table

2.2. Dataset Preparation

ASLA uses Cascade R-CNN [2] as the object detector for region segmentation. In addition, ASLA uses LayoutLMv3 [3] that is a pre-trained model specific to document AI tasks as a training model for the object detector. To improve the performance of region segmentation for Japanese document images, we fine-tune the model by using a dataset of Japanese document images prepared in advance.

The ASLA prototype uses 103 document images of the doctoral dissertation of the Graduate School of Educational and Developmental Sciences of Nagoya University provided by the Nagoya University Academic Repository [4] and 87 document images of the paper presented at the 2021 Kyushu Branch Joint Conference of the Institutes of Electrical and Related Engineers [5] as document images dataset for fine-tuning.

2.3. Structure

Fig. 1 shows the structure of ASLA. It consists of the following three processing parts.

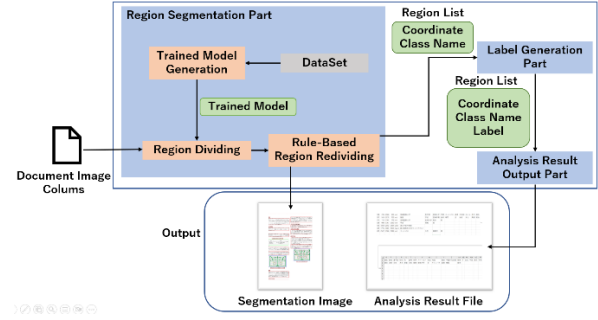
- Region Segmentation Part:
  Region Segmentation Part at first generates a trained model by fine-tuning LayoutLMv3 with a previously prepared dataset. Next, it divides region by using Cascade R-CNN from the input document image with the generated trained model. This generates the top-left and bottom-right xy-coordinates and class names for each region. Thereafter, it redivides the region to modify the misalignment of regions. The rule-based region redividing is described later in Section 2.4. Finally, based on the results of region segmentation, a segmentation image is output. Since this, text class regions are referred to as text region, figure class regions as figure region, and table class regions as table region, respectively.
- Label Generation Part:
  Label Generation Part generates labels that are all nouns included in the text region for the text region. For the figure and table regions, it generates a label that is the text of each caption. Here, it extracts characters from Japanese text using Tesseract that is an OCR tool, and it generates labels from the extracted characters using MeCab which is a morphological analysis tool.


Fig. 1 The structure of ASLA.
Fig. 2 The Process of rule-based region redividing.

- Analysis Result Output Part:
  Analysis Result Output Part outputs an analysis result file as a CSV format file based on the analysis results obtained by Region Segmentation Part and Label Generation Part.

2.4. Rule-Based Region Redividing

There are several studies that use object detectors to divide regions on document images [3], [6], [7]. The purpose is to roughly divide each region in a document image, such as layout analysis of a document image. Therefore, the existence of small misalignments between the divided regions and the actual regions is not a major problem. However, region segmentation in ASLA extracts the characters within a region after the region is divided. Therefore, if there is even a small misalignment, some characters cannot be extracted. This causes the problem that correct labels cannot be generated. Another problem with segmentation by the object detectors exists that it is difficult to detect small regions [6], [7].

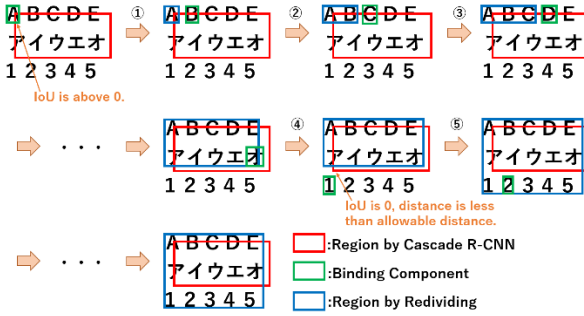
Therefore, ASLA performs rule-based region redividing. This eliminates the misalignment of regions with region segmentation by the object detector, and also divides smaller regions that were not detected before. Fig. 2 shows the flow of the rule-based region redividing. In the region redividing process, each binding component extracted by the binding component extraction process determines which region is the same as the region that was divided using the object detector. Alternatively, binding components that are far from any region are divided as a new region. Fig. 3 shows an example of the region redividing process in rule-based region redividing. In Fig. 3, the region redividing process redivides the region to eliminate misalignment of text region segmented by Cascade R-CNN.


Fig. 3 An example of the region redividing process in rule-based region redividing.
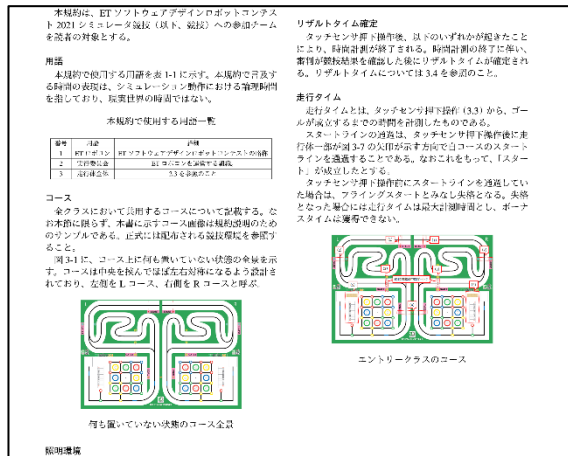

Fig. 4 Input document image sample
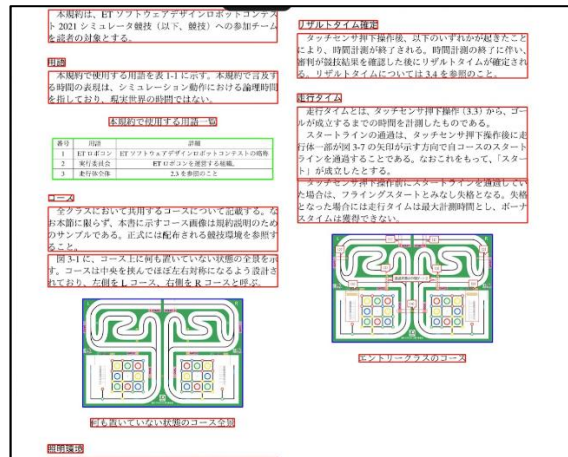

Fig. 5 Segmentation image

2.5. *Input/Output Example*

Fig. 4 shows an example of a document image to be analyzed by ASLA. Fig. 5 shows the segmentation image generated by applying the document image in Fig. 4 as input for ASLA. Fig. 6 shows an image of an analysis result file. From Fig. 5, we have confirmed that ASLA can divide the document image into text, figure, and table regions, as defined in Table 1.

Fig. 6. Result output file image

Table 2. Comparison of the time required for ASLA and manual region segmentation.

	Single column	Two columns	Average
Manual (Average)	2m6s	4m8s	3m7s
ASLA	5s	6s	6s

Table 3. Comparison of the time required for ASLA and manual labeling.

	Time
Manual (Average)	8m40s
ASLA	5s

3. Evaluation

We evaluate the usefulness of ASLA developed in this paper. It is evaluated in terms of the execution time and performance of region segmentation.

3.1. *Evaluation of the Execution Time*

We compare the time required for region segmentation by using ASLA and manually. Two document images are used for region segmentation. They are single column document image and two columns document image. In the manual region segmentation, five subjects divide regions on document images, and their working time is measured. Table 2 shows the comparison of the time required for region segmentation by using ASLA and manually. From Table 2, we have confirmed that ASLA reduces the time required for region segmentation by about 3 minutes (97%) per document image.

We compare the time required for label generation by using ASLA and manually. In the manual label generation, five subjects generate labels on document images that had been divided regions in advance, and their working time is measured. This labeling task involves extracting all nouns within each region. Table 3 shows a comparison of the time required for ASLA and manual label generation. From Table 3, we have confirmed that ASLA reduces the time required for label generation by about 8 minutes (99%) per document image. Based on the above, it can be said that ASLA helps reduce the time required for label generation.

Kanta Kakinoki, Tetsuro Katayama, Yoshihiro Kita, Hisaaki Yamaba, Kentaro Aburada, Naonobu Okazaki

Table 4 Comparison of precision and recall for Cascade R-CNN and Mask R-CNN with and without rule-based region redividing, respectively.

	IoU	Precision			Recall		
		Text	Figure	Table	Text	Figure	Table
Only Mask R-CNN	0.8	0.768	0.846	0.4	0.651	0.846	0.455
	0.9	0.348	0.154	0.2	0.295	0.154	0.182
Mask R-CNN and rule-based region redividing	0.8	0.906	0.929	0.9	0.955	1.0	1.0
	0.9	0.877	0.929	**0.9**	0.924	**1.0**	**1.0**
Only Cascade R-CNN	0.8	0.808	0.846	0.4	0.691	0.918	0.818
	0.9	0.337	0.317	0.2	0.305	0.308	0.182
Cascade R-CNN and rule-based region redividing	0.8	0.945	0.942	0.9	0.955	1.0	1.0
	0.9	**0.936**	**0.942**	**0.9**	**0.955**	**1.0**	**1.0**

3.2. *Evaluation of Region Segmentation Performance*

In addition to ASLA, there are other studies that divide region on document images [6], [7]. These studies use Mask R-CNN [8] as an object detector for region segmentation. Here, we evaluate the performance of region segmentation for each of the Cascade R-CNN used in ASLA and Mask R-CNN. The dataset used for performance evaluation consists of 8 document images. These document images consist of 4 single column document images and 4 two columns document images. The evaluation is based on the calculation of IoU for the regions and class names defined in Table 1 to calculate the precision and recall. Furthermore, to evaluate the usefulness of rule-based region redividing, we calculate the precision and recall with and without rule-based region redividing.

Table 4 shows the calculated precision and recall. From Table 4, we have confirmed that the combination of Cascade R-CNN and rule-based region redividing used in Region Segmentation Part of ASLA has the highest values for both precision and recall. We have confirmed that the usefulness of ASLA for region segmentation. In addition, the rule-based region redividing also has achieved the highest precision and recall when the IoU threshold is set to a high value of 0.9. We have confirmed that the usefulness of rule-based region redividing.

4. Conclusion

This paper has proposed a prototype of ASLA that is a deep learning tool for region segmentation and label generation, in order to reduce the time required to divide document images and generate labels. The proposed ASLA performs region segmentation and class identification on the input document image, generates labels each region, and outputs the segmentation image and the analysis result file.

After applying the document images to ASLA, we have confirmed that ASLA works correctly. Furthermore, we have compared the time required for region segmentation with the use of ASLA and manually. As a result, we have confirmed that the time required for region segmentation per document image could be reduced by about 3 minutes (97%). We also have compared the time required for label generation by using ASLA and manually. As a result, we have confirmed that the time required for label generation per document image could be reduced by about 8 minutes (99%). Furthermore, we have evaluated the performance of region segmentation. As a result, we have confirmed that the rule-based region redividing achieves high precision and recall even with a high IoU threshold value.

The future issues are as follows.

- Support for document images with non-white backgrounds.
- Automatic generation of sentences or nouns that represent the contents of figures or tables.
- Handling of text regions that do not make sense as Japanese.

Abstract

Modular robotics is one of the subfields of mobile robotics, which is emerging as a new trend in various sectors. Modular mobile robots can be reconfigured to perform a wide variety of tasks. In this paper, applications of modular mobile robots in various sectors such as industry, space, surgery, rescue and entertainment tasks are discussed. Based on the study, an improved design of a modular mobile robot for navigating through different terrains during a rescue operation is presented. Simulation study of the robot is included to demonstrate a motion capability of the modular mobile robot.

Keywords: Modular robots, Applications of modular robots, Design, Simulation study

1. Introduction

Robots were known to assist people in a wide variety of tasks such as industrial [1], [2] household [3], rescue [4], [5], medical [6], [7] space [8], defense [9], and entertainment [10] fields. The emergence of artificial intelligence elevated a performance of robots [11]. Most industrial operations are currently performed by robotic systems due to its better performance capabilities compared to human operators. Robots are proved to be more precise and accurate in carrying out a task compared to human operators. Employers are forced to build unmanned workplaces due to a variety of factors such as increasing wages, absence of skilled employees, dangerous work conditions, etc. Hence, most industries are replacing human operators with multi-tasking robotic systems. However, some of the challenging tasks inside industrial and service sectors are nowadays carried out in a collaboration mode. Such robots are known as collaborative robots [12].

Medical, service and space sectors have started to explore the capabilities of mobile robots [13]. The major reason is the multifunctional capabilities of mobile robots especially modular mobile robots. These kinds of robots can be controlled remotely to use in places or environments which are not accessible for a human operator to work. Service sectors are employing modular mobile robots to invigilate the conditions of patients and logistics tasks inside hospitals [14]. Modular robots are also used in space explorations and rescue operations. Ground and aerial modular robots are nowadays employed in places of natural calamities such as earthquakes [15], landslides and [16] and floods [17]. Modular robots can reach any location due to its shape shifting, flexible design and motion capabilities.

2. Applications of mobile and modular robot

Mobile manipulation combines the advantages of manipulation and navigation. Basiri *et al.* [18] developed a mobile robot with a UR5e [19] arm for performing activities in a construction field. The four-wheeled mobile platform was 78 cm long and 55 cm tall. The platform can support a payload of 25 kg. Bricks for construction purposes were identified and moved using a vision-based technique. Lio [20] was a service mobile robot developed as a care assistant to patients admitted in a hospital. It consisted of a 6 degrees-of-freedom (dof) arm and a mobile base with 4 wheels.

Mobile manipulators can be used in cooperative and collaborative tasks to compensate a growing demand for a workforce in industrial sectors. Robots in the industrial sector must follow safety regulations and have been proved to save a significant amount of time and money. Collaborative robots were developed for carrying out

activities combinedly by human operators and robots in a shared configuration space [21]. A team of mobile manipulators used for carrying payload was presented in [22]. Each robot consisted of a 2 dof mobile base and a 2 dof planar arm for transferring an object from one place to another. Another set of mobile manipulators used for a collaborative 3D printing process was illustrated in [23]. Experimental validation proved that using collaborative robots increased a performance of a collaborative task.

Modular robots can perform a variety of tasks and adapt to the environment quickly. Connect-R [24] was a modular robot developed for implementing in an industrial environment. Each module has the ability to rotate around other modules, link to other modules, and extend based on the available space. A reconfigurable modular robot named Deformable Modular Robot (Datom) was presented in [25]. Each module of the robot was connected to other modules using a Face-centered cubic lattice pattern. The robot has a capability to separate from neighbouring modules during a task. FreeSN [26] was a modular reconfigurable robot consisted of strut and node modules. A node module was constructed using a low carbon steel spherical shell and a magnetic connector was used as a joining mechanism. SMORES-EP [27] was a modular robot used in construction sector. It can self-assemble to generate 3 different topologies based on a task. A docking control strategy was used for a successful docking of the robot. A self-reconfigurable mobile robot with 2 dof with a docking mechanism was demonstrated in [28]. It consisted of a hybrid mobile base with wheels and tracks. An image processing technique was used for locating a docking station for the charging of the modular robot.

Modular robots are also used in household and entertainment sectors. Roombots [29] were a group of modular robots designed to employ both as a payload carrier in houses and also act as toys for children. Roombots can act as adaptive and reconfigurable mobile robots and used for supporting furniture during relocation. The reconfigurable modular robot consisted of 12 modules with 36 dof. It can autonomously change shape, grasp, and move furniture. KAIRO-II, a modular robot developed for rescue operations was given in [30]. It consisted of 6 drive modules interconnected using 5 joint modules. KAIRO -II can ascend short stairs and steps shorter than 55 cm. Modular robots are more efficient in carrying out multiple tasks compared to mobile robots. Nowadays modular robots are used for navigating through different terrains using different modes of base motions. Unmanned ground and aerial modular mobile robots are used in rescue applications. These mobile robots can reach a specified location and invigilate the conditions of the environment using sensors attached to them. A design of a modular robot capable of navigating through uneven terrains was proposed in [31]. A hybrid wheel base for the robot was developed with both wheels and tracks. The robot consisted of a vertical translation unit, which was used for moving the robot in uneven terrains. Design of a homogenous modular robot consisted of revolute and prismatic joints was demonstrated in [32]. It consisted of a rotary plate docking mechanism that allows the robot to change configurations during a task.

Robots are used for carrying out surgeries and operations in the medical field. Versatile modular robotic arms are used in robotic surgeries, which can be assembled and dissembled based on task requirements. Robotic capsules are used for carrying out an endoscopy to detect internal diseases. Cameras and biochemical sensors used in these devices can detect internal body issues. Numerous distinct terrestrial modular robotic systems are employed for carrying out space related tasks. However, due to extreme terrestrial conditions, only few robots have been in active employment currently. However, modular robots are preferred for space related tasks since a reconfigurable robot can carry out multiple tasks [33], [34]. Mobile modular robots have been also used in military operations to reach complex terrains [35].

3. Advantages of modular robots

Generally, the cost of a robot manufactured is directly proportional to the size of the robot due to material requirements. Due to the high cost of industrial robots, most of the industries are not able to employ such robots for execution of tasks. However, modular robots are compact and cost-effective in terms of their size and materials.

Capabilities of mobile robots available in current market are not adequate to carry out complex tasks. In comparison to mobile robots, modular robots are more effective and successful when dealing with emergency situations. Modular robots are employed for rescue operations and in narrow pathways, where normal sized mobile robots cannot navigate. Another major capability of a modular robot to transform the shapes and patterns of individual modules.

One of the most important requirements for accomplishing a logistics-related operation is the capability to provide required speed of navigation. The ordered item is anticipated to be delivered as soon as possible. Traditional mobile robots cannot traverse through complex terrains due to mobile base mechanism limitations. However, a modular robot can transform its shape and pattern to control speeds during navigations.

One of the major issues faced by mobile robots is the limited space for navigation. Modular robots are proved to be traversable through narrow and curved pathways without any difficulty. This is mostly due to their shape shifting capabilities and ability to adapt to different

environments. Hence, modular robots can be employed remotely to reach disaster zones for monitoring situations.

4. A design of a mobile robot

A design process of a modular robot is very complex since modular robots must be able to shift shapes based on requirements. Specifications of a modular robot play a crucial role in completing a task successfully. A traditional modular robot has 2 or more modules based on the requirements. Multiple modules can be manipulated for shifting shapes and configuration of the robot. In some circumstances, each module of a modular robot can be operated as a single robot, with no connectivity to other modules.

In this paper, a design of a modular mobile robot, which can be used for search and rescue operations was presented. The specific design (Fig. 1) allowed the robot to enter areas inaccessible to human rescue operators. It can carry necessary equipment, medicines, and has capability to convey information to communicate with online remote operators. A modular robot with two modules each with 4 wheels was designed in Tinkercad software [36], which is significantly more simple in modelling and operating than popular Gazebo [37], [38] or Webots [39], [40] robotic simulators. The design of each module consisted of a mobile robot with 4 wheels. One module with 4 wheels can be moved above the other. An 8-wheeled single-decker vehicle can be created by lining up two distinct vehicles in a row with a rail system in between the wheels. Self-rotating pallets were used for rotating one module and placing it on top of another module. The two modules can also be used separately depending on the task requirements. In such cases, GPS technology is used to detect positions of each module and reach a location for docking.
Fig. 1 Modular mobile robot with 2 modules

Each module of the robot consisted of a hydrogen fuel battery, a Raspberry PI 4 as processor and a WIFI module (Fig, 2). The batteries presented in the robot were charged using a coil. Raspberry PI 4 was used to control an overall process of the modular mobile robot. WIFI module was used for receiving and sending information. The robot was charged using a wireless charging method also. A

rectifier and a filter were equipped inside the robot to manipulate incoming and outgoing currents. Magnetic resonance technique can also be used for charging the robot.
Fig. 2 WIFI equipped on modular robot

5. Simulation study

A simulation study was conducted for analysing motion capabilities of the modular robot. A task was assigned to the robot to reach a goal location from an initial location in a stacked configuration. The initial configuration of the modular robot is shown in Fig. 1. The rear module of the modular robot was sliding on to the top of front module using the wheel rotations as shown in Fig. 3. The final configuration of the robot when rear module reached the top of front module is shown in Fig. 4. The rear module can revert back to its initial pose using the same motion shown in the Fig. 4. The designed modular robot can be traversed using 8 wheels or 4 wheels by keeping rear module on the top based on the space constraints.
Fig. 3 Intermediate position of rear and front modules
Fig. 4 Stacked configuration of the modular robot

The modular robot was able to reach the goal location in a stacked configuration. The motion of the robot was smooth on a flat terrain.

6. Conclusion

In this paper, applications and advantages of available designs of modular robots in various sectors were reviewed. Based on the study, a design of a modular robot with two modules was introduced. The modules can traverse individually or in combined pattern based on the space constraints and assigned tasks. A simulation study was carried out to analyze a motion capability of the designed modular robot. The nature of motion obtained was smooth and able to complete the task within limited time period. The motion capabilities of the designed modular robot in complex terrains and 3D spaces will be analyzed in future works. The energy capacity of the modular robot will be analyzed during a task for determining the operation runtime of the robot.

Abstract

Mobile robots typically operate in a dynamically changing unknown environments. The Bug family algorithms were developed to address path planning challenges for ground vehicles within 2D configuration spaces of unknown environments. These algorithms utilize local sensory data about obstacles encountered during navigation. This paper introduces the implementation of Bug1 and Bug2 local path planning algorithms in ROS Noetic. Traditional 2D Bug algorithms are extended into 3D Gazebo simulation environment. Performance evaluation of Bug1 and Bug2 were conducted using the TurtleBot3 Burger model in both simple convex and maze environments.

Keywords: BUG Algorithms, Path Planning, Navigation, Mobile Robots, ROS, Gazebo

1. Introduction

There are two main path planning models distinguished by the type of information they utilize. The first model, known as path planning with complete information or global navigation, assumes that a robot possesses comprehensive information about its surroundings. In contrast, the second model, known as path planning with incomplete information, introduces uncertainty about an environment [1]. It is essential to integrate both global and local path planning strategies to ensure secure robotic navigation. In this context, a primary objective of local planners is to adhere to an initial plan provided by global planners [2]. Thus, an implementation of a safe and reliable local navigation algorithm, tested in conditions close to real-world scenarios, holds a significant importance.

The Boundary-following and Ultimate Goal (BUG) family of algorithms is among the most renowned in the field of local path-planning. The BUG algorithms follow a simple cycle consisting of two states. In the first state, a robot pursues a directly or intricately calculated path to a target point until encountering an obstacle. The second step involves circumnavigating the obstacle until an exit condition is met.

This paper outlines challenges and potential solutions for implementing local path-planning algorithms within 3D environments, utilizing Bug1 and Bug2 as reference models. It marks an initial step toward an implementation of more complex BUG algorithms [3], [4]. The algorithms were implemented in ROS and evaluated in Gazebo simulator using TurtleBot3 Burger [5]. Custom-designed environments were used for testing while as a part of our ongoing work the algorithms are being validated employing a broad set of environments generated by an automatic tool for Gazebo simulator [6] and a number of standard warehouses' models [7].

2. Algorithms Overview

The Bug1 and Bug2 algorithms are a foundation for the entire BUG family, encompassing algorithms such as Class 1, 2 and 3 [8], Alg1 and Alg2 [9], [10], VisBug21 and VisBug22 [11], Wedgebug [12], Rev1 and Rev2 [13],

Ilya Spektor, Aidar Zagirov, Ramil Safin, Evgeni Magid

Distbug [14], TangentBug [15], CautiousBug [16] and others. Both algorithms operate by transitioning between two states: move-to-target and boundary-following (Fig. 1). These algorithms require a robot to be equipped with a touch sensor, rendering them useful for compact machinery. Next, we offer a brief overview of Bug1 and Bug2 algorithms. For a more in-depth analysis refer to the original work of Lumelsky and Stepanov [1].
Fig. 1. Trajectory of Bug2 algorithm. Red lines depict the move-to-target state, while blue lines illustrate the boundary-following state.

We use the following notations for both algorithms:

- *Target* – a destination point that the robot should eventually reach.
- L_i (leave point) – a point defined when departing from an *i*-th obstacle to resume moving toward *Target*.
- H_i (hit point) – a point defined when an *i*-th obstacle is encountered.

2.1. Bug1 Algorithm

For the Bug1 algorithm we introduce variable Q_m that stores an encountered point with a minimal distance between an obstacle boundary and *Target*. Additionally, we will introduce three registers: R_1 to store coordinates of the point Q_m, R_2 for a length of the obstacle boundary from H_i to Q_m, and R_3 for a length of the obstacle boundary from Q_m to H_i. The following steps are executed at every point of a continuous path:

1) From point L_{i-1} move toward *Target* along a straight line until one of the following events occurs:
    (a) *Target* is reached: stop the algorithm.
    (b) An obstacle is encountered: define hit point H_i and proceed to step 2.
2) Follow the obstacle boundary using a local direction (local information about the obstacle's boundary):
    (a) If *Target* is reached: stop the algorithm.
    (b) Otherwise, traverse the boundary and return to H_i. Define new leave point $L_i = Q_m$ and proceed to step 3.
3) Apply a test for target reachability. If *Target* is not reachable, stop the algorithm. Otherwise, using

content of registers R_2 and R_3, determine a shorter way along the boundary to L_i, use it to get to L_i. Increment counter *i* and go back to step 1.

2.2. Bug2 Algorithm

Steps of Bug2 are executed at any point of a continuous path as follows:

1) From point L_{j-1}, move along a straight line (*Start, Target*) until one of the following events occurs:
    (a) If *Target* is reached: stop the algorithm.
    (b) An obstacle is encountered: define hit point H_j and proceed to step 2.
2) Follow an obstacle boundary:
    (a) If *Target* is reached: stop the algorithm.
    (b) If line (*Start, Target*) is met at point Q such that distance $d(Q) < d(H_j)$, and line $(Q, Target)$ does not cross the current obstacle at point Q. Define leave point $L_j = Q$. Increment counter *j* and go back to step 1.
    (c) If the robot returns to H_j and, hence, completes a closed curve (the obstacle boundary) without defining next hit point H_{j+1}, it means that *Target* cannot be reached, stop the algorithm.

3. Implementation

Several challenges were encountered during Bug1 and Bug2 algorithms' implementation in ROS/Gazebo. The first problem was a simulation of a touch sensor for the TurtleBot3 Burger robot. It is equipped with a 180 degrees field of view range sensor for safety and integrity reasons [5]. To simulate a touch sensor, we restricted the sensor's vision range to $\rho_v = 1.5R_b$, where R_b is a radius of a robot's body circumcircle. Touch sensors usually provide boolean values: *true* means that a robot is touching an obstacle, *false* otherwise. In our implementation we divided a field of view into five quadrants (of 36 degrees each) and register collision events within each quadrant independently. Another problem is that Bug1 and Bug2 do not limit robot's forward and angular velocities [1]. The most straightforward solution is to set a constant velocity. Potential further enhancements may incorporate a PID controller into the algorithm's pipeline.

Our implementation and validation were conducted using Ubuntu OS, employing robust capabilities of Robot Operating System (ROS) Noetic Ninjemys and the Gazebo simulator [17], [18]. The system configuration for the rigorous testing and validation is outlined in Table 1. For testing purposes, we selected the TurtleBot3 Burger (see Fig. 2) as the robot model [19]. The algorithms were initially implemented in Python, leveraging its popularity and the ease of prototyping and development. However, recognizing the importance of computational efficiency, we plan to reimplement the algorithms in C++.

Table 1. System configuration

Component	Specification
OS	Ubuntu 20.04 LTS
ROS	Noetic Ninjemys
Gazebo	11.11.0
Processor	Intel Core i5-11300H @ 3.10GHz
RAM	24 GB
Fig. 2. TurtleBot3 Burger in the Gazebo environment.

There are three ROS nodes created to simulate a cycle of switching the states:

1) **Main**: operates continuously, responsible for calculating an optimal time to switch between the states based on predefined conditions.
2) **Go-to-Target**: orients and moves the robot toward the target.
3) **Follow-Wall**: facilitates the circumnavigation of obstacles. In the case of Bug1, there are two instances of this node – one for clockwise rotations and another for counterclockwise rotations.

4. Validation

To ensure the robustness and effectiveness of the Bug1 and Bug2 algorithm implementations, a comprehensive validation process was undertaken in Gazebo simulator using ROS navigation stack [19], [20]. The validation encompassed a diverse set of tests conducted in 3D simulation world featuring individual complex obstacles and a maze [6]. To ascertain the correctness of the target point reachability determination, a testing scenario was implemented for both Bug1 and Bug2 algorithms. The validation process involved 30 tests for each algorithm on maps with convex obstacles. Half of these tests featured reachable targets, while the remaining half featured unreachable targets.

Given the Bug1's requirement to fully circumnavigate obstacles, testing in maze environments was time-consuming. Thus, only 10 tests for each algorithm were conducted on the maze map, with an equal distribution of reachable and unreachable target scenarios. All target points were accurately identified for reachability in every

test scenario. When a point was deemed reachable, the robot successfully navigated its path to the target, affirming the efficacy of the Bug1 and Bug2 algorithms.

The outcomes of the Bug1 and Bug2 algorithms were visually demonstrated through simulations in Gazebo. Fig. 3 illustrates a resulting path in an environment with convex obstacles, achieved by the Bug1 algorithm. Fig. 4 presents a resulting path in the same environment by Bug2. Notably, a difference was significant, with Bug2 path displaying a more straightforward trajectory, which is observed in a substantial portion of the conducted tests.
Fig. 3. Path of Bug1 in the environment with convex obstacles (white dashed line).
Fig. 4. Path of Bug2 in the environment with convex obstacles (white line).

5. Conclusion

In this work we presented the implementation of the Bug1 and Bug2 algorithms, delving into the challenges encountered while integrating local navigation algorithms into realistic ROS/Gazebo simulations. This article lays a ground for future implementations of more complex BUG family algorithms.

Abstract

Two standard approaches for a robot path planning include a global and a local navigation. The later does not require to store an environment model in a robot memory. This paper presents implementations of two local navigation algorithms, Alg1 and Alg2, with a robot having no prior information about an environment and obstacles. It calculates a path in a real time, continuously changing its states depending on correspondent conditions. The algorithms were implemented for an existing differential drive robot Turtlebot3 Burger using Robot Operation System (ROS). Virtual experiments were performed in the Gazebo simulator employing a simple 3D environment with only convex obstacles and a small 3D maze.

Keywords: path planning, mobile robots, local navigation, Alg1, Alg2, Gazebo, ROS Noetic

1. Introduction

Mobile robots and autonomous navigation are gradually integrated in various aspects of human activities, from occasional operations in dangerous scenarios to daily social interactions. The former include firefighting services [1], [2], urban search and rescue operations [3], [4], and special military operations [5], while the later improve processes in education [6], [7], manufacturing [8], [9], medicine [10], [11], agriculture [12], [13], rehabilitation [14] and service tasks [15], [16]. These tasks require advanced sensory-based autonomous navigation in various environments [17], [18]. Autonomous navigation allows a robot to decide on its motion and actions, based on onboard sensory data about its environmental and current location [19].

There are two types of path-planning: a global navigation and a local navigation [20]. In the global planning approach, a mobile robot has a well-defined map of an environment in which the robot can build its path. In more realistic settings, a robot deals with uncertain maps and relies on its sensors to plan a path [21]. which is called the local navigation. In the local planning approach a robot is being placed at a starting position and must reach a target or report if it cannot be reached while no other information is known to the robot in advance [22]. In this case, the robot uses local sensory data [20] to detect obstacles within its radius of vision [23], which allows the robot to encounter an obstacle only when it hits the obstacle in most algorithms [24].

Boundary-following and Ultimate Goal (BUG) family algorithms were designed to solve the local navigation problem without generating a full map of an environment [22]. Following a BUG family algorithm, a robot could operate in a broad variety of environments [25] and (by an algorithm design) attempts to construct a shortest path toward its destination [26]. BUG algorithms have two modes of motion: moving towards a target and following an obstacle boundary. A robot goes towards the target until it hits any obstacle. Then it starts to follow the boundary until a straight path towards the target becomes clear again [27]. A condition that defines if the path is clear differs depending on a particular algorithm.

In BUG model a robot is considered as a point object [22] in a 2D-map. In this paper a path-planning sensory-based navigation was simulated in a 3D-environment with a real mobile robot model, which employs Alg1 [28] and Alg2 [29] algorithms. The algorithms were implemented using robot operating system (ROS) [30] and evaluated using Gazebo simulator [31].

2. Brief description of the algorithms

Alg1 and Alg2 algorithms belong to BUG family. Two states of a robot under BUG strategy are: 1) go to the target; 2) follow the boundary. Most algorithms employ a line from start point to target, which is called *M-line*. The robot switches from state 1 to state 2 when it hits an obstacle at a point that is defined as a *Hit-point* (*H-point*). The switch from state 1 to state 2 occurs when the robot decides to abandon the current obstacle at a point that is defined as a *Leave-point* (*L-point*). Both H-point and L-point are defined differently by particular algorithms.

2.1. Alg1 algorithm

Alg1 algorithm improves basic Bug2 algorithm [24] in a sense of excluding multiple traces of long segments of a path. It collects H-points (H_i) and L-points (L_j) of previous iterations and uses this information to generate shorter paths by changing a local direction to the opposite. The algorithm works as follows [32]:

0) Initialize iteration i to 0, define *M-line* as line connecting start S and target T points.
1) Increment i and follow *M-line* toward T until either:
   - T is reached. Stop.
   - An obstacle is hit. Define this point as H_i. Go to step 2.
2) Keeping the obstacle on the right, follow the obstacle boundary. Do this until one of the following occurs:
   - T is reached. Stop.
   - A point y is found such that:
     - it is on *M-line* and
     - $d(y, T) < d(x, T)$ for all x ever visited by the robot along *M-line* and
     - The robot can move towards T at y.
   Define this point as L_i and go to step 1.
   - A previously defined point H_j or L_j is encountered such that $j<i$. Change the local direction one and return to H_i. When H_i is reached, follow the obstacle boundary keeping the wall on the left. This rule cannot be applied again until L_i is defined.
   - The robot returns to H_i. T is unreachable. Stop.

2.2. Alg2 algorithm

Alg2 algorithm upgrades Alg1 algorithm by abandoning *M-line* concept. The leaving condition is that

the robot became closer to T than before. The algorithm operates as follows [30]:

0) Initialize iteration i to 0 and $Q = d(S, T)$.
1) Increment i and proceed in the direction of T whilst continuously updating Q to $d(x, T)$ if $Q < d(x, T)$, where x is a current position. Q should now represent the closest to T point where the robot has ever been. Repeat this until one of the following occurs:
   - T is reached. Stop.
   - An obstacle is hit. Define this point H_i. Go to step 2.
2) Keeping the obstacle on the right, follow the obstacle boundary continuously updating Q to $d(x, T)$ if $Q < d(x, T)$. Do this until one of the following occurs:
   - T is reached. Stop.
   - A point y is found such that:
     - $d(y, T) < Q$ and
     - The robot can move towards T at y.
   Define this point as L_i and go to step 1.
   - A previously defined point H_j or L_j is encountered such that $j<i$. Change the local direction and return to H_i. When H_i is reached, follow the obstacle boundary keeping the wall on the left. This rule cannot be applied again until L_i is defined.
   - The robot returns to H_i. T is unreachable. Stop.

3. Implementation details

Ubuntu operating system and ROS Noetic Ninjemys were used. Gazebo simulator was employed for debugging and verifying algorithms' implementation with Turtlebot3 Burger robot model (Fig. 1) from an open source software kit [33].

Alg1 and Alg2 were implemented in Python3 programming language and arranged as a package with two files, containing Alg1 and Alg2 respectively. A main service uses services for going to a point and a wall following in a clockwise and counter clock-wise order.

The following libraries and modules were used for all the services:

- *rospy* – a pure Python client library for ROS;
- *geometry_msgs* module used for generating and sending messages for setting robot's position;
- *sensor_msgs* module to register laser range finder's measurements;
- *gazebo_msgs* module to define and set a robot's current state;
- *tf* module for angles' operations;
- *nav_msgs* module for odometry;
- *std_srv* module for *ros services*.
Fig. 1. Turtlebot3 Burger in the Gazebo environment

A main difficulty that was encountered while implementing the algorithms was a definition of suitable constants that allow comparing distance measurements. For example, one of the problems was to define a threshold ε>0 that could be employed to define two distinct robot positions. This way we define that if a Euclidean distance *Dist* between two points p_k and p_m is less than ε, it means that the two points coincide with each other:

$$Dist(p_k, p_m) \leq \varepsilon \iff p_k = p_m \tag{1}$$

A value of ε was chosen empirically to fit all types of environments.

Another problem relates to the construction of the robot that causes stuck because the robot sensor does not consider the robot's wheels, which poke out from the mobile base. In some cases, the robot does not register an obstacle when its wheels already have hit a convex corner. A possible solution is an increase of a threshold δ that helps defining a *H-point* as:

$$Dist(p_k, p_{obs}) \leq \delta \implies p_{obs} = H_i \tag{2}$$

where p_{obs} is a point on a boundary of a currently hit obstacle, p_k is a current position of the robot, H_i is a newly defined *H*-point. Yet, this may cause the algorithms' failure since the robot may miss a *H-point* and thus skips a switch of its state into the boundary following mode.

Finally, one more difficulty appeared only for Alg2 algorithm at step 1 when it checks whether the robot became closer to *T* than before ($Q < d(x, T)$). While in a mathematical sense this comparison is performed constantly, in practice a particular small time step *Δt* between checking a new value of *x* should be selected. The value of *Δt* was found empirically so that it successfully works for both employed types of maps: separate convex obstacles and mazes.

4. Validation

To validate the implementation of Alg1 and Alg2 algorithms 45 tests within two different types of environments were conducted. While there exist several popular tools for environment construction for Gazebo worlds, ranging from semiautonomous generators of single environments from 2D images [18],[34] to autonomous generators of multiple environments, including maze-like environments [35] and random step environment generators [36] using ergonomic graphical user interfaces, it was decided to construct two environments manually in order to ensure interesting cases for algorithms' testing. The first constructed environment was bounded by an external non-traversable black wall with five green towers and contained separate convex obstacles in a form of nine identical columns. The second environment was a maze. 25 and 20 test cases within the convex environment and the maze were conducted, correspondingly. For each test cases four runs were conducted. In total, 90,5% of the tests were successful while seven tests in the convex environment and ten tests in the maze failed due to the problems that were stated in Section 3. Additional tests for the target reachability were performed successfully in both environment. Table 1 presents the system configuration.

Table 1. System configuration

Parameter	Characteristics
Operation System details	Ubuntu 20.0.4
Memory	8.00 GB
Processor	Intel(R) Core (TM) i7-4510U CPU @ 2.00GHz 2.60 GHz

Fig. 2 presents a path constructed by Alg1 algorithm in the convex environment. Due to the environment's simplicity, a path of Alg2 algorithm was almost identical. Fig. 3 and Fig. 4 demonstrate paths with the same *S, T* locations that were constructed in the maze environment by Alg1 and Alg2 respectively. In this particular case Alg2 outperformed Alg1; it is wrong to state that Alg2 always outperforms Alg1 in every case as a result depends on the *S, T* and the environment selection.
Fig. 2. A path of Alg1 in the convex environment is shown by white lines. The arrows depict the direction of motion, the red star marks the target.

5. Conclusions

The paper presented the implementation of Alg1 and Alg2 algorithms in Python programming language for Turtlebot3 Burger robot model using ROS Noetic. The conducted tests successfully validated the implemented algorithms in the simple convex environment and in the maze. A number of difficulties that were encountered while implementing the algorithms are discussed.

Abstract

Local navigation algorithms are crucial for autonomous robots operating in unknown environments where a presence of obstacles and dynamic changes pose significant challenges. A focus of these algorithms is to enable a real-time path calculation, allowing a robot to adapt its states dynamically based on corresponding environmental conditions, despite an absence of prior knowledge about surroundings. This paper presents an implementation of the VisBug-21 and VisBug-22 algorithms, designed to address challenges of a local navigation. The algorithms were implemented for a differential drive robot Turtlebot3 Burger using Robot Operation System (ROS). Virtual experiments were performed in the Gazebo simulator employing a simple 3D environment that contained only convex obstacles and a small 3D maze.

Keywords: Path-Planning, Mobile Robots, Local Navigation, VisBug-21, VisBug-22, Gazebo, ROS Noetic

1. Introduction

Robotics researchers face a significant challenge when it comes to efficient navigation [1]. A current focus in robot motion planning concentrates around two different models, each based on distinct assumptions about available data for planning [2]. The first model, known as a path planning with complete information or the *piano movers problem*, assumes perfect knowledge about a robot and obstacles [3]. This paper is concerned with the second model, which is a path planning with incomplete information [4]. In this model, some degree of uncertainty exists, and missing data are obtained from local sources, e.g., laser range finders or cameras. One advantage of this model is the ability to incorporate sensory feedback, transforming a motion planning into a continuous dynamic process. It also eliminates a need for an analytic representation of obstacle boundaries [5]. A key issue in the motion planning with incomplete information is how to integrate sensory data into a planning function [6], [7].

This paper describes how to implement two mathematically described algorithms that can guide a mobile robot through complex environments with various obstacles, using basic distance data provided by a range finder or stereo vision. To achieve this goal, a simplified model of a vision sensor [8] is proposed, which functions similarly to a rangefinder, providing the robot with coordinates of obstacles' boundaries within a limited radius of its visibility [9].

2. Algorithms' overview

BUG family of algorithms provides efficient and effective ways for robots to navigate through populated with obstacles environments and reach their target locations [10]. These algorithms are widely used in robotics research and are valuable tools for path planning and navigation applications. VisBug-21 and VisBug-22 algorithms are an enhanced version of the basic BUG algorithm [8], which allow the robot making more informed decisions by introducing a vision control.

2.1. *VisBUG-21*

Incorporating vision into Bug2 algorithm is to mentally reconstruct a segment of Bug2 path visible to the robot at each step [11]. Using this reconstructed path, the robot identifies a farthest point and moves directly towards it. It is important to note that a segment continuity is a crucial factor in this process, rather than remembering the entire segment itself [12], [13]. The algorithm is comprised of two key components: a main body that plans a motion along a path responsible for generating the

Viktoria Mirzoian, Maksim Mustafin, Evgeni Magid

next intermediate target T_{i+1}, and a procedure "Compute T_{i+1}" that tests its reachability [8]. Typically, the main body only operates in step S1, but step S2 is executed when the robot is navigating a (locally) convex boundary of an obstacle, preventing it from utilizing its vision to define next intermediate target T_{i+1}.

Main body:

1. Move towards current target T_i, execute "Compute T_i-21" and check:
   a. If start point C = target point T, stop the procedure.
   b. If T is unreachable, stop the procedure.
   c. If C = T_i, go to step 2.
2. Move along the obstacle boundary, execute "Compute T_i-21" and check:
   a. If C = T, stop the procedure.
   b. If T is unreachable, stop the procedure.
   c. If C $\neq$ T_i, go to step 1.

Procedure Compute Ti-21 builds a path that BUG2 algorithm would build, and then selects a farthest point on a section of a path that it sees. This point becomes a next current target.

2.2. *VisBug-22*

It is possible to create a different method, similar to BUG2 mechanism but with a more opportunistic approach compared to VisBug-21. Instead of strictly following a BUG2 path, the robot can deviate from it if it spots more promising opportunities, while still ensuring a convergence. This alternative process is referred to as VisBug-22. A design of this algorithm bears a strong resemblance to VisBug-21 algorithm, albeit with one notable difference - the robot no longer prioritizes making sure that all intermediate targets T_j are located on the BUG2 path [11]. Instead, it strives to select intermediate targets that are as close as possible to the target T while still being on the same line. This leads to a distinct convergence mechanism and a behavior that sets it apart from VisBug-21 algorithm. The algorithm is made up of two parts: a main body, which is the same as the main body of VisBug-21, and a procedure named «Compute T_i-22». This procedure calculates a next intermediate target T based on a current position C of the robot and also checks if the target can be reached.
Fig.1. Turtlebot3 Burger in the Gazebo environment

Procedure Compute T_i-22 keeps identifying points along the BUG2 path or a quasi- BUG2 path segment, until a better point (in terms of its proximity to T), S', is identified on the line Start-Target. Then S' becomes the starting point of another quasi- BUG2 path segment, and the process repeats. As a result, unlike algorithms Bug2 and VisBug-21, where each defined hit point has its matching leave point, in VisBug-22 no such matching necessarily occurs.

3. Configuration

An environment configuration consists of Robot Operation System (ROS), Gazebo, and the TurtleBot. ROS was chosen due to its modular framework that allows developers breaking down complex algorithms into smaller, reusable software components known as nodes. This modularity enables easier development, testing, and maintenance of robot motion algorithms [14]. Additionally, ROS provides a wide range of sensor drivers and libraries that make it easier to integrate different sensors into a robot's system. This allows robots gathering data from various sources, such as cameras, LiDAR, or depth sensors, which is crucial for navigating in unknown environments [15].

The benefit of using Gazebo for programming algorithms for robot movement in unknown conditions is a realistic physics simulation environment for robots [16], [17] allowing developers to test and refine their algorithms in various unknown conditions without a need for physical prototypes and without damage risks. This enables faster development and iteration cycles. Gazebo provides a highly customizable and extensible platform where developers can create virtual environments with different terrain types, lighting conditions, or weather effects to simulate distinct unknown conditions [18]. This flexibility allows for comprehensive testing and robustness evaluation of algorithms in various scenarios.
Fig. 2. Schematic representation of the search for "interesting" points

TurtleBot 3 Burger virtual model of a robot was employed for experiments in Gazebo simulator (Fig. 1) due to its simplicity that makes it accessible for users of
Fig. 3. VisBug-21 path in the map with convex pillars

all levels of expertise, including beginners [19], round shape and differential drive chassis that ease local navigation. The robot's small size allows navigating through tight spaces, making it suitable for various environments, including confined ones.

4. Implementation details

Python 3 was utilized to implement VisBug-21 and VisBug-22. The package includes two separate files containing the algorithms for VisBug-21 and VisBug-22, representing distinct processes. Additionally, the main service offers user services for point navigation, clockwise and counterclockwise wall following. To ensure the functionality of all services, the following libraries and modules were employed [20], [21]:

- *rospy*: is a Python client library specifically designed for ROS.
- *sensor_msgs* module: records laser measurements.
- *geometry_msgs* module: generates and transmitts messages pertaining to setting the robot's position and utilizing points.
- *gazebo_msgs* module: defines and configures the robot's current state.
- *nav_msgs* module: odometry use.
- *tf* module: allows angle transformations.
- *std_srv* module: involved in running ROS services.

A main difficulty in implementing the algorithm was a vision system design for the robot. The original articles [8], [11] described only a visual sensor range concept. It was decided to model the vision system using a rangefinder package of ROS. The algorithm contains a method that serves as a callback for processing laser scan messages. The purpose of this function is to extract specific ranges of data from the laser scan message and store them as global variables. It defines global variables for each range of 360 degrees around the robot, populates a range dictionary with minimum range values from specific ranges and assigns a maximal vision range value if no valid readings are available.
Fig. 4. VisBug-21 path in the maze

Another difficulty was related to a practical identification of "interesting" points that were described in [1], [2]. At the current location C of the robot (Fig. 2), the algorithm processes a grid of its sensor's vision within its radius r (an area inside the orange circle). The robot rotates 360 degrees in place and searches for interesting points (marked with blue dots) that form three groups:

- corners of obstacles (indicated as *a, b, c, d, e, f*);
- visible points of obstacles' boundaries at distance r (indicated as *i*);
- visible intersections of M-line and obstacles (*g, h*).

5. Validation

The algorithms' implementation was validated in two types of environments: a world of identical pillars of a cylindric shape and a maze. Virtual tests in Gazebo were carried out for reachable and unreachable targets. 20 (Start, Target) pairs were selected in the first environment and 25 pairs in the second. Each test was run multiple times. While most tests were successful, 9.5% of the tests failed due to situations at the boundaries of the obstacles where the robot's wheels were not considered by the sensors and thus the robot got stuck.

Table 1 presents system configuration that was used for the validation.

Table 1. System configuration

Parameter	Characteristics
Operation System details	Ubuntu 20.0.4
Memory	16.00 GB
Processor	AMD Ryzen 5 4600H with Radeon Graphics 3.00 GHz
Fig. 5. VisBug-22 path in the maze

Fig. 3 present a path constructed by VisBug-21 algorithm in the convex environment. Fig. 4 and Fig. 5 demonstrate paths with the same S, T selection in the maze environment by VisBug-21 and VisBug-22 respectively.

6. Conclusions

The paper presented the implementation of VisBug-21 and VisBug-22 algorithms in Python programming language for Turtlebot3 Burger robot model using ROS Noetic. The implementation was validated in two different environments of Gazebo simulator and demonstrated a success in 90.5% of the test cases.

Abstract

Algorithms of path-planning in an unknown environment play an important role in robotics. They do not require a prior information about obstacles' locations around a robot and allow calculating a path in a real time. This article presents an implementation of a sensory-based DistBug algorithm, which operates reactively using range data for immediate decision-making without constructing a world model. The algorithm was programmed in Python using robot operating system (ROS) and validated in the Gazebo simulator. For virtual experiments Turtlebot 3 Burger mobile robot was employed. The experiments were conducted in two types of environment: an environment with convex obstacles and a maze. The paper demonstrates analysis of experiments using several standard criteria of a path quality estimation.

Keywords: BUG algorithm, path planning, sensor-based navigation.

1. Introduction

A basic motion planning issue is to compute a path from a given starting point to a specified destination point [1]. In robotics, there are two approaches for path planning: global and local [2]. Global planning typically relies on preliminarily known data about an environment [3]. Local path planning uses measurements from sensors and knowledge of a target point [4] while the robot moves in an unknown environment avoiding obstacles [5].

The algorithms of the BUG family use only local sensory information and odometry data to control movement and address a challenge of local navigation without a need to create a comprehensive map of an environment [6]. BUG algorithms have two motion modes: moving toward a target and following a boundary of an obstacle [7]. The robot moves in a straight line towards the target until it reaches a minimum distance to an obstacle [8]. Further, the robot follows a boundary of the obstacle [9]. The algorithm uses *leaving conditions* to determine when to exit the obstacle boundary and head directly toward the target again [10]. The robot receives measurements from its sensors to detect nearby obstacles and plan a subsequent trajectory [11].

In this article, we present an implementation of the DistBug [12] algorithm using robot operating system

(ROS) [13]. The algorithm was tested in the Gazebo simulator [14]. The navigation was performed in a 3D environment for the TurtleBot 3 Burger robot model [15]. The robot measures a distance to an obstacle with a 2D LiDAR of 3.5 m range and 360 degrees field of view.

2. A brief description of the DistBug algorithm

The sensory-based DistBug algorithm was designed to reach a goal in an unknown environment or indicate that the goal is unreachable [12]. The robot does not construct a model of the world and relies on sensory data to make decisions [16]. The method consists of two behavior models, represented as movement modes: a straight-line motion towards the goal and an obstacle boundary following. A condition for leaving an obstacle is based on a free range in a goal direction when the target is on a line of sight or a distance to it gradually decreases. The algorithm utilizes sensory data with a limited range of view, and the robot moves in steps of a given size. The core concept of the algorithm is the following:

1) Moving from starting point S to target point T in a straight line:

- If T is reached, the navigation is successfully completed.

- If an obstacle is encountered, a collision point with the obstacle is determined, and the algorithm proceeds to step 2.

2) The robot follows a boundary of the obstacle, taking steps of a specified size. If the robot reaches *T*, the navigation is successfully completed. Otherwise, the robot leaves the obstacle and heads towards *T* from a point of exit, referred as a *leaving point*. The selection of the leaving point depends on achieving the following conditions:

- The robot can move towards *T* without colliding with the obstacle.
- $Free_{dist} > 0$, and ($Curr_{dist} - Free_{dist} \leq 0$ or $Curr_{dist} - Free_{dist} \leq Best_{dist}$), where $Free_{dist}$ is a distance within the line of sight from a current location to a nearest obstacle in a direction of *T*, $Curr_{dist}$ is a distance from the current location to *T*, and $Best_{dist}$ is a difference between the distance from the collision point with the obstacle to *T* and the step size.

3) If the robot cannot find a leaving point or it returns to a position it was at a previous step, then *T* is unreachable.

3. System setup

The algorithm was implemented in Noetic Ninjemys version of ROS. The algorithm uses ROS topics to obtain measurements from sensors and wheel odometry [17], and to control the robot. Messages are transmitted using standard types predefined in ROS: *sensor_msgs:: PointCloud*, *geometry_msgs::Twist*, *nav_msgs::Odometry*, and *geometry_msgs::Point*.

The algorithm was tested in the ROS-compatible Gazebo 11 simulator [18]. The Gazebo simulator creates realistic environments that allow conducting experiments with virtual robot models. The robot can be equipped with any of the standard sensors, and Gazebo has a support for third-party plug-ins. The Robot Visualization tool (RViz, [19]) is used to visualize a robot's position, measurements from sensors, and a path trajectory. The tool allows setting a target point as a 2D Nav Goal. A message is sent to an appropriate topic and accepted by a local planner.

The TurtleBot3 robot model (Fig. 1) with an open-source software was selected. The TurtleBot3 Burger [20] model was used, which has necessary sensors for navigating an environment under DistBug protocol. The robot's design allows making a transition from a 3D configuration space to a 2D one, which simplifies a path calculation [21].

4. Implementation details

DistBug algorithm was implemented in Python programming language, version 3.7. The implementation relies on ROS libraries and modules, including *rospy* (a Python client library for ROS), *geometry_msgs* (contains a type of messages for exchanging a position of the robot), *sensor_msgs* (contains types of laser measurement messages and motion commands), *gazebo_msgs* (contains types that determine a robot state), *tf* (manages transformations between coordinate systems), *nav_msgs* (contains the odometry data type), *std_srv* (contains packages for creating services in ROS) [22].

Fig. 1. Turtlebot3 Burger model in the Gazebo.

The algorithm's implementation contains three nodes. The first and second nodes regulate a robot motion directly to the target and the clockwise wall following motion, respectively. Each node implements a ROS server to activate and deactivate the mode. The third node launches a certain mode via a request to a corresponding server. The server choice depends on measurements received from the laser rangefinder. If the rangefinder indicates an occupied space ahead of the robot while the robot is moving towards the target, the robot changes the motion mode. Similarly, if a space in a direction of the target is free while the robot is moving along an obstacle boundary, the robot switches the mode. When the stop condition occurs, the algorithm turns off all nodes. To evaluate a performance the algorithm logs its operation time, all trajectory points (to calculate a path length), and a number of encountered obstacles during a path search.

To configure the algorithm, the following parameters were introduced: a timeout, a stopping threshold, a range of the rangefinder (i.e., radius of the robot's vision), and a robot's step size. The stopping threshold was empirically defined to determine a point where the robot stops when a certain coordinate value is reached. The timeout allows avoiding robot's stuck cases: despite a static environment, in some cases the TurtleBot 3 robot can get stuck at an obstacle boundary if one of its wheel touches an outer corner of the obstacle. This occurs due

to a rangefinder's placement that may cause a misregistration of occupied cells of the environment as free cells. If the robot gets stuck, a timer is activated and after the timeout expires, the algorithm stops with an error message. The rangefinder range and the step size are user provided parameters. The range should be less than the step size. A small step size causes a better precision of a computed path with regard to a theoretical path of an infinitely smell step and affects how often the obstacle detour check is be performed. With a large step size a robot may miss the target. The rangefinder measurements were divided into sectors by their direction. The value of a sector was determined by a minimum distance to an obstacle in the range.

5. Validation

To evaluate the implementation, tests were conducted in two types of environment: an environment with convex 3D obstacles of a cylindrical shape and a maze. The tests included reachable and unreachable goals. In the latter case the algorithm returned an error after reaching the stop state. The test results were recorded into a file that contained tracked metrics for each (start S, target T) pair.
Fig. 2. A path of the DistBug in the simple map. The green star marks the start, the red star is the target.

We made 20 selection of (S,T) for the simple map (Fig. 2) and 15 pairs for the maze (Fig. 3). For each pair a number of runs was performed and they demonstrated approximately 97% success. The failures were cause by the problem mentioned in Section 4. Fig. 2 and Fig. 3 present the resulted paths of the robot using DistBug in the simple map and in the maze respectively. The virtual experiments were conducted using a PC with Ubuntu 20.0.4(LTS) operation system, 6.00 GB memory and AMD Ryzen 5 5500U processor with 2.10 GHz Radeon Graphics. While the environments for testing were constructed manually, a part of our ongoing work is to test the algorithm in automatically constructed environments for Gazebo, e.g., [23], [24], [25].
Fig. 3. A path of the DistBug in the maze

6. Conclusions

The paper presented an implementation of DistBug algorithm in the ROS Noetic environment. The evaluation was performed in two different types of environment and with a set of different target points. After reaching the stop condition, the control node logged the metrics, which included a flag of arrival to the target, a trajectory of the robot, a total time of the algorithm execution, and a number of encountered on the way obstacles. The tests demonstrated 97% of success. The implemented method can be adapted for other robot models and environments by empirically adjusting the timeout and the stopping threshold, while setting corresponding to the robot sensor range and the step size.

Abstract

Sensor modeling in the Gazebo simulator is fundamental to robotics advancement. This review explores sensor modeling intricacies, methodologies, and applications, while emphasizing a critical role of a precise sensor modeling. Application scenarios demonstrate a sensor modeling's broad utility across fields including medical diagnostics, autonomous navigation, and industrial automation. Differences in research focus, methodology, and implementation underline a varied nature of sensor modeling studies. Key challenges include a need for more detailed world models. The paper guides a research in sensor modeling and identifies crucial questions.

Keywords: Overview, Gazebo, Sensor modeling, Sensor simulation.

1. Introduction

In contemporary robotics and autonomous systems, simulation plays an important role [1]. It offers researchers and engineers the means to create and test robots in virtual environments, reducing costs and ensuring safety during the development of robotic systems [2]. However, for simulations to produce realistic results, precise modeling of sensors, such as cameras, lidars, infrared, and ultrasonic sensors, is paramount. These sensors are instrumental in perceiving the robot's surroundings and interacting with them. Accurate sensor models in simulators have become fundamental for the successful development and testing of perception, navigation, and control algorithms for robots.

In this review article, we delve into a significant issue within the realm of robotic simulation, focusing on sensor modeling in the Gazebo simulator [3]. Among robotic simulators, Gazebo stands out for its powerful functionality and flexibility. It allows for the creation of complex 3D robot models and their environments, along with the simulation of a wide range of sensors [4].

The objective of our article is to provide readers with an overview of contemporary methodologies and approaches to sensor modeling within the Gazebo simulator. We will explore the challenges researchers address in this domain, the methods employed for precise sensor modeling, and the profound impact these models have on the development of robotic systems. Moreover, we will discuss the primary challenges researchers encounter and outline potential directions for future research in this rapidly evolving field.

2. Methodologies

The choice of a specific method and methodology for modeling sensors in the Gazebo simulator depends on several key factors. Initially, this is the type of sensor that is required to simulate, since different sensors have different characteristics and requirements. For example, the modeling of the camera requires accounting for optical parameters [5], while the modeling of the ultrasonic sensor can be based on acoustic properties [6]. The objectives of the study also play an important role in choosing a methodology. If the main goal is to assess the accuracy of the sensor, then the methods focused on comparison with real dimensions can be the most suitable [7]. If the goal is to develop and test new algorithms for processing data from the sensor, then modeling taking into account noise and distortion can be more relevant [8]. The level of detail also plays a key role. Highly detailed models of sensors may require large

computing resources and time for simulation, while simplified models can be less accurate, but more effective in terms of computing resources [9].

Some of the common methodologies include: Physical modeling, including taking into account the physical properties of the sensor and its interaction with the environment [10]. Methods of machine learning that allow training sensors based on real data and apply it in simulations [11]. Geometric modeling, focused on the exact reconstruction of the geometry of the environment and objects with which the sensor interacts [12]. Statistical modeling methods: include statistical approaches to take into account various sources of noise and uncertainty in the measurements of sensors [13]. This may include methods for filtering, smoothing and assessing the state that allow you to take into account the statistical characteristics of measurements.

Table 1 provides an overview of recent and noteworthy publications related to sensor modeling within the Gazebo simulator. This table showcases articles that have leveraged Gazebo for simulating sensors, highlighting the various contexts and applications where these models have been employed.

3. Common aspects

One of the key tasks of research involving sensor modeling is to evaluate and analyze the accuracy of various sensors, such as cameras, lidars, ultrasonic and infrared sensors, in a virtual environment. This allows researchers to understand how the sensors interact with the environment and how accurate the data they provide [5], [6].

Research in this area often involves the creation and testing of data processing algorithms for sensors. These algorithms may include computer vision methods, image processing, machine learning, and other techniques used to analyze data collected from sensors [14].

Gazebo's sensor modeling research aims to create virtual scenarios that are as close to real-world conditions as possible. Researchers strive to accurately model the objects with which sensors interact and whose condition can affect the simulated sensor readings [6], [15].

Researchers often use sensor simulations to validate the algorithms of their robots. This allows them to test the validity of their designs under different conditions. Research may also involve integrating sensor modeling into real robotic platforms. This helps researchers adapt the results of their work for use in actual robots [15], [16].

In summary, research related to sensor modeling in the Gazebo simulator aims to improve the understanding of sensor behavior in robotics systems, develop efficient data processing algorithms, and create realistic simulation environments for testing and training in the field of autonomous systems and robotics.

4. Distinctions

Each scientific paper can focus on different aspects of sensor modeling. For instance, one paper may investigate camera modeling for robot navigation [17], while another may emphasize lidar sensors for obstacle detection [16]. Consequently, the research topic can substantially differ.

Researchers can use various methods and techniques for sensor modeling. For example, some may develop their own sensor models [18], [19], while others might utilize standard tools and libraries available in Gazebo [20]. This can impact the accuracy of modeling and the scope of the results.

Studies may also differ in terms of research objectives. Some papers may aim to optimize sensor performance [21], while others seek to develop new data processing algorithms or assess sensor reliability in various scenarios [22].

Different studies may be oriented toward various types of robotic systems. For example, research may target mobile robots, autonomous vehicles [23], robot manipulators [6], [24], or drones [25], and each of these system types may have unique characteristics in sensor modeling.

Scientific papers can be directed toward diverse applications of sensor modeling, such as medical diagnostics [26], autonomous navigation [17], [27], and more.

These differences in research themes, methods, and objectives make each scientific paper unique and specialized. Collectively, they contribute to the advancement of sensor modeling in the Gazebo simulator, providing new knowledge and tools for developers and researchers in the field of robotics.

5. Application scenarios

Modeling sensors in the Gazebo simulator finds applications in various fields of robotics and autonomous systems.

One of the key applications of sensor modeling in Gazebo is the development and testing of autonomous transportation systems, such as self-driving cars [30]. Virtual simulations enable engineers to assess navigation and control algorithms under diverse conditions, ensuring safety before these vehicles hit the roads.

Table 1. Relevant publications in Gazebo sensors simulation.

Sensor modeling context	Sensor type	Application	Reference
A software package for ultrasound sensor modeling in the Gazebo simulator	Ultrasound sensor	Medical Robotics	[6]
Incorporating sensors into the model	LRF, IMU sensor, cameras	USAR, AMR	[15]
Incorporating sensors into the model	LIDAR, IMU, GPS/GLONASS, Side sonars	Autonomous Vehicles	[23]
It is explained how to incorporate sensors into models in Gazebo	LRF, IMU sensor, cameras	Robotics Education, AMR	[28]
Shows physical integration of the main types of sensors in UAV domain both for navigation and collision avoidance	LIDAR, sonar, radar, video	Autonomous Vehicles, UAV	[16]
Automatic tool allows creating realistic landscapes in Gazebo simulation based on results of real world sensor-based exploration	LIDAR, RGBD-camera	UAV, UGV	[12]
The simulated tactile sensor can produce high-resolution images from depth-maps captured by a simulated optical sensor	GelSight tactile sensor	Tactile Sensing Visualization	[18]
Simulating the operation of LIDAR sensors in real-time, considering LASER beam propagation and attenuation of LASER energy in adverse weather conditions such as fog and rain	LIDAR	Automotive	[7]
An algorithm for detection of obstacles and lines was implemented for the IR sensors	IR	Robotics Education	[20]
The scalability investigation of LIDAR-type sensor simulation in ROS-supported Gazebo	LIDAR	AMR	[29]
Evaluate a variety of visual and LiDAR SLAM algorithms in a simulated environment	LIDAR, RGB-D-camera	Mobile Robots	[21]
Simulation of the RFID readers-antennas mounted on robots reading RFID tags in the environment	RFID	UAV	[19]
A method to simulate the ARVA transceiver	ARVA	Search And Rescue, UAV	[10]
Test the control-level and sensor-level algorithms in simulation environment	LIDAR	UAV	[25]

In the medical domain, Gazebo's sensor modeling capabilities can be used to create virtual training environments [31]. These environments allow medical professionals to practice operating medical robots and other devices [6]. Additionally, it is beneficial for research in the field of medical robotics, including surgical robots and rehabilitation devices.

Gazebo is frequently used in the educational field to teach students and researchers the fundamentals of robotics [28]. Sensor modeling permits students to experiment with various sensor types and data processing algorithms, enhancing their understanding of robotics principles.

Sensor modeling in Gazebo is invaluable for simulating complex urban search and rescue (USAR) scenarios [15]. It allows researchers and first responders to test various robotic systems that can navigate disaster-stricken areas, locate survivors, and assess structural damage, all while avoiding risks to human life.

These applications showcase the versatility of sensor modeling in the Gazebo simulator. They represent only a fraction of the possibilities offered by sensor modeling, with its utility extending to various challenges and

objectives in the realms of robotics and autonomous systems.

6. Main challenges and future directions

While sensor modeling in the Gazebo simulator has seen remarkable advancements, several challenges persist, and promising future directions are emerging. Here, we outline some of the key challenges and areas of potential growth.

Many studies have identified the need for further refinement of the world models used in simulations [6], [15]. Realism of sensor simulations often depends on the complexity of the environment being simulated. Future research may focus on enhancing world models to better mimic real-world scenarios, including factors like lighting, weather, and dynamic objects.

Some articles focused on the complexity of sensory synthesis [32]. As robotic systems become more sophisticated, sensor fusion, the integration of data from multiple sensors, poses a growing challenge. Future developments may revolve around creating more

advanced sensor fusion models to handle the increasing complexity of robotic applications.

Balancing realism and computational efficiency remains a fundamental challenge. Simulations with high levels of detail can be computationally intensive, limiting real-time performance [29], [33]. Researchers may explore novel techniques to achieve a harmonious balance between realism and efficiency.

Leveraging AI and machine learning for sensor modeling is a burgeoning area [34]. Future research may delve into integrating AI techniques for sensor data interpretation, enabling robots to learn from simulated sensor inputs.

As robots increasingly interact with humans, modeling sensors for human-awareness becomes vital. Future work may focus on simulating sensors that enable robots to perceive and respond to human actions and intentions.

With the rise of autonomy in robotics, future directions include the development of sensor models that support high-level decision-making in autonomous systems.

In summary, sensor modeling in Gazebo continues to evolve, aiming for realism, efficiency, and applicability. Addressing these challenges and exploring these future directions will contribute to the continued growth of robotics and autonomous systems.

7. Conclusion

In conclusion, this review article has explored the intricate world of sensor modeling within the Gazebo simulator. We've delved into the aspects of sensor modeling, discussed current research directions, and identified key research questions in this evolving field. Through an examination of various methodologies, application scenarios, and the distinctiveness of each research endeavor, we've gained a comprehensive understanding of how sensor modeling contributes to the advancement of robotic systems. As the field of robotics continues to expand, the importance of accurately modeling sensors in virtual environments has become increasingly clear. This review serves as a foundational resource for further research and innovations in the domain of sensor modeling within the Gazebo simulator.

Abstract

Visual sensors play an important role in a broad variety of robotic systems applications. Even though Kinect technology appeared over 10 years ago, Kinect sensors are still actively employed by researchers around the world. This paper presents an overview of Kinect and Kinect 2 sensors' applications in a human gesture based control. We analyzed existing research papers to estimate a popularity of particular feature extraction and gesture recognition methods, recommendations on a distance between an object of interest and a sensor, reported accuracy and latency of the sensor. Our analysis is supposed to facilitate a selection of a suitable combination of methods for a particular application of Kinect sensor in gesture recognition while considering its performance.

Keywords: Microsoft Kinect, robotics, gesture control, gesture recognition.

1. Introduction

Robotics has achieved a significant progress, enabling robots to autonomously plan routes [1] and interact with humans in medicine [2], education [3], and rescue operations [4]. Controlling robots with a voice and gestures is the most natural way of interaction [5] due to daily habits of using these methods by humans. Control using gestures can be implemented with vision sensors [6], electromyography methods (that track human muscle contractions [7]), employing a touch screen, an accelerometer or other sensors [8]. This paper overviews gesture control implementations in robotics using Kinect sensor. Kinect is originally a Microsoft motion controller for gaming that uses computer vision methods for a gesture based control. Later Microsoft enabled a custom application development with Software Development Kit for Windows [9]. This study summarize information about Microsoft Kinect use in robotics, compares accuracy of different gesture recognition methods and emphasizes a reported latency of Kinect in various tasks.

2. Kinect in Robotics

Kinect sensor (Fig. 1a) is a device introduced by Microsoft in 2010 for XBOX 360 gaming console control. A combination of an infrared sensor and RBG-D camera makes Kinect suitable for human body tracking purposes. Software Development Kit [10] allows developing a custom software for a variety of tasks including gesture based robot control. The introduced by Microsoft in 2013 Kinect v2 was (Fig. 1b) a second generation of Kinect device that also combines RGB-D and infrared sensors. Similar to its predecessor, Kinect v2 is intended for a gesture-based control. However, due to technical improvements such as adding a wide angle time of flight (ToF) camera [11] and upscaling a color camera resolution to 1080p [12], it exhibits a better performance compared to the first generation, which is demonstrated in Section 4.

a. Kinect

b. Kinect v2

Fig. 1. Microsoft Kinect first generation and Kinect v2.

Kinect and Kinect v2 capture color and depth data of a scene and are broadly used in computer vision for object recognition including gesture recognition. The distinctive feature of Kinect family is its versatility compared to counterpart sensors. Leap Motion Controller is also used in robotics for gesture-based robot control [13], [14]. Yet, this device is designed to recognize only hand movements, whereas Kinect does not have such limitations and can be employed for a full-body gesture recognition [15] and a face tracking [16]. In addition, Kinect v2 contains an embedded microphone that enables a voice control [17], which can augment a gesture-based control. Leap Motion Controllers could be used in pairs, e.g., to recognize each hand separately [18], which may increase the system's load. Similarly, Kinect sensors can form complicated systems for tracking and motion capture system purposes [19], [20]. However, in some cases Kinect sensor may not be a right solution, e.g., authors in [21] complained that Kinect is not compatible with Linux systems as Kinect's Software Development Kit has only Windows OS support. To solve this issue, the researchers employed Asus Xtion Pro Live with an RGB-D camera similar to Kinect.

In robotics, Kinect could be used to control different types of real robots. In [17] authors presented a Kinect-based industrial robot control and demonstrated that Kinect could be successfully integrated into simulators. In [22] Kinect was applied for a remote control of a mechanical arm that replicates operator-defined gestures. A gesture-based control using Kinect could also be implemented in mobile robotics, where Kinect serves as a robot control panel [23].

3. Gesture Recognition Methods

Choosing a gesture recognition method for Kinect based control is important, as it directly affects an overall system performance. If a gesture recognition method is not accurate enough, not suitable for a particular task or

a recognition system demonstrates significant delays, a different method of control should be considered. In this section, we summarize information about methods of Kinect based control and emphasize their accuracy.

Table 1 presents an analysis of studies that used various combinations of feature extraction and gesture recognition methods. The first column of the table describes a particular task; the second column *Dist* specifies a recommended optimal distance between an object of interest (gesture producer) and a sensor in meters; the third and the forth – a feature extraction *FEM* and a gesture recognition methods *GRM*, respectively. The fifth column *Acc* shows an accuracy of each approach in percents (as reported by its authors); the sixth *Skeleton* emphasizes if an approach employs a skeleton extraction; the last one *Rf* refers to a corresponding paper. N/A in the table denotes that a paper does not contain corresponding data.

As Table 1 shows, a combination of the Histogram of Oriented Gradients (HOG) for feature extraction and Support Vector Machine (SVM) for gesture recognition ([24], [33]) is a popular approach among researchers. The same combination was used at an earlier stage of [26] research, however, a deep learning AlexNet model eventually was chosen due to a better performance. In [31] the authors emphasized an influence of a distance at which gestures were recognized by Kinect on a recognition accuracy. The highest accuracy of 87% was achieved at a distance of 3 meters from the Kinect, while the lowest accuracy of gesture recognition of 25% was obtained at a distance of 5 meters from the sensor. The importance of a classifier selection when controlling a robot with user-defined gestures was confirmed in [23], where the SURF and FLANN methods were employed, to extract arbitrary points from an image and to recognize gestures. During the experiments, it was discovered that the FLANN library failed to achieve required results in recognizing gestures as it could not match corresponding features in a variety of gestures.

Majority of studies in Table 1 used a method of a skeleton construction, where a skeleton consists of joints of a human body or hands only. This approach allows a more accurate extraction of special points, which are further required for a gesture recognition. An alternative approach built a 3D model of a hand [34]; yet the authors did not provide accuracy indicators for the gesture recognition, and thus a usability of the method for a real gesture recognition system is questionable.

4. Kinect Latency

Latency has a significant importance when operating technical devices. Latency can be caused by hardware

Table 1. Gesture Recognition Methods

Task	Dist, m	FEM	GRM	Acc, %	Skeleton	Rf
Static hand gesture recognition	N/A	Histogram of Oriented Gradients	Support Vector Machine	98.3	No	[24]
Hand gesture recognition	1.2–3.5	Skeleton Extraction	Artificial Neural Network	97.8	Yes	[25]
Touchless visualization of 3D medical images	2.5-3.5	Histogram of Oriented Gradients	AlexNet (CNN)	96.5	No	[26]
Hand gesture recognition	N/A	MediaPipe Palm Detector	MediaPipe Gesture Recognition	95.7	Yes	[27]
Sign language recognition for Arabic speakers	N/A	Used (not specified which one)	RandomForest Classifier + Ada-Boosting	93.7	Yes	[28]
Dynamic hand gesture recognition	N/A	N/A	Dynamic Time Warping	92	Kinect embedded	[29]
Full body gesture recognition	N/A	CNN	Fast Dynamic Time Warping + CNN	90.8	Yes	[30]
Smart home control	3 m	Self-developed	Self-developed	87	Yes	[31]
Sign language recognition	N/A	Histogram of Oriented Gradients	Dynamic Time Warping	86	Yes	[32]
Hand gesture recognition	2.5-3 m	Histogram of Oriented Gradients	Dynamic Time Warping	76.7	Yes	[33]

and software factors. Moreover, a task-dependent software delay sums up with a hardware delay, which leads to a decrease in device performance. This section discusses a latency between a user input and an expected system output, which differ for a particular task.

Table 2. Latency Measurements of Kinect

Task	Latency, ms	Ref
Kinect		
Skeleton detection	106-500	[35]
Human fall incident detection	300	[36]
Contactless hand tracking for surgical robot	89-576	[37]
Skeleton position estimation	100	[38]
Skeleton detection	200-400	[39]
Kinect v2		
Human gait analysis	29-127	[40]
Human gait analysis	200	[41]
Skeleton detection	66-100	[42]
IRB4400 industrial robot control	20 (only a hardware latency)	[43]
Rat behavior tracking	80-126	[44]
3D content capture	65-67	[45]

Table 2 presents ab information about latency measurements of both generations of Kinect devices employed in various tasks. Note that reference papers of Table 1 and Table 2 are different since Table 1 papers did not specify a latency as they considered a different aspect of Kinect usage.

In [41] authors emphasized a 20 ms hardware latency as a minimum latency level of the device itself, which cannot be reduced. While official manufacture stated latency data for the first generation of Kinect is not available, the study [36] reports the latency value of 100 ms. Based on the surveyed in Table 2 papers we concluded that the average latency for the first generation Kinect is 267 ms, while the average latency for Kinect v2 is 123 ms. However, even though the Kinect v2's average latency significantly improved over the first generation, its effectiveness still depends on a specific task in which it is used and could achieve up to 200 ms.

5. Conclusions

This paper presents an overview of Microsoft Kinect sensor applications for gesture based control in robotics. Kinect first generation and Kinect v2 related research papers were analyzed in terms of range and accuracy in a number of typical tasks that require a sensor with RBG-D capabilities. Based on the survey we concluded that the average overall latency of the first generation Kinect is 267 ms, while the average latency for Kinect v2 is 123 ms. However, even though the Kinect v2's average latency has improved over the first generation, its effectiveness naturally depends on a specific task and could achieve up to 200 ms.

Abstract

The purpose of this research is to investigate how an interaction between humans and robots influences a safety of an autonomous obstacle avoidance task. The research collected and analyzed data from surveys and interviews using a combination of quantitative and qualitative methodologies. The findings contributed to our understanding of a complex interplay between a human-robot interaction, a perception, and a robot navigation safety. Based on these findings, the study proposed a number of recommendations for improving both physical and psychological safety aspects of an autonomous robot navigation.

Keywords: Human-robot interaction, HRI, autonomous obstacle avoidance, navigation safety

1. Introduction

Autonomous robots are becoming an integral part of diverse human environments due to the advancements of robotic technologies from personal healthcare [1] to automated manufacturing fields [2], [3]. The progression is expected to lead to a future in which both humans and robots coexist and interact on a regular basis [4], [5]. However, the integration of autonomous robots into human environments is not without significant challenges, particularly when it comes to ensure safety during autonomous obstacle avoidance tasks [6], [7]. Autonomous obstacle avoidance [8] and human following [9] is a critical feature for any autonomous robot operating in a human-populated environment [10]. It is a capability that allows a robot to navigate through an environment avoiding static and dynamic obstacles, including humans. A robot which can precisely avoid obstacles is considered safe [11]. Understanding and addressing various aspects of safety require a comprehensive exploration of the relationship between humans and robots [12], [13]. This involves indulging

into the complex dynamics of human-robot interaction (HRI), which encompasses the objective behavior of the robot, subjective experiences and perceptions of the human [14], [15].

The objective of this research is to provide an in-depth examination of the relationship between humans and robots, focusing on its impact on the safety of autonomous obstacle avoidance. Specifically, the research will investigate how humans interact with robots that are capable of autonomous navigation. The investigation will contribute to a deeper understanding of this critical aspect of autonomous robotics, providing insights that could help improve the design and operation of future autonomous robots. It will also address gaps in the existing body of knowledge, particularly in the intersection of autonomous navigation, HRI, and perceived safety [16]. Surveys and interviews were conducted in a group of people, who had experience with robotic environments. The inferences obtained through these surveys and interviews were used to conclude about the current status of HRI in various fields [17].

2. Methodology

The methodology outlines the research approaches that were utilized to investigate the relationship between HRI and the safety of autonomous obstacle avoidance. The research began with a comprehensive review of existing literature from databases, journals, and conference proceedings related to HRI, robotic safety, and autonomous obstacle avoidance. Following the comprehensive literature review, the research focused on the development of an experimental setup, which consisted of a robot equipped with a capacity for autonomous navigation and obstacle avoidance. A restaurant delivering food to customers using a mobile robot (shown in Fig. 1(a) was selected for the survey. The robot can move to assigned tables and deliver food as shown in Fig. 1(b).
Fig. 1 Robot navigation (a) A food delivery robot (b) The robot delivering food to customers

The robot avoided collision with static and dynamic obstacles using IR sensors fixed on the base of the robot. Fig. 2 depicts the stages of a food delivery using the mobile robot. Fig. 2 represents the robot waiting for the food delivery near the restaurant kitchen. Fig. 2(a) and (b) represent a motion of the robot towards the assigned table and destination table respectively. A customer receiving the food items are shown in Fig. 2(d).

To obtain a human-centered perspective on the safety and comfort of autonomous robots, surveys and semi-structured interviews were conducted with individuals who had interacted with the robot. Questions were designed to explore various phases of human-robot interaction, including social acceptability, perceived safety, and trust in the robot's autonomous decision-making capabilities. The customers and employees working in the restaurant were participated in the survey. The gathered data were subjected to rigorous analyses using suitable statistical techniques. This critical process of data analysis allowed the transformation of raw data into meaningful information, thereby offering both quantitative and qualitative insights into the correlation between HRI and the safety of autonomous obstacle avoidance.

Fig. 2 Different phases of the robot work: (a) Robot waiting for collecting food items (b) Moving to towards a destination table (c) Robot reached the destination table (d) A customer taking the food item from the robot

The final step in the methodology involved the validation of the findings. This was done through peer-reviews and expert consultations, ensuring the research conclusions were robust, reliable, and could stand up to scrutiny. This step served as a quality check and ensured that the research had been conducted in a methodologically sound manner. Further, it also provided an opportunity for receiving recommendations for future studies, thereby adding to the overall value and impact of the research. This methodological approach aimed to provide a comprehensive, multi-dimensional understanding of the research topic, combining the strengths of both empirical and qualitative research methods.

3. Results/findings

In this section, we present and analyze the results gathered from our research and the insights obtained from the HRI studies. we conducted surveys and interviews with participants after they observed or interacted with the robot. A total of 60 participants attended the survey and expressed their opinions and suggestions regarding the coexisting of humans and robots inside a restaurant environment. The qualitative data suggested a generally positive perception of safety, comfort, and trust in the robot's autonomous capabilities. Approximately 90% of the participants reported that they felt safe with the robot's movements and obstacle avoidance capabilities. Interestingly, a correlation was observed between the

robot's behavior and participant responses. Smoother and slower robot movements were associated with increased comfort and trust ratings from the participants. About 80% of the participants conveyed that the robot food delivery was faster compared to human food delivery services. However, some of the participants are concerned about the precision of delivery and quoted about interaction difficulties they faced during food order updating.

The perception of risk and social acceptability associated with the autonomous robot were also included in the survey. We interpreted that in a populated environment, participants perceived the robot as less risky compared to a controlled environment, contrary to our expectations. This might be attributed to the social dynamics of a populated setting, where humans provide an additional layer of unpredictability that makes the robot's autonomous capabilities more evident and appreciated. The social acceptability of the robot was rated highly by 82% of participants, signifying the successful integration of social robotics principles in its design and operation. However, 27% of the customers preferred contactless delivery. 70% of the participants considered robot usage inside a restaurant as an eco-friendly option. 20% of the participants chose human workers in place of autonomous rover delivery due to safety concerns. Most participants concerned about the robot malfunctioning, and navigational errors.

4. Discussion

The study was designed to investigate the relationship between HRI and the safety of autonomous obstacle avoidance, contributing to the growing body of knowledge in this field. The multi-dimensional methodological approach, combining both empirical and qualitative research methods, was integral in producing a comprehensive understanding of the research topic. The survey results regarding autonomous navigation and obstacle avoidance revealed that the robot was successful in navigating the environments and avoiding obstacles with a high success rate.

Results from the HRI revealed a generally positive perception of the robot's autonomous abilities, showing trust in the robot's decision-making and overall satisfaction with their interaction. These findings provided valuable insights into the subjective aspects of robot safety, complementing the quantitative data obtained. Risk perception and social acceptability were also significant factors in our study. Results suggested that participants perceived the autonomous robot as safe and socially acceptable, even in densely populated environments.

When performing HRI activities, robots must be equipped with adaptive abilities to prevent accidents and task incompletions. There are a lot of static and dynamic obstacles present in a restaurant setting. In order to prevent collisions when moving from the food pickup location to the destination table, the robot needs to be employed with an effective collision avoidance approach. By utilizing proper sensors and controllers, the robot can steer clear of obstructions and prevent crashes during the motions. Reserving separate paths for robots can minimize chances of collisions with obstacles. To help users comprehend how the robot is moving, the robot can also show path details on a screen or verbally during its motion.

The study's findings also had several theoretical implications. They reinforced the theories of autonomy, social robotics, proxemics, risk perception, and planned behavior [15]. The robot's autonomous performance aligned well with the theory of autonomy in robotics. The feedback from participants suggested that social robotics theories were applicable in real-world environments, reinforcing the necessity of developing robots that respect human social norms.

5. Conclusion

In conclusion, the research undertaken successfully addressed the primary goals of investigating the relationship between HRI and the safety of autonomous obstacle avoidance. The investigation revealed that the interaction between humans and robots is multi-faceted. It emphasized that the concept of safety in autonomous obstacle avoidance is not limited to the physical ability of the robot to navigate without causing collisions or accidents. It also heavily depends on the subjective feelings of safety, comfort, and trust experienced by the humans who interact with or are in the vicinity of these robots. Therefore, the importance of considering both objective and subjective factors when evaluating the safety of autonomous robots in environments shared with humans was strongly underscored. This research also pointed towards potential areas for future study, demonstrating that the quest for knowledge in this domain is far from exhausted. For instance, it suggested the need for further exploration into how different design elements and behavioral parameters of the robot might influence human perception and interaction. This could include aspects such as the robot's size, color, speed, motion patterns, and communication methods. Research into these directions could yield interesting results that might further refine the approach to designing and deploying autonomous robots in human environments.

Abstract

The objects grasping is one of the fundamental robotic problems. Accurate and efficient real-time object detection is crucial for successful grasping in robots equipped with monocular vision. Deep machine learning has made significant progress in solving problems of object detection and image segmentation. At the same time, classical computer vision methods do not lose their relevance and can also be used for these tasks. In this research, we conduct a comparative analysis of the effectiveness the YOLOv8-seg neural network model versions for solving the image segmentation problem with classical segmentation methods. The obtained results allowed us to formulate some recommendations on the choice of a particular method for object detection depending on the surrounding environment conditions.

Keywords: Robotic grasping, Robotic arm, Object detection, Object segmentation

1. Introduction

Robotic grasping is one of the fundamental tasks of robotics, relevant to all its branches [1], including industrial [2], service [3] and social robotics [4]. Grasping can be particularly important in collaborative robotics, when a robot and a person use common tools or perform joint assembly [5].

Obtaining information about the shape of the captured objects is an important stage in the implementation of grasping [6]. The shape of objects can be determined using various sensors, including cameras and lidars. At the same time, solutions that allow detect grasping objects using monocular cameras are also of practical interest. Deep machine learning has made significant progress in solving problems related to object detection [7] and image segmentation [8]. However, classical computer vision methods do not lose their relevance and can also be used for these tasks. In this paper, we present the results of our experiments aimed at comparing classical object detection methods with object detection and segmentation using the YOLOv8-seg models family. The aim of our research is to evaluate the accuracy and effectiveness of various methods for detecting object contours in robotic grasping.

2. Related Work

In the past few years, there has been a lot of research reported on robotic grasping problems. Some approaches to solving the problem of robotic grasping are presented in the review [9]. The overview of different approaches to computer vision-based robotic grasping presented in [10] and [11]. The effectiveness of deep machine learning in object detection on RGB-D images for robotic grasping is well demonstrated in the work [12]. At the same time, detecting objects in RGB images seems to be a much more difficult task, since such images do not contain depth information. Examples of works exploring the challenges of robotic grasping using monocular vision and RGB images include works [13] and [14].

Often, the effectiveness of grasping area detection methods is evaluated using one of the popular datasets, such as Cornel dataset [15] and Jacquard dataset [16]. The use of publicly available datasets allows comparing the effectiveness of different approaches. According to the data from the "Paper with Code" platform [17] the accuracy of various grasping methods based on machine learning, estimated with the help of Cornel Dataset was made from 88% in 2016 for Multi-Modal Grasp Predictor [18] to 98.2% in 2021 for Ainetter and Fraundorfer CNN-based architecture [19] and 98.9% for Efficient Grasping model by Cao et. al [20]. At the same time, the accuracy estimates on the Jacquard dataset for the Ainetter and Fraundorfer model [19] was 92.95%, and for the Efficient Grasping model by Cao et. al [20] was 95.6%.

As it can be seen, estimates of the accuracy of different methods may vary from the quality of the test dataset. In addition, although public datasets provide an overview of the effectiveness of a given method, these datasets do not always take into account the peculiarities of objects and

Nikita Kolin, Elvira Chebotareva

environments encountered in real cases. Therefore, datasets that are close to the real conditions of a particular task are always of special interest. In this research work we will make a comparative analysis of various methods of objects detection on own dataset, adapted to the real object grasping task. As an example of a model that provides acceptable accuracy along with the high inference speed and usability we use the YOLOv8-seg model for object segmentation. The YOLOv8-seg model is based on variant of the U-Net architecture [21]. The YOLO models family based on hybrid convolutional neural network architecture [22], [23] and often used in robotics.

3. Materials and Methods

3.1. *Object detection problem statement*

We model a situation in which the working cell of a robotic manipulator is equipped with a single monocular camera fixed above the working area. During the experiment, the camera does not change its position. This camera transmits image of the table area, on which three objects can be placed at random: pliers, screwdrivers and PIR sensor. We assume that the objects are homogeneous, so we can assume that the center of mass of each object coincides, or is close, with its geometric center. Therefore, the optimal gripping points must also be near the geometric center of each object.

Thus, in the context of the task of detecting objects for their robotic grasping, we need to determine the object class (pliers, screwdriver, or PIR sensor), the contours of the object, the geometric center of the object (the center of mass of the contour) and the orientation of the object. Note that in order to calculate the center and orientation of an object in this case it is enough to define its contour.

3.2 *Datasets*

For our experiments, we have prepared a set of 100 images with resolution 640×480 pixels containing three different target objects: pliers, screwdriver and PIR sensor. The choice of objects is determined by the context of collaborative tasks in which it is planned to use this robot in the future. In addition, these objects have different shapes and colors, which can help identify potential issues with specific object detection methods. The images were taken under various lighting conditions and against different backgrounds.

However, to test the hypotheses of our study, we also prepared 20 images with backgrounds that differed from those in the training dataset images. A total of 165 annotated images were prepared for model training, with 132 included in the training dataset, 17 images in the validation dataset, and 16 in the test dataset. To improve the quality of training, 236 images derived from the original 132 training dataset images were added to the

training dataset through rotation and perspective distortion.

3.3 *Object detection methods*

For our experiments, we used the YOLOv8n-seg and YOLOv8s-seg models pre-trained on the COCO dataset by Microsoft. YOLOv8n-seg and YOLOv8s-seg models trained on a set of 368 images of size 640×480.

To extract the object's contours we used two classical methods. The first method is based on the conversion to HSV space and channel thresholding. And the second method uses the Canny edge detector, as well as auxiliary erosion and dilation transformations. The classification of the extracted contours is based on a single feature – the aspect ratio of the bounding box.

3.2. *Evaluation*

Each method of object detection and segmentation was evaluated using two commonly used metrics: the Jaccard index (1) – also known as the IoU (Intersection over Union) metric, and the Dice coefficient (2) – also known as the F1-score metric. These metrics are based on the formulas (1) и (2). In formulas (1) and (2) A is the set of pixels belonging to the real object in the image, B is the set of pixels of the result of segmentation.

$$IoU = \frac{A \cap B}{A \cup B} \qquad (1)$$

$$F1 = 2\frac{|A \cap B|}{|A| + |B|} \qquad (2)$$

For each method, we also measured the inference time per frame in the test video and calculated the inference speed as the number of processed frames per second (FPS).

4. Experiment Results and Discussion

At the first stage of the experiment, we evaluated the average values of IoU and F1-score for 100 images from our dataset. Then, at the second stage of our experiment, we conducted the evaluation using 20 images with significantly different backgrounds compared to the backgrounds of the images in the training dataset. The results of these stages are presented in Table 1 and Table 2.

Table 1. The object detection methods accuracy obtained on images with conditions similar to the training dataset.

Method	IoU	F1-score
Thresholding	0.4112	0.4658
Canny edge detector	0.1720	0.2257
YOLOv8n-seg	0.8248	0.8811
YOLOv8s-seg	0.8612	0.9185

Table 2. The object detection methods accuracy obtained on images with conditions differing from the training dataset.

Method	IoU	F1-score
Thresholding	0.8047	0.8771
Canny edge detector	0.0252	0.0469
YOLOv8n-seg	0.3186	0.3477
YOLOv8s-seg	0.2299	0.2535

Thus, in the case where the images background was present in the training dataset, the best result was obtained by YOLOv8s-seg and YOLOv8n-seg models. However, the YOLOv8n-seg model showed an expectedly lower result compared to YOLOv8s-seg model. The thresholding-based method showed significantly lower results than the YOLOv8-seg models, but exceeded the Canny edge detection method. Examples of object detection and segmentation using models YOLOv8n-seg and YOLOv8s-seg are presented in Fig. 1 and Fig. 2.

Fig. 1. The example of successful recognition of all objects using the YOLOv8n-seg model.

However, in cases where the background on which the objects are located differed from the backgrounds in the training images, the method based on threshold processing of channels in the HSV color space showed better results compared to both the YOLOv8s-seg and YOLOv8n-seg models, as well as the method based on Canny edge detector. Fig. 3 presents an example of object detection and segmentation on an image with a background different from the training dataset. In this instance, the YOLOv8s-seg and YOLOv8n-seg models failed to detect object contours on the complex

Fig. 2. The example of successful recognition of all objects using the YOLOv8s-seg model.

background not included in the training dataset. The method based on Canny edge detector also did not give positive results.

Fig. 3. The example of object contour detection using a classic threshold-based method in cases where YOLOv8n-seg and YOLOv8s-seg models failed.

Table 3 presents the results of FPS evaluation on the test video for all the considered methods. The best inference speed result belongs to the method based on the Canny edge detector, followed by the threshold-based method in second place, and the YOLOv8s-seg model demonstrated the worst result.

Table 3. Results of FPS evaluation for the considered methods.

Method	FPS
Thresholding	21.8
Canny edge detector	32.6
YOLOv8n-seg	4.2
YOLOv8s-seg	2.1

5. Conclusion

The obtained results allowed us to formulate some recommendations on the choice of a particular method for object detection depending on the surrounding environment conditions. In cases where the scene is not overloaded with a large number of objects, the environmental conditions remain stable, and the objects significantly differ from the background and have relatively homogeneous texture, classical methods can be quite successfully applied to extract the contours of the target objects. Moreover, in contrast to machine learning methods, these methods do not require the preliminary collection of a large amount of training data and annotation, and they also characterized by higher inference speed. However, if the environmental conditions change dynamically, these methods become practically inapplicable. In this case, the optimal solution would be to train a previously pre-trained neural network model. However, the training dataset must be close to the real conditions in which recognition is planned, in particular, it is necessary that the background on which the target objects are located is the same as in real

Nikita Kolin, Elvira Chebotareva

conditions. Otherwise, the quality of detection and segmentation is significantly reduced.

Abstract

Medical robotics is an emerging field of robotics within a healthcare sector. This interdisciplinary field focuses on prototyping, building and developing advanced robots for numerous clinical application. Modern robotic technologies have a tremendous potential for performing medical examination procedures such as ultrasonography using robotic manipulators that act in an autonomous manner. A manipulator navigation plays a key role in a safe and efficient exploration of a human body. This paper presents a development of a vision-based autonomous navigation system for a 6-DOF UR3e robotic arm. The developed system is based on a 3D point cloud and uses MoveIt for path planning. Gazebo was used as a simulation framework to validate the navigation system.

Keywords: Medical robotics, Manipulator, Autonomous navigation, ROS, MoveIt, Gazebo

1. Introduction

The healthcare industry has been making a notable progress in recent years with an advancement of robotics technologies [1], [2]. Due to COVID-19 pandemic an automation of medical procedures employing robotics technologies became critical [3], [4]. Robots are progressively being employed for a broad spectrum of tasks that include surgery [5], rehabilitation [6], diagnostics [7], and drug delivery [8], offering precision, efficiency and remote operational capabilities [9]. Modern robotic technologies have a tremendous potential for performing medical examination procedures using robotic manipulators [10] that employ various end-effectors to provide additional functionalities within specific tasks. Nowadays, robotic arms became a major focus for medical research groups [11]. Robotic manipulators feature a lightweight reconfigurable arm design, high precision actuators and motion control systems. These robots are used in medical scenarios that require a high degree of precision and quality of a task performance, e.g., tissue suturing [12], minimally invasive surgery [13], [14], and ultrasonography [15].

An autonomy enables an unskilled human worker to easily configure a robotic system in a setup phase before performing a medical procedure. Autonomous manipulators execute tasks consistently without a variability that can be introduced by human operators [16]. This consistency is crucial in medical examination scenarios where uniformity is essential. Manipulator navigation plays a key role in a safe and efficient autonomous exploration of a human body [17]. The exploration refers to autonomously move, position, and control a trajectory of a manipulator within a designated space. Vision-based manipulator navigation is an approach of guiding and controlling a robotic manipulator's movement using visual information. A robotic system relies on cameras or other vision sensors to perceive and interpret an environment [18].

This paper presents a development of a vision-based autonomous navigation system for medical examination using a 6 degrees of freedom (DoF) UR3e robotic arm. The developed system is based on 3D point cloud data. 3D point clouds are produced by a depth camera, which measure physical dimensions of a human body. MoveIt package [19] was used for motion planning, manipulation,

and control of the robotic arm. Gazebo [20] was used as a simulation framework to validate the navigation system.

2. System setup

A UR3e manipulator (Fig. 1, left), manufactured by Universal Robots, stands as a suitable robotic system for automating low-weight processing tasks. The capability to grab and move a medical tool is facilitated by its payload capacity of 3 kg, providing a sufficient control to navigate an end-effector. Flexible motion planning is achieved using the UR3e arm's capability for 360 degrees of rotation in all its joints. For a virtual robot setup a ROS-based UR3/UR3e controller with simulation in Gazebo was used (Fig. 1, right).
Fig. 1. UR3e robotic arm: a real robot (left) and a virtual manipulator model (right)
Fig. 2. Depth data: a 3D point cloud (blue) of a region of interest

A depth sensor is a type of imaging device that captures depth data along with visual data. Unlike traditional cameras that record color and intensity information, depth cameras provide additional details about a distance from a camera to an object. In a Gazebo simulation environment, integrating a Kinect camera model involves configuring a depth camera plugin. ROS/Gazebo provides a package *gazebo_ros_pkgs* that contains wrappers and tools for using ROS with Gazebo. The package includes *gazebo_ros_openni_kinect* plugin that serves as a driver for interfacing a Kinect camera with Gazebo simulation framework. The Gazebo camera plugin publishes depth data on a ROS topic of type

sensor_msgs/Image. Depth data captured by the virtual Kinect camera is used by a 3D point cloud processing module. Fig. 2 shows a 3D point cloud of an abdomen.

A simulation environment in Gazebo contains a UR3e manipulator model. UR3e is mounted on a supporting base that allows to effectively cover a table used for examinations. The Kinect camera model with a depth camera plugin captures visual and depth data of a human body. A human body model is placed on the examination table within the manipulator workspace and the Kinect camera range. UR3e is equipped with a transducer device used as an end-effector. The virtual environment is depicted in Fig. 3.
Fig. 3. Gazebo environment: a human, an examination table and UR3e manipulator, that explores a chest.

3. Navigation

A proposed navigation system consists of three modules: a 3D point cloud processing, a path planning and a motion planning. The first module serves as a foundation for a spatial perception. The second module, which is responsible for waypoint generation, takes the processed point cloud data and calculates series of feasible waypoints for navigation. The third module focuses on translating the planned paths into executable motion commands for the manipulator.

A point cloud is a collection of data points defined by their coordinates in 3D space. Each point represents a specific position in an environment and may include additional information, such as color or intensity. The module processes raw 3D point cloud data obtained from the depth camera. This step involves filtering input depth data and removing invalid points. Point Cloud Library (PCL) library [21] was utilized to process raw 3D point cloud data and create a digital representation of a human body's specific region of interest.

Waypoint generation determines a set of points that represents a desired path for the manipulator. The module is responsible for generating waypoints and utilizes the processed 3D point cloud model as an input. Normal vectors of points are employed to calculate a rotation matrix for the end-effector. The output is a sequence of feasible waypoints for motion planning (Fig. 4, bottom).

A motion planning process involves converting a trajectory into a series of motion commands. The motion planning module uses MoveIt framework to plan a motion for the robotic system, validate it and then execute the motion plan (Fig. 4, top). MoveIt uses inverse kinematics solvers for determining joint configurations and collision checking to ensure safe motion of UR3e.
Fig. 4. Navigation in RViz: red markers denote waypoints that MoveIt uses for motion planning

RViz software [22] is commonly used together with MoveIt for visualization of motion planning tasks. A control ROS node is written to bring up the autonomous navigation system and start path planning.

4. Conclusions

This paper presented a vision-based autonomous navigation system for medical examination using a 6-DOF UR3e robotic arm. The developed system relies on depth-sensing cameras and utilizes a 3D point cloud. MoveIt motion planning framework was used for path planning and control of the robotic arm. The validation of the developed navigation system was conducted in Gazebo simulation framework. As a part of our future work, we plan to validate the proposed navigation system on a real UR3e robot. To achieve this, we will use a real Kinect depth camera and a human mannequin.

Abstract

Robot-assisted language learning (RALL) is a direction in education that uses robots in the process of studying foreign languages. In this paper, we present the results of our research work devoted to studying trends in the quantity of publications in the field of using social robots for learning foreign languages. Additionally, we have analyzed some published paper in the field of RALL, which has allowed us to identify several popular robot models used in practical research in recent years. Among these models were the NAO, Pepper and DARWIN OP-2 robots. We have found that these robots are actively used in the educational process for learning foreign languages. In particular, these models are used to improve language and communication skills during implicit learning and interactive games.

Keywords: Robot-assisted language learning, Foreign language learning, Robot teaching assistant, Social robotics

1. Introduction

The last decades have seen significant progress in the field of Artificial Intelligence (AI), which has become an integral part of human life. This development has resulted in the emergence of many systems with the ability to replace certain aspects of human activity. Modern AI systems are innovative technological solutions capable of functioning effectively in various fields of activity, including manufacturing, medicine, finance, transportation, and others. Some studies speculate about the prospects of symbiosis of human and cybernetic systems [1]. Robotics is closely related to artificial intelligence and also applies the results of progress in this area [2]. Thanks to artificial intelligence, it is possible to generate a three-dimensional space for robot testing in simulation [3], generate a maze [4] and create obstacles to further calibrate algorithms for complex tasks [5]. Robots, thanks to machine learning algorithms, are able to navigate in the Gazebo simulation environment [6], [7], in real-world environments [8], and can also follow humans [9] and independently plan a route to move [10].

The significant achievement of robotics is the direct assistance to humans, which makes this field in demand nowadays. Modern robots perform a huge range of tasks: they can provide the necessary assistance to the elderly [11], they can be used for medical procedures and examinations [12], [13] and find application as personnel in hospitals [14], and they are also used in areas of high risk for humans, in rescue operations [15].

Currently, robotics is widely used in education [16]. There it finds application in the creation of programs and exercises for students [17], as well as can be an assistant in learning foreign languages [18]. The use of social robotics in education has great potential and is of significant interest to researchers in both the humanities and technical fields of science. Robot assisted language learning (RALL) is a direction in education that uses robots in the process of studying foreign languages. Education using robots is aimed primarily at increasing student motivation and the degree of interactivity of the learning process itself, as well as adapting the educational process to the individual needs of students.

The aim of this paper is to study the dynamics of the number of publications devoted to the use of social robots for learning foreign languages. Additionally, we will examine the robot models used by researchers in the field of RALL.

2. Analysis of Publication Activity in the Field of RALL

In order to assess the interest of researchers in the field of RALL, we counted the number of published papers for the query "robot-assisted language learning" in the Google Scholar search engine. In total, based on the results of this search query, we received more than 900 scientific papers. Among the collected papers, we have selected those published no earlier than 2010 (totaling 889 papers) and counted the number of publications in each year from 2010 to 2023. The resulting diagram of the number of published papers in each year is presented in Fig. 1. Based on the diagram presented in Fig. 1 we can conclude that interest in social robotics and, in particular, in robot-assisted language learning has increased over the last decade.
Fig.1 A number of published papers (X-axis) on robot-assisted language learning in the Google Scholar search engine per year (Y-axis)

According to Fig. 1, starting in 2019, interest in robots assisting with foreign language learning began to grow noticeably. Thus, among the papers presented in the search results there were 80 papers published in 2019, and 148 papers published in 2022. This increase in interest may be attributed, among other factors, to the impact that the COVID-19 pandemic has had on the methods of communication in society in general, and within educational systems in particular. Due to restrictions on traveling and face-to-face meetings, many people have turned to online education and digital solutions to learn foreign languages. Robots capable of teaching languages provide a convenient and affordable way to learn virtually. This has further influenced the growth of technology in this field. These results confirm that social robotics and robot-assisted language learning have great potential and will continue to attract the attention of researchers and society at large.

3. Robot Models Used in RALL

To identify the robots currently utilized in robot-assisted language learning research, we conducted an analysis of around 100 papers derived from the search query "robot-assisted language learning" in the Google

Scholar search engine. Among the most popular models of robots used in practical research were the NAO robot and the Pepper robot from SoftBank Robotics, as well as the DARWIN-OP2 robot from ROBOTIS.

The NAO robot model was referenced in 3 research papers [19], [20], [21]. The study [19] examined the impact of the NAO robot functioning as a teacher's assistant on university students' English vocabulary improvement. The research [20] implemented a system of implicit learning utilizing two NAO robot models. In study [21], the NAO robot was utilized in teaching a second language to 5-year-old children. Two research papers [22], [23] referenced the Pepper robot model. In [22], the Pepper robot was employed for interactive game-based learning in single-user and team versions of a quiz game. In study [23], a project was presented which involved the Pepper robot being used as the basis for developing for robotic teaching of the endangered Ainu language. The DARWIN-OP2 robot was also mentioned in two research papers [18], [24]. The study [18] presented the experimental verification of English language lesson scenarios with the DARWIN-OP2 robot in the Gazebo simulator. The study [24] introduced a pilot experiment involving the interaction of preschool children aged 5-6 years with the DARWIN-OP2 robot, serving as a teacher's assistant.

4. Discussion

In this section, we provide the general characteristics of the NAO, Pepper, and DARWIN-OP2 robots, and also review key characteristics of the studies presented in the previous section.

The robots NAO, Pepper, and DARWIN-OP2 share characteristics that make them attractive for research in the field of RALL. The robot NAO has small dimensions - about 58 cm in height, and a humanoid form with a head, arms, and legs. The DARWIN-OP2 robot has more compact dimensions - about 45 cm in height, and a simpler design. Pepper is a taller robot - about 120 cm in height. Like NAO and DARWIN-OP2, Pepper has a head and two arms. However, unlike NAO and DARWIN-OP2, Pepper does not have legs, and overall, Pepper has a more monumental appearance. Overall, the visual design of all three robots is conducive to social interaction.

From the point of view of using these robot models in an educational environment when learning foreign languages, all three robot models also have a number of common attractive characteristics. First of all, these models are programmable models and can be adapted to various educational contexts. From a technical point of view, robots NAO, Pepper and DARWIN-OP2 provide ample opportunities for speech synthesis and recognition, integration of computer vision and machine learning. All this allows researchers to achieve a high

level of human-robot interaction, including the interaction with children.

In Table 1 we provide a comparative analysis of some of the characteristic features of the studies we indicated in previous section, in which the NAO, Pepper and DARWIN-OP2 robot models were used.

Table 1. Key characteristics of studies using the NAO, Pepper and DARWIN-OP2 robots.

The application area	
NAO	Assistant English teacher for university students improving their vocabulary. Implicit learning through conversation.
Pepper	Studying English grammar in universities. Learning an endangered language.
DARWIN-OP2	English lessons with preschool children.
Objectives of the experiments	
NAO	Studying the effect of a robot on improving students' vocabulary.
Pepper	The effectiveness of game-based learning.
DARWIN-OP2	Interaction with preschool children in English lessons.
Distinctive features of the studies	
NAO	The use of implicit learning as a primary learning style.
Pepper	Using a robot as a play partner with an educational interactive quiz.
DARWIN-OP2	The optimization of the English language learning process with the help of the Gazebo simulator and global human-robot interaction scenarios

From the presented in Table 1 training scenarios, it can be concluded that the NAO, Pepper and DARWIN-OP2 robots demonstrate a wide range of capabilities in the context of educational environments. They have been successfully used in university classrooms, ranging from helping students learn foreign language and improving students' vocabulary to using them in game-based learning. In addition, these robots successfully interact with preschool children, optimizing the language learning process using advanced simulators and global human-robot interaction scenarios. Thus, learning cases using these robots reflect their applicability in various educational contexts and their ability to effectively support and improve students' language skills.

5. Conclusions

Our analysis of the number of published papers related to "robot-assisted language learning" demonstrates a steadily growing interest among researchers in the RALL field. Data obtained from a Google Scholar search show a noticeable increase in the number of

publications since 2019, indicating a growing interest in robots helping with foreign language learning. This increase in interest can be partially attributed to the impact of the COVID-19 pandemic, which has prompted a shift to online education and digital language learning solutions due to travel restrictions and social distancing measures. Among the most frequently used robot models in RALL research were the NAO, Pepper, and DARWIN-OP2 robots. These robots are used to improve language skills and communication in a variety of educational scenarios, including implicit learning and interactive games.

Abstract

An automated beekeeping is a promising approach to addressing various issues associated with a beekeeping. Among primary problems, a swarming procedure stands out as a major concern. An uncontrolled swarming can lead to significant financial losses. During a swarming period a potential for losing a bee swarm is high, therefore a noise monitoring at this period gains a significant importance. Our long term research aims at a development of an intelligent monitoring system for beehive conditions, based on a hive-generated noises analysis. This paper presents an experiment that collected data about acoustic characteristics of bee states using an Arduino microcontroller and a MAX9814 microphone module. The obtained data analysis is discussed.

Keywords: beehive condition monitoring, acoustic level analysis, Arduino microcontroller, microphone, anthropogenic disturbance

1. Introduction

Currently, beekeepers are increasingly facing an issue of a rising mortality among honeybees, attributed to various factors [1]. This problem carries significant ecological and economic consequences that may cause a heavy impact on a biodiversity of wild plants [2] and agricultural production [3], [4]. One of the most destructive phenomena in this field is Colony Collapse Disorder, in which honeybees abandon their hives [5], [6], [7]. This colony collapse or demise is a result of multiple negative factors that can act independently, combine, or amplify one another [8]. A mortality of honeybees can be attributed to various factors, which can be classified into two main groups: a natural factor and a anthropogenic factor. Natural factors include bee infestations by Varroa mites and a swarming. The former are major parasites of honeybees, leading to a reduced hive viability and a decreased honey production [9]. A swarming, on the other hand, is a natural process of dividing a bee colony into two parts [10]. During the swarming, some worker bees and one or several queens leave a current nest to establish a new colony elsewhere. However, this process can pose a challenge for beekeepers as it involves a loss of some bees and, consequently, a decline in honey production.

To deal with Varroa mite a number of methods were proposed including computer vision approaches [11], [12], [13] and real-time visualization systems [14] that allow monitoring of honeybee activity by counting their entry and exit from a beehive [15], [16]. Sensor fusion [17], [18] and fiducial markers [19] can also be incorporated into the monitoring process to provide more robust and accurate measurements. Researchers identified a correlation between the swarming and a hive weight, a sound, a temperature, and a humidity inside a hive [20]. Particularly noteworthy is an analysis of sounds produced by honeybees, which has proven to be one of the most effective methods for detecting the swarming [21]. Scientific studies in this field demonstrated a correlation between specific sound frequencies and the swarming process [22], [23], making an acoustic analysis of bee sounds a promising avenue for monitoring and studying a condition of bee colonies.

This article presents results of a pilot experiment that analyzed a hive noise under normal conditions and after

Ramis Kulmukhametov, Ramil Safin, Tatyana Tsoy, Kuo-Hsien Hsia, Evgeni Magid

bee disturbances. It is a part of our long term goal of constructing an IoT-based monitoring system that could improve a productivity of honeybees by a timely detection of various events inside beehives and reporting results of AI-based analysis to beekeepers.

2. Experimental Setup

The Arduino UNO microcontroller acts as a main processor, performing key monitoring functions of the experimental setup. The microcontroller receives data from MAX9814 microphone module. The microcontroller and the microphone were placed together into a cardboard box with a power and data wire connected to a notebook computer. The box was placed under a hive cover, above hive frames. The setup and the device placement within a beehive are depicted in Fig. 1.

a   b
Fig. 1. Experimental setup: (a) the device; (b) the container placement inside a beehive

The device was programmed using the Arduino open-source software development platform. Arduino IDE was used for programming the microcontroller and reading data from the microphone. Upon powering up the microcontroller, the program initializes variables and opens a serial port at a baud rate of 115200. Data are transmitted through UART communication, and obtained by the microphone values are converted to decibels. A flow of the program is depicted in Fig. 2.

3. Results

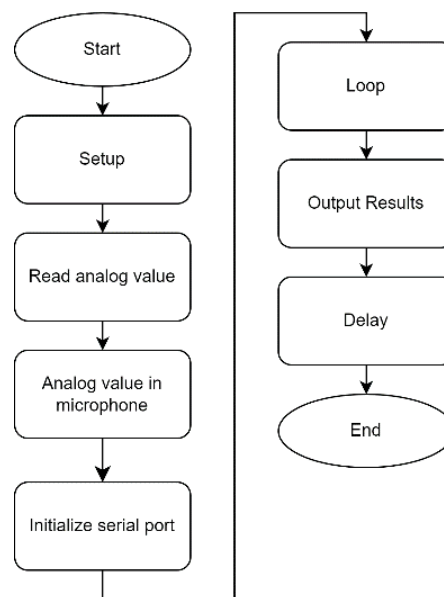
A pilot experiment targeted to examine a state and a behavior of bees in terms of acoustic changes under artificial human-made disturbances. The pilot experiment was conducted on October 8, 2023, at 14:30:00 of the local time. By this time of the year, bees completed their main honey gathering season and started preparations for the upcoming winter season.


Fig. 2. Acoustic monitoring flowchart

The device was placed into a beehive and the microphone collected acoustic data from bees. The experiment was divided into two phases, 30 seconds each. The first phase corresponded to normal conditions of the beehive. In the second phase an anthropogenic disturbance was generated by knocking the hive for 3 seconds in order to provoke a response from the bees. The phase aimed to investigate changes in the bees' behavior.
Fig. 3. An acoustic level at a human disturbance event

Fig. 3 presents experimental results of acoustic levels that were measured within the beehive for one minute. It is worth noting that the measurements were taken during a cool weather, which could have affected the acoustic level, making it lower compared to the main honey harvesting period. Initially, in a state of a rest, the measured acoustic level was -240 dB. The highest recorded acoustic level was -170 dB, which occurred at the beginning of the second phase (14:30:31) when the

beehive was subjected to a 3-seconds knocking. At this moment, the bees transitioned to an alarmed state, that was reflected in the acoustic level of -210 dB, which gradually decreased over several seconds. Interestingly, when the device was removed from the beehive, there was a clustering of bees around its location. This behavior could be interpreted as an attempt of the bees to protect their colony. They formed a small cluster around the device, and as their stings proved ineffective against the potential threat, they attempted surrounding the "*intruder*" with their bodies, creating a defensive barrier. This behavior impacted the acoustic level, which increased by several decibels in the period from 14:30:27 to 14:30:29, prior to the anthropogenic disturbance.

Based on the experimental observations, it was concluded that while the device could collect valuable acoustic data, a safer placement of a microphone and the processing block should be selected (which could be done using a virtual environment [24]), e.g., on an outer surface of a back wall of a beehive that is opposite a bees' entrance. This would protect the device from overheating and other factors generated by the bees themselves and ensure a more reliable data acquisition.

4. Conclusions

In this study, a part of the bee monitoring system designed to collect data on an acoustic level within a beehive was successfully developed and tested. The experiment aimed to study a bees' behavior under conditions of an anthropogenic disturbance. This experiment represents a step towards a better understanding of bees behavior and their response to interventions. Based on the experimental observations, it was also concluded that a proper selection of the monitoring device and sensors' location is crucial.

Authors Introduction

Mr. Kulmukhametov Ramis

He received a BSc degree from Ufa State Aviation Technical University in 2022. Currently, he is a first-year student of Master degree program in Intelligent Robotics at the Institute of Information Technology and Intelligent Systems at the Kazan Federal University. He is also a professional beekeeper.

Mr. Ramil Safin

Ramil Safin is a Ph.D. student and a research assistant at the Laboratory of Intelligent Robotic Systems, Institute of Information Technology and Intelligent Systems, Kazan Federal University, Russia. He teaches the following courses: «Fundamentals of technical vision», «Robotic systems sensors», «Algorithms and data structures» His main interest is computer vision for robotic applications.

Ms. Tatyana Tsoy

In 2012 she graduated from International Area Studies Master's Degree Program at the University of Tsukuba. In 2023 completed a PhD in Computer science and information processes at the Institute of Information Technology and Intelligent Systems (ITIS) of Kazan Federal University.

Associate Professor Kuo-Hsien Hsia

He received a Ph.D. degree in Electrical Engineering at the National Sun Yat-Sen University, Kaohsiung, Taiwan. He works at the National Yunlin University of Science and Technology.

Professor Evgeni Magid

He is a Head of Intelligent Robotics Department, a founder, and a Head of Laboratory of Intelligent Robotic Systems (LIRS) at Kazan Federal University, Russia. Senior member of IEEE. He obtained Ph.D. degree in Robotics Engineering from the University of Tsukuba, Japan.

Restoration of Guqin Music by Deep Learning Methods

Abstract

Guqin （古琴）music played an important role in the history of Asia cultures. The notation of Guqin ancient music remained more than 600, however, only about 100 of them are played in nowadays. The reason is that the handwritten Guqin notations named "Jianzi Pu" is hard to be understood, however, we challenge to restore the Guqin music by deep learning methods and few Jianzi Pu images. VGG16 and YOLOv5 were adopted in the recognition experiment for Guqin music restoration. For a well-known Guqin music "Sen-O-So"（仙翁操）, 55 kinds of single characters of Jianzi Pu and 4,951 images of them were collected from 23 kinds of Sen-O-So version found by the Internet or obtained by image processing such as rotation, enlarge (zoom-in), reduce (zoom-out), filtering, etc. The average accuracies of VGG16 and YOLOv5 were 87.50% and 88.47% for the test data, respectively. Additionally, it was realized an online output of Guqin music as its output of audio or video forms by YOLOv5 in this study.

Keywords: deep learning, VGG16, YOLOv5, SVM, Guqin, Jianzi Pu, AI music

1. Introduction

Many kinds of ancient cultures and civilizations have disappeared in the past. A Chinese stringed instrument named "Guqin" （古琴）(or "Qin"（琴）) (Figs. 1 and 2) has a history more than 3,000 years, however, few players in the world exists in the last century. Recently, more Chinese youngers are learning this ancient musical instrument, however, it is very difficult to use its notation, named "Jianzi Pu", which is a kind of handwritten character using Chinese character and its original characters (see Figs. 3 and 4). There are more than 600 Guqin musical pieces in the history, meanwhile, the performed pieces in nowadays only about 100 [1], [2]. These Guqin music are translated from Jianzi Pu to modern staff notation by experts of Guqin players, and this translation process is called "Dapu" [3].

 Jianzi Pu recognition by computer has been studied since last century in China [4], [5], [6], however, the practical results are not obtained.

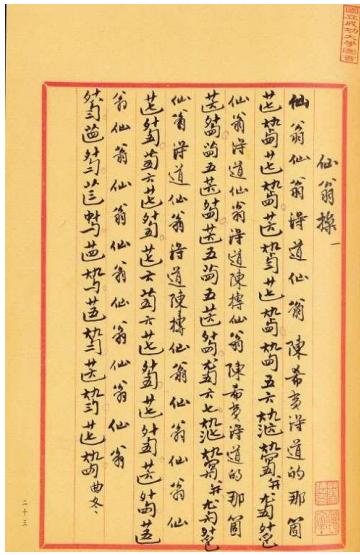

Fig. 3 A sample of Guqin musical notation "Sen-O-So".
Fig. 4 A sample of a single Jianzi Pu and its meaning in Japanese.

In our previous work [7], [8], machine learning methods such as support vector machine (SVM), deep learning models VGG16, ResNet50, and the hybrid models VGG16 with SVM, ResNet50 with SVM were adopted to be classifiers of single character of Jianzi Pu. In the comparison experiments using a dataset of a well-known Guqin music "Sen-O-So"（仙翁操）, VGG16 with SVM had the highest average accuracies to 15 kinds of single characters data which were the first and the second line of Sen-O-So Jianzi Pu in 1,500 images, i.e., 99.11% in training and 88.33% for unknown data.

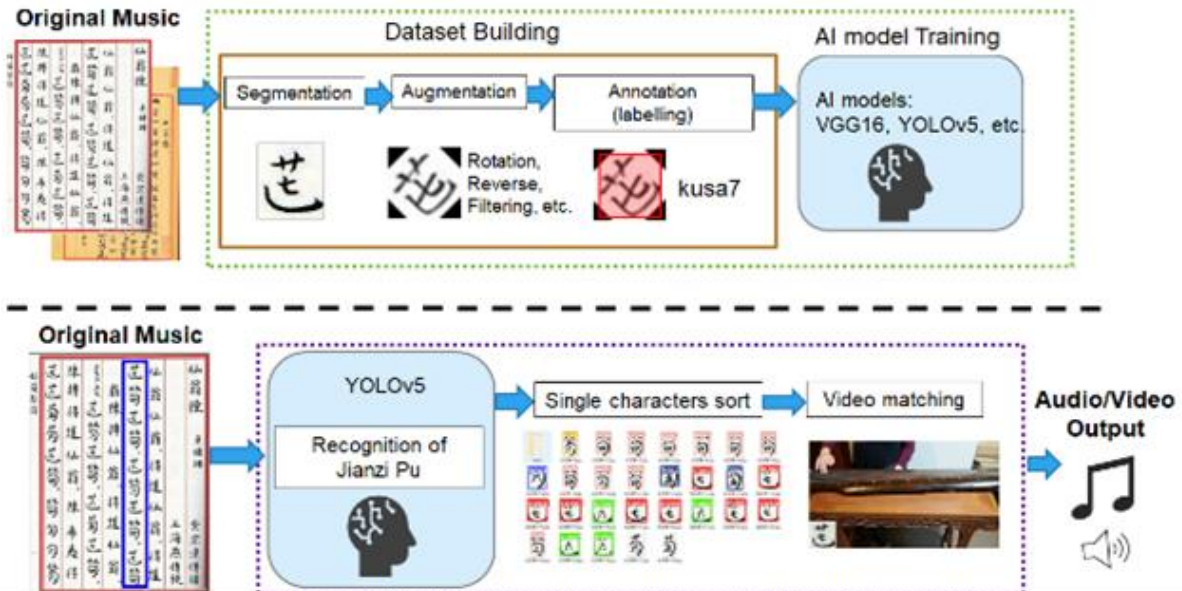
In this study, we built a bigger dataset for total single characters of Sen-O-So Guqin notation. 55 kinds of images of single characters were collected from 23 kinds of original Jianzi Pu from the Internet, and 4,951 single characters were obtained including data augmentation by image processing such as rotation, reversion, size enlargement (zoom in), size reduction (zoom out), and filtering. To realize online recognition, deep learning model YOLOv5 [9], [10] was adopted into the system as a classifier. The validation accuracy of YOLOv5 after 300 training arrived at 88.47% which was higher than the case of VGG16 87.50%. Additionally, audio/video data of single characters of Sen-O-So were created by Japan Society for the promotion of Guqin [2], and they were matched to the recognition results by YOLOv5.


Fig. 5 A restoration system of Guqin music.

2. A Guqin Music Restoration System

A Guqin music restoration system, as shown in Fig. 5, is proposed in this study. It is aimed to realize that when a Jianzi Pu image is presented to the system, Guqin music in audio/video forms are output. The system is constructed by a fine-tuned deep learning model YOLOv5 [9], [10] and a matching process of the output of YOLOv5 and a single character database in audio and video forms.

Fig. 6 A sample of 55 single characters of Sen-O-So.

2.1. *A Database of Jianzi Pu*

To train the deep learning models, a database of single characters of a well-known Guqin music "Sen-O-So" in Jianzi Pu form is built at first. 23 versions of Sen-O-So Jianzi Pu images were collected by the Internet. 55 kinds of single characters were segmented from the Sen-O-So notation, and totally 343 images of single characters were obtained. Data augmentation is adopted by image processing such as rotation, reflection, parallel translation, enlarge (zoom-in), reduce (zoom-out), filtering to the original single character images. As the result, 4,951 images of single characters were obtained as a database of Jianzi Pu. A sample of the original single character images and a sample of data augmentation were shown in Fig. 6 and Fig. 7, respectively.

Fig. 7 A sample of data augmentation.

2.2. *Deep Learning Models*

A well-known deep learning model VGG16 [7], [8] and an online object recognition model YOLOv5 [9], [10] were investigated their recognition accuracies to single characters of Jianzi Pu. The state of art of YOLO is YOLOv8, and we are investigating its performance for Jianzi Pu recognition recently.

3. Experiments and Results

Using the database of Sen-O-So described in Section 2, VGG16 and YOLOv5 were fine-tuned with 300 epochs. The average recognition accuracies of the single characters were 87.50% and 88.47% respectively.

The change of accuracies in training of two models is shown in Fig. 8. It can be confirmed that the accuracies (training accuracy and validation accuracy) of VGG16 were converged from 200 epoch (Fig. 8a), meanwhile, it converged from 100 epoch in the case of YOLOv5 (Fig. 8b).

Fig. 8 Learning curves of VGG16 and YOLOv5.

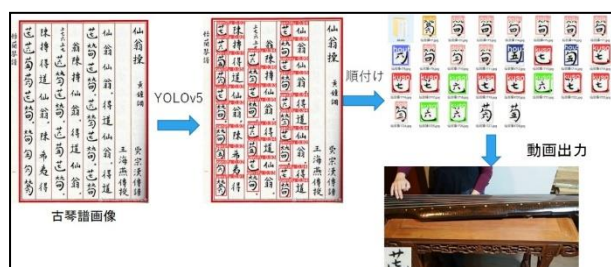
Fig.9 A sample of audio/video data matched to a single character of Jianzi Pu.


Fig.10 A sample of the processing result of the proposed system.

Single characters of Jianzi Pu were played by a professional Guqin player, Mrs. Yuki Takei [2] and recorded in audio/video forms as shown in Fig. 9. The order of single characters in a Guqin musical notion was given by their position detected by YOLOv5. By matching the recognized single characters to audio/video data, the system output music and videos as shown in Fig. 10.

4. Conclusion

To restore Guqin （古琴）music written in Jianzi Pu notation, a deep learning system constructed by YOLOv5 was developed in this study. The main contribution includes the making of dataset of a well-known Guqin music Sen-O-So (仙翁操) and the restoration system developed with artificial intelligence (AI) technology. The experiment results showed the effectiveness of the proposed system, and the future work of this study is to build more single character datasets of Jianzi Pu using more Guqin musical notations.

Prof. Dr. Takashi Kuremoto

He received his B.E. degree from the University of Shanghai for Science and Technology, China, in 1986, M.E. and Ph.D. degrees from Yamaguchi University, Japan, in 1996 and 2014, respectively. He worked as a system engineer at the Research Institute of Automatic Machine of Beijing from 1986 to 1992 and until 2021, he was an Assistant Professor at Yamaguchi University. He was an Academic Visitor of the School of Computer Science, the University of Manchester, U.K., in 2008. Currently, he is a Full Professor with the Department of Information Technology and Media Design, Nippon Institute of Technology, Japan. His research interests include artificial neural networks, fuzzy, evolutionary computation, time series forecasting, and intelligent systems

Mr. Kazuma Fujino

He received his B.E. degree from Nippon Institute of Technology, Japan, in 2023. He works at SET Software Co., Ltd., Tokyo, Japan, currently.

Mr. Hirokazu Takahashi

He received his B.E. degree from Nippon Institute of Technology, Japan, in 2023.

Mr. Shun Kuremoto

He received his B. F. degree from Shanghai University of Finance and Economics, China, in 1989, and M. A. in Commerce degree from Waseda University, Japan, in 1997. Currently, he is a guest researcher of the Institute for Future Engineering, Japan, as well as Director of Japan Society of Promotions of Guqin, and a doctoral program student in Yamaguchi University, Japan.

Dr. Mamiko Koshiba

1. She received her B.E., M.E. and Ph.D. degrees from Tokyo University of Agriculture and Technology, Japan, in 2001, 2002 and 2005, respectively. She worked as a postdoctoral neuroscientist at National Center of Neurology and Psychiatry 2005 to 2007 and until 2013, she was a Visiting Associate Professor at Tokyo University of Agriculture and Technology and from 2013 to 2016 at Saitama Medical University, Currently, she was an Associate Professor of Yamaguchi University, Japan. Her research interests include application of artificial neural networks for neuronal system evolution and development.

Mr. Hiroo Hieda

He is a Fellow of the Institute for Future Engineering. Longtime, he did comprehensive research on science and art. Currently, he researches on the history of Qin (七絃琴) in early modern Japan, especially in the Edo period. He published a book named "A study to the history of Qin in early modern Japan" (近世琴学史攷) in 2018.

Prof. Dr. Shingo Mabu

He received his B.E and M.E. degrees from Kyushu University, Japan, in 2001 and 2003, respectively, and his Ph.D. degree from Waseda University, Japan, in 2006. From 2006 to 2007, he was a visiting lecturer at Waseda University, Japan, and from 2007 to 2012, an assistant professor at the same university. From 2012 to 2017, he was an assistant professor at Yamaguchi University, Japan, and from 2017 to 2020, an associate professor at the same university. He is currently a professor at the Graduate School of Sciences and Technology for Innovation at the same university.

Constructive Nurse Scheduling Using Reinforcement Learning Considering Variations in Nurse Work Patterns

Abstract

It is very difficult to create a work schedule that satisfies all the different requirements in nurse scheduling. For this reason, numerous studies have been conducted on the nurse scheduling problem. However, the created shift schedule is often not practical as it is, because adjustments including various constraints and evaluation criteria are required. Therefore, we have proposed a work revision method using reinforcement learning in a constructive nurse scheduling system. In this paper, we investigate the feasibility of creating a practical work schedule even when there are nurses with different work pattern evaluations, i.e., the feasibility of creating a practical work schedule that takes each nurse's life stage into consideration.

Keywords: nurse scheduling, reinforcement learning, constructive search, work patterns, life stages

1. Introduction

Various studies have been conducted on the nurse scheduling problem [1], which is the creation of a shift schedule for nurses. However, for practical use, adjustments including various constraints and evaluation values are required, and the created shift schedule is often not practical as it is, so many head nurses still feel burdened by creating shift schedules [2]. Therefore, we have proposed a work revision method [3] using reinforcement learning [4] on a constructive nurse scheduling system [5].

In this paper, we investigate the feasibility of creating a practical work schedule even when there are nurses with different work pattern evaluations, i.e., the feasibility of creating a practical work schedule that takes each nurse's life stage into consideration. In addition, the work pattern evaluations of the obtained modified work schedules are visualized. Furthermore, none of the previous studies on nurse scheduling considered the evaluation of different work patterns.

2. Constructive nurse scheduling system

2.1. *Features*

The features of the constructive nurse scheduling system [5] are as follows.
1. The system creates a schedule for each day, starting from the first day.
2. The priority calculation can be extended to consider detailed conditions.
3. It does not consider the evaluation value for the entire shift schedule for a month.

2.2. *Work Revisions*

The constructive scheduling system considers only the basic constraints that would be required in a hospital with many nurses, and the possibility exists that a feasible solution that does not satisfy the head nurse is obtained. For this reason, Kurashige et al. [5] describe the following two procedures for the actual modification.
(1) A work shift of the nurse in the case that does not satisfy the head nurse is manually exchanged with a work shift of another nurse.
(2) A work shift of the nurse in the case that do not satisfy the head nurse is exchanged to other work shift as designated work shift, and the rescheduling is done.

Next, we introduce our proposed system [3] that learns this exchange procedure using reinforcement learning.

3. Work Revision Method Using Reinforcement Learning

3.1. *Problem Setting for Reinforcement Learning*

The shift schedule created by the constructive nurse scheduling system, which is created in order from the first day, satisfies the shift constraints (such as the number of nurses required for each day). On the other hand, the shift schedule for the entire scheduling period (e.g., one month) is checked, there may be several cases in which the nurse constraints (such as the limited number of workdays) are not satisfied for each nurse.

Therefore, the number of violations *Vnw* of work shift *w* is calculated as the number of days exceeding *UTnw*, the upper limit of the number of assignments of work shift *w* to each nurse *n*, from the work schedule, and a revision is repeated according to the following:

$$min \ \sum_n \sum_v V_{nw} \qquad (1)$$

The following procedure is to be used for one revision.
(1) Select a work shift w_0 that is the source of the exchange (usually the one with the most violations).
(2) Determine the nurse n_0 with the highest number of violations in the shift w_0.
(3) If the shift w_0 is the night shift, the shift w_0 with the highest number of violations, whether it is evening or late-night shift, is designated as w_0 for the nurse n_0.
(4) If there is a work shift that is below the lower limit of the number of assignments for the nurse n_0, that work shift w_1 is designated as a destination of the exchange shift. If not, day shift without the upper and lower limits of the number of assignments is used as the exchange.
(5) Determine the day d_0 with the highest priority among the days when the shift w_0 is exchanged to w_1 for nurse n_0.
(6) Deduce the group $g(j_0)$ in which the nurse n_0 is in charge of a job j_0, which is assigned as the shift w_0.
(7) Determine a nurse n_1 who belongs to group $g(j_0)$ and whose shift on the day d_0 is w_1. If there is more than one applicable nurse, determine the nurse n_1 with the highest priority among the nurses when the shift w_1 is exchanged to w_0 on d_0.
(8) The nurses n_0 and n_1 are exchanged their shifts on d_0.

In case there is no corresponding nurses in any of the procedures, the exchange is not valid. In addition, it is also not valid to undo a previous exchange.

Here, minimizing the number of violations is a very difficult problem, because the number of possible modifications depends on which work shift is being exchanged.

3.2. *RL Agent*

Q-learning [6] is applied to the proposed method to learn an appropriate exchange procedure. The state space of the RL agent consists of 4 dimensions: the previous exchange days (1 to 30), the total number of violations by all nurses for evening, late-night shift, and holiday: V_{nw} (w=1,2,3), to be a Markov decision process. The number of possible actions is 4, which is the exchange of evening, late-night, holiday, and night shift.

1 step is defined as 1 exchange including unsuccessful cases, 1 episode is defined as the time when the shift schedule reaches the target state, or 100 steps passed. Here, the target state is defined as the sum of violations for all nurses and shifts, $\sum_n \sum_v V_{nw} = 0$ (excluding over-holiday violations). The positive reinforcement signal $r_t = 10$ (reward) is given only when the target state is reached and the reinforcement signal $r_t = 0$ is given at any other steps. At the start of each episode, the shift schedule will be in its initial state.

4. Computational Experiments

Table 1. Evaluations of work pattern for 2 days.

shift on previous day	shift on the day			
	day	evening	late-night	holiday
day	15	1	13	11
evening	0	5	0	12
late-night	0	8	5	4
holiday	23	3	0	17

Table 2. Evaluations of work pattern for 2 days allowing transitions from the evening shift to the late-night shift.

shift on previous day	shift on the day			
	day	evening	late-night	holiday
day	15	1	13	11
evening	0	2	8	7
late-night	0	8	5	4
holiday	23	3	0	17

Table 3. Parameters for experiments

Parameter	Value
α_Q	0.1
γ	0.9
τ	0.1

4.1. *Nurse Scheduling Problem*

The extended method is applied to a nurse scheduling problem like that of Kurashige et al. [5]. First, a three-

shift system (day, evening, and late-night shift) is adopted, and the number of nurses is 23, including the head nurse. Furthermore, the number of positions is classified as 3 (head nurse, assistant head nurse, and general), the number of teams is 2 (A and B), and the skill level is 3 (experienced, mid-career, and new). The other constraints are outlined below.

- Restrictions on the number of nurses for each shift:
  (1) Required number of day shift on weekdays is greater than or equal to 10.
  (2) Required number of day shift for weekends and holidays is 5.
  (3) Required number of late-night shift is 5.
  (4) Required number of evening shift is 5.

Next, Table 1 shows the evaluation of work patterns for 2 days with M = 2. The evaluation of work patterns can be set using the current work schedule as a reference.

Here, we investigate the feasibility of creating a feasible modified work schedule in the situation where all nurses have the work pattern evaluations shown in Table 1 (Situation 1) and only Staff 6 and Staff 17, the experienced nurses of Team A and Team B, respectively, have the work pattern evaluations allowing transitions from the evening shift to the late-night shift shown in Table 2 (Situation 2).

4.2. *RL Agen
t*

In the state space of the RL agent, the total number of violations is assumed to be [0, 2] and can take 3 states.

The computational experiments have been done with parameters as shown in Table 3. In addition, all initial Q-values are set at 5.0 as the optimistic initial values.

Fig 1. Required steps for accomplishing the task.

Fig. 2. Total number of violations when accomplishing the task.

4.3. *Results*

The average of the numbers of steps required for accomplishing the task and the average of the total number of violations when accomplishing the task in Situations 1 and 2 were observed during learning over 20 simulations, as described in Fig. 1 and Fig. 2, respectively.

It can be seen from Fig. 1 and Fig. 2 that (1) in Situation 1, the target state was reached in about 5 steps, and the number of violations was reached at 3, (2) in Situation 2, the target state was reached in about 2 steps, and the number of violations was reached at 2. Thus, we confirmed that a feasible modified work schedule could be created not only in Situation 1, but also in Situation 2, where nurses have different work pattern evaluations.

The average of each nurse's work pattern evaluations for each day (the average of the previous day's and the day's work pattern evaluation, and the day's and the next day's work pattern evaluation) and the total average of the work pattern evaluations on the modified work schedule for Situations 1 and 2, respectively, are shown in Figs. 3 and 4. In addition, the 24, 25, and 26 days of Staff 6, indicated by the red boxes in Fig. 4, represent the average of the pattern evaluation of the late-night shift, evening shift, and late-night shift, respectively, and the 7, 8, and 9 days of Staff 17 represent the average of the work pattern evaluation of the holiday, evening shift, and late-night shift, respectively.

It can be seen from Fig. 3 and Fig. 4 that (1) the total average of the work pattern evaluations is the same for Situation 1 and Situation 2.

Although additional experiments are needed, setting the work pattern evaluations to values that each nurse him/herself desires will enable him/her to realize a work style (work pattern) that suits him/her life stage and, in addition, will help him/her to understand the work schedule creation process.

Fig. 3 Average evaluations of work pattern in the revised work schedule in Situation 1.

Masato Nagayoshi, Hisashi Tamaki

Fig. 4 Average evaluations of work pattern in the revised work schedule in Situation 2.

5. Conclusion

In this paper, we confirmed that the proposed method can create a feasible modified work schedule in a situation where there are nurses with different work pattern evaluations, specifically, where there are two nurses who can work from evening shift to late-night shift. In addition, the work pattern evaluations of the obtained modified work schedules were visualized and the total average of the work pattern evaluations in the situation was compared with the total average of the work pattern evaluations in the normal situation where evening shift to late-night shift is not possible, and we confirmed that the evaluation was equivalent to that in the normal situation.

Our future projects include to confirm the effectiveness of the proposed method in situations where nurses evaluate even more diverse work patterns, etc.

Abstract

Reinforcement learning requires a lot of learning time for the agent to learn. Transfer learning is a method to reduce this learning time, but it has the problem that the user does not know which knowledge is effective in which environment until it is learned. Therefore, it is necessary for the user to consider the relationship between the source and destination when transferring knowledge. Therefore, this study proposes Indicator of adaptation criteria that can determine this relationship in advance. In simulations, we demonstrate the usefulness of the proposed method by using some example problems.

Keywords: Reinforcement learning, Transfer learning, Maze problems

1. Introduction

In recent years, machine learning has achieved rapid growth with results in various fields such as natural language processing and image processing. Reinforcement learning [1], [2] which is capable of self-learning, is expected to further develop in all fields in the future. Reinforcement learning has the problem that it requires a lot of learning time because the agent learns from scratch in a new environment by trial and error.

Many studies have been conducted to reduce learning time, one of which is transfer learning. Transfer learning is a method of adapting and reusing previously learned material from similar tasks for a new task. Since there is no need to relearn, learning time can be reduced. However, the effectiveness of the transferred material is not known until it is transferred and learned. Therefore, when transfer learning is performed, the user needs to consider the relationship between the transferee and the transferee source, but even then, there is a possibility that the learning will not be successful and negative transfers will occur [3]. Therefore, this study proposes several indicators of adaptive criteria that can discriminate in advance the validity of knowledge.

2. Reinforcement learning

Reinforcement learning is a branch of machine learning in which an agent learns through interaction with its environment. Reinforcement learning is characterized by the fact that the agent chooses an action to achieve a certain goal and receives a reward signal for that action as it learns. Optimal behaviour rules are learnt by repeating steps 1 to 4 below.

1. Agent observes the state
2. Decides on a course of action based on cues from measures
3. Memorizes experience of which states, which actions and which rewards
4. Seeks measures based on experience

Reinforcement learning is also formulated as a Markov decision process, expressed as M=(S,A,P,R) as follows.

- S: Set of states
- A: Set of actions
- P: State transition $p(s_t = s'|s_t = s, a_t = a)$
- R: Behaviour rules $\pi(s, a) = R(s_t = s, a_t = a)$

Reinforcement learning aims to acquire behaviour rules that maximize the expected reward.

Satoshi Sugikawa, Kenta Takeoka, Naoki Kotani.

2.1. *Q-learning*

In this study, Q-learning [3] was used as a reinforcement learning algorithm learning updates the Q-values that the agent associates with a combination of states and actions, and finds an action rule that selects the action with the maximum Q-value in each state. The formula for updating the Q-values is as follows.

$$Q(s_t, a_t) = Q(s_t, a_t) + \eta \\ * (R_{t+1} + \gamma \max Q(s_{t+1}, a) \\ - Q(s_t, a_t))$$

In this study, the ϵ-greedy method was also used as the agent's action selection method. In the ϵ-greedy method, the agent acts randomly with a probability of ϵ and selects an action with a probability of 1- ϵ with a maximum Q value.

3. Transfer learning

In transfer learning [4], [5], the goal is to reduce learning time by transferring knowledge learned at the transfer source as prior knowledge at the transfer destination with similar tasks. However, if there is no similarity between the source and destination, a negative transfer may occur. Therefore, the user must consider the similarity between the source and destination in advance. Therefore, it is necessary to determine the similarity between the source and destination to determine which knowledge is transferred to which destination.

In this study, we aim to formalize the adaptation criterion by determining the similarity between mazes using the maze problem.

3.1. *learning model*

The algorithm used for learning in reinforcement learning is Q-learning. There are five actions that the agent can take: up, down, left, right, left and right, and no action. The reward design is +1 if the agent reaches the goal, and -0.01 if it collides with a wall or a step elapse.

3.2. *transition method*

As the transfer method uses Q-learning, the transfer learning adopts the value function transfer type.
The Q-table obtained by the learning of the transfer source is transferred to the transfer destination agent.
The degree of re-use of the behavioural value function is adjusted using the transfer rate τ. The transfer rate τ is adjusted in the range of $0 < \tau < 1$. In this study, τ was set at 0.5.

$$Q^c(s, a) = Q^t(s, a) + \tau Q^s(s, a)$$

4. Similarity Indicators

The following five indices are used to compute the similarity.

4.1. *Similarity by pixel value*

In this calculation example, the similarity by pixel value is determined. As the mazes used in this study have the same size, the percentage of pixel values matched between the images is determined.

4.2. *Cosine similarity between maze sequences*

In this example calculation, the maze is transformed into arrays and the cosine similarity between the source and destination arrays is calculated. The transformed array is the same as the array used for training, with the maze walls set to 1 and the paths set to 0.
- s is a vectorization of the base maze
- t is a vectorization of the destination maze.

$$cos(s, t) = \frac{\sum_i s_i t_i}{\sqrt{\sum_i s_i^2} \sqrt{\sum_i t_i^2}}$$

4.3. *Similarity using maxQ as weights*

In this calculation example, maxQ is used to determine the similarity. The total of the differences between the mazes is calculated using maxQ of maze A, which is the source of the transition, as the weight. The sum of the differences between the mazes is calculated using maxQ of maze A as the weight, and divided by the total value of maxQ.

$$p = 1 - \frac{\sum_i (s_i - t_i) \max_a Q_{s_{i,a}}}{\sum_i \max_a Q_{s_{i,a}}}$$

4.4. *Cosine similarity using maxQ*

Finally, in this calculation example, the Q values obtained after learning are used to obtain the cosine similarity. The Q values obtained after normal learning in each maze $(12 \times 12 \times 5)$ are changed to an array of 12×12 by finding the maximum value (maxQ) in each square. However, this is not known before application as it is an outcome. It is calculated as part of the evaluation for measuring similarity.

$$cos(Max_a Q_s, Max_a Q_t) = \frac{\sum_i Max_a Q_{s_{i,a}} Max_a Q_{t_{i,a}}}{\sqrt{\sum_i Max_a Q_{s_{i,a}}^2} \sqrt{\sum_i Max_a Q_{t_{i,a}}^2}}$$

5. Simulation

Five mazes were prepared to test the usefulness of the index. Maze A is the original maze and was applied to mazes B, C, D, and E, respectively. Fig. 1, Fig. 2, Fig. 3, Fig. 4, and Fig. 5 show the mazes.
Fig.1 Maze A
Fig.2 Maze B
Fig.3. Maze C
Fig.4 Maze D
Fig.5 Maze E

The similarity of the mazes to each indicator is shown in Table 1.

Table 1 Similarity Results

	Maze A to Maze B	Maze A to Maze C	Maze A to Maze D	Maze A to Maze E
Similarity by pixel value	82.95	77.08	80.02	79.44
Similarity between maze sequences	80.29	75.96	78.71	77.66
Similarity using Qmax	98.86	60.96	82.49	77.37
Cosine similarity using Qmax	72.97	5.89	41.17	28.91

S The Similarity results show that maze B, maze D, and maze C have the highest similarity in that order. Similarity by pixel value, similarity between maze sequences, and similarity using Qmax, in that order. The use of Q-values allows us to focus on differences only in important locations. Fig. 7, Fig. 8, and Fig. 9 show results of the transfer learning. Transition from maze A to maze C is not shown in the figure because the goal was not achieved. Reinforcement learning is represented by the red line and transfer learning by the blue line.
Fig.7. Transfer learning from maze A to maze B, left panel shows number of steps to goal and episodes, right panel shows total reward and number of episodes.
Fig.8. Transfer learning from maze A to maze D, left panel shows number of steps to goal and episodes, right panel shows total reward and number of episodes
Fig.9. Transfer learning from maze A to maze E, left panel shows number of steps to goal and episodes, right panel shows total reward and number of episodes

From these figures, the goal is reached faster with transfer learning than with reinforcement learning. This indicates that transition learning is effective in these mazes. Based on the results in the figures and the cosine similarity using Qmax, it seems reasonable to focus on the Q value.

Satoshi Sugikawa, Kenta Takeoka, Naoki Kotani.

Fig. 10 shows the results of applying reinforcement learning to the mazes. Fig. 11, Fig. 12, Fig. 13 and Fig. 14 show the results of applying transition learning to each maze. Red indicates locations with high rewards. The reward of maze A was applied to each maze. Therefore, the maze was routed from the top towards the goal. This demonstrates the validity of this simulation.
Fig.10 Result of Reinforcement Learning on maze A
Fig.11 Result of Transfer learning on maze B
Fig.12 Result of Transfer learning on maze C
Fig.13 Result of Transfer learning on maze D
Fig.14 Result of Transfer learning on maze E

6. Conclusion

In this study, we conducted basic research on measures focusing on environmental similarity in reinforcement learning. Simulation results confirmed the validity of focusing on maxQ. The validity of the indicator was also confirmed to some extent. In the future, the creation of more accurate indicators is required.

Abstract

The objective of this study is to predict air conditioning loads for existing buildings using operational data, weather forecasts and visitor forecasts. The proposed prediction method is based on a neural network approach. However, it is important to note that the proposed method does not learn the entire loads. Loads are divided into factors which can be predicted by traditional thermodynamics and factors which are subject to machine learning. The proposed method has been applied to an example instance using operational data from an underground mall in Kobe, and its validity has been confirmed.

Keywords: Cooling Load Prediction, Air Conditioning System, Existing Building Data, Machine Learning

1. Introduction

If air-conditioning load are accurately predicted, it is expected which the system is optimally operated, e.g. setting of changes in chilled water supply temperature, selection of heat source models, setting of operation times, for saving energy [1].

The purpose of this study is to predict future load of an air conditioning systems on the next day for which exists, using operational data of existing buildings, weather forecasts and visitor volume forecasts. The prediction algorithm is combining mathematical calculation and neural network (hereafter NN) methods. The proposed method has applied to an example based on operational data of an underground shopping mall in Kobe and compared with the actual measured cooling load.

Air conditioning load prediction for existing buildings differ from load calculations for new buildings in the followings.

1. Therefore historical operating data and corresponding load data exist, they can be used for forecasting by machine learning. The large amount of training data can be used for the load prediction without having to establish physical causal relationships between load calculation conditions and load values.
2. The actual situation regarding how the building is used is known, not the assumptions made at the time of design.
3. The process of changing the parameters and improving the accuracy of the predictions is expected, as results are immediately available on the correctness of the predictions.

The scope of this study is as follows.

1. The proposed approach predicts the hourly heat source load for the next day in the existing building.

2. The target of forecasting is limited to cooling loads, where more energy savings are expected, and does not deal with heating loads.

3. If the predicted cooling load is spatially subdivided, the approach is more valuable for air-conditioning operations, although, load performance monitoring points must also be taken at the same granularity. The detailed measurement has become realistic in recent years due to advances in IT technology, however, this research aims the cooling load forecast for the existing building, considering the suppression of renovation work costs.

2. Air-Conditioning Load

With reference to the dynamic load calculation method based on the response factor method [2], [3], the air-conditioning loads were classified into two categories: those estimated by mathematical calculations and those estimated by machine learning, assuming that each element has its own explanatory variables. The explanatory variables for each load element were selected on the basis of whether they could be measured in a typical building.

In this section, the term "current" indicates the point in time at which the forecast is made.

2.1. *Load Factors Subject to Machine Learning*

1. Load of exterior wall through-flow heat due to temperature difference between interior and exterior including through-flow load from glass. The explanatory variables for this load are: current outdoor air temperature, past outdoor air temperature (going back about 50 hours), past daily average outdoor air temperature (going back about 3 months), current horizontal solar radiation, and past horizontal solar radiation (going back about 50 hours).

2. Load of interior wall penetration heat from adjacent room. The explanatory variables for this load are the current outdoor air temperature and the past outdoor air temperature (going back about 50 hours).

3. Load due to solar radiation transmitted through glass. The explanatory variables for this load are current daylight hours, horizontal solar radiation, and historical horizontal solar radiation (going back about 10 hours).

4. Load due to drafts. The explanatory variables for this load are current outdoor air temperature, current outdoor air humidity, current external wind direction and speed, and building opening condition.

5. Load due to heat storage of intermittent air conditioning operation. The explanatory variable

for this load is the past room temperature of the room concerned (going back about 20 hours).

6. System losses, .e.g. fan reheat, duct losses and mixing losses.

2.2. *Load Factors Subject to Actuarial Calculations*

7. Load due to human metabolism. The explanatory variables for this load are current manpower, past manpower (going back about 10 hours), and average work intensity.

8. Load due to heat dissipation of lighting fixtures. The explanatory variables for this load are current power consumption and past power consumption (going back about 10 hours).

9. Load due to heat dissipation from other indoor equipment. The explanatory variables for this load are current heat generation, and past heat generation (going back about 10 hours).

10. Outdoor air load. The explanatory variables for this load are outdoor air intake, outdoor air temperature, and outdoor air enthalpy.

3. Prediction Method for Cooling Load

A prediction method which combines mathematical computation and machine learning approach is build.

3.1. *Learning Phase*

When training with measurement data, the data set is composed for NN [3] as follows.

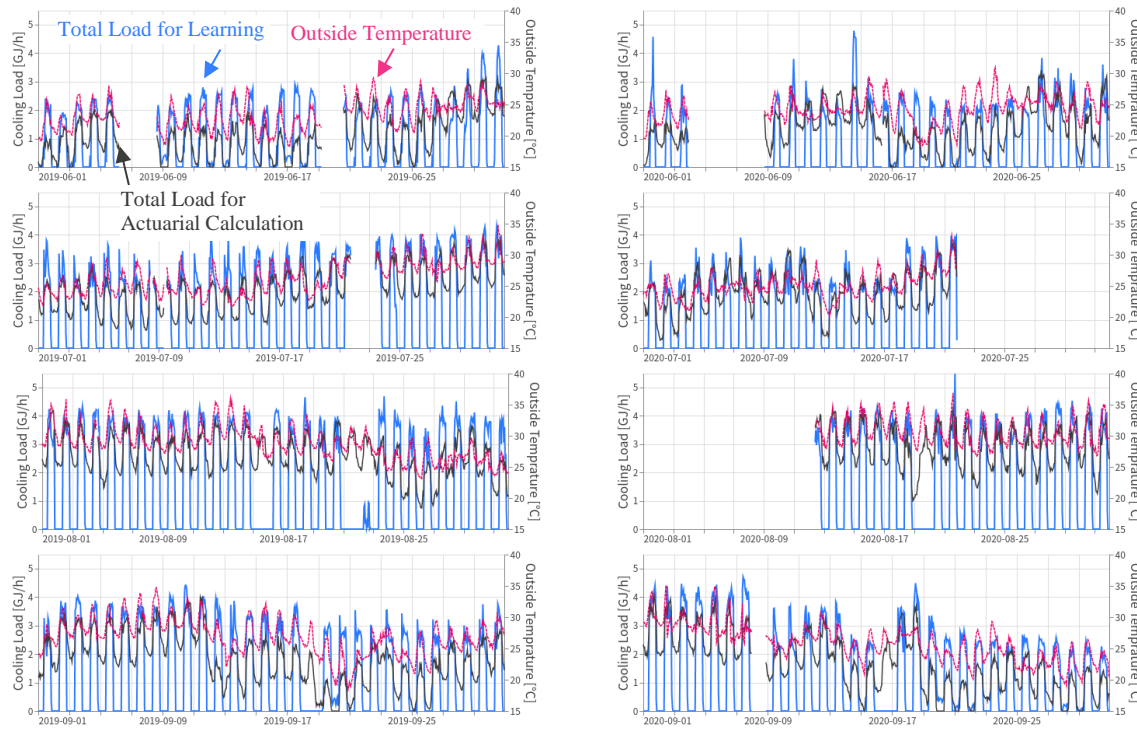
- Teaching data are the differences between the overall loads and the loads of Section 2.2.
- Input data are the explanatory variables for loads of Section 2.1.


Fig. 1 Monthly Cooling Load of the Example Instance in 2018 and 2019.

4. Computational Experiment

4.1. *Example*

An example of air conditioning load forecasting is consists of two years of measured data for the overall air conditioning load and the explanatory variables for each air conditioning load for the underground shopping mall in Kobe, see Table 1. Fig. 1 shows the cooling loads of 2 years.

Table 1. Outline of Underground Mall

Name	Santica
Year of construction	1963 (1st phase)
	1966 (2nd phase)
Management Entity	Kobe Chikagai Co., Lt
Total floor area	19,109m2
Retail area	10,145m2
Business Hours	10:00-20:00 (merchandising)
	11:00-21:00 (food and
	beverage)
	6:00 - 24:00 (passageway)

4.2. *Learning setting*

Since the subject is an underground mall, the effect of solar radiation was ignored among the air conditioning load elements. See [4] for the measurement method of the current people flow. The settings of the NN method are shown in Table 2.

Table 2. Setting of NN method.

Input Layer	Input Size	28
Intermediate Layer	Number of Layers	2
	Type	Fully-Connected Layer
	Activation Function	ReLU
	Number of Units	20 (first layer)
		10 (second layer)
Output Layer	Type	Fully-Connected Layer
	Output Size	1
Others	Batch Size	10
	Epoch Size	30
	Trial	10

Makoto Ohara, Hideo Isozaki

4.3. *Prediction setting*

In this manuscript, calculations are performed on historical data sets to verify the performance of the NN method. Where weather forecasts or other forecasting data should be used in actual use, measurement values are used. The people-flow prediction method is described in [5].

4.4. *Result*

Fig. 2 shows the difference between normalized predicted and actual measurements by time period. The errors are particularly large between 8:00 and 10:00 and at 20:00. The prediction accuracy is expected to improve when the conditions at the start and end of cooling are considered.
Fig. 2 Result of Prediction.

5. Conclusion

In this study, a method for predicting air-conditioning loads is investigated with the goal of efficient air-conditioning operation in underground malls with open areas. The proposed method has been applied the example based on actual data from the underground mall in Kobe. Future issues include evaluation of predictions based on actual use and examination of accuracy in comparison with existing studies.

Abstract

This study aims to investigate various aspects of intelligent logistics handling robots, including mechanical design, automatic control, and image recognition. With the continuous development of the logistics industry and advancements in automation technology, intelligent logistics handling robots play a crucial role in improving logistics efficiency and reducing costs. Leveraging existing technologies, we have designed and developed an omnidirectional mobile intelligent logistics handling robot equipped with a SCARA-type robotic arm. The robot integrates functions such as task acquisition, global positioning, material detection, warehouse identification, material handling, and stacking, achieving a fully automated and streamlined logistics handling process.

Keywords: Logistics handling robots, Automatic control, Image recognition, Global positioning

1. Introduction

In modern industrial production, logistics handling is a time-consuming and labor-intensive task. The modern industry faces rapidly changing market demands and a complex and dynamic production environment, making traditional manual logistics handling methods relatively outdated. In this situation, there is an urgent need for a more flexible, efficient, and adaptive logistics handling approach to meet the requirements of modern industry. This new type of handling method should be able to adapt to changes in different factory environments and production processes, completing a large number of handling tasks in a short time to improve production efficiency. This is precisely the significant advantage that intelligent logistics handling robots can bring to modern industry.

The intelligent logistics handling robot studied in this project comprehensively designs and analyzes aspects such as mechanical structure, robotic arm control and coordinate calculation, chassis control and global positioning, image recognition, and processing. A multifunctional intelligent logistics handling robot (AGV) is designed based on the omnidirectional wheel structure chassis and planar articulated (SCARA) robotic arm [1], [2], [3], [5]. It integrates functions such as positioning, environmental perception, path planning, material recognition and grasping, material placement, and stacking. This integration significantly reduces the number of operators, enhances the speed and accuracy of logistics operations, and greatly improves the efficiency of the logistics system.

2. Intelligent Logistics Handling Robot Overall Program Design
2.1. Operational site

In this thesis, the robot's operation site is based on the 9th China University Students Engineering Practice and Innovation Competition "Intelligent +" track logistics handling robot competition. The robot drives on the gray lane, and the rest of the area is matte white or yellow. In the competition venue, the start-stop zone, raw material zone, roughing zone and temporary storage zone are set up. The start-stop zone is blue in color and is used for the robot to go back and forth. Fig. 1 shows the exact location of the given raw material area, roughing area and staging area within the competition venue.

Yanchao Bi, Jiale Cheng, Limei Wang, Yizhun Peng
Fig. 1 Schematic diagram of the robotics field

The raw material area adopts a round electric turntable to arrange materials, and materials are identified by color. The top surface of roughing area, staging area, finishing area and finished product area are equipped with color rings and or circles for measuring the accuracy of material placement.

2.2. Mandate requirements

The robot follows a "one-key" start-up procedure, moving from the start-stop zone to the QR code panel within a specified time to read the QR code. It obtains two handling tasks (the sequence for handling materials of three different colors). According to the task requirements, the robot moves between the material area, rough processing area, and temporary storage area, carrying out placement and stacking tasks. After completing the tasks, it returns to the start-stop zone.

2.3. *Design proposal*

According to the task requirements, the overall design of the intelligent logistics handling robot is illustrated in Fig. 2. In terms of mechanical structure, the chassis adopts a Mecanum wheel [1], [5] double-layer shock-absorbing design, controlled by DJI brushless motors to achieve closed-loop control. The robotic arm employs a planar articulated (SCARA) design, driven by stepper motors and closed-loop stepper motors, allowing real-time reading of the angles of each joint for feedback control.

The electronic control system is mainly divided into three parts: chassis motion control system, robotic arm motion control system, and visual recognition system. The chassis motion control system, centered around the

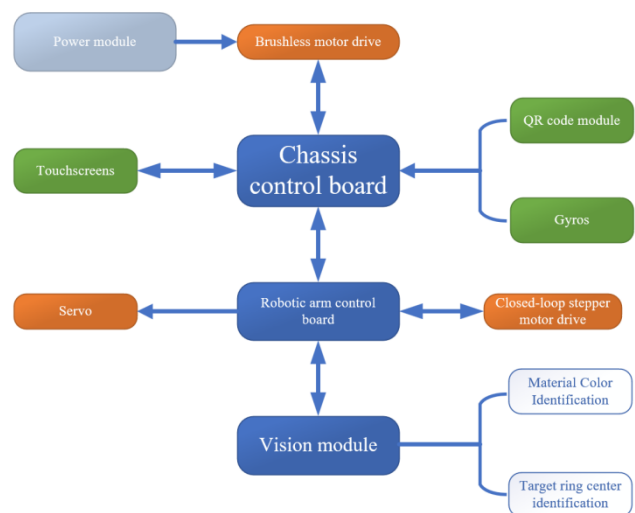
chassis control board, includes external devices such as a QR code recognition module, gyroscope, touchscreen, and brushless motor driver. The robotic arm motion control system integrates servos and utilizes closed-loop stepper motors for precise control of the robotic arm. The visual module, developed based on OpenCV, includes functions for material color recognition and target ring center recognition. The chassis control board, robotic arm control board, and visual module are all powered simultaneously by the power module.


Fig. 2 Overall design schematic

3. Design of Mechanical Structural Systems

3.1. *Intelligent logistics handling robot overall mechanical structure design*

To ensure the flexibility and efficiency of the robot, the chassis adopts a Mecanum wheel chassis, and the mechanical arm structure adopts a standard three-axis SCARA structure.

a. Robot 3D drawing
b.   Robot Physical Picture
Fig. 3 Image of Intelligent Logistics Handling Robot

3.2. *Chassis mechanical structure design*

The chassis adopts a double-layer design with Mecanum wheels, made of aluminum alloy with electroplating process. The lower layer of the chassis houses the electronic control system, while the upper layer accommodates the mechanical arm, material storage, and human-machine interaction module, among others. The overall structure is well-defined.

The motion system of the chassis requires a high level of grounding for the Mecanum wheels [5]. To ensure stable movement of the robot, the lower layer of the chassis adopts a double-plate coaxial structure, ensuring that all four wheels touch the ground simultaneously. This design increases shock absorption and solves the problem of Mecanum wheels slipping when not in contact with the ground [1].

a.   Top view

b.   Bottom view
Fig. 4 Chassis structure

3.3. *Mechanical structure design of mechanical arm*

This robotic arm is of the three-axis SCARA type [2], made of PLA material and manufactured using 3D printing technology. It is lightweight in quality.
Fig. 5 3D model of the robot arm

The upper arm of the robotic arm is connected to the arm axis through a linear bearing, while the lower arm is equipped with a thrust ball bearing to withstand axial forces and reduce friction between the upper and lower arms. The robotic arm can achieve three degrees of freedom through the motion of stepper motors, including vertical movement, rotation of the upper arm, and rotation of the lower arm.

3.4. *Mechanical Structure design of mechanical claw*

The mechanical claw is one of the key components of an intelligent logistics handling system. It is manufactured using 3D printing technology and made of PLA material.

Yanchao Bi, Jiale Cheng, Limei Wang, Yizhun Peng
a.   3D drawing
b.   Concrete drawing
Fig. 6 Robotic Gripper Structure

The mechanical claw is used for grasping and identifying materials. When grasping materials, the mechanical claw needs to firmly grip the materials. The mechanical claw is divided into active and passive parts, with the active part being directly driven by a servo motor to rotate, and the active part drives the passive part to rotate through gears. The identification of materials involves the use of a camera and a visual recognition system. The camera is installed in the center of the mechanical claw.

4. Three-axis SCARA Robot Kinematic Model

4.1. *Kinematic modeling of a three-axis SCARA robotic arm*

SCARA robotic arms are usually characterized by high accuracy, high speed and repeatability [2], [3]. In this project, the SCARA robotic arm is designed as a three-degree-of-freedom, containing one rotational degree of freedom in the XY plane, one lifting degree of freedom in the Z-axis, and one moving degree of freedom in the

Z-axis. The process of solving the operational science model of the three-axis SCARA robotic arm is as follows:

Determination of joints, connecting rods and their parameters. The robot arm uses a rotating chassis at the bottom, lifting and lowering using a stepper motor screw Z-axis, and a rotating arm in the XY plane, for a total of three degrees of freedom, and the analysis process is simplified by dropping the end-effector [3].

Simplify the model to set the coordinate system. With the vertical upward as the +Z-axis and the center of the Z-axis as the coordinate origin from the top view, establish a plane right-angle coordinate system with the body as the reference system.
Fig. 7 Simplified coordinate system model

As shown in Fig. 7, for the big arm of the robot arm, for the small arm of the robot arm. For the rotation angle of the big arm, controlled by the bottom disk; for the rotation angle of the small arm, controlled by the stepping motor through the synchronous belt.

Inverse kinematic modeling calculations. We set the point coordinates to (x, y, z), the length of the big arm to be L1, and the length of the small arm to be L2, then the length $L3 = \sqrt{L1^2 + L2^2}$. The angle of rotation of the large arm θ_1 and the angle of rotation of the small arm θ_2 need to be solved for. This leads to Eq. (1). The rotation angle of the big arm θ_1 and the rotation angle of the small arm θ_2 can be found (Eq. (2)).

$$\begin{cases} \cos(\theta_1) = \dfrac{L2^2 + L3^2 - L1^2}{2 * L2 * L3} \\ \cos(\theta_2) = -\dfrac{L1^2 + L2^2 - L3^2}{2 * L1 * L2} \end{cases} \quad (1)$$

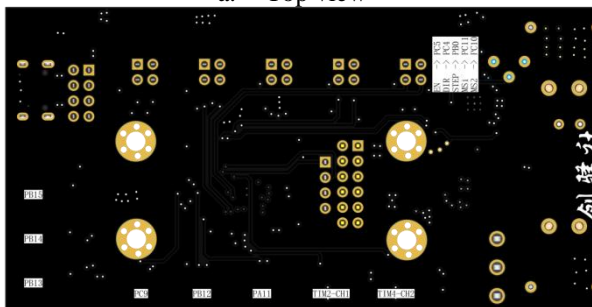
$$\begin{cases} \theta_1 = arccos(\dfrac{L2^2 + L3^2 - L1^2}{2 * L2 * L3}) \\ \theta_2 = arccos(-\dfrac{L1^2 + L2^2 - L3^2}{2 * L1 * L2}) \end{cases} \quad (2)$$

4.2. *Robotic arm electronic control system design*

(1) Robotic arm control board circuit design

The robotic arm control board uses STM32F405RGT6 as the main control chip [4], with an externally integrated power module, stepper motor drive module and communication module. The power supply module part, the input voltage is 12V, using TPS5430 decompression to generate 5V voltage, and then through the AMS1117 on the 5V voltage regulator to generate 3.3V, thus generating all the voltages required for system operation. The control board integrates the TMC2209 stepper motor driver, which is powered by 12V and has the advantages of silence, high speed and low failure, and is used for open-loop control of the stepper motor. The closed-loop stepper motor driver is controlled using a UART interface. In order to realize a UART interface and multiple closed-loop stepper motor driver communication problems, we use a diode plus pull resistance way to enhance the serial port receiving ability, shielding the interference signal.

(2) PCB Overall Layout

The control board of the robotic arm is a four-layer board, and the shielding layer is set up to shield the power supply and signals, which improves the signal stability of the system. As Fig. 8 are the front and back of the chassis control board.
a.   Top view


b.   Bottom view

Fig. 8 Robotic arm control board

(3) Robotic arm software design

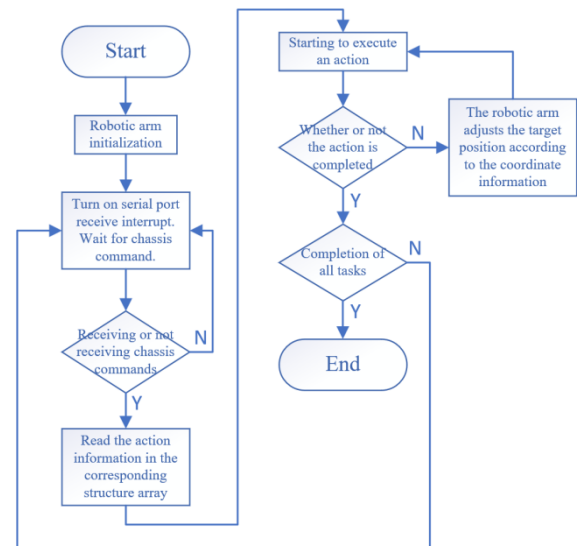
The robotic arm performs numerous actions, and the use of sequential execution of robotic arm actions will occupy a large amount of program storage space, and the code logic is confusing and redundant. This system uses structure variables to save the spatial coordinates of each step of the robotic arm action and information such as gripping operation, and establishes structure arrays for storing the information of the robotic arm action during the whole operation process. After the robotic arm is powered on, it initializes the peripherals and stepper motors, servos and so on. After the initialization is completed, turn on the serial port to receive interrupts and wait for the chassis controller to send task execution instructions. When the task execution instruction is received, the robotic arm starts to move, reads the action information in the structure array, and executes it step by step. The vision system will send the material color, target ring coordinates and other information to the robotic arm, and the robotic arm will calibrate and correct the position through this information. When all the actions are completed, the robotic arm task is completed and returns to the initial state. The workflow of the robotic arm motion control system is shown in Fig. 9.


Fig. 9 Flow chart of robotic arm motion control system

5. Chassis Motion Control System Design

5.1. *Mecanum wheel chassis kinematics model*

The Mecanum wheel platform kinematic model is to establish the relationship between the rotational speed of the four Mecanum wheels and the speed of the geometric center [4]. The positive kinematics model is to know the rotational speed of the four Mecanum wheels and calculate the speed of the Mecanum wheel platform center point CENTER; the inverse kinematics model is to know the speed of the Mecanum wheel platform center point CENTER and calculate the speed of the four Mecanum wheels.

As an example, the inverse kinematics model of the Mecanum wheel is used to establish a coordinate

system with the geometric center point CENTER of the top view of the chassis as the origin [5]. The distance between the CENTER point and the point of contact between the Mecanum wheel and the ground is r. r_x and r_y denote the projected distances on the x-axis and y-axis, respectively, of the CENTER coordinate system (both positive). The velocity of the CENTER point is known to be $[v_c \ w_c]^T$. v_{cx} and v_{cy} are the components of a on the x and y axes, respectively.
Fig.10 Decomposition of Mecanum Wheel Platform Motion

After calculation, the inverse kinematic equation of Mecanum's wheel can be obtained.

$$
\begin{bmatrix} w_1 \\ w_2 \\ w_3 \\ w_4 \end{bmatrix} = \frac{1}{R} \begin{bmatrix} 1 & -1 & -(r_x + r_y) \\ 1 & +1 & -(r_x + r_y) \\ 1 & -1 & +(r_x + r_y) \\ 1 & +1 & +(r_x + r_y) \end{bmatrix} \begin{bmatrix} v_{cx} \\ v_{cy} \\ w_c \end{bmatrix} \quad (3)
$$

The positive kinematics equations are based on the rotational speeds of the four Mecanum wheels to calculate the velocity of the point CENTER, and the theoretical analysis is similar to the inverse kinematics, and the simplest way to do this is to invert Eq. (3), which can be expressed as Eq. (4).

$$
\begin{bmatrix} v_{cx} \\ v_{cy} \\ w_c \end{bmatrix} = \frac{R}{4} \begin{bmatrix} +1 & +1 & +1 & +1 \\ -1 & +1 & -1 & +1 \\ -1 & -1 & 1 & 1 \\ r_x + r_y & r_x + r_y & r_x + r_y & r_x + r_y \end{bmatrix} \begin{bmatrix} w_1 \\ w_2 \\ w_3 \\ w_4 \end{bmatrix} \quad (4)
$$

5.2. Full-field positioning method

The full-field localization method studied in this project does not require the addition of the rest of the extra sensors or encoders and uses the robot's own

Mecanum wheel as the encoding wheel. When the robot starts to move, the Mecanum wheel starts to shift rotation. According to the positive kinematics model of the Mecanum wheel, the velocity of the robot at the current moment can be obtained from the rotational speeds of the four wheels with respect to the current coordinate system of the robot itself [5]. Assuming that the angle between the current robot's own coordinate system and the world coordinate system is θ (Fig. 11).
Fig.11 World Coordinate System and Own Coordinate System

The expression for converting the robot's velocity in its own coordinate system to the velocity in the world coordinate system is Eq. (5).

$$
\begin{bmatrix} v_x \\ v_y \\ w_z \end{bmatrix} = \begin{bmatrix} cos\theta_0 v_{cx} + sin\theta_0 v_{cy} \\ -sin\theta_0 v_{cx} + cos\theta_0 v_{cy} \\ w_c \end{bmatrix} \quad (5)
$$

With the same time units, the conversion to a displacement expression is Eq. (6).

$$
\begin{bmatrix} x_x \\ x_y \\ \theta_z \end{bmatrix} = \begin{bmatrix} cos\theta_0 x_{cx} + sin\theta_0 x_{cy} \\ -sin\theta_0 x_{cx} + cos\theta_0 x_{cy} \\ \theta_c \end{bmatrix} \quad (6)
$$

In this case, the calculated displacement is the relative displacement in the world coordinate system for an instantaneous moment. Since the angle between the robot's own coordinate system and the world coordinate system is always changing, therefore, to obtain the displacement of the robot in the world coordinate system over a period of time, it is necessary to integrate the displacement value calculated at any moment (discrete data summation) [6], assuming that over a period of time, a total of N times the robot's displacement relative to the

world coordinate system at a given moment, the cumulative displacement expression is Eq. (7).

$$\begin{bmatrix} \Delta x_x \\ \Delta x_y \\ \Delta \theta_z \end{bmatrix} = \begin{bmatrix} \sum_{i=0}^{N} cos\theta_i x_{cxi} + sin\theta_i x_{cyi} \\ \sum_{i=0}^{N} -sin\theta_i x_{cxi} + cos\theta_i x_{cyi} \\ \Delta \theta_c \end{bmatrix} \quad (7)$$

In Eq. (7), i represents the number of operations.

5.3. *Chassis electronic control system design*

(1) Chassis control board circuit design

The main control and power scheme of the chassis control board is the same as that of the robotic arm control board, in addition to the integrated communication module. The chassis motion control system adopts a variety of communication interfaces to communicate with various peripherals, mainly including communication with gyroscope, QR code scanning module through UART serial port, communication with touch screen through SPI and IIC, and communication with brushless motor driver through CAN [7].

(2) PCB Overall Layout

The PCB is fabricated using a two-layer board design with careful planning and design of the overall layout. As Fig. 12 show the front and back view of the chassis control board.
a.   Top view

b.   Bottom view

Fig.12 Chassis control board

5.4. *Chassis software design*

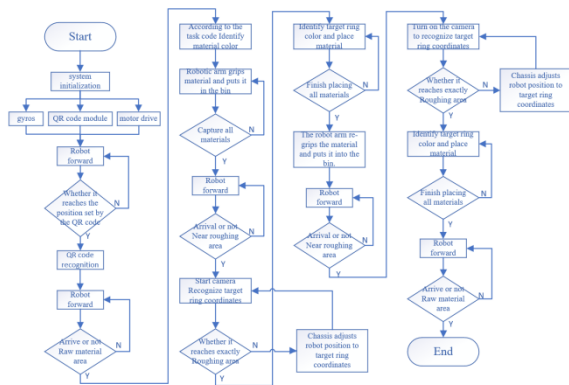
Prepare a chassis motion control system flowchart according to the task requirements. After the system is powered on, the program starts running and the peripherals are initialized. After the initialization is completed, the robot drives out of the start-stop area, runs to the QR code board, and starts the QR code scanning module to start scanning the QR code to receive the task code. The robot enters the next running task and proceeds to the raw material zone. When the robot runs to the raw material area, the vision system is activated to identify the color of the material according to the task code, and the robotic arm starts to grasp and place it into the bin on the robot. After completing the grasping of all materials, the robot continues to move forward. When the robot travels to the vicinity of the roughing area, the vision system starts to recognize the coordinates on the target ring in the roughing area. The chassis control board adjusts the robot position according to the coordinate data so that the robot is accurately close to the rough machining area. At this time, the vision system starts to identify the center of the target ring, and the robotic arm will place the corresponding color materials in the target ring according to the position of the target ring. After all materials have been placed, the robot will pick up the materials again in the order in which they were placed and place them in the bin on the robot. When the above operation is complete, the robot will move on to the staging area and resume the material placement operation. This operation is the same as the robot placing material in the roughing area. When all tasks are completed, the robot returns to the start-stop area.


Fig.13 Chassis Motion Control System Flowchart

6. Visual identity system

6.1. *Material Color Identification*

The task requires the robot to be able to recognize the color of the material and grab the material in the order of the task code. This project uses OpenCV library for color recognition and detects the center of gravity of the material in the image. The idea of specific color recognition is to confirm the HSV color space threshold of the color and binarize the image with this HSV threshold to get a binary image [8]. At this point, the image is expanded so that the outline of the material in the image tends to be more like a circle. Based on this outline, it can be determined to circle the material and determine the coordinates of the center of gravity of the material.

As in Fig. 14, the robot gripper is directly above the blue material, at this time, the visual recognition system is turned on to identify the material color. The outline of the material will be wrapped by the black outline line, and the center of the material will be marked (center).

a. Identification process

b. Identification results

Fig.14 Visual identification of material colors

6.2. *Target ring center identification*

The task requires the robot to be able to recognize the target ring coordinates and place the material accurately into the target ring coordinates. This project uses the OpenCV library to identify the center of the target ring, which is a circle with color. When dealing with the target ring detection problem, this system does not directly detect the target ring directly by means of Hough's circle transformation, but first binarizes the image. After that, the contours in this image are searched and the contours are filtered to find the contour of the target ring. The contour of the target ring is drawn as the smallest enclosing circle, which is very close to the position and size of the target ring itself, and the circle is the center of the target ring.

As shown in Fig. 15, the robot gripper is directly above the blue target ring, and at this time, the visual recognition system is turned on to detect the center of the target ring. The center of the blue target ring will be marked by a blue dot.
a. Identification process
b.   Identification results
Fig.15 Visual recognition target ring center

7. Conclusion

This project designs an intelligent logistics handling robot (AGV) for industrial logistics scenarios, which is equipped with a chassis motion control system based on an omnidirectional moving chassis with Mecanum wheels, a robotic arm motion control system based on a planar articulated (SCARA) robotic arm, and a material recognition system based on machine vision. The chassis motion control system is used to control the robot motion, pick up the task code, and perform full-field localization. The robotic arm motion control system realizes material gripping and placing operations through the movement of the robotic arm. The visual recognition system then identifies the color of the material and the center of the target ring. The chassis motion control system sends commands to the chassis motion control system to control the robotic arm to perform tasks. When the robotic arm performs the task, it needs to receive the data returned by the visual recognition system to correct the coordinate position. Each system cooperates with each other to accomplish the task.

The design simulates the handling and palletizing tasks under industrial operations, which will greatly improve the rapidity and accuracy of logistics operations and greatly improve the efficiency of the logistics system.

Abstract

This device is to solve the traditional pesticide spraying method on the human body has a greater impact and other issues, through the STM32-based visualisation of the intelligent greenhouse to achieve automatic spraying of pesticides and remote monitoring and other functions, the establishment of a visualisation of the intelligent greenhouse monitoring platform. This equipment through the MQTT protocol, not only through the Internet of Things platform real-time monitoring of crop growth status in the greenhouse, but also through the platform to determine whether to spray pesticides, data transmission, so as to use the cross slide to control the position of the nozzle, and then through the visual recognition algorithms to improve the accuracy of the visual recognition part of the accuracy of the spraying of plants affected by insect pests, the realization of the digital intelligent greenhouse.

Keywords: STM32, Monitoring Platform, MQTT, Visual Recognition

1. Introduction

This project is dedicated to solving problems such as the potential impact of traditional pesticide spraying methods on the human body. Through the STM32-based [1] visualised intelligent greenhouse, automatic pesticide spraying and remote monitoring functions are realised, and a complete visualised intelligent greenhouse monitoring platform is constructed. We adopted the MQTT [2] protocol, which not only monitors the growth status of crops in the greenhouse in real time, but also replenishes different colours of light in a targeted manner according to the light conditions inside the greenhouse to improve the efficiency of photosynthesis. This is not only more energy efficient than traditional white light supplementation, but also significantly increases crop yields and helps to make the system carbon neutral.

In addition, our system also features indoor temperature monitoring and control, which promotes the accumulation of organic matter in crops by adjusting the temperature difference between day and night. For a more precise response to pests, we utilise a cross slide to control the position of the nozzles and incorporate visual recognition algorithms to improve the accuracy of spraying on pest-affected plants [3]. For a sustainable energy supply, we added solar panels to the exterior of the greenhouse to provide a constant source of energy for the system, while improving long-term human health,

reducing air pollution and greenhouse gas emissions, and positively impacting human health [4].

For the electrical control part of the project, we carried out systematic modelling and simulation through the Proteus simulation platform to determine the optimal operating conditions. Subsequently, we used Altium Designer to create the design, programming and debugging, and finally succeeded in building an efficient intelligent greenhouse monitoring platform [5].

The rest of this paper is organised as follows. The second part describes the hardware used and the theoretical calculations. The third part describes the method of controlling the nozzle and the visual recognition algorithm. Part IV describes how the smart shed works and shows some of the operational results. Part V summarises the main points of the paper.

2. Design of Hardware Structure

2.1. Selection of the main control board

This work needs to deal with a large amount of data, has a more complex circuit, and needs a lot of memory, so it needs a microcontroller that can deal with a lot of song peripheral devices at the same time, so the STM32F4 became the team's first choice. the physical diagram of the STM32F4 is shown in Fig. 1.

Fig. 1 STM32F4 Physical

2.2. Relay Modules

This work is controlled by mobile phone APP, through the Internet of Things platform, the corresponding signal will be sent to the STM32 core board, and it will control each module. In order to save power, they will use a relay to control the switch of some modules, so that some non-working modules are in the off state when they are not working, this work uses the JQC-3FF-S-Z relay, the physical picture is shown in Fig. 2.

Fig. 2 Relay Physical Diagram

2.3. Driver Modules

This work needs to be as precise as possible when it comes to pesticide spraying so that the pesticide can be sprayed where we need it, so we chose to use stepper motors and stepper motor drives. The physical drawing of the stepper motor and stepper motor drive is shown in Fig. 3.
Fig. 3 Physical drawings of stepper motors and stepper motor drives

2.4. Mechanical components

The mechanical part is designed as shown in Fig. 7, its motion system consists of two axes, X-axis and Y-axis, to control the position of the nozzle and the pump.

The nozzle structure is to control different spraying methods and the pump structure is used to spray different concentrations of pesticides. The mechanical structure is modelled as shown in Fig. 4.

Fig. 4 Mechanical structure modelling drawings

The main issues considered in the design: Since the crops inside the greenhouse are scattered all over the place, a mechanical structure that can bring the nozzles and pumps to every part of the greenhouse is needed, they refer to the mechanical structure that controls the movement of the nozzles in the 3D printers, and they designed and chose the above solution.

2.5. Sensor selection

In order to obtain more information about the greenhouse, this work chooses a variety of sensors. The temperature and humidity sensor can always sense the temperature and humidity inside the greenhouse, which is convenient for the adjustment of the internal temperature of the greenhouse [6]; the light intensity sensor monitors the change of the light intensity inside the greenhouse, so as to judge what colour and intensity of light needs to be reinforced; the visual sensor can intuitively observe the growth status of the plants inside the greenhouse and transmit the information to the user's mobile phone APP, so as to achieve real-time monitoring. The digital temperature and humidity sensor, light intensity sensor and OpenMV are shown in Fig. 5.

Fig. 5 The digital temperature and humidity sensor, light intensity sensor and OpenMV

2.6. Motion control of nozzles and pumps

Motion control of spray nozzles and pumps means that the mobile phone APP or various sensors send signals to the main board, so as to control the spray nozzles and pumps to move according to the predetermined paths and speeds in the two-dimensional space through the cross-axis structure. They use stepper motors to drive the nozzles and pumps along the X-axis and Y-axis, and the rotation angle and speed of the stepper motors are controlled by pulse signals sent from the main board, and the frequency and number of pulse signals are determined by the concentration of pesticides that need to be configured [7].

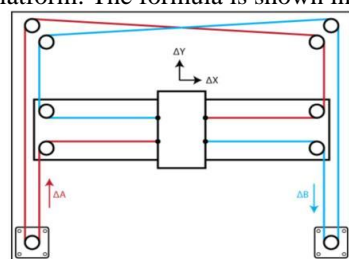
The principle of this mechanism is to control the movement of X-axis and Y-axis by two motors at the same time, when the left and right motors are in the same direction, they move towards X-axis, and when the two motors are in the opposite direction, they move towards Y-axis. The simultaneous action of the two motors provides a more stable force than a single motor controlling one axis, and reduces the weight of one motor on the XY platform. The formula is shown in Fig. 6.


Fig. 6 Formula

2.7. Pesticide concentration configuration

They will configure pesticides in different concentrations according to the needs of different crops

There are several formulas for pesticide formulation:

Conversion between per cent concentration and parts per million concentration: parts per million (ppm) = $10,000 \times$ per cent concentration

Conversion between the multiplier method and the percentage concentration: Percent concentration (%) = (original concentration/dilution times) $\times$ 100

Calculate the amount of diluent according to the active ingredient:

Dilution of 100 times or less: Diluent dosage = Weight of the original agent $\times$ (concentration of the original agent - concentration of the formulated agent) / Formulation Concentration of formulated agent

Dilution more than 100 times: Diluent dosage = weight of the original agent $\times$ concentration of the original agent / concentration of the formulated agent

Calculate the amount of diluent by the multiplier method:

Dilution less than 100 times: Diluent dosage = Original agent weight $\times$ Dilution times - Original agent weight

Dilution more than 100 times: Diluent dosage = original agent weight $\times$ dilution times

Mass percent concentration: Mass percent concentration (%) = solute mass/solution mass 100%

Molar concentration: molar concentration (mol) = solute moles / solution volume (litres) [8].

Equivalent concentration: Equivalent concentration = gram equivalent of solute / volume of solution (litres)

Mass-volume concentration: Mass - volume concentration = mass number of solute (grams or milligrams) / volume of solution (cubic metres or litres)

2.8. Solar panel steering design

A common method in solar panel steering design is to use a microcontroller and a photoresistor module to collect light intensity data in four directions, and then convert them into digital signals through ADC, and then drive the servo or stepper motor to adjust the angle of the solar panel through comparison and control algorithms.

The specific calculation process is as follows:

Collect light intensity data in four directions through ADC, respectively x0 , x1 , y0 , y1, and can take the average value several times to improve the accuracy. Calculate the difference between the two directions of light intensity, respectively, dx = x0 - x1 , dy = y0 - y1, these two values reflect the solar panel and the degree of deviation from the sun. Based on the positive, negative and magnitude of dx and dy, the direction and angle to be adjusted are determined. For example, if dx > 0 and dy > 0, the solar panel needs to be rotated to the upper left; if dx < 0 and dy < 0, the solar panel needs to be rotated to the lower right; and if dx = 0 and dy = 0, the solar panel has been aligned with the sunlight.

According to the direction and angle to be adjusted, calculate the corresponding PWM signals or pulse numbers, and then generate PWM signals or pulse signals to drive the servo or stepper motor to rotate the corresponding angle by timer interrupt or other means.

Repeat the above steps until dx and dy are close to zero, i.e. the solar panel is perpendicular to the sunlight.

3. Software design

3.1. Pesticide spraying design

When the vision system detects that a plant is infested, it automatically feeds back a signal to the stepper motor system. The stepper motor system responds quickly and accurately drives the pesticide nozzle to position itself near the infected plant. The stepper motors then co-ordinate the spraying of the pesticide to ensure efficient and precise spraying of the pesticide in the affected area. This intelligent system not only responds to pest problems in a timely manner, but also provides a reliable solution for plant healthcare by maximising spraying efficiency through the collaborative operation of the vision system and stepper motors [3], [7]. The stepper motor working process is shown in Fig. 7.
Fig. 7 The stepper motor working process

3.2. Visual Inspection

(1) Acquisition of plant leaf datasets

They acquired a detailed and rich batch of plant leaf datasets and leaf disease datasets, a valuable resource that will fully support in-depth research. The data covers multiple dimensions, including plant growth, dynamics of physiological parameters, and the potential impact of environmental factors on tobacco quality. By carefully analysing this dataset, they will be able to gain insight into all aspects of plant growth. The plant leaf dataset is shown in Fig. 8, and the diseased plant dataset is shown in Fig. 9.
Fig. 8 The plant leaf dataset

Fig. 9 The diseased plant dataset

(2) Annotate

He carefully and systematically annotated the leaf dataset and leaf disease dataset of this batch of plants. Through the annotation scheme designed by him, he captured and recorded the characteristics of the plants at different growth stages, from roots to leaves, from physiological parameters to environmental adaptations. And he captured the characteristics of plants suffering from pests, diseases and so on. This kind of annotation not only enriches the connotation of plant data, but also lays a solid foundation for subsequent data analysis and model construction. The process diagram of leaf annotation is shown in Fig. 10, and the process diagram of disease point annotation is shown Fig. 11.
Fig. 10 The process diagram of leaf annotation
Fig. 11 The process diagram of disease point annotation

(2) Identification

Through CNN neural networks, he successfully implemented the functions of leaf recognition and pest identification [9], and cleverly combined them to form an efficient and comprehensive system. Through deep learning and computer vision techniques, he accurately recognised different types of tobacco leaves in the leaf images, and based on this, the system was able to keenly detect possible insect pests through careful algorithm design. The leaf recognition and pest recognition diagram is shown in Fig. 12. The final recognition result is shown in Fig. 13.

Fig. 12 The leaf recognition and pest recognition diagram
Fig. 13 The final recognition result

3.3. Optimisation

Since the disease target is very small, the sensory field of the original smallest detection head is still larger than the size of the target, so it is necessary to improve the original network, starting from the optimisation algorithm, firstly, the activation function is improved, they use leaky relu activation function in the middle layer, and the S-type activation function is selected for the last detection layer, and at the same time, the mish activation function is used; and the loss function is improved , using the CIOU loss as the loss of the bounding box, which can

bring faster convergence speed at the same time, have better performance [10]. The activation function is shown in Fig. 14.
Fig. 14 activation function

4. Experiment

4.1. Pesticide spraying programmes

In the smart greenhouse system, they have introduced an advanced disease monitoring and prevention mechanism. Once the system recognises the presence of a plant disease, the automated control system is instantly activated, transferring the information to the stepper motor system. The stepper motors precisely manoeuvre the pesticide nozzles to move to the exact location of the infected plant. The intelligent system then implements precise and efficient spraying according to a pre-set pesticide spraying programme to maximise the suppression of the spread of the disease.

Future research directions include further optimising disease detection algorithms, improving the system's ability to accurately identify different disease types, and incorporating advanced pesticide selection and use techniques to achieve more precise and sustainable disease prevention and control strategies. Such innovations will lead to more sustainable and efficient plant health management solutions in the field of smart agriculture.

4.2. Mobile Application Programming

By running a well-designed mobile application, he successfully implemented a real-time greenhouse monitoring system on his mobile phone. The application provides an intuitive and detailed user interface that enables users to easily monitor the status of the greenhouse remotely and access key environmental indicators in real time. Users can easily access data such as temperature, humidity, light and soil moisture, as well

as plant growth conditions in each area of the greenhouse, anytime, anywhere, using their smartphones [11].

Through the mobile app, users can set customised alarm thresholds, and the system will immediately send notifications to alert users of any abnormal changes in environmental conditions. This real-time monitoring and response mechanism provides users with timely decision support, enabling them to quickly take the necessary measures to safeguard plant health and growth.

In addition, the mobile app supports remote control of the greenhouse system. Users can adjust parameters such as temperature control, humidity regulation, light management, and irrigation system through the mobile phone to achieve intelligent remote control of the greenhouse environment. Such flexibility enables users to make adjustments according to real-time changing needs, improving the adaptability and operability of the greenhouse system. The running diagram of the programme is shown in Fig.15.

Fig. 15 The running diagram of the programme

5. Conclusion

Nowadays, with the rapid development of artificial intelligence and Internet of Things technology, the visualised smart greenhouse designed in this paper is precisely in line with the trend of technological development, combining the knowledge of microcontroller, machine vision, artificial intelligence, and many other things with each other to form a complete system, and it is believed that in the future, this design will be more widely used in the agricultural market. This design combines the knowledge of multiple disciplines,

improves the human-computer interaction experience, and improves efficiency while protecting people's safety, and I believe that the demand for this type of product in the agricultural market will grow.

Abstract

The work is centered on ROS and integrates speech recognition and natural language processing modules to enhance the environmental awareness of the stroller and monitor the baby's condition to ensure a timely and appropriate response. The Raspberry Pi is the main control unit of the stroller and connects to a cloud-based IoT platform via the MQTT protocol. The platform facilitates seamless communication between the Raspberry Pi and cloud data for efficient data visualization on mobile devices. This innovative solution solves the challenge of balancing parental responsibilities with career advancement, promoting healthier and happier babies while allowing parents to maintain a harmonious work-life balance.

Keywords: Natural Language Processing, MQTT Protocol, Data Visualization, Cloud Computing, Raspberry Pi

1. Introduction

In order to reduce greenhouse gas emissions and at the same time enhance the safety and interactivity of the stroller, this work designs a modular photovoltaic intelligent portable stroller system with active safety, micro-environmental monitoring and remote monitoring of mobile terminals [1], and carries out a scientific and intelligent design of the software and hardware of the photovoltaic environmentally friendly portable stroller movement system and monitoring system [2].

The work uses polycrystalline solar panels to charge lithium-ion batteries, sets three power modes, and adopts aluminum alloy and other carbon-saving materials, which helps to reduce air pollution and greenhouse gas emissions, and responds to the national call for promoting green and low-carbon development [3]. The work uses STM32 development board as the bottom control center, and DC motor and drive circuit to build the bottom drive system hardware; adopts ROS as the core, and applies IoT technology with voice recognition and natural language processing module to realize the stroller's perception of the surrounding environment and the baby's state and make appropriate responses; adopts Raspberry Pi as the upper host computer of the stroller, and builds a cloud IoT platform and a cloud IoT platform based on MQTT protocol, and uses Raspberry Pi as the upper host computer. Raspberry Pi is used as the host controller of the stroller, and a cloud-based IoT platform based on MQTT protocol is built and the interaction scheme between Raspberry Pi and cloud data is designed to realize the convenient interaction function of data visualization in the mobile terminal [4].

The rest of the paper is organized as follows. The second part introduces the system program design. The third part introduces the working principle of the stroller, which includes the design of automatic following and safe obstacle avoidance function, automatic cradle function design, microenvironment sensing system design, baby crying sound sensing and recognition design and baby expression recognition design. The fourth part summarizes the main content of this paper.

2. System Programming

The team carried out the overall design and technical analysis of the system for the modular photovoltaic smart eco-friendly baby stroller. The function realization part of the stroller is a set of integrated motion device, which contains modules such as automatic cradle, autonomous following, etc.; and the monitoring part is a complete set of intelligent IoT solutions, which contains modules such as intelligent interaction, active safety, and visual surveillance [5]. The multi-angle view of the smart eco-friendly stroller is shown in Fig.1.
Fig. 1 The multi-angle view of the smart eco-friendly stroller

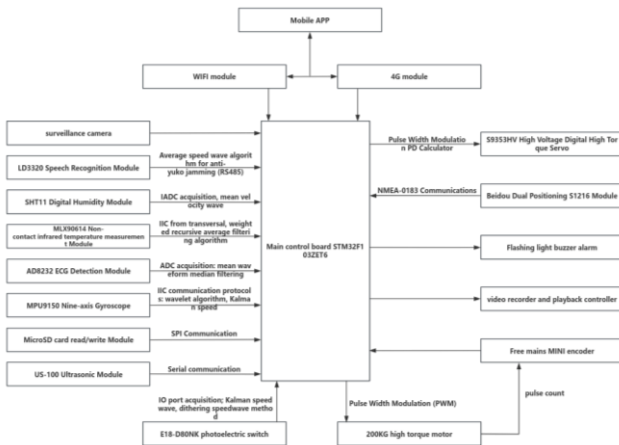
The modular photovoltaic intelligent eco-friendly stroller realizes the corresponding functions by controlling a variety of intelligent modules such as motor drive module, autonomous motion module, automatic brake module, automatic bed shaking module, deep learning module, visual monitoring module, intelligent interaction module and so on through the embedded system, and the intelligent system based on the Internet of Things (IoT) can make the stroller connected to the mobile terminal and provide real-time feedback for the parents on all kinds of information of the baby in the stroller. The system block diagram is shown in Fig. 2.


Fig. 2 The system block diagram

The sensor data collected by the controller is susceptible to external interference and is not highly accurate. In this work, different sensor data types are processed by mean filtering, weighted recursive average filtering, median filtering, Kalman filtering, dithering filtering, first-order hysteresis filtering, etc., and the data accuracy is improved. The schematic diagram of data processing is shown in Fig. 3.
Fig.3 The schematic diagram of data processing

3. How Strollers Work

3.1. Automatic Following and Safe Obstacle Avoidance Function Design

The automatic following function is calculated by the ultrasonic distance measuring module through the acoustic wave reflection time length, to get the distance between the stroller and the person being followed, and through the PID algorithm to control the motor drive module to make the distance between the stroller and the person being followed stay within the set range [6]; the safety obstacle avoidance function also uses the ultrasonic distance measuring module to measure the distance, when the distance between the stroller and the obstacle in front of the stroller is less than the set value, the stroller brakes and stops. When the distance between the stroller and the obstacle in front is measured to be less than the set value, the stroller brakes and stops. In signal processing, Kalman filtering algorithm will be used to eliminate other interferences, to ensure that the smart stroller follows accurately, so that parents can have a more secure experience.

3.1.1. Distance Measuring Sensor

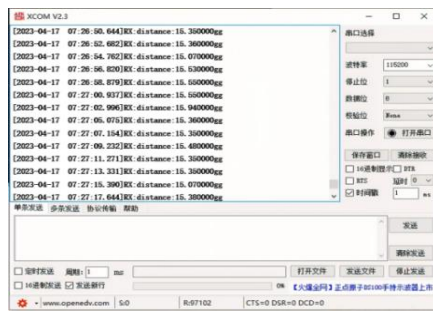
The ultrasonic distance module was selected for the distance sensor. Use low power consumption, low price and easy to connect HC-SR04 ultrasonic distance sensor. The module uses a transceiver split probe to range objects within a distance of 1cm-6m, to achieve the function of avoiding obstacles and following people. Ultrasonic distance measurement structure is shown in Fig. 4.


Fig. 4 Ultrasonic distance measurement structure

The team added temperature and humidity sensors to the work, thus using different speeds of sound for distance measurements by monitoring different temperatures, increasing the accuracy of the distance measurements and further securing the safety of the stroller. The temperature-speed of sound relationship graph is shown in Fig. 5.
Fig. 5 The temperature-speed of sound relationship graph

3.1.2. Bluetooth Module

The system uses HC-05 Bluetooth module to realize two-way wireless function, through the micro-controller control device and voice control system communication, to realize the remote control cradle car front and back, left and right in all directions, or cell phone APP connects to Bluetooth to realize the cell phone APP control movement [7]. The cell phone Bluetooth app interface is shown in Fig. 6.

Fig.6 The cell phone Bluetooth app interface

3.2. Automatic Cradle Function Design

The design adopts the temperature and humidity compound sensor DHT11. It has humidity measurement elements to measure humidity and NTC temperature measurement elements to measure temperature, and its correction factor is stored in OTP memory by program.

3.2.1. Cradle Control Functional Design

The function of this module is divided into semi-automatic bionic rocking and fully automatic bionic rocking. When the semi-automatic cradle is turned on, parents can control it by connecting the cell phone APP through the Bluetooth module, and the stroller will simulate the parents' shaking once for every click on the turn on automatic shaking button; while when the fully automatic cradle is turned on, the automatic cradle module will work together with the cry detection module and the camera to automatically turn on the automatic cradle function when the baby's cry is detected and the function will decide the direction and strength of shaking according to the baby's posture fed back by the camera. This function will decide the direction and strength of rocking according to the baby's posture feedback from the camera, so that the baby is in the most comfortable cradle environment.

3.2.2. Attitude Sensing Module

The stroller is equipped with posture sensing module MPU6050, which sets the balance state data limit, autonomously monitors the swinging condition of the cradle without voice control [8], and the Raspberry Pi accepts the data and transmits it to the control board, which ensures that the cradle is always kept in a horizontal state without human intervention, providing safety for infants and toddlers to move around in the cradle. The test results of the attitude sensing module are shown in Fig. 7.

Fig.7 The test results of the attitude sensing module

3.2.3. Voice Interaction Module

The stroller is also equipped with voice interaction module LD3320, which can recognize the user's commands and make corresponding interactive commands. Considering that some babies are accustomed to listening to their parents' voices to sleep, when the stroller is told to "play mommy's words" or other commands, it will play the audio recorded by the parents in advance to coax the child to sleep, which reduces the pressure on parents' childcare. The test data of the voice interaction module is shown in Fig. 8.

Fig.8 The test data of the voice interaction module

3.3. Design of Microenvironment Sensing Systems

Sensing system design, temperature and humidity sensors can monitor the temperature and humidity in the stroller, when the temperature is too high, it will remind the baby moms and dads through the cell phone to ventilate in time, and when the humidity is too low, it will prompt the baby moms and dads to turn on the humidification device; the light intensity sensor automatically senses the strength of the light around the sun, and when it meets with the strong light environment, the sunshade will automatically extend and unfold, and play the effect of the sun, and if the baby moms and dads want to let their children sunbathe in the sun, they can turn it off the automatic sun-shading function through the cell phone app and turn the sunshade on.

3.3.1. Light Intensity Sensor

BH1750 internal by the photodiode, operational amplifier, ADC acquisition, crystal, etc. PD diode through the photovoltaic effect will be converted into an input light signal into an electrical signal, amplified by the operational amplifier circuit, the voltage collected by the ADC, and then through the logic circuit is converted into a 16-bit binary number stored in the internal registers, in short, is that the stronger the light, the greater the photocurrent, the greater the voltage is. larger, and using

its high resolution can detect a larger range of light intensity changes.

3.3.2. Temperature and Humidity Sensor

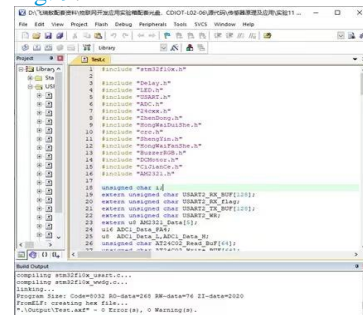
DHT11 is a temperature and humidity composite digital signal sensor, the sensor to digital acquisition technology and sensor technology integrated development, with years of market reputation and excellent performance. The sensor's clever single-wire serial interface design scheme, so that power consumption, volume has a greater reduction in the extremely demanding scenarios, the sensor can still maintain good performance and stability. The temperature and humidity sensor operation interface is shown in Fig. 9.


Fig.9 The temperature and humidity sensor operation interface

3.4. Infant Cry Sensing and Recognition Design

Infant cry perception and recognition design uses a cry recognition system, when the baby cries, the detection device will receive the cry signal, and then filtering processing, feature extraction through the basic acoustic features to get the feature data [9]. The results of the human infrared sensor test are shown in Fig. 10.

Fig.10 The results of the human infrared sensor test

3.4.1. Sound Classification Algorithm Based on Inception-v4 network

By studying Dunstan's theory of infant cry classification, our team collected videos and audios of infant cries from video websites and manually edited and labeled them to obtain the speech spectrograms of five categories of infant cry sound samples, which are the speech

spectrograms of sound samples of cries due to wanting to hiccup, being uncomfortable, feeling sleepy and wanting to go to sleep, being hungry and wanting to eat, and being bloated and in pain in the abdomen [10]. The five kinds of speech maps are shown in Fig. 11.
Fig. 11 The five kinds of speech maps

3.4.2. Network Model Structure Details

The database used in the work is the personal self-constructed infant crying database described in this paper, with a total of 7,500 spectrograms converted from infant crying data. In the experiment, the team used 6500 infant crying speech maps as a training set and 1000 infant crying speech maps as a test set. The categories were categorized using Oberschländerstein's theory of baby crying for 5 categories, which were manually labeled.

The tool used to build the network is the Tensorflow deep learning framework, and the task of categorizing different categories of infant cries is accomplished by modifying the Inception-v4 network model. The upper computer gives different feedback for different cries as shown in Fig. 12.

Fig. 12 Different feedback for different cries

3.5. Baby Expression Recognition Design

The baby expression recognition system consists of four main components, namely: baby expression image acquisition and detection, baby expression image preprocessing, baby expression image feature extraction, and matching and recognition.

3.5.1. Image Acquisition and Detection of Baby Expressions

In terms of baby expression image capture, different baby expression images can be captured by the camera lens. When the baby is within the capture range of the capture device, the capture device automatically searches and captures the baby expression image; baby expression detection is mainly used in practice for preprocessing of

baby expression recognition, i.e., accurately calibrating the position and size of the face in the image. Baby expression images contain rich pattern features, such as histogram features, color features, template features, structural features and Haar features [11]. Baby expression detection is to pick out this useful information and use these features to achieve baby expression detection. Baby expression detection is shown in Fig. 13.

Fig. 13 Baby expression detection

Mainstream baby expression detection methods use Adaboost learning algorithm based on the above features, which combines some of the weaker classification methods together to combine new very strong classification methods, which can effectively improve the detection speed of the classifier.

3.5.2. Baby Expression Image Preprocessing

Image preprocessing for baby expressions is a process of processing images and ultimately serving feature extraction based on face detection results. The original image acquired by the system often cannot be used directly due to the limitations of various conditions and random interference, and it must be subjected to image preprocessing such as grayscale correction and noise filtering in the early stage of image processing. For the baby expression image, the preprocessing process mainly includes light compensation, gray scale transformation, histogram equalization, normalization, geometric correction, filtering and sharpening of the baby expression image.

3.5.3. Baby Expression Image Feature Extraction

The methods of infant expression feature extraction are summarized into two main categories, one is the knowledge-based characterization method; the other is the characterization method based on algebraic features or statistical learning.

Knowledge-based characterization methods are mainly based on the shape description of infant expression organs and the distance characteristics between them to obtain feature data that help to classify infant expressions. Infant expression consists of eyes, nose, mouth, chin and

Suqing Duan, Yizhun Peng

other localities, the geometric description of these localities and the structural relationship between them can be used as an important feature for recognizing the face; the basic idea of the algebraic feature-based method is to transform the high-dimensional description of the face in the spatial domain into a low-dimensional description in the frequency domain or in other spaces, and the characterization methods are the linear projection characterization method and the nonlinear projection characterization method.

3.5.4. *Image Matching and Recognition of Baby Expressions*

The feature data of the extracted baby expression image is searched and matched with the feature templates stored in the database, and the result obtained from the matching is outputted by setting a threshold value when the similarity exceeds this threshold value. Baby expression recognition is to compare the face features to be recognized with the obtained baby expression feature templates, and to judge the baby state information based on the degree of similarity.

4. Conclusion

The Modular Photovoltaic Environmentally Friendly Portable Stroller's is dedicated to innovatively solving social problems through a modular photovoltaic smart portable stroller system, while reducing greenhouse gas emissions and enhancing the safety and interactivity of the stroller. The work uses polycrystalline solar panels, aluminum alloy and other environmentally friendly materials, as well as three power modes, fully responding to the initiative of green and low-carbon development. In terms of hardware design, the STM32 development board builds the underlying control center and implements the active safety and motion system. In terms of software, ROS serves as the core, combining with IoT technology, speech recognition and natural language processing to equip the stroller with the ability to intelligently sense and respond to the surrounding environment and the baby's state. Through the Raspberry Pi as the host controller of the upper computer, a cloud-based IoT platform based on the MQTT protocol is built, which realizes the convenient interaction of data and the visualization and monitoring of the mobile terminal. By improving the intelligent level of the stroller, it enables parents to better balance their work and family

responsibilities, and realizes the further penetration of intelligence and advancement in the field of childcare.

Abstract

"Teenage Mutant Ninja Turtles - Bionic Quadrupedal Rescue Robot is a quadrupedal robot based on the principle of bionics, inspired by the quadrupedal animals in nature. The robot has rescue and life detection capabilities and can perform rescue operations at disaster sites. The design of the robot enables it to operate efficiently and stably in complex environments, and at the same time it has the qualities of bravery and toughness, which are in line with the image of the Teenage Mutant Ninja Turtles. The robot can be used in a wide range of application scenarios, such as earthquake, fire and other disasters, to provide more efficient and safer support for rescue work.

Keywords:Biomimetic Machinery,Artificial Intelligence, Life Detection, Wifi Module

1. Introduction

With the development of society, mankind is faced with more and more natural disasters and man-made accidents, such as earthquakes, fires and mining accidents, which often result in a large number of casualties and property losses, bringing great harm to society. At the scene of these disasters, rescuers often need to risk their lives to enter the danger zone to carry out life detection, environmental exploration, material transportation, etc. Constrained by the number of rescuers, capacity, equipment, time and other factors, it is difficult to achieve high efficiency, safety and comprehensiveness [1].

To solve this problem, a bionic quadruped rescue robot called "Teenage Mutant Ninja Turtle" has been developed. The animated image of "Teenage Mutant Ninja Turtles" is a brave, invincible and courageous little turtle, and the rescue robot designed by the team has the same qualities of bravery and toughness, "Teenage Mutant Ninja Turtles" animated image is a brave, invincible and courageous little turtle, and the rescue robot designed by the team has the same qualities of bravery and toughness essence of the spirit, and therefore the name of this rescue robot for the "Teenage Mutant Ninja Turtles". The legs of "Ninja Turtle" use eight servos as joint actuators, and the legs can be replaced with wheel-type, bionic foot-type, negative pressure suction cup-type and three kinds of modularized structures to cope with different working scenarios, such

as flat, rugged,vertical and muddy.It is equipped with acoustic obstacle avoidance system with superb obstacle-crossing ability.It is also equipped with 4G infrared transmission for working in dark environments and entering collapsed pits for life detection and environmental exploration [2].

The rest of this article is organized as follows. Part II describes the modules used in the hardware system design. Part III describes the design of the bionic mobile joint. Part IV builds the model and tests to determine the foot structure. Part V summarises the main points of the paper [3], [4].

2. The Hardware System Design

In terms of hardware design, the Teenage Mutant Ninja Turtles Bionic Quadrupedal Rescue Robot has been carefully PCB-drawn, including the design and layout of several key modules, to ensure the stable and efficient operation of the robot. The design of the PCB board is shown in Fig. 1.

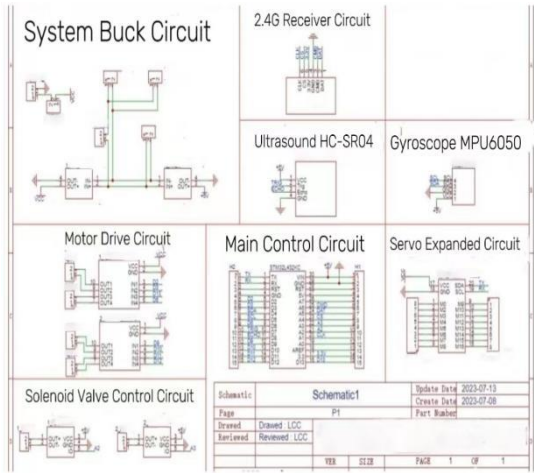
Hongpi Zhao, Yingfan Zhu, Zhihan Zhao, Xin Liang, Lei Lv, Yizhun Peng


Fig. 1 The design of the PCB board

2.1 Circuit module section

Buck modules are an important part of power management, used to reduce the input voltage to a suitable operating voltage for each electronic component, helping to ensure system stability and power efficiency.

2.2 Motor drive module

Used to control the robot's motors, using PWM to control the speed and direction of the motors.

2.3 Bluetooth module

Enables the robot to communicate with external devices over Bluetooth, providing a convenient way for remote control and data transfer.

2.4 Ultrasonic sensors

Measures distance by sending and receiving ultrasonic signals for obstacle detection, navigation and localisation, providing robots with environmental awareness.

2.5 Wi-Fi wireless mapping module

Using the Wi-Fi wireless mapping module, the robot can transmit real-time images and video streams to remote devices, providing powerful support for teleoperation and environmental exploration [5].

The hardware design is shown in Fig. 2.
Fig. 2 Hardware design Hardware design

3. Design of bionic mobile joints

The parts design drawing is shown in Fig. 3. Detailed descriptions of functions and uses are shown in Table 1.
Fig. 3 Component design drawing

Table 1 Functions and uses

Functions and Uses	
Connecting rod	Transmission elements for connecting different joints and actuators to ensure coordinated movement of the robot's limbs
bear	Used to provide a rotational connection that allows the robot's joints to rotate freely without excessive friction
Servo 1	Used to control the swinging motion of the thighs
Servo 2	For controlling the elevation movement of the lower leg
shafts	Allows the robot to control the attachment and release of suction cups by varying air pressure, thus enabling the ability to climb and attach to different surfaces
suction pad	Uses a vacuum or pneumatic system to create a suction force to enure that the robot is firmly attached to the target surface.

A sophisticated system has been designed for Teenage Mutant Ninja Turtles Bionic Quadrupedal Rescue Robot in Pneumatic Adsorption System. The system has a strong adsorption and climbing function and ensures strong adsorption by negative vacuum -55KPa. The suction cups can withstand wall loads from 1.25kg to 1.7kg, allowing the robot to safely support its own weight and other additional loads. The design of the pneumatic adsorption system is complex and requires consideration of material selection, airflow control, negative pressure generation and other factors to ensure that the robot performs reliably in a variety of environments. Such systems are not only used in bionic robots, but are also widely used in industrial automation, glass suction handling, and handling equipment [6]. The pneumatic adsorption system is shown in Fig. 4.
Fig. 4 Pneumatic adsorption system

4.Modelling and Testing

4.1 Multi-body dynamics modelling

In the mechanism dynamics simulation, a multi-body dynamics model is adopted, focusing on the kinematic mechanism of the robot leg, and the swinging of the thigh joint, the lifting and lowering of the calf joint, and the linkage between the thigh joint and the calf joint are simulated and analyzed, respectively [7]. And the model diagram is shown in Fig. 5.
Fig. 5 Multi-body dynamics model

4.2 Stress and deformation maps

The structure of the Teenage Mutant Ninja Turtles (TMNT) bionic quadrupedal rescue robot was studied in depth in a finite element static analysis to evaluate its performance under different workloads and environmental conditions. This analysis includes the generation of stress and deformation maps, as shown in Fig. 6.
Fig. 6 Stress and deformation cloud diagrams

Stress distributions also help to ensure that the robot does not suffer from material fatigue or damage during operation; deformation clouds show how the robot's structure deforms under different loads. They are presented through colour coding or arrows to visualise the change in shape of the robot under stress.

5.System testing and results

Continuous optimizations and upgrades are performed to ensure good product performance. Through continuous product iterations, system testing and results are closely monitored to validate and improve the effectiveness of each iteration round. Over the course of the program's continuous development, five generations of products have been witnessed with significant progress and improvements.Firstly, the first generation of the product identified a quadrupedal structural solution with a four-link structure, which significantly enhanced the airframe's manoeuvrability. However, this was only the beginning [8]. The first generation is shown in Fig. 7.
Fig. 7 First generation products

Subsequently, the introduction of the second generation of the robot brought significant improvements with the adoption of a high torque servo, MG996, to make the robot more agile and the introduction of modularly designed legs to improve ease of maintenance. The second generation is shown in Fig. 8.

Hongpi Zhao, Yingfan Zhu, Zhihan Zhao, Xin Liang, Lei Lv, Yizhun Peng
Fig. 8 Second-generation products

The third generation product further extends the function by adding tail and head structure, introducing automatic obstacle avoidance function and wireless mapping technology to make the robot more intelligent and adaptable to different environments. The third generation product is shown in Fig. 9.
Fig. 9 Third-generation products

The highlight of the fourth generation is the addition of tracks and McNamee wheels, which give the robot the ability to not only move in all directions, but also steer in a more flexible manner. The fourth generation is shown in Fig. 10.
Fig. 10 Fourth generation products

Finally, the fifth generation product has undergone an in-depth industrial design to resemble the appearance of the robot to a turtle, giving it a more vivid and adorable image and enhancing its user-friendliness. The fifth generation product is shown in Fig. 11.

Fig. 11 Fifth generation products

At each iteration stage, we conducted system tests and analysed the results to ensure stability and performance optimisation of the new features. These tests included the robot's performance in various terrains and environments, its manoeuvrability, the reliability of the automatic obstacle avoidance function, the effectiveness of omnidirectional movement, and the aesthetic design.

Abstract

The Complex environmental grass grid growers based on adaptive suspension adopted the high-performance stm32 as the master chip, and use the Bluetooth communication module, so that users can easily control the vehicle driving, feeding and the posture of the pressing wheel through the mobile phone application. In addition, we have introduced new mechanical structures such as adaptive suspension to ensure effective planting of grass squares in complex terrain such as sloping land. Our vehicle uses a Mecanum wheel motion system to squeeze seeds by rotating the friction wheels at high speed.

*Keywords:*STM32F103ZET6, Adaptive suspension, Machine vision, Machine learning

1. Introduction

In recent years, severe weather has become more and more frequent. In some inland China, the rainfall is decreasing year by year, and the land desertification is becoming increasingly serious. The sharp decrease of arable land has led to the harsh environment such as yellow sand, which seriously affects People's Daily life. With the scientific concept of development to today's clear waters and green mountains are gold and silver mountains, China has formed a set of localized sand control route: grass square sand fixing. Grass square sand is getting more and more attention because of its extraordinary sand prevention effect [1]. However, most of the existing grass square planting methods in China are still artificial. Although there has been professional grass planting equipment in recent years, the investigation and interview found that most of the machines can only be applied to flat land. Under rolling roads and dune landforms, there is no machine to plant, and it is still manual work. The harsh and changing environment in the desert greatly increases the risk of manual work [2].

In order to conduct the actual test of the developed grass square planting system, the team designed and developed the corresponding mechanical structure that can control the movement and integrate the feeding and planting. In the circuit of this project, the stm32 microchip as the main control chip and the Bluetooth as the communication module can control the walking, feeding and grass wheel posture of the vehicle through the mobile phone APP [3], and then complete the grass square planting in the slope with the new adaptive suspension and other mechanical structures. The method is the McNham wheel motion system, which uses the motor to drive the friction wheel and squeeze the tennis ball at high speed to launch, and uses STM32 to control.

The remainder of this paper is organized as follows. The second part introduces the mechanical structure design for the implementation of the robot function. In the third part, the hardware circuit design of the robot is given. In the fourth part, the electronic control program design of the robot is given. The fifth part summarizes the main content of this article.

2. A Mechanical Structure Design

2.1. An Adaptive structure design

In the four-wheel movement system, the front and rear wheels on the same side are connected by the connecting rod structure shown in the figure, and the left and right side connecting rods are connected through two sets of

Shaokai Tian, Wenqi Fu, Yizhun Peng

swing arm structure. The swing arm can move up and down through the linear bearing, and finally the left front wheel and the right rear wheel move up and down synchronously, and the left rear wheel and the right front wheel move up and down synchronously. The above structure can realize the all-directional adaptive of various slope landforms, and can operate in the desert undulating terrain [4]. Adaptive suspension diagram is show in Fig. 1.

Fig. 1 Adaptive suspension diagram

2.2. An Electric swing arm link design

In order to better adapt to the undulating terrain such as desert and Gobi, the wheel group hanging swing arm is designed with three degrees of freedom, which can meet the rotation of Pitch axis, Yang w axis rotation and Y axis sliding at the same time.

The following is the details of the upper and lower movement of the swing arm: the village sleeve and the screw set the distance between the two steel swing arms, the flange is fixed on the swing arm through the screw, the straight bearing is fixed on the flange by welding, and the steel column is fixed on the steel plate 1 and 2 with the screw, thus fixed on the frame. The linear bearings can move up and down around the steel column or rotate. Structural details of the swing arm connecting rod contact point: the sliding shaft and the crosshead are fixed, through the sliding shaft, the sliding coat can be rotated by a small margin, and the swing arm can be rotated around the shaft through the thrust bearing and steel column. The distance of the distance is fixed between the two links by rigid jacket. Through the above mechanism, the movement realizes the slip and the rotation on the whole node space.[5]Details of the swing arm mechanism is show in Fig. 2.
Fig. 2 Details of the swing arm mechanism

2.3. A Material supply design

The double output motor 1 is flange and the power is transferred to the roller 4. The roller is fixed on the aluminum pipe base through the bearing and steel shaft. The roller connected with the motor is the active wheel, and the roller not connected with the motor serves as the driven wheel.

During operation, the motor rotates, the active roller rotates, the active roller and the driven roller pre-tighten, the active rod rotates and drives, and produces friction with the grass between the main and slave roller, so as to realize the feeding function.

The slot explains: adding the slot can realize the adjustment of forage with different thickness and width, so as not to produce excessive stress between the rollers and increase the practical service life of the structure. Material supply mechanism diagram is show in Fig. 3.
Fig. 3 Material supply mechanism diagram

2.4. A Management mechanism design

This structure adopts multi-link structure, through the rotating motion into linear motion, drive the upper rod 3 rotate around the hinge 8 , the swing of the upper rod 3 will make the shock absorber 4 compression, then transfer the force to the lower rod 6 , the lower rod 6 will rotate around the steel shaft centering by the horizontal support, so as to realize the upper and lower movement of the pressing wheel.

According to the calculation and analysis, the structure has only one degree of freedom, so the control of the structure can be fully realized by controlling the number of circles turned by the motor, and the structure is

simple and easy to use. Managing mechanism diagram is show in Fig. 4.
Fig. 4 Managing mechanism diagram

2.5. A Design of shock absorption structure

(1) The function of the shock absorber
- Realize the transmission of force;
- The expansion of the shock absorber 4 can ensure the balance between the grass pressing wheel and the ground of the force, to ensure the quality and efficiency of planting;
- Bear the impact of the irregular ground, protect the vehicle structure, improve the service life;

(2) Advantages: This system does not use the rigid connection, but uses the shock absorber as a flexible connecting rod, thinking from suspension, innovative application solved the rolling road may produce the disadvantages of rigid stress stress structure, and by ensuring the range between the ground wheel always small fluctuations and always fit the ground, so the car can not only in the plane planting, but also can be in the plane planting (slope, tunnel, etc.), and has the very good practical application [6]. Damper is show in Fig. 5.
Fig. 5 Damper

3. A Hardware Circuit Design

3.1. STM32F103ZET6 Master control module

Up to 8 timers, containing a separate watchdog timer and a window-type timer, allowing for automatic microreset. This chip has up to 72 MHz working frequency. The bus system is a synchronous serial peripheral interface that enables the MCU to communicate with various peripherals in a serial manner to exchange information. The MCU architecture features an easy-to-use STM 32 platform ideal for motor drive [7]. STM32F103ZET6 Master control module is show in Fig. 6.

Fig. 6 STM32F103ZET6

3.2. A4988 Stepper motor drive module

Can adapt to the effects of various natural environments to better achieve work in harsh environments. The selected A4988 DMOS micro-step drive module with converter and overcurrent protection has more stable performance. A4988 Stepper motor drive module is show in Fig. 7.

Fig. 7 A4988 Stepper motor drive module

3.3. The HC-12 Bluetooth module

The super-long transmission distance and acceptance performance of the Bluetooth module can well realize the

purpose of long-distance control. The HC-12 Bluetooth module is show in Fig. 8.
Fig. 8 The HC-12 Bluetooth module

3.4. L298N DC motor drive module

L298N can be used to drive our 12V DC deceleration motor, L298N can directly control the motor, set the control level through the I / O input of the main control chip, can drive the motor forward reversal, simple operation, good stability, can meet the high current driving conditions of the DC motor. L298N DC motor drive module is show in Fig. 9.

Fig. 9 L298N DC motor drive module

3.5. 12V DC deceleration motor

12V DC deceleration motor is widely used, because its excellent performance is often used in smart home, electronic products, smart car driver, precision medical equipment, etc. In this grass square unmanned planting car, the price is appropriate, product depression purchase and assembly and other excellent performance. L298N DC motor drive module is show in Fig. 10.

Fig.10 L298N DC motor drive module

3.6. Circuit logic control

The overall electrical route of the machine is arranged to make the machine line structure stable and safe, and will not be damaged due to external or internal interference, especially for the line layout where the line is concentrated. Circuit chassis design makes most of the circuit placed in the back of the body, increase the convenience of human-machine interaction, while the circuit, convenient line arrangement.

Select the power line, signal line and other electronic components needed for the robot, reasonably arrange the line of the robot, to ensure the stability and safety of the robot operation [8].

3.7. A Chassis module design

(1) Main components: Bluetooth module, STM32 main control, L298N DC motor drive module, 12V DC deceleration motor.

(2) Implementation mode: the main control board receives the chassis control instruction through the Bluetooth module, then calculates the corresponding instruction as the corresponding control information, and controls the motor speed with a PWM control pulse through the IO port.

(3) Electrical connection: the 12V power supply directly supplies power to the L298N DC motor drive module, and the motor drive module is connected to the motor and directly supplies power to the motor. The 12V power supply supplies power to the STM32 main control board after the 12-5V step-down module, and the development board supplies power to the HC-12 Bluetooth module through the 3.3V interface.

3.8. A Material supply module design

(1) Main components: Bluetooth module, STM32 main control, L298N DC motor drive module, 12V DC deceleration motor.

(2) Implementation mode: the main control board receives the control instruction through the Bluetooth module, then calculates the corresponding instruction as the corresponding control information, and issues the PWM control pulse to control the feeding motor through the IO port, so as to realize the material supply and discharge.

(3) Electrical connection: the 12V power supply directly supplies power to the L298N DC motor drive module, and the motor drive module is connected to the motor and directly supplies power to the motor. The 12V power supply supplies power to the STM32 main control board after the 12-5V step-down module, and the development board supplies power to the HC-12 Bluetooth module through the 3.3V interface.

3.9. A Management module design

(1) Main components: Bluetooth module, STM32 master control, A4988 step motor drive module, 42 step motor.

(2) Implementation mode: the main control board receives the control instruction through the Bluetooth module, then calculates the corresponding instruction as the corresponding control information, and sends the PWM control pulse and IO level control the rotation of the stepping motor through the IO port, so as to realize the control of the depth of the pressing structure.

(3) Electrical connection: the 12V power supply directly supplies power to the A4988 stepping motor drive module, and the motor drive module is connected to the stepping motor to directly supply power and control it. After the 12V power supply supplies power to the STM 32 through the 12-5V step-down module, and the development board supplies power to the HC-12 Bluetooth module through the 3.3V interface [9].

4. An Electric Control Program Design

4.1. A System main body logic design

Program flow chart is show in Fig. 11.
Fig. 11 program flow chart

4.2. A Chassis system logic design

Chassis.c Three subroutines are set up, namely, chassis motor initialization program, stepper motor initialization program and chassis control program.

(1) In the chassis initialization program, complete is the GPIO used for the chassis motor.

(2) In the initialization program of the stepping motor, the initialization of the IO port of the control stepping motor is completed.

(3) In the chassis control program, according to the control information after the incoming processing, set the PWM wave with different duty cycle ratio to complete the control of the motor speed and steering under the corresponding situation.

4.3. A Logical design of the communication system

After receiving the message at the serial port, we need to process it. However, because there is more logic in this project, we set up a separate structure to integrate the information flow and facilitate us to process the data uniformly.

In this structure, we integrate the information of chassis speed, direction, stepping motor status and feeding motor status. In the serial receiving interrupt, we directly judge the received message in the interrupt, a character check function is called to judge the instruction

Shaokai Tian, Wenqi Fu, Yizhun Peng

according to the received characters and rewrite the variables of the structure body.

In addition, in order to facilitate the user's control, we also set a timer interrupt, for timing to clear instructions, can realize the micro operation of the robot, complete fine control.

5. Conclusion

Dunes or gobi desert governance is a long time, now large machinery is mainly plane industry planting, planting can not complete the dunes, moreover, due to the dune itself has strong liquidity, not only lead to human resources in the same repeated continuous consumption, also has a potential danger: quicksand, a threat to people's life and property safety. However, in order to create a long-term sustainable green water peak, we shall not ignore the one in the field of governance, so the team proposed adaptive suspension has been practical, break through the existing laying machinery technical problems, can set foot on the ecological restoration in this field, and the wireless control, no one to close interference do industry, great guarantee the personal safety, the design breakthrough existing laying machinery technical problems.

Abstract

The intelligent ecological multi-functional system for animal and plant cultivation integrates PLC programmable controllers and microcontroller-based automatic control technology. This innovative approach amalgamates aquaculture with horticulture, fostering a symbiotic environment for the breeding of animals and plants. The system's operations are categorized into four key components: mechanical structure, environmental perception, automatic control, and intelligent networking. Its comprehensive functionality encompasses plant monitoring, self-checking of temperature and humidity, group control for fertilizer replenishment, consistent temperature regulation, full-spectrum illumination, advanced filtration, fogging supplementation, versatile water management, fertilizer blending, and water purification through sterilization.

Keywords: Intelligent Ecology, PLC programmable controller, Environmental sensing, Eco-agriculture, microcontroller, monitoring

1. Introduction

With the rapid development of science and technology, intelligent technology has emerged in the field of agriculture. Based on Siemens S7-1200 version PLC programmable controller and AT89C51 microcontroller automatic control technology [1]. this thesis aims to integrate aquaculture and horticulture planting, and innovatively realize plant and animal symbiotic aquaculture. The most important feature of the system is that it can realize ecological energy saving, environmental protection recycling and symbiotic breeding of plants and animals, which pushes the intelligent ecological breeding to a new height.

The work is mainly composed of four modules: mechanical structure, environmental sensing, automatic control and intelligent networking. System functions include plant monitoring, temperature and humidity self-checking, group control and fertilizer renewal, constant temperature and heating, full illumination, multiple filtration, fogging supplementation, multi-purpose water, fertilizer mixing and sterilization of water purification and other special functions [2]. In addition, the system introduces an animal feeding system, which includes an adaptive feeding cabin and an intelligent feeding system that monitors the physiological parameters of the animals and automatically feeds them at regular intervals and quantities in order to realize intelligent feeding management.

The rest of this paper is organized as follows. The second part introduces the top ten functional designs. The third part introduces the working principle of the intelligent ecological multifunctional plant and animal breeding system. The fourth part is hardware design, including mechanical structure part design, environment sensing part design, automatic control part design and intelligent networking part design. The fifth part is the software design. The sixth part summarizes the main content of this paper.

2. Ten functional designs

Intelligent ecological multi-functional animal and plant breeding system aims to realize fully automatic group control of plants and aquatic animals, which contains ten key functions such as plant monitoring, temperature and humidity self-checking, group control and fertilizer renewal, constant temperature and heating, full illumination and light supplementation, multiple filtration, and fogging supplementation. The application of these technologies not only significantly reduces manual intervention and improves breeding efficiency and production, but also promotes the recycling of resources and realizes environmentally sustainable production.

This intelligent ecological multi-functional plant and animal breeding system realizes all-round monitoring and management of plants and animals by integrating advanced monitoring and control technologies,

Suqing Duan, Yuntian Xia, Siyi Wang, Yizhun Peng

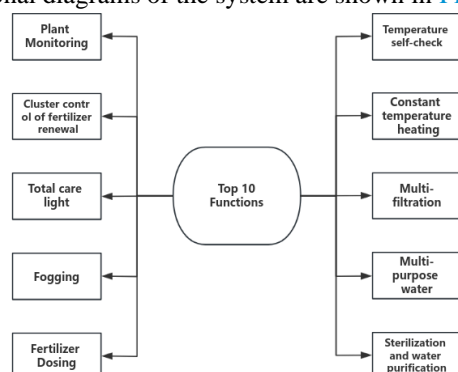
minimizing manual operations and thus improving overall breeding efficiency and production. The top ten functional diagrams of the system are shown in Fig. 1.


Fig. 1 The top ten functional diagrams of the system

2.1. Aquaponics Technology Design

Based on the concept of energy recycling, the system is guided by the concept of watering vegetables with fish water and improving the growth environment of fish with vegetables, integrating aquaculture and hydroponic cultivation technologies to build a harmonious aquaponics system. In urban family application, this technology can reduce the purchase expenditure of vegetables and fishery products and create a green and energy-saving family living environment.

2.2. Temperature parameter change automatic judgment sliding table contraction design

The system monitors the ambient temperature through an RS485 industrial-grade temperature and humidity transmitter to ensure that the slide table is intelligently triggered to retract automatically in adverse climatic conditions (less than 15 degrees Celsius or more than 30 degrees Celsius) to prevent plants from being damaged by cold or overheating. Meanwhile, through intelligent determination of the current time, the system realizes artificial light supplementation at 18:00 pm to ensure that plants can still obtain sufficient light when it is dark, while it automatically extends at 8:00 am to absorb sunlight to provide a good growing environment for plants. Such time determination and intelligent regulation mechanism effectively guarantees the growth needs of plants in different time periods.

2.3. Plant group control automatic humidification design

The system is equipped with a humidity sensor to monitor the humidity of the plant growth environment in real time. When the humidity is lower than 80%, the intelligent system automatically triggers the humidification device to ensure that the photosynthesis, respiration and transpiration of plants proceed normally. Through time triggering and intelligent determination of air humidity at 8 a.m., 11 p.m. and 5 p.m., the system decides whether or not to humidify to meet the humidity needs of the plants at different times of the day, thus providing a suitable growing environment [3]. This intelligent humidification system helps to maintain the physiological activities of plants and improve the breeding efficiency.

2.4. Plant group control automatic fertilization design

The system performs real-time sensing and calculation through sensors at the height of the plants, and judges the reasonable amount of fertilizer (CM/MG) according to the growth status of the plants. In terms of time triggering, the system intelligently sets 3:00 pm to 10:00 pm every day as the fertilizer application time period to ensure that the plants get the right amount of nutrients during this time period. In addition, soil sensors are used to monitor the levels of nitrogen, phosphorus, potassium and other fertilizers in the soil. The system intelligently determines the soil condition according to the plant species and the seasons, and applies the right amount of fertilizer when needed. Such an intelligent fertilizer application mechanism is designed to ensure that plants are supplied with appropriate nutrients, thereby improving breeding efficiency and yield.

2.5. Plant group control automatic watering design

The system decides whether watering is needed by checking whether the soil moisture reaches the set value through real-time soil moisture monitoring every 10 minutes. In addition, the system intelligently takes into account plant species and seasonal changes, and based on these factors determines whether watering is required for the day, ensuring that soil moisture meets the plant's growth needs. This integrated intelligent watering mechanism aims to provide plants with the right amount of water according to the actual situation, ensuring that they receive appropriate irrigation in different seasons and growth stages, and improving breeding efficiency.

2.6. Plant group control automatic nutrient replenishment design

The system intelligently calculates the corresponding levels of nutrients such as nitrogen, phosphorus and potassium (CM/MG) through plant height sensing. In terms of time triggering, the system is set to automatically replenish nutrients once a month to improve plant resilience and resistance and activate microbial vitality in the soil [4]. This integrated highly sensible and automatic replenishment mechanism helps to

ensure that plants are supplied with appropriate nutrients at different growth stages, improving their resilience and thus enhancing the ecological balance of the whole aquaculture system.

2.7. Automatic Oxygen Supply Design for Aquatic Animals

According to the change of water temperature, automatic oxygen supply is realized to ensure the oxygen demand of fish in different temperature ranges.

2.8. Automatic sterilization design

The system adopts the principle of ozone sterilization, through which ozone acts on the cell membrane of microorganisms, leading to cell death, so as to achieve the purpose of sterilization, anti-inflammation and detoxification. In addition, the system also applies UV germicidal lamps, which utilize UV rays to destroy the DNA or RNA molecular structure in the cells of various microorganisms in the water, effectively killing various pathogens in the water in order to keep the water quality clean. This integrated sterilization system is designed to ensure the hygienic condition of aquaculture water, improve water quality, and guarantee the healthy growth of plants and animals.

2.9. Solar photovoltaic power generation system design

The system is centered on PLC and HMI, and is powered by electricity from the solar photovoltaic power generation system reserve. According to the light condition, the system realizes automatic switching of power supply to ensure the normal operation of the equipment under different light conditions. In addition, the system intelligently utilizes LED plant growth lights for automatic replenishment. When natural light is insufficient, the solar PV system activates the LED plant growth lights to provide an additional light source to promote plant growth. This integrated PLC and solar photovoltaic power generation system, as well as the automatic replenishment function of the LED plant growth lamps, effectively guarantees the sustainable operation of the system and the growth needs of plants under different light conditions.

2.10. Design of LED Plant Grow Lights for Yield Improvement

Spectral regulation is crucial to plant growth, and red light promotes chlorophyll formation and carbohydrate synthesis, fuels the growth of long sunlight plants, delays the growth of short sunlight plants, and promotes seed germination. Theoretical and experimental evidence shows that red light has the strongest photosynthetic

effect, and the use of red-rich light sources for supplemental lighting can advance plant flowering and fruiting and promote organ formation. Blue light helps stomata open, promotes the entry of external carbon dioxide, increases the rate of photosynthesis, and is conducive to protein synthesis. Blue light accelerates the growth of short-daylight plants, slows down the growth of long-daylight plants, and promotes leaf growth. Artificial supplemental light using a blue light-rich light source can delay flowering and allow full plant growth [5].

Plant grow lights are electric light sources designed to stimulate plant growth by emitting electromagnetic waves suitable for photosynthesis, and are used in applications where natural light is not available or where additional supplemental light is required. In winter, when daylight hours are insufficient to meet the needs of plants, plant lights are used to extend light hours and prevent plants from growing unduly. Meanwhile, the plant curtain green light realizes cooling effect in summer by blocking heat, shading strong sunlight and providing a cool indoor environment; in winter, it prevents cold air from intruding and provides thermal insulation. The ambient light is used to provide extra light, highlight the color of the fish, and meet the fish's need for light. In the absence of sunlight, the ambient light creates a comfortable environment for the fish tank, creating a more perfect viewing effect. The finished rendering and exterior design are shown in Fig. 2.

Fig. 2 The finished rendering and exterior design

3. Working Principle

Firstly, the ornamental and convenient management of plants is realized through the design of plant sliding table. The plant sliding table can display the plants in the balcony or outdoor community, and when the environment changes, the plants can be cooled, humidified, and replenished with light through PLC control in order to reduce the labor cost and improve the breeding efficiency. The plant curtains are driven by 24V motor for 90 degree opening and closing. Secondly, the system supports hydroponic plant cultivation, which can save space utilization by putting the plant curtains away. The root system of hydroponic plants can filter the fish tank water flowing through the plant curtains, realizing the recycling of aquaponics resources. Finally, the system

is equipped with an industrial control touch screen to realize real-time feedback on the monitoring of plants and animals and human-computer interaction.

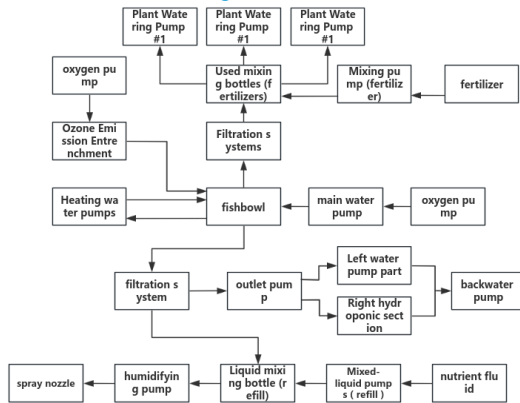
For automatic sensor detection, ultrasonic ranging, soil sensors, environmental sensors, PLC time calculation and other multiple logic judgments are used to improve the accuracy of plant control and help improve the survival rate of plants. Fertilizer pump adopts peristaltic pump, and through the "one drop one number" control method, it realizes the precision of fertilizer application and avoids the situation of using too much or too little fertilizer. In the filtration system, through a variety of filtration methods, such as hydroponic plant stalks, UV lamps, ozone and active filters, etc., the depth of the fish tank water poisoning and filtration, to achieve the healthy operation of the aquaponics system. The working schematic is shown in Fig. 3.


Fig. 3 The working schematic

4. Hardware Design

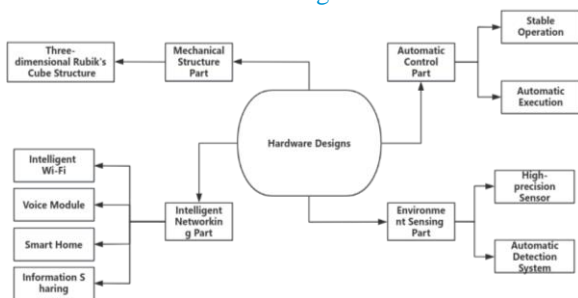
The overall structure of the intelligent ecological multifunctional plant and animal breeding system is divided into the following four major components. The overall structure is shown in Fig. 4.


Fig. 4 The overall structure

4.1. Mechanical structure design

The three-dimensional Rubik's Cube structure is adopted, which is inspired by the aerospace station. The

three-dimensional Rubik's Cube structure is characterized by a large available space, which is divided into five different unfolding surfaces, with different functions corresponding to different surfaces, which are specifically divided into the "display and observation surface", "aquatic planting surface", "photovoltaic surface" and "energy collection surface" [6]. The different surfaces have different functions, specifically divided into "display and observation surface", "water planting surface", "photovoltaic surface", "energy collection surface", "sliding platform structure surface" and "control and manipulation surface".The mechanical structure is shown in Fig. 5.

Fig. 5 The mechanical structure

4.2. Environment Sensing Part Design

Composed of various high-precision sensors, the environment sensing part is equivalent to the "eyes" and "ears" of the intelligent ecological multi-functional animal and plant breeding system, which can automatically detect the working state of the system and convert various process parameters such as temperature, humidity, flow rate, liquid level and composition into uniform standard signals. Physical quantities such as temperature, humidity, flow, liquid level, composition, etc. are transformed into uniform standard signals to meet the requirements of information transmission, processing, storage, display, recording and control, etc. It is the first link to realize automatic detection and automatic control. The high precision sensor map is shown in Fig. 6.

Fig. 6 The high precision sensor map

4.3. Automatic control part design

The system is mainly composed of four parts: controller, sensor, actuator and transmitter. The controller is the core

of the system, responsible for automated control tasks without direct human intervention. Through a type of work, a state or a parameter in a machine, equipment or production process, it operates automatically according to pre-set rules. Electricity or other energy sources are used and converted into drive action by means of motors or other devices [7]. Sensors are responsible for detecting process parameters and transmitting the measured values in the form of specific signals for display and regulation. The role of the sensors is to convert various process parameters, such as temperature, flow rate, composition and other physical quantities, into uniform standardized signals, which are then transmitted to the regulator and touch screen for regulation, indication and recording. Such an automatic control system ensures the continuity of the production process and stabilizes the system operation. The controller and controlled object diagram is shown in Fig.7.

Fig. 7 The controller and controlled object diagram

4.4. Intelligent networking part design

As the communication hub of the intelligent ecological multi-functional animal and plant breeding system, the intelligent Wi-Fi module plays an important role in connecting with the outside world, including the close connection with other intelligent devices. As the core component of the smart home LAN, the module is able to independently complete a variety of functions of the home internal network without the intervention of other devices. It converts and shares information between communication protocols, realizing efficient data exchange between networks. Meanwhile, the data exchange function between the smart Wi-Fi module and the external communication network enables the smooth realization of intelligent functions such as remote control, scene control, linkage control and timing control. The design ensures an efficient and seamless connection between the smart farming system and external devices and networks, further enhancing the intelligence of the whole system [8]. The smart Wi-Fi module diagram is shown in Fig. 8.

Fig. 8 The smart Wi-Fi module diagram

5. Software Design

5.1. System logic circuit diagramEnvironment Sensing Part Design

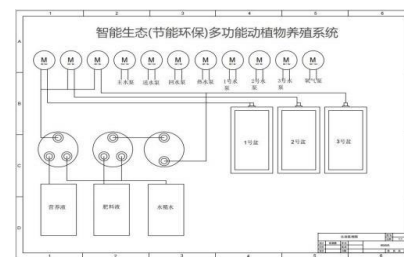
The software system of the Intelligent Ecological Multifunctional Animal and Plant Breeding System is the "brain" of the system, which is responsible for monitoring, controlling and coordinating various components to realize efficient animal and plant breeding. The system logic circuit diagram is a graphical representation of the internal logic structure of the software system, showing the relationship and information flow between different modules. The system logic circuit diagram is shown in Fig. 9.


Fig. 9 The system logic circuit diagram

5.2. Human-computer interaction diagrams

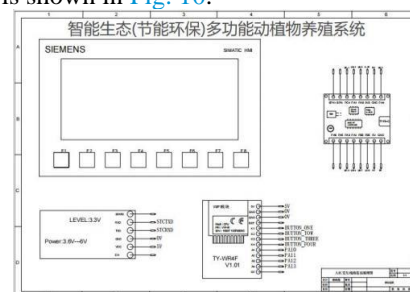
The human-computer interaction diagram of the software system of the intelligent ecological multifunctional animal and plant breeding system is the part of the system that interacts with the user directly, providing the user with a friendly operation experience through an intuitive graphical interface. The human-computer interaction diagram is shown in Fig. 10.


Fig. 10 The human-computer interaction diagram

5.3. Relay and Communication

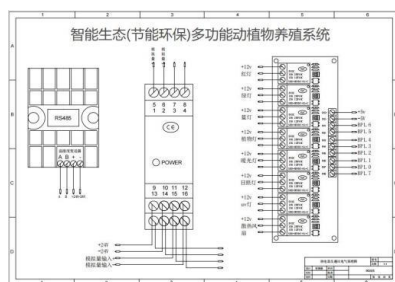
The relay and communication diagram of Intelligent Ecological Multifunctional Animal and Plant Breeding System software system includes PLC, sensors, relay module, communication module, network connection, data transmission protocol, remote monitoring equipment, etc. PLC realizes equipment control through relay module, sensors monitor environmental parameters, and communication module realizes equipment data transmission and remote monitoring [9]. The relay and communication communication diagram is shown in Fig. 11.


Fig. 11 The relay and communication communication diagram

5.4. Aquaculture System Logic Diagram

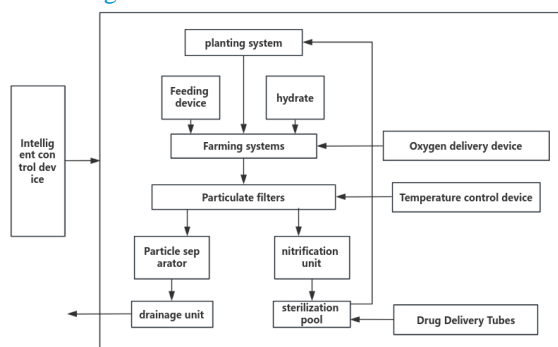
In the software system of Intelligent Ecological Multifunctional Animal and Plant Farming System, the logic diagram of aquaculture system is mainly related to the monitoring, control and optimization of aquatic ecology. The logic diagram of the aquaculture system is shown in Fig. 12.


Fig. 12 The logic diagram of the aquaculture system

5.5. Human-computer exchange design

Our system integrates advanced technologies and provides five control modes such as touch, WIFI, voice, Bluetooth, and physical buttons, which provide users with more convenient means of controlling and managing animal and plant breeding. At the same time, the system also introduces intelligent self-learning function, which can automatically update the best planting plan to improve the breeding efficiency and realize the effective use of resources.

5.5.1. Main Picture

The main drawing is shown in Fig. 13.

Fig. 13 The main drawing

(1) Manual mode screen selection
(2) Automatic mode screen selection
(3) Data monitoring screen selection
(4) Running status screen selection
(5) Plant weekly record screen selection
(6) Plant status screen selection

5.5.2. Manual Mode

The manual mode diagram is shown in Fig. 14.

Fig. 14 The manual mode diagram

The system status is divided into running and stopped, and the water colonization system performs sterilization and water filtration every 15 minutes. At the same time, the plant aquatic curtains and outreach sliding table has five states: not in motion (stopped), retracted (being retracted), retracted to complete, stretching out (being stretched out), stretched out to complete. The logic of such states is clear and helps the user to understand the system operation status in real time.

5.5.3. Automatic Mode

The automatic mode diagram is shown in Fig. 15.

Fig. 15 The automatic mode diagram

When the system is running, the user can set the running time of the automatic mode through the timer function to ensure that the system automatically performs the breeding tasks according to the preset plan within a specific time period. At the same time, the system monitors the growth of the plants in real time and ensures that the necessary breeding operations, such as fertilization and watering, are carried out at the right time through the real-time feedback of the plant height. In addition, the system also takes into account the needs of different plants and provides a potted plant species selection function, which allows users to choose the appropriate breeding method according to the specific plant species, ensuring a more intelligent and adaptable system.

6. Conclusion

Our system is of great significance in promoting the development of modern agriculture. Facing the problems of shortage of social agricultural workers, low production efficiency and low value-added of agricultural products, our design builds a unique and independent animal and plant breeding system based on technologies such as artificial intelligence, Internet of Things, cloud computing and big data. In addition, our plant and animal breeding system also has the potential for mixed plant and animal breeding in large-scale agro-ecological farms. Through smart WiFi and 3D management functions, the system is able to realize precise management of plants and animals, which improves the efficiency of agricultural production. More importantly, this system helps to solve the problem of environmental pollution, especially in large-scale agro-ecological farms, where our technology can effectively minimize the impact on the environment and provide more high-quality ecological agricultural and sideline products. By enhancing people's aesthetic requirements for a beautiful ecological environment, our work plays an active role in building a more sustainable and healthy agro-ecosystem.

Abstract

With the progress of science and technology and the development of society, the world's countries on industrial production efficiency, intelligent manufacturing transformation continues to grow. Therefore, we designed a fully automatic logistics handling platform, which is a multi-modular device based on mechanical design, microcontroller control, visual positioning, the device can realize autonomous identification, autonomous transportation, improve production efficiency, the device has a wide range of applications, can be applied to food packaging, parts processing, intelligent manufacturing, and other automation scenarios.

Keywords: Mechanical design, Circuit design, stepper motor drive, logistics and transportation

1. Introduction

With the development of society and the progress of science and technology, artificial intelligence technology is gradually changing the traditional mode of industrial production [1]. Through the introduction of intelligent manufacturing technology, some advanced products such as unmanned technology, drone courier, intelligent medical care and so on are born. This design is based on the fully automatic logistics handling platform in the context of intelligent manufacturing technology, which effectively solves the problem of time-consuming and labor-consuming manual operation [1], [2], [3], [4].

The rest of this article is organized as follows. the second part introduces the mechanical model and related structural analysis, the third part gives the finite element analysis, and the fourth part shows the related hardware design

2. Mechanical modeling and related structural analysis

Automated item transportation and handling systems are an essential part of the production line in modern factories. Its main purpose is to transport items from one place to another and to perform handling and assembly operations when needed. Such systems usually consist of many different mechanical, electrical and control components to accomplish various tasks. In this product, the transportation and handling of items is mainly achieved by means of a screw slide and rack and pinion mechanism. The main features of this system design are stability and reliability in the face of a variety of items to be transported.

2.1 Design of mechanical parts

The mechanical part of the transportation and handling system of this design is mainly composed of the following parts:
(1) Screw slide: used to transport items from the starting position to the designated position.
(2) Rack and pinion mechanism: used to ensure stability and reliability during transportation.
(3) Pneumatic Cylinder: Used to carry out the transportation and stamping assembly of the articles.
The design of the mechanical part is shown in Fig. 1.
Fig. 1 The Mechanical design drawings

2.2 Component Introduction

(1) Screw slide table: It is a kind of mechanism that utilizes the principle of screw rotation to carry out linear motion, which consists of threaded rod and slider, and pushes the slider to carry out linear motion through the rotation of the threaded rod. Screw slide has the advantages of high precision, good stability and smooth movement, so it is widely used in automated item transportation and handling systems. Screw slide is one of the most important components in the system and is responsible for transporting items from the starting position to the specified position. Screw slides usually consist of a threaded rod, a slider and a guideway. The threaded rod rotates to drive the slide in a linear motion, while the guide rails are used to ensure the orientation and stability of the slide.

(2) Rack and pinion mechanism: it consists of a set of gears, racks and guiding shafts, which is mainly used to realize the overturning and handling of the goods and ensure the stability of the goods in the transportation process. At the same time, the guiding shaft in the rack and pinion mechanism can avoid the lateral displacement of the spiral slider in the transportation process.

(3) Cylinder: It is used to realize the handling and stamping assembly of the articles. When the article reaches the specified position, the cylinder starts to work, clamps the fixture to the article, and moves the article to the stamping assembly area for operation.

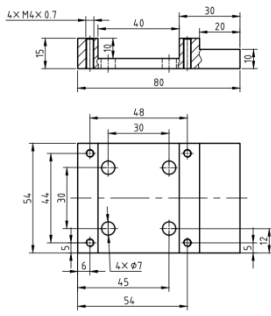
The system has a variety of functions, including transportation, handling and stamping assembly of items, etc., and at the same time, it is characterized by stability and reliability, easy operation, safety and high efficiency. It is suitable for various application scenarios in logistics, production and manufacturing industries.

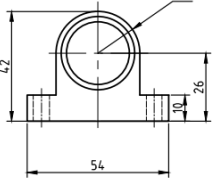
3. Mechanical design

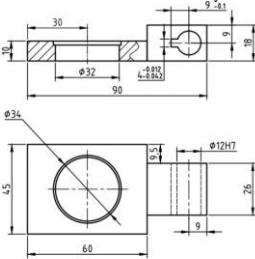
The following focuses on the mechanical design of the handling part of the automated article transportation and handling system.

3.1 Design Idea

The syringe pushes the rack and pinion to mesh with the gear to provide the circumferential force, the gear is connected with the shaft in the handling mechanism through the key to drive the shaft to rotate circumferentially, and at the same time the shaft is connected with the loading fixture in the handling mechanism through the key to realize that the syringe drives the loading fixture to rotate circumferentially to realize the handling of the goods.

3.2 Material selection






The material selection of the parts of this system is 6063 aluminum alloy, because 6063 aluminum alloy has excellent weldability, extrudability and plating, good corrosion resistance, toughness, plasticity, and can meet

the high requirements of precision machining.

3.3 Manufacturing process

The mechanical parts in this system mainly take two kinds of machining methods: turning and milling, in which turning is mainly used for machining shaft system parts, and milling is used for machining other configurations of parts.

The following table provides a brief parts drawings, drawings include a brief machining accuracy, assembly requirements note. As shown in Table 1.

Table 1 Parts Drawings

Part Name	Summary Drawings
	Machining precision

Part Name	Summary Drawings / Machining precision
Turntable	
Flip Table Stand	
Flip Carrier	

ensure its safety.

Next is the flip shaft, as the most core part, its safety is also the most important part of the flip mechanism. As shown in Fig. 3.

Flap axle

4. Finite Element Analysis and Simulation

Finite element analysis is the use of mathematical approximations to simulate real physical systems. By utilizing simple but interacting elements, it is possible to approximate a real system with a finite number of unknowns to an infinite number of unknowns.

The tipping mechanism is based on mechanical design to analyze the degree of deformation when it is subjected to forces to ensure its safety. Because the material of the device is aluminum alloy 6063, by checking its permissible stress is 160MPa, through solid works finite element analysis, the following diagrams are obtained. As shown in Fig. 2 is the cylinder table.

Fig. 3 Flap axle

From the above figure, it can be seen that the maximum shear stress of this shaft is 2.553×10^7 Pa, while the permissible stress of aluminum alloy 6063 is 1.6×10^8 PA.

Therefore this shaft is safe.

There is also the fit between the rack and pinion, which is the key condition for the flip mechanism to be able to flip. This is shown in Fig. 4.

Fig. 4 Pinion

Fig. 2 Cylinder table

As can be seen from the figure, this design is not safe, although the actual cylinder table is not subjected to such a large force, but it can be added with reinforcement to

As can be seen from the figure, the maximum shear stress is 3.102×10^9 Pa, which is too large compared with the permissible stress, so it is not safe, but it is still feasible in the flip mechanism because it is calculated not

to use such a large force.

Overall, the designed tilting mechanism is completely feasible.

5. Hardware design

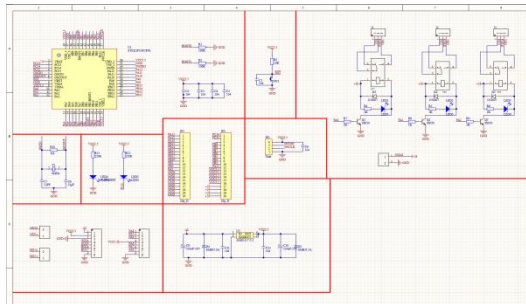
To accomplish this, the team designed a PCB motherboard that implements the above features. The PCB schematic diagram is shown in Fig. 5.


Fig. 5 PCB schematic diagram

The design of this PCB board with STM32F103C8T6 as the main chip, equipped with a stepper motor driver and a three-way relay, realizes precise stepper motor control and solenoid valve on/off. Through programming, the board can control the speed, direction and movement distance of the stepper motor, while it can control the on/off of the circuit through the relays to realize automation control.

5.1 Solenoid Valve Drive:

The Relay is shown in Fig. 6.
Fig. 6 Relay

Through the main control board to send high and low level signals to control the relay on and off, and then control the solenoid valve on and off.

5.2 Stepping motor drive:

This design mainly adopts two stepper motor driving methods, the first one is stepper motor driver and the second one is TB6612FNG stepper motor driver module [4], [5], as shown in Fig. 7.
Fig.7 Stepper Motor Driver and TB6612FNG Stepper Motor Driver Module

The actual principle of a stepper motor driver is to convert a pulse signal from a control system into an angular displacement of the stepper motor. Whenever the stepper driver receives a pulse signal, it drives the stepper motor to rotate in a set direction at a fixed angle (called the "step angle"). The stepper motor rotates step by step at a fixed angle. The angular displacement can be controlled by controlling the number of pulses for precise positioning. The speed and acceleration of the motor rotation can also be controlled by controlling the pulse frequency for speed regulation [5], [6], [7], [8], [9].

5.3 Voltage regulator module

This design voltage regulator module mainly uses the chip for AMS117-3.3V for 3.3v voltage regulator design.

6. Product Summary

Through the test, the product can complete the recognition of objects and achieve the desired position to achieve flipping and stamping through the precise control of the stepper motor, which can be adapted to the automatic scenes such as product packaging and parts processing.

Abstract

With the rapid development of digital technology and artificial intelligence, the innovation and exploration of traditional painting forms in the field of digital art have become increasingly captivating. The focus of this research is to create a brush calligraphy and painting robot system based on PLT files. It digitizes user creative instructions to autonomously generate brush calligraphy and landscape paintings. This technology not only advances the deep integration of digital art and traditional culture but also opens new perspectives and vast possibilities for artistic creation.

Keywords: Artificial intelligence, Calligraphy and painting robot, Brush word, Landscape painting, Digital art

Introduction

With the rapid progress of digital technology [1] and artificial intelligence, traditional art forms [2] are experiencing a profound digital change, and brush painting and calligraphy as a precious heritage of traditional Chinese culture is no exception. This study aims to further explore the influence of digital technology on traditional painting, and explore the widespread application of this technology in the field of art creation. The core concept of the brush calligraphy and painting robot system is planted on the basis of the PLT file. It receives the user's creative instructions in a digital manner and aims to independently draws brush characters and landscape painting. The rise of artificial intelligence provides strong technical support for the design of brush calligraphy and painting robots. The algorithm of machine learning such as deep learning enables the machine system to imitate the unique brush strokes of the brush, and even understand the emotion and artistic conception expressed by the artist in landscape painting. This technology not only injects new vitality into traditional art, but also expands the boundaries of art creation, and provides users with more diversified and innovative creative methods. In this study, we will introduce the technical principles, design frameworks and application scenarios of the brush calligraphy and painting robot system. Through in -depth excavation of these aspects, we expect to provide in -depth insights for the integration of digital art and traditional culture, and contribute to the innovation and inheritance of traditional culture of digital art.

1. The main text

The design scheme uses a robotic arm, a set of linear guide systems, as well as painting tools such as pen, ink, paper, and inkstone. The robotic arm is mainly responsible for grasping the brush and realizing dipping ink, writing and painting [3]. The robotic arm is cleverly placed on the linear guide to expand its movement range and improve accuracy and efficiency [4]. For the overall design effect, see Fig. 1.

Fig.1 overall arrangement

2. Core structure of robotics

The robotic arm chooses the desktop four-axis robotic arm of Yuejiang Technology. As shown in Fig. 2, the robotic arm works radius of 320mm, the load is 0.5kg, the repeated positioning accuracy is 0.2mm, and it has high accuracy in the vertical direction. And in the horizontal direction, it can be moved quickly, with a light weight and a small volume. The length and width of the base are 158mm. You can complete the writing or painting work of this robot. The first

freedom of the robotic arm is the rotation freedom composed of a shaft base. The second and third degree of freedom is the rotation freedom composed of large arms and small arms. Four freedom is located at the end of the robotic arm, which is rotating freedom [5]. You can install a fixture or suction cup at this location. The robot chooses a fixture to pinch the brush.

Fig. 2 Manipulator

The core parameters are shown in Table 1.

Table 1. The core parameters of the robotic arm.

Weight	3.4 kg
Base Dimension (Footprint)	158 mm x 158 mm
Materials	Aluminum Alloy 6061, ABS Engineering Plastic
Controller	Dobot Integrated Controller
Robot Mounting	Desktop
Number of Axes	4
Packing Size (L X w X H)	421 mm x 334 mm x 352 mm
Payload	500g
Max.Reach	320mm
Position Repeatability	0.2mm
Communication	USB\WIFI*\Bluetooth*
Power Supply	100-240 V,50/60 Hz
Power In	12V/6.5 A DC

3. The innovation point

The convolutional neural network (CNN) [6] is usually used in tasks such as image recognition and feature extraction, and the PLT file is a format for describing the graphic drawing instruction sequence. In the design of the brush calligraphy and painting robot, the two can be used with each other.

First, convolutional neural networks can be used to generate training of PLT files. The robot can draw a specific pattern or imitate a certain style. It can use convolutional neural networks to train images, and then use the characteristics to generate the corresponding PLT files. CNN can help identify the characteristics of strokes, lines, and shapes in the image, thereby generating the corresponding drawing instructions. Fig. 3-1 is the "chrysanthemum picture" entered by the user, Fig. 3-2 is the picture form in the PLT file generated after program processing.

Fig. 3-1 Original Picture   Fig. 3-2 Processed pictures

Secondly, convolutional neural networks can be used for image recognition and PLT file generation. When the robot receives the image input provided by the user, the convolutional neural network can be used for image recognition and identify the content and characteristics of the image [7]. Then, the corresponding PLT file is generated according to the recognition result, so as to guide the robot to complete the drawing task. Fig. 4 is the calligraphy of the robot

Fig. 4 the calligraphy

3.1. The use of PLT files

The PLT file provides a digital approach for describing painting instructions. By using PLT files, you can digitize traditional paintings and landscape painting such as landscape painting to make it meet the needs of modern digital art.

The PLT format is a vector graphic format, also known as HPGL (Hewlett Packard Graphics Language) format. It is a drawing language developed by HP, which was originally used to control the output of the drawer. This format is now widely used in fields such as drawing, engineering and manufacturing.

The PLT file is a text file that can use any text editor to open the viewing and editing. It contains drawing commands and coordinates, which can be drawn through these commands.

3.2. Convolutional neural network

Convolutional neural network (CNN) is a feeding neural network structure that is designed to process large image data and performs well in the fields of image and voice recognition. The network structure consists of one or more convolutional layers, full connection layers, pooling layers, and linear rectifier layers. It has the ability to capture the two -dimensional structure of the input data, especially in the field of image processing.The components of convolutional neural networks include:

(1) Convoiced layer: The convolutional layer can generate a set of parallel feature maps, and performs operations by sliding the convolution nuclear on the input image. The convolution nucleus and the input image perform the computing of the component of the element and the computing of the element. This process is called the rod. The size of the convolution nucleus is small. Enter the image through overlapping or parallel effects to share the same weight and bias item to effectively extract image features.

(2) Linear rectifier: Linear rectifier uses linear rectifier (RELU) as an incentive function to enhance the non -linear characteristics of the entire neural network without changing the output of the convolution layer.

(3) Pondalization layer: Pondization is a non -linear form of downgrade, of which the largest pooling is a common form. This layer divides the input image into a rectangular area, outputs the maximum value of each sub -area to achieve the purpose of reducing the data dimension.

(4) Complete connection layer: After the convolution and pooling layer, the neural network is high -level reasoning through the complete connection layer. The neurons in the complete connection layer are connected to all the activation in the previous layer, and activation is calculated through imitation transformation, including the addition of matrix multiplication and bias items.

4. Conclusion

This research focuses on the design and development of a brush calligraphy and painting robot system based on PLT files. By digitizing user creative instructions, the system autonomously generates brush calligraphy and landscape paintings. The rise of artificial intelligence and convolutional neural networks provides robust support for the robot's design, enabling it to mimic unique brush strokes and comprehend the emotions expressed by artists in landscape paintings. This technology not only deepens the integration of digital art and traditional culture but also explores new avenues and vast possibilities for artistic creation.

5. Future outlook

The design and application of brush calligraphy and painting robots have opened a new era of deep integration of digital art and traditional culture. In the future, the development of brush calligraphy and painting robots will inject new vitality into the field of digital art, while promoting traditional culture in the digital age. The continuous evolution of this technology will bring more possibilities to artists, educators, and cultural and creative industries, and bring a more colorful future to our art world.

Abstract

With the continuous development of society and human civilization, people, especially the disabled and the elderly, need more and more to use modern high technology to improve their lives and improve the comfort of life. Therefore, this paper introduces a single-chip microcomputer-based non-contact body temperature and facial recognition-based heart rate measurement method and applies it to the intelligent wheelchair system. Monitor the vital signs of the elderly, and give early warnings in time when abnormal values occur, so that family members or caregivers can rescue them in time.

Keywords: Smart wheelchairs，Non-contact，heart rate，Body temperature measurement

1. Introduction

Population aging has become a global phenomenon. China's elderly population is huge, the aging rate is fast, and the problem of elderly care and daily care for the elderly is becoming increasingly severe. Wheelchairs are indispensable means of daily life for the elderly and people with lower limbs, and a cost-effective, comprehensive and reliable intelligent wheelchair can not only improve the quality of life of the disabled and the elderly, but also reduce the burden on caregivers. Smart wheelchairs. Research plays an important role in the development of elderly care projects in China [1]. Since the development of the first intelligent wheelchair in the United Kingdom in the 80s of the 20th century, the United States, Japan, France and other countries have also carried out research on intelligent wheelchairs [2], [3], [4], [5], [6]. The research on intelligent wheelchairs in China started late, but in recent years, some research results have been achieved. The research of intelligent wheelchairs based on visual tracking [7], autonomous driving [8], electromyography [9], head [10], multi-sensor fusion [11], and voice [12] has also been progressing, but these wheelchairs are still in the laboratory stage, which are expensive, and their safety and real-time performance cannot meet the demand. Therefore, this study takes the above problems as the starting point, and carries out the system improvement design on the basis of the existing wheelchair machinery to meet the current needs.

2. Infrared body temperature measurement

Based on the stm32 microcontroller, the B-1 infrared temperature measurement module is used to complete the non-contact body temperature measurement. The physical diagram is shown in Fig. 1.
Fig. 1 Photographs of the B-1

The module has a built-in 24-bit high-precision AD conversion chip, and its working principle is that when the object is higher than absolute zero (-273℃), it will radiate infrared energy outward, and the infrared sensor receives the infrared light reflected back by the object, and obtains the induced temperature data through the high-precision program algorithm in the CPU.

Table 1 Temperature measurement results

Temperature	1	2	3	4
Measure the temperature/℃	36.7	36.2	37.3	35.9
True temperature/℃	36.8	36.0	37.1	36.2

3. Non-contact heart rate measurement

3.1 Technical principle

There are two commonly used methods to measure heart rate in clinical practice: electrocardiogram (ECG) and optical volume scanner (PPG) PPG is a method of detecting blood volume pulses (BVP) in human blood tissues using photoelectric means, such as fingertip pulse oximeters, exercise bracelets, etc

Remote photoplethysmography (RPPG): Diffuse and specular reflections of light after passing through the skin, both of which can be captured by the camera. According to Lambert-Beer's law, the strength of a substance's absorption of a monochromatic light is related to the concentration of the absorbent substance and the thickness of its liquid layer. Since the periodic beating of the heart causes the same periodic change in the concentration of blood in the blood vessels and capillaries, it leads to a periodic change in the concentration of light absorbed by the blood, so that the intensity of the diffuse reflected light received also changes periodically, that is, the pulse wave information.

When the heart contracts, the concentration of blood increases, the human skin absorbs more light and reflects less light; When the heart stretches, the concentration of blood decreases, the human skin absorbs less light, and the reflected light increases [13]. The schematic diagram is shown in Fig. 2.
Fig. 2 Schematic diagram of the principle

3.2 Data set

This experiment uses a UBFC dataset of a total of 10 RGB videos, recorded in an indoor environment, including light changes and head movements, with a pixel resolution of 640x480. At the same time, the fingertip oximeter was used to synchronously record the real BVP signal and heart rate value as label data.

3.3 Test results

According to the distribution of the Bland-Altman diagram, the blue scatters are basically within the red

dotted line and around the black dashed line. According to the distribution of the Fig. 3 scatter plot, the distribution of the sample points of the predicted value and the true value is basically around the straight line y=x, which indicates that the consistency between the predicted value and the true value is good. Fig. 4 shows that the experimental consistency is good
Fig. 3 Scatter plot
Fig. 4 Bland-Altman

4 Experimental analysis
Fig. 5 Comparison chart

Fig. 5 shows that the true value curve is in good agreement with the predicted value curve. Table 1 shows that the error between the measured and true values of body temperature is within acceptable limits.

5 Conclusion

In addition to the non-contact heart rate and body temperature measurements presented in this article, a smart wheelchair system is a highly intelligent device that integrates a variety of sensors, controllers, and actuators to help improve the quality of life for the elderly and people with disabilities with reduced mobility. At the same time,

the human-computer interaction module enables users to easily communicate with the wheelchair. In the future, with the continuous development of technology, smart wheelchairs will be able to provide convenient and safe travel solutions for more people in need.

Abstract

During the production of automotive axle holes, the roundness error at the pipe opening leads to low detection efficiency due to manual measurements, rendering real-time inspection unfeasible. This paper proposes a method for detecting and sorting the roundness of automotive axle holes based on visual inspection. Ensuring accuracy in grasping, it establishes the kinematic model of the robot Aubo_I5. Targeting automotive axle holes for grasping, it employs adaptive threshold segmentation to highlight the section features of the axle hole. The Canny algorithm is then used to extract edge information, and finally, the least squares method is utilized to detect roundness errors for sorting the axle holes based on this error.

Keywords: Axle Hole, Assembly, Vision Deep, Learning

1. Introduction

The assembly of mechanical components constitutes the subsequent phase in the entire manufacturing process. Manual assembly is characterized by low efficiency, and the assembly speed is affected by factors such as worker labor intensity. Traditional assembly robots have mostly been controlled through teaching or offline programming [1], [2]. Consequently, these robots strictly follow predefined assembly procedures, lacking the ability to promptly respond to changes in the surrounding environment or objectives, thus exhibiting poor robustness. With the advancements in computer and visual technologies, automation machinery on production lines gradually possesses visual perception capabilities. This enables real-time dynamic recognition and localization of targets, facilitating visual-guided adjustments of robot poses and grasping [3].

The emergence of deep learning has improved issues regarding detection accuracy in visual recognition. However, due to the complexity of the assembly process, uncertainties such as lighting conditions, backgrounds, workpiece sizes, shapes, and other factors in the working environment are critical issues affecting target recognition and localization.

2. Kinematic Modeling

Establish the joint coordinate system of the Aubo_I5 robot as shown in Fig. 1, and the structural model and dimensions of each joint as illustrated in Fig. 2. To more accurately define the sorting model coordinate system, the gripper coordinate system G_{xy} is established at the end joint.
Fig. 1 Structure of the Aubo_I5 Robot

Junsheng Zhang, Dongpo Ma, Yizhun Peng
Fig. 2 Robot Joint Coordinate System

Fig 2: Establishing the Joint Coordinate System of Aubo_I5

Based on the joint coordinate system, the corresponding D-H parameter table is shown in Table 1 [4], where each link parameter is defined as follows:

α i-1 represents the distance moved along Xi-1 axis from Zi-1 to Z_i;

ai-1 represents the angle rotated around Xi-1 axis from Zi-1 to Z_i;

d_i represents the distance moved along Z_i axis from Xi-1 to X_i;

θ _i represents the angle rotated around Z_i axis from Xi-1 to X_i.

Table 1 D-H Parameter Table for AUBO_I5 Robot

i	α_{i-1}/deg	a_{i-1}/mm	d_i/mm	θ_i/deg
1	0	0	$d_1 = 98.5$	θ_1
2	90°	0	$d_2 = 140.5$	θ_2
3	180°	$a_3 = 408$	0	θ_3
4	180°	$a_4 = 376$	$d_4 = -19$	θ_4
5	−90°	0	$d_5 = 102.5$	θ_5
6	90°	0	$d_6 = 94$	θ_6

2. 1 Robot Forward Kinematics Analysis

Forward kinematics analysis involves determining the

pose relationship between the tool coordinate system of a robot relative to the polar coordinate system, given the known motion angles of each joint. This is accomplished using the homogeneous transformation matrix $^{i-1}_iT$ between adjacent link pairs, as shown in Equation (1):

$$^{i-1}_iT = \begin{bmatrix} C\theta_i & -S\theta_i & 0 & a_{i-1} \\ S\theta_iC\alpha_{i-1} & C\theta_ic\alpha_{i-1} & -S\alpha_{i-1} & -S\alpha_{i-1}d_i \\ S\theta_iS\alpha_{i-1} & C\theta_iS\alpha_{i-1} & C\alpha_{i-1} & C\alpha_{i-1}d_i \\ 0 & 0 & 0 & 1 \end{bmatrix} \quad (1)$$

In the equation：$C\theta_i = \cos\theta_i, S\theta_i = \sin\theta_i$

According to the D-H parameter table of Aubo_I5, calculate the homogeneous transformation matrices for each of the seven joints ^0_1T、^1_2T、^2_3T、^3_4T、^4_5T、^5_6T、^6_7T As shown below：

$$^0_1T = \begin{bmatrix} C1 & -S1 & 0 & 0 \\ S1 & C1 & 0 & 0 \\ 0 & 0 & 1 & d_1 \\ 0 & 0 & 0 & 1 \end{bmatrix} \quad (2)$$

$$^1_2T = \begin{bmatrix} C2 & -S2 & 0 & 0 \\ 0 & 0 & -1 & 0 \\ S2 & C2 & 0 & d_2 \\ 0 & 0 & 0 & 1 \end{bmatrix} \quad (3)$$

$$^2_3T = \begin{bmatrix} C3 & -S3 & 0 & a_3 \\ -S3 & -C3 & 0 & 0 \\ 0 & 0 & -1 & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix} \quad (4)$$

$$^3_4T = \begin{bmatrix} C4 & -S4 & 0 & a_4 \\ -S4 & -C4 & 0 & 0 \\ 0 & 0 & -1 & d_4 \\ 0 & 0 & 0 & 1 \end{bmatrix} \quad (5)$$

$$^4_5T = \begin{bmatrix} C5 & -S5 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ -S5 & -C5 & 0 & d_5 \\ 0 & 0 & 0 & 1 \end{bmatrix} \quad (6)$$

$$^5_6T = \begin{bmatrix} C6 & -S6 & 0 & 0 \\ 0 & 0 & -1 & 0 \\ S6 & C6 & 0 & d_6 \\ 0 & 0 & 0 & 1 \end{bmatrix} \quad (7)$$

Combining the above formulas, the robot's forward kinematics equation can be obtained by simultaneous.

$$^0_6T = {}^0_1T{}^1_2T{}^2_3T{}^3_4T{}^4_5T{}^5_6T = \begin{bmatrix} n_x & o_x & a_x & p_x \\ n_y & o_y & a_y & p_y \\ n_z & o_z & a_z & p_z \\ 0 & 0 & 0 & 1 \end{bmatrix} \quad (8)$$

2.2 Robot Inverse Kinematics Analysis

Inverse kinematics involves calculating the joint angles θ_i of a robot given the pose of the tool coordinate system. Considering the robot's link coordinate systems, the axes of joints 4, 5, and 6 intersect at one point, satisfying the Pieper criterion, indicating the existence of a closed-form

solution. Assuming the end pose ${}^{0}_{6}T$ in Equation (8) is known, solving is performed using an analytical method, and the inverse solutions for each joint are presented in Table 2.

Table 2: Inverse solution formula of joint

$$\theta_1 = arctan \frac{u_1}{\pm\sqrt{1 - u_1{}^2}} - arctan \frac{p_y}{p_x}$$

$$\theta_5 = arctan \frac{\pm\sqrt{1 - u_2{}^2}}{u_2}$$

$$\theta_6 = arctan \frac{o_x S_1 + o_y C_1}{n_y C_1 + n_x S_1}$$

$$\theta_3 = arctan \frac{\pm\sqrt{1 - g^2}}{g}$$

$$\theta_2 = arctan \frac{k}{\pm\sqrt{1 - k^2}} - arctan \frac{u_4}{v_4}$$

$$\theta_4 = arctan \frac{v_5}{u_5} - \theta_3 + \theta_2$$

Among which:

$$u_1 = \frac{d_4 - d_5}{\sqrt{p_x{}^2 + p_y{}^2}}$$

$$u_2 = -a_x S_1 - a_y C_1$$

$$u_3 = C_1(p_x + d_6 o_x - d_5 C_6 a_x - S_6 n_x) + S_1(d_5 C_6 a_y - p_y - d_6 o_y - S_6 n_y)$$

$$g = \frac{u_3{}^2 + v_3{}^2 - a_3{}^2 - a_4{}^2}{2a_3 a_4}$$

$$u_4 = a_3 + a_4 C_3 - a_4 S_3$$

$$v_4 = a_3 + a_4 S_3 + a_4 C_3$$

$$k = \frac{u_4 + v_4}{\sqrt{u_4{}^2 + v_4{}^2}}$$

$$u_5 = C_1(o_x S_5 + n_x C_5 C_6 + a_x S_6) - S_1(o_y S_5 + n_y C_5 C_6 + a_y S_6)$$

$$v_5 = o_z S_5 + C_5(n_z C_6 + a_z S_6)$$

2.3 Mage Preprocessing

Before conducting roundness measurement, in order to eliminate the effects of metal debris, noise from the surrounding environment, and surface wear on the workpiece, the captured images need preprocessing. This involves removing noise and the influence of lighting while retaining the edge features of the workpiece [5]. Image preprocessing mainly includes:

1）Image Denoising: Using specific filtering algorithms to reduce noise in the image while preserving edge features.

2）Threshold Segmentation: Highlighting the target contour features more effectively.

(1) Image Filtering

Image filtering refers to the suppression of noise in an image while preserving detailed features, and its effectiveness directly impacts subsequent image processing. Common filtering algorithms include mean filtering, median filtering, Gaussian filtering, and others.

1）Mean filtering is a typical linear filtering algorithm that replaces the grayscale value of a particular pixel with the average pixel value in its surrounding area. Its mathematical expression is as follows:

$$g(x, y) = \frac{1}{mn} \sum_{(i,j) \in S_{xy}} f(i, j) \qquad (9)$$

Where represents the center point at, and is the size of the filtering window. By controlling the window size, the filtering effect can be adjusted. A larger value for results in a more pronounced filtering effect.

2）The median filtering algorithm is a common non-linear filter that calculates the median value of points within a neighborhood range in an image for a particular pixel, replacing the original pixel value. The mathematical expression is as follows:

$$g(x, y) = median_{(i,j) \in S_{xy}} \{f(i, j)\} \qquad (10)$$

Median filtering controls the size of to adjust the filtering effect. Compared to mean filtering, median filtering not only removes salt-and-pepper noise but also better preserves edge information.

3) Gaussian filtering is also a type of linear smoothing filter. It involves the weighted averaging process of the entire image and is primarily used to remove uneven lighting or sensor noise.

To compare the effects of the three filtering methods, experiments were conducted on the images, and the results are shown in Fig. 3.

From the results, it's apparent that after applying median filtering, not only has the original noise in the image and the interference from oil stains on the workpiece surface reduced, but it has also effectively preserved the edge features. Hence, median filtering is employed to filter the images of the pipe end face.

(2) Threshold Segmentation

Image threshold segmentation is a crucial step in segmenting the target region. Determining the threshold is a key aspect of image segmentation. If the threshold is set too high, target points may be considered as background

Junsheng Zhang, Dongpo Ma, Yizhun Peng

and ignored, while setting it too low might lead to background points being identified as target features. Common threshold segmentation methods include adaptive thresholding algorithms, Otsu's method, iterative threshold segmentation, and others. Due to varying surface qualities of the hole, there's no fixed threshold selection. Therefore, this paper conducts comparative experiments among several commonly used segmentation algorithms to choose the appropriate threshold segmentation algorithm suitable for the cooling pipe imaging environment [6].

(a)Mean Filtering

(b)Median Filtering

(c)Gaussian Filtering

Fig. 3 Comparison of filtering algs

After applying median filtering to the captured borehole regions, comparative experiments of three segmentation algorithms were conducted, and the results are shown in Fig. 4.

From the segmentation results above, it's evident that the adaptive algorithm has better segmentation results, preserving the edge features of the pipe end more completely. Therefore, this paper adopts the adaptive segmentation algorithm.

From the segmentation results above, it's evident that the adaptive algorithm has better segmentation results, preserving the edge features of the pipe end more completely. Therefore, this paper adopts the adaptive segmentation algorithm.

(a)Adaptive Algorithm

(b)OTSU Algorithm

(c)Iterative Algorithm

Fig. 4 Comparison of threshold segmentation

2.4 Edge Detection

After threshold segmentation, the next step is edge detection for the borehole. To ensure better contour detection, reducing noise interference is essential to maintain the integrity and clarity of edge information. Commonly used edge detection algorithms include the Canny algorithm, Sobel algorithm, Laplacian algorithm, etc. Compared to other edge detection algorithms, the Canny algorithm is less susceptible to noise interference [7].

The Canny algorithm first applies a Gaussian filter to smooth the image, reducing its sensitivity to noise. Then, it calculates the gradients in the X and Y directions using the Sobel operator, performs non-maximum suppression, and finally uses dual thresholds to determine edges. The Canny edge detection effect for the port block is shown in Fig. 5.

Fig. 5 Canny detection algs

2.5 Borehole Circular Detection

After edge extraction, detecting circles is a crucial part of roundness measurement. The most commonly used methods for circular detection are the Least Squares Circle Fitting and Hough Transform [8]. To measure circles accurately, it's essential to filter out the circular contours for measurement. As shown in the image, after pre-processing the image, the contour of the borehole is extracted using Canny edge detection. The contour points of the borehole are then sorted for subsequent roundness measurement.

Using the detected circle center as the reference [9], [10], the roundness error is represented by the difference between the maximum contour circle radius Rmax and the minimum contour circle radius Rmin, expressed as Rerr= Rmax − Rmin.

$$erro = \sqrt{(x_{max} - x_c)^2 + (y_{max} - y_c)^2} - \sqrt{(x_{min} - x_c)^2 + (y_{min} - y_c)^2} \quad (11)$$

among which : $(x_{max}, y_{max}), (x_{min}, y_{min})$ The coordinates of the farthest and nearest points from the fitted circle center, respectively, correspond to the contour.

The principle of the least squares fitting circle involves several steps: 1) detecting the actual contour, 2) applying the least squares fitting to find a circle, 3) creating a circle with the least squares circle center and the maximum distance to the contour, and 4) creating a circle with the least squares circle center and the minimum distance to the contour. The difference between the maximum and minimum radii of these circles is used as the basis for evaluating roundness.

The circle fitted using the least squares circle algorithm for the axle hole contour is depicted in Fig. 6. The coordinates of the fitted circle's center are (232.87733, 85.63195), and the fitted circle's radius is R = 63.36658.3
Fig. 6 Least squares circle fitting

3. Target recognition network based on YoloV4

The YoloV4 algorithm can be divided into four parts: input end, backbone feature extraction network, enhanced feature extraction network and output end. The input end includes image preprocessing, converting the size of the input image to the specified input size, and normalizing the image information. Secondly, it is the backbone feature extraction network. CSPDarknet53 formed after YoloV4 is added to CSPNet serves as the backbone feature extraction network. YoloV4 's enhanced feature extraction network consists of a PANet structure, which is used to improve the diversity of feature expressions and strengthen the fusion of feature information; the last is the output end, which is used to perform classification and regression tasks and output the final prediction results.

YoloV4 has three outputs after passing through the backbone feature extraction network, namely L3, L4 and L5. Among them, L3 and L4 will be output to the enhanced feature extraction network for corresponding feature fusion after one 1 × 1 convolution; L5 will be input to the spatial pyramid pooling layer SPP after three convolutions, and then enter the enhanced feature Extract the network for feature fusion. Finally, the final detection result can be obtained by sending it to the output terminal.

YoloV4''s backbone extraction network CSPDarknet53 is an improvement based on Darknet53. The original residual module is changed to the CSP structure as shown in Fig. 7. The CSP structure changes the original residual module into two parts, one part goes through the residual network and the other part Directly merging with the output of the residual network, this method can reduce the among of parameters and calculations while maintaining a high accuracy.
Fig. 7 CSP structure block

The PANet network is used to build a feature pyramid, analyze semantic features from top to bottom, and use the feature layer results obtained by down sampling and up sampling to reduce the loss of underlying feature information during the propagation process of the FPN

algorithm by increasing the bottom-up feature fusion path. problem [69], which improves the richness of the feature map and the detection accuracy of the algorithm. The feature map after feature fusion is predicted in three different sizes by Yolo-head. The prediction results include offset x, y, detection frame size w, h, and confidence level c of target information. Finally, redundant ones are eliminated through IOU and NMS. Detect the and NMS. Detect the frame and complete the target prediction.

3.1 Shaft hole type identification

As shown in Fig. 8, after the roundness detection of shaft holes of different sizes is completed, the YoloV4 algorithm needs to be processed to predict the category and position frame of the shaft hole. Before attitude detection, in order to remove the shaft hole target in the image, The effects of other complex backgrounds, noise, and light damage on the target surface existing in the sorting environment can be used for subsequent shaft hole type identification. We have preprocessed the image above, and then use YoloV4 to predict the image.

Fig. 8 Shaft hole image after inspection by YoloV4

4 Experiments and Analysis

4.1 Dataset and environment configuration

The data set used in the experiment of this article contains a total of 6 categories, with 600 data for each category. In order to prevent overfitting due to too little data, this article uses Gaussian noise and random color transformation for data enhancement. The final data the quantity is 3600 sheets.

The training and testing environment of this article is running on a Windows 10 system, NVIDIA GeForce RTX 4060TI GPU, and 8G video memory. The 3600 data sets

are divided, 90% of which are used for training and 10% for verification. Train for 100 epochs, and freeze the next 50 epochs. The initial value of the learning rate for the first 50 epochs is 0.01, and the batch size is 32. The initial value of the learning rate for the last 100 epochs is 0.001, and the batch size is 16. The Adam optimizer is used during training, and the cosine annealing learning rate decay strategy is adopted.

4.2 Experimental results and analysis

From the global loss function curve in Fig. 9, we can see that the loss curve drops rapidly in the early stages of iteration, indicating that the model is fitting quickly and the model's learning efficiency is high. When epoch is 40, the network model gradually becomes stable. After 100 iterations of training, the loss function of the final model converged to 1.50. In addition, by observing the consistency of the loss curves of the training set and the verification set, it can be seen that the generalization ability of the model has reached the best state.
Fig. 9 Loss value curve

Fig. 10 shows the detection effect of the Yolov4 model. It can be seen that the network model accurately identified all buckles without missing detection. It can be seen from the above results that this method has a high accuracy in detecting targets and is practical.
Fig. 10 Yolov4 detection results

In this experiment, a plastic bottle was placed next to the shaft hole as an interference object through the above steps, and 50 sorting tests were conducted, in which the positions of the plastic bottle and the shaft hole were randomly placed. The robot grabbing effect is shown in Fig. 11. The robot successfully avoided other interference and grasped the target shaft hole.

Fig. 11 Robotic arm grabs shaft hole

5 Conclusion

The vision-based automobile shaft hole roundness detection system proposed in this article improves the applicability of detection and can be widely used in roundness error detection of various workpiece nozzles. In the image pre-processing stage, by comparing various threshold segmentation algorithms and filtering algorithms, the adaptive threshold segmentation algorithm combined with the median filter algorithm was selected, which can not only remove the noise in the image, but also retain the edge features of the nozzle. The Canny detection algorithm is used to identify the contour of the nozzle, and the least squares method is used to detect the roundness error of the nozzle, and then combined with the YoloV4 algorithm to complete type recognition, and finally the robot completes the shaft hole identification and grabbing work. The results show that the designed detection system can not only improve the real-time performance and efficiency of detection, but also complete the subsequent grabbing work.

Abstract

In recent times, intelligent robots have found applications across diverse fields. In scenarios demanding both repetitive and non-routine tasks, the likelihood of work errors increases. To address this, we have proposed methods encompassing both forward and backward recovery. Forward recovery suits minor modifications, while our focus is on backward recovery for substantial failures. Our study introduces a novel evaluation method to discern the optimal recovery path among various options.

Keywords: error recovery, task stratification, error classification, evaluation standard

1. Introduction

At the present day, information technology, particularly generative AI, is making rapid strides, a trend mirrored in the progress of robotic intelligence. As a consequence, robots face an increasing array of tasks during execution, often grappling with challenging assignments prone to errors and failures. This underscores the pressing need for effective methods to address these issues [1], [2], [3], [4], [5].

Over several years, our research [6], [7], [8], [9], [10] has focused on systematizing error recovery theory, resulting in a method based on task stratification and error classification concepts. The primary components of the robot system include sensing, modeling, planning, and execution sequences (Fig. 1). When an error occurs, the process transitions to the recovery phase. This section involves estimating the error's cause, classifying it, and correcting the original system. The refined process then operates on an enhanced, reliable system.

The proposed error recovery technology returns to the process before the step where the failure occurs and starts over from there. In practice, not only this type of backward recovery but also forward recovery, which moves forward after failure, is used. This study considers various paths from failure to recovery execution.

The concept of skills, which are motion primitives comprising a task, is described in Section 2. The fundamental technique for generating an error-recovery path is described in Section 3. Multiple possibilities for various recovery paths are presented in Section 4. Various evaluation standards and methods for selecting the most suitable path using the new evaluation method are considered in Section 5, and examples are presented in Section 6.

2. Concept of Skill

This section provides a brief overview of essential aspects of these skills [11], [12], [13].

2.1. Skill primitives

Motion primitives constituting tasks, termed "*skills*," were derived by analyzing the human behavior. Three crucial skills, "*move-to-touch*," "*rotate-to-level*," and "*rotate-to-insert*" (Fig. 2), are highlighted. A person's behavior, including representative and similar skills, serves as a model for the robot's motion primitives.

2.2. Stratification of tasks

The use of task hierarchies, as shown in Fig. 3, is effective for the execution of automated plants. The layer "$task^{(i+1)}$" occurs one tier above the layer "$task^{(i)}$," and the layer "*skill primitive*" is represented by the lowest layer "$task^{(0)}$."

Akira Nakamura, Kensuke Harada

3. Error Recovery

In an actual work environment, contrasting to an ideal case, various factors can lead to errors in the execution of a robot. This section outlines the error classification concept and error recovery technique [6], [7], [8], [9], [10].

3.1. Error classification

The errors can be categorized into several groups based on their possible causes. We considered four error groups: execution, planning, modeling, and sensing (Fig. 4).

3.2. Error recovery based on classification

First, if an error occurs, the cause is determined. Next, appropriate corrections are made to the system based on the tentative causes. The process returns to the previous step, and the task is executed again in this step (Fig. 4). Since a modified process was executed, the same error was less likely to occur. If the error scale is small, the process returns to the previous step in the lowest hierarchy (Figs. 4 and 5). Conversely, if the error scale is large, the process returns to the previous step in the highest-ranking layer of the hierarchy and is executed again from that step (Fig. 5).

4. Various recovery paths

The error recovery methods we proposed have primarily centered on rerunning the process by reverting to the step before an error occurs, constituting a backward error recovery process. However, alternative recovery procedures exist, including backward recovery for significant errors (failures) and forward recovery for minor errors. Additionally, errors may impact the environment, altering the arrangement or shape of surrounding objects, necessitating modified recovery processes. This section introduces several recovery procedures focusing on the degree of destruction of the environment surrounding an object according to [10].

Consider an indicative task sequence composed of n subtasks from the start to the goal (Fig. 6(a)). Suppose a failure occurs in the qth subtask during the process (Fig. 6(b)).

4.1. Recovery sequence I (RS-I): Complete restart

This method restarts work from the original starting point using the same process (Fig. 6(c)). If needed, the environment is restored to its original state, and if necessary, the original object or part is replaced with a new one and executed.

4.2. Recovery sequence II (RS-II): Restart from the middle of a prior process (without another process)
Fig. 1 Robot task system with an error recovery function

(a) Move-to-touch skill   (b) Rotate-to-level skill

(c) Rotate-to-insert skill
Fig. 2 Three fundamental skills
Fig. 3 Hierarchy of taskS

This method resumes work in the same process from subtask$_p$, the point in the middle of the process before the failure in the original process occurs (Fig. 6(d)).

4.3. Recovery sequence III (RS-III): Restart from the middle of a prior process (with another process)

This method resumes work from a point in the middle of the original process before a failure occurs (Fig. 6(e)). Unlike RS-II, a sequence from subtask$_t$ to subtask$_u$, not included in the original planning, restores the environment without causing problems for subsequent work.

4.4. Recovery sequence IV (RS-IV): Restart from the middle of a process that was supposed to come up later (with another process)

This method restarts work from the middle of the original process (Fig. 6(f)), differing from RS-III by reverting to its original process with subtasks scheduled after the original process failure. It includes a sequence from subtask$_v$ through subtask$_w$, not in the original plan.

(e) Original repetition from step along the way (with another process)

(f) Restart from step in the middle of the original process scheduled to run later

(g) Continuation of work, including consideration of any recovery process that may be required later

Fig. 6 Various error recovery sequences

4.5. Recovery sequence V (RS-V): Continuation of work including consideration of recovery needed later

In this method, work continues as long as possible after a failure. When further work becomes impossible, the environment is corrected, and work progresses (Fig. 6(g)). This modification involves a sequence from $subtask_x$ through $subtask_y$, not included in the original planning.

4.6. *As mentioned above, this study briefly categorizes the recovery sequences into five types. Recovery sequences RS-I through RS-III are backward recovery processes, whereas recovery sequence RS-V is a forward recovery process. Recovery sequence RS-IV is not a*

forward recovery process because it does not continue working after failure has occurred. However, because recovery sequences are subtasks scheduled to be executed after failure of the original process, this study included the recovery sequence RS- IV in the forward recovery process for convenience.

5. Selection of a recovery path

As explored in Section 4, a single failure often presents multiple possible recovery processes. The study advocates the use of evaluation standards to discern the most suitable process from several candidates. This research incorporates 11 evaluation standards, expanding on the four to eight standards introduced in [9].
Fig. 7 Picking and placing task using a gripper

5.1. Various evaluation standards

(i) Cost

Cost is considered the most important evaluation standard. A recovery process with the minimum practical cost is selected.

(ii) Time

Time is an important evaluation standard. Priority is given to paths that require shorter recovery times.

(iii) Reliability

Reliability is considered a representative evaluation standard. The path with a high success rate is prioritized for accomplishing the recovery task.

(iv) Safety

Safety is considered a representative evaluation standard. Priority is assigned to paths that are less likely to harm people.

(v) Finishing

Finishing is considered an important evaluation standard. It prioritizes paths displaying excellent completion of the operation on the target object.

(vi) Recovery data

Recovery data is considered as the evaluation standard. Processes with a lot of useful data are prioritized.

(vii) Tool

The tool used for recovery is evaluated based on workability, with priority given to tools displaying high efficiency.

(viii) Operator skill.

Operator skill during the recovery process is an evaluation standard, favoring processes managed by a larger number of skilled experts.

(ix) Work efficiency.

Work efficiency is considered as an evaluation standard. Selecting an efficient work plan, that is, a route that is not unreasonable, wasteful, or uneven, is important. This index is common to (i) cost and (ii) time, but even if it is an efficient route, it may not necessarily be cheap or fast; therefore, it was set as a separate indicator.

(x) Environmental impacts

Environmental indicators, including noise levels, are considered, accounting for overall environmental problems such as air, ocean, and water pollution.

(xi) Damage

Damage is a measure of the difference between an object without and with errors. Although it may not be readily visible externally, the quality of an object could change owing to errors in the production process.

5.2. Selection of a recovery path using evaluation standards for each section

Reference [9] details how to choose the best recovery path for each evaluation standard. In contrast, this study proposes specifying indicators for each section of the recovery process and selecting the path with the superior total indicator. This prevents situations where a path chosen by a single indicator may be partially inappropriate.

Furthermore, evaluations may vary depending on the recipient of the standard. Table 1 delineates whether the evaluation is from the Manufacturer/Operator side or the Consumer/User side, indicating the degree of involvement with symbols ◎, ○, △, and - in descending order. For instance, a process with high manufacturer/operator involvement may be chosen in the first half of the recovery stage, while a process with high consumer/user involvement may be selected in the second half. This ensures optimal restoration on the manufacturer/operator side and maximum satisfaction with the finished object on the consumer/user side.

6. Example of error recovery in product display

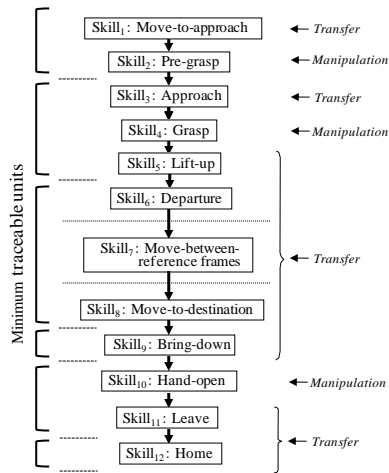
The task involves utilizing a manipulation robot to arrange products on shelves or in the display window of a convenience store. The objective is to position and posture the products optimally, as a tidy arrangement significantly boosts customers' inclination to make purchases, as opposed to disorganized placements. Fig. 7 displays an image illustrating a pick-and-place task that transfers a single object from a product stock to a display space. Furthermore, Fig. 8 showcases the command sequence constituting a singular pick-and-place task. In this instance, the task revolves around evenly arranging 12 identical rectangular products in a layout of three rows


Fig. 8 Task sequence of picking
and placing a product

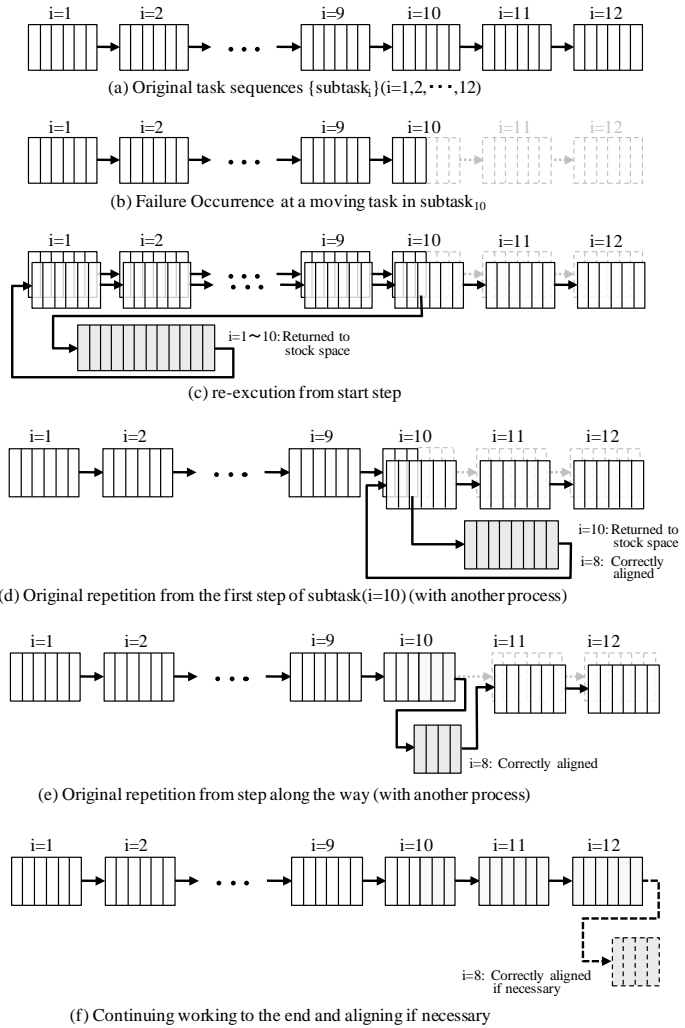
and four columns, as depicted in Fig. 9. Fig. 10 illustrates an error scenario; Fig. 10(i) demonstrates a carry-and-place operation for a pre-planned 10th object. Subsequently, Fig. 10(ii) portrays an instance where a hand interferes with the 10th object during the carry-and-place operation, causing the displacement of the 8th item from its original position. Finally, Fig. 10(iii) presents a scenario wherein the hand impacts the 8th item during the carry-and-place operations for the 10th item, resulting in the toppling of the 8th item.

Fig. 11 shows various recovery patterns. Fig. 11(a) illustrates normal planning in which no errors occur. Fig. 11(b) depicts the point at which the aforementioned failure occurred during the pick-and-place operation of the 10th object. Figs. 11(c)–11(f) show the respective


recovery patterns. Fig. 11(c) demonstrates the error recovery of the backward type back to the start, in which the 1st object through the 8th object are returned to their original stock space, and the task is rerun from the beginning. Fig. 11(d) displays the error recovery of the backward type, where the recovery task is to return the 10th item to its original stock space, restore the 8th item to its original position and orientation, and pick and place the 10th item again. Fig. 11(e) shows the forward error recovery, which executes a recovery task that places the 10th item in its designated position even after an error occurs and then returns the 8th item to its original position and orientation, followed by the 11th pick-and-place. Fig. 11(f) shows a special type of forward error recovery, which is a recovery task that continues the work to the end even after an error occurs and returns the eighth

Akira Nakamura, Kensuke Harada

product to its original position and orientation, if necessary. If a product is displayed in a store, it may not matter much if it is misplaced or even fallen over; that is how to deal with it. However, if it resonated with a customer's willingness to buy, it is executed. Although this is a particularly obvious example, it is sometimes desirable to perform the first half of the recovery task based on the operator's criteria and the second half of the recovery task based on the user's criteria.

7. Conclusion

When an error arises during the primary task, the process transitions into the recovery phase. This section explores diverse recovery paths utilizing our proposed error recovery method, grounded in both task stratification and error classifications. We introduced a method to systematically derive the optimal recovery path, aligning with evaluation standards for each section.

As discussed, numerous recovery paths exist, and choosing the right one poses challenges. While this paper introduced a method for optimal path selection, it does not delve into defining evaluation standards for each section. Addressing this aspect becomes imperative for future research endeavors.

Abstract

This paper presents a robotic end-effector that addresses challenges of automated robotic food handling. We utilize a variable stiffness fabric on the finger surfaces of the gripper. Depending on its temperature, the finger stiffness changes to tackle grasping food items with different physical characteristics. Hard objects can be grasped with the hard mode of the finger while a fragile object can be safely grasped with the soft mode. This gripper design was validated empirically through force and object-grasping experiments.

Keywords: robotic end-effector, food picking, variable stiffness, temperature dependence

1. Introduction

Within industry, the adoption of robotic automation is driven by the promise of heightened efficiency and the reduction of laborious, repetitive tasks that can exert both mental and physical strain on humans [1]. The food industry is a continuous source of opportunities for advancements in automation. Successful automated food handling can improve product quality and production rates [2], however, is a challenge due to inherent inconsistencies in food size, texture, and delicacy [3]. The automated processes may take significant time or fail to adjust for these variances. This paper addresses these challenges by utilizing a compact, mechanically simple design that takes advantage of the dynamic control of its applied force and stiffness variability. The adjustable compliance of the device's material is used in combination with force feedback sensors to successfully eliminate the chance of bruising that pinching or other enclosing end-effectors can cause [2]. Force feedback or tactile sensors are commonly used in industrial robotics [4], allowing the design to remain industry compatible. The goal of this paper is to demonstrate the potential of

utilizing this material to handle items requiring different amounts of applied force by only altering the temperature exposed to the gripper - eliminating the need for extensive or challenging control procedures required by other soft robotic grippers [5]. We attached the variable stiffness material to the finger surface of a two-fingered gripper and the compliancy increases as the temperature becomes higher. We demonstrate the gripper can successfully adapt to grasping a variety of food materials by changing the finger stiffness according to the stiffness properties of food. The effectiveness of the proposed gripper is verified by experimental results.

2. Related Work

Food items that are heavy, slippery, fragile, or have a minimal-height profile commonly experience grasping difficulties with currently proposed gripper designs [6], [7]. This gripper is compatible with objects having these attributes that other developed variable-stiffness general grippers are not [8]. The design proposed by A. Pettersson et al. utilizing magnetorheological fluid [9] also maintains a secure grasp through a gripper with high and adaptable compliance. However, an improvement

Rozilyn Marco, Prashant Kumar, Xinyi Zhang, Weiwei Wan, Kensuke Harada

this paper introduces is the compactness of the design — a crucial attribute for practical deployment in confined spaces [10]. Other grippers that grasp food items by the side surfaces require the object's size to be predetermined [10]. The paper by G. Endo et al. [11] required the height of the samples to be known and constant. Food items can vary in size and shape even between samples of the same food, different apples for example, and this requirement limits the success and robustness of the gripper. The design proposed in this paper eliminates that requirement through its dynamic force application and compatibility with force feedback implementation. The gripper by R. Maruyama et al. [12] was successful in handling fragile and soft food items but required predetermination of the required force to apply to obtain a successful grasp. The design of this gripper allowed for more innate tolerance in this aspect, allowing it to work with food items not encountered previously.

3. Design

The goal of the design was to achieve both simplicity and effectiveness. Simple mechanical design minimizes the risk of contamination during usage due to component separation [10] and the gripper's achieved compactness, increases the ease of adoption in practical scenarios [10]. Relying on the variability of the gripper's compliance from temperature exposure as the means of adapting the force application decreases the requirement for precise mechanical human adjustments thus not requiring an upskill in labour [13].

3.1. Concept

The robotic end-effector incorporates a variable stiffness fabric as its primary functional component and is the main contributor to the gripper's low mechanical complexity. This fabric exhibits temperature-dependent properties, becoming more flexible as the temperature rises and stiffer as it decreases. When controlled, this dynamic behaviour can be used to handle objects with different structural integrities. Explicitly, the end-effector can be subjected to higher temperatures when the target for transportation is fragile or soft as the fabric would apply less force while in this more compliant state. Likewise, when the fabric stiffens when exposed to lower temperatures, the gripper can exert greater force, making it suitable for firmly grasping rigid food items. This ultimately allows for a secure hold and movement

without causing deformation or damage to samples in both scenarios.

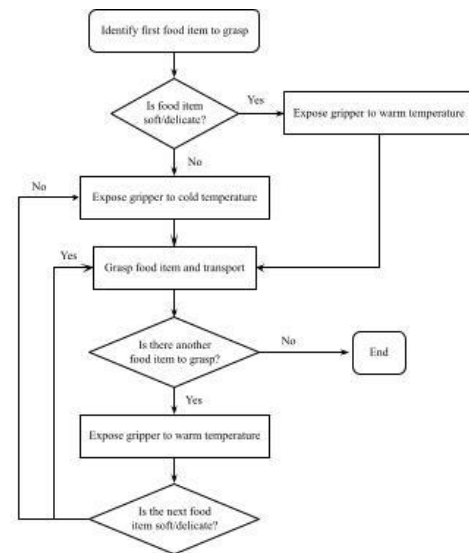
Between grasps, warm temperature can be applied to return the fabric to its neutral position. This methodology of subjecting the gripper to warm temperature after each grasp will be applied during the experiments used in this paper and can be seen in the flow chart of Fig. 1.


Fig. 1. Decision flow chart when picking an item.

3.2. *Implementation*

The base structure of the gripper was created through CAD software and was 3D printed (Fig. 2) with the fabric attached via sewing. Aside from providing a strong foundation, the base material is inconsequential to the functioning of the gripper. It can thus be substituted for a hygienic material such as stainless steel [14].
Fig. 2. Gripper physical implementation and CAD model: (A) Front Profile, (B) Three Quarter Profile, and (C) CAD side profile of gripper (i) 73.7°, (ii) 20.5mm, and (iii)2mm.

An essential feature of the gripper base is the curved nature at the bottom which guides the fabric beneath the item and provides support to the bottom when the gripper encloses it. This creates a secure position between the fabric and the food item and prevents the item from slipping through the bottom during transportation. To prevent the loss of the curved formation (Fig.2.B), the fabric was attached to the base while exposed to warm temperature. This was a method of pre-tensing the fabric to ensure the curved position remains taut as the fabric's innate stiffness is reduced at higher temperatures.

The 2mm between the bottom face and the fabric (Fig. 2.C.iii) enables effective grasping of items with narrow height profiles. The angle of the stem and the radius of the inner curvature of the base are 16.3° and 11mm respectively. These values were chosen to minimize the gap between the hands of the gripper and maximize the amount of fabric held vertically. Minimizing the gap between the hands increased the minimum width of food items that could demonstrate the enclosing property of the gripper i.e. in Fig. 2.C.ii. Maximizing the amount of vertical fabric increases the area that applies uniform force along the side of an object. Future design iterations will investigate methods of allowing these dimensions to be variable, increasing the versatility of the gripper.

4. Experiments

The first experiment executed was a force gauge experiment to observe the force applied to the fabric depending on displacement and fabric temperature. The second was a set of demonstrative experiments to display the success of the gripper in a variety of arrangements and sample types. Water was selected as the stimulus medium as it possesses a high heat capacity, meaning it requires a relatively high amount of energy to change its temperature by one degree [15]. This ensured it maintained at a considerably stable temperature throughout the execution of an experiment sequence.

4.1. *Force gauge experiment*

The force gauge experiment was conducted with the gripper to analyze the force applied to an object over time under two temperatures and at three final displacement positions. Specifically, 30°C and 67°C, and 10mm, 20mm, and 30mm respectively. The experiment setup consisted of the force gauge sensor mounted onto a cart of a linear motion apparatus with a blocking cart positioned at the desired displacement away from the

force gauge's starting position (Fig. 3). To depict the behaviour throughout the different segments of a standard pick-and-place operation, the carts were:

- manually moved the same velocity until the final displacement to mimic the initial grasping,
- maintained its position for approximately 10 seconds to simulate the effect the gripper would have during the time required for transportation,
- and then released, as if the object has arrived at its final location.
Fig. 3. Force gauge experimental set-up: (A) gauge cart and displacement blocker cart on track, (B) gripper and gauge prong, and (C) entire force gauge setup.

4.2. *Food picking experiment*

The goal was to showcase and verify the final design's practical ability to handle a variety of characteristics - heavy, slippery, fragile, brittle, flat, and rigid. Accordingly, corresponding food items were used during testing as seen in Table 1 and Fig. 4.

Table 1. Food Item Characteristics and Water Temperature Assignment

Item	Characteristics	Water Temperature
A	Heavy – 66 g	Hot
B	Hard, non-uniform vertical profile	Cold
C	Malleable, slippery plastic surface	Hot
D	Soft, narrow	Hot
E	Fragile	Hot
F	Hard, spherical	Cold
G	Brittle	Hot
H	Hard, narrow – 12.95 mm	Cold
Fig. 4. Experimental food items.

Rozilyn Marco, Prashant Kumar, Xinyi Zhang, Weiwei Wan, Kensuke Harada

The gripper was exposed to temperatures depending on whether the physical properties of the target object are better suited for greater or weaker applied force during grasping. Each food item was tested individually on the platform as well as in more complicated combinations including multiple items on the platform grasped in continual sequence and objects in a stacked formation (Fig. 5). A successful grasp is defined in this paper by moving a sample from its initial to final location without causing damage or the item slipping mid task.
Fig. 5. Experiment arrangements: (A) Sequential (B) sequential (C) stacked, and (D) combined stacked and sequential.

The gripper was attached to an industrial robot and integrated with software that controlled grasp planning and execution while employing a depth camera for the identification of item locations. The gripper's linear actuator operates using force feedback to determine when an adequate clamping width has been achieved.

5. Results

5.1. *Force gauge*

The results are seen in Table 2 and Fig. 6 for each final displacement value, the fabric exposed to the cooler temperature applied more force compared to when exposed to a higher temperature. This confirms the premise of the gripper i.e. force applied increases as the temperature of operation decreases and vice versa.

Table 2. Force Gauge Experiment Key Values

Displacement	Max Force	Plateaued Force	Velocity
Hot Temperature - 67°C			
10 mm	0.6 N	0.4N	1.429 mm/s
20 mm	1.8 N	1.3 N	1.818 mm/s
30 mm	3.8 N	2.8 N	1.887 mm/s
Cold Temperature - 30°C			
10 mm	2.8 N	0.7 N	1.613 mm/s
20 mm	6.5 N	2.5 N	1.538 mm/s
30 mm	9.6 N	3.8 N	1.657 mm/s
Fig. 6. Results of the force gauge experiment plotted: (A) all displacements and (B) each displacement individually.

The constant velocity of the gripper movement meant that time and displacement differed by a constant factor. Therefore, while accounting for this factor, modelled relationships with respect to time can proxy relationships with respect to displacement. The constant velocity portion of the experiment was isolated and time vs. force - or equivalently displacement vs. force - was analyzed using both linear and second-order polynomial models. A strong second-order polynomial relationship was determined between the displacement of the gripper and the force applied as seen with the R-squared values in Table 3. In future work, an analytical model will be formalized to depict the force a sample will experience depending on the item's width (i.e. the gripper displacement) and considering the temperature.

Table 3. Force Gauge Experiment Model Performance

Displacement	Linear Model	Polynomial Model
Hot Temperature - 67°C		
10 mm	0.909	0.927
20 mm	0.971	0.971
30 mm	0.969	0.983
Cold Temperature - 30°C		
10 mm	0.931	0.932
20 mm	0.957	0.962
30 mm	0.888	0.936

When the final displacement is achieved, the force quickly decreases and then plateaus. This is ideal as there is no prolonged period of unnecessary high force applied after the fabric has molded to the shape of the target. As seen in Table 2, there is a directly proportional

relationship between this plateaued value and the displacement of the gripper and an inversely proportional relationship between the force and temperature. Given that in practice, the displacement of fabric - i.e. a target's width - is immutable, plateaued force can be controlled with temperature. The relationship between this plateaued force, the temperature of the fabric, and the final displacement value can be further investigated to optimize and formalize the temperature used for various targets with different ideal handling requirements.

5.2. *Food picking*

The gripper was successful in grasping and transporting each food sample from its respective initial positions to their final destinations. Fig. 7 shows the end-effector gripping pose for each food item from Fig. 4 and Fig. 8 shows the gripper throughout experiment D from Fig. 5.
Fig. 7. Gripping snapshots of each food item.

Fig. 8. Snapshots during the execution of experiment D.

Unsuccessful grasping attempts were seen with samples with widths comparable to the maximum open position width of the gripper and with the samples in experiments with. These failures can be attributed to incorrect positioning of the gripper prior to closure. This could be corrected by further developing the method of identifying the desired initial location through the calibration matrix of the software. Additionally, the gripper can be modified to have a bigger difference in the open position width of the gripper compared to the size of the samples to have larger tolerance limits to account for the margin of error between generated and desired locations.

6. Conclusion

The robotic gripper proposed in this paper was designed to utilize its variable stiffness property to successfully grasp food samples with commonly difficult-to-handle features without causing damage and while maintaining mechanical simplicity and compactness. This concept was formed on the basis that allowing the material of the gripper to do the bulk of adapting to the shape and delicacy of a given sample permits the gripper to be functional without human intervention or immediate control. The gripper's variable force application was validated in a force gauge experiment conducted under two temperature conditions and at three displacement values, confirming the viability of our design concept. The practical capabilities of the gripper were demonstrated experimentally with the gripper performing food-picking sequences involving a diverse range of items, each possessing distinct properties and arranged in both sequential and stacked configurations.

In future developments, enhancing the gripper's versatility could involve the implementation of variable width and height dimensions to accommodate an even broader range of items. Moreover, expanding the range of temperatures utilized for more customized force applications can be investigated for more tailored handling of samples.

Abstract

This research proposes to create a machine vision using YOLOv5 model to detect maturity of the tomatoes on farm field which categorized by raw, half-ripe, and ripe. The use of multiple color space RGB, HSV, and LUV dataset aims to overcome external disturbances such as light and shadows. The results are the machine vision can differentiate fruits by its category with minor bias and obtaining a good mAP50 rates with the greatest result is LUV color spaces model. This machine vision with custom datasets in multiple color spaces can be implemented on farm field which is considered based on the purposes, environment and external disturbances. These models are developed for autonomous harvesting robot on farm field.

Keywords: Machine Vision, YOLOv5, Color Space

1. Introduction

The gradual maturity of technology has developed in many sectors, one of them is in the agricultural sector called as precision agriculture. Many agricultural systems still using traditional method, particularly in the maturity detection level. The research on precision agriculture aims to transform traditional method into digitalization precisely [1]. Robotics and automation are expected to have a significant impact on farms of the future by increasing efficiency in production for fruits grading which are gradually shifting to automation through a Computer Vision based on fruits detection. In addition, image processing can provide understanding of individual health, nutritional condition, and maturity level. However, the complexity of the field environment as well as the unstructured features of fruits resulting a great challenge to the target detection, particularly for maturity level measurement [2]..

Computer Vision (CV) is a key point for future implementation on farming technology, particularly in the fruits grading and classification, yield estimation counting, health condition, and maturity. Fundamentally, CV generated using Machine Learning (ML) algorithm which enable the analysis of massive quantities of data more rapidly and precisely, instead traditional or manual method. CV traditionally execute image by primary color Red, Green, and Blue (RGB), so the images collected by RGB based camera at RGB wavelength. In addition, grading fruits can be classified by using color, texture, and share feature descriptors. RGB color detection has a good level accuracy when using CV, however, at some condition, CV cannot detect object which has rough or irregular environment, such as on farm field. On the fam field, the objects can be disturbed by external factor, for example, sun rays, leaf, and shadows [3], [4]. To overcome this issues, execution process of CV can be implemented using multiple color space identification.

Color space basically can also describe as the way in which human eyes can perceive color vision. Color space shaped from the development of color model which the color is associated with an accurate definition of the way the components are to be inferred and the situations are viewed with the set of resulting colors. There are many different color spaces such as RGB, NTSC, LUV, HSV, CMYK, and HSI. Each color space has specified function and color model [5].

In the recent years, many researches have conducted to accomplish the best algorithm for ML, basically in image processing, particularly in the fruit's detection based on its color space. Detection of seedling using machine-transplanted rice has been developed using machine vision [6] which aimed to detect paddy seedlings using many color spaces and plant the seeds using a paddy machine. Research [7] conducted research by tomato recognition and localize the object using YOLOv5 algorithm only in RGB images. Research [8] discussed about a quality evaluation for two type of grapes using random forest model to identify quality of each fruit type. Another implementation of ML in image processing on farming activity also developed for palm fruit [9] which purposed to classified the oil palm fresh fruit based on the textures and palm's skin.

This research proposed to determine maturity level for tomato fruits based on three different color space using ML and YOLOv5 model on the real farm implementation to develop the previous similar researches. The maturity level of the tomato was divided into three class those are raw, half ripe, and ripe. In addition, this research was classified the greatest result of dataset's performance based on its color space.

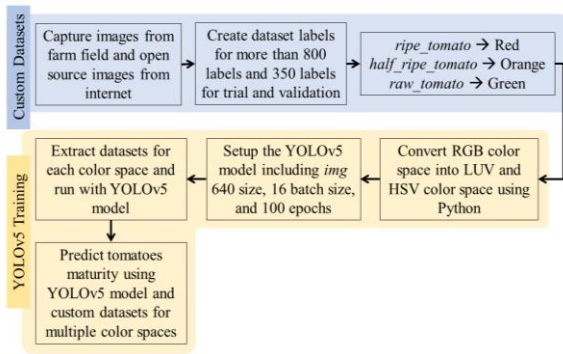

Fig. 1. Flowchart of proposed system.

2. Methodology

2.1. Proposed System

The overall flowchart of the proposed system is presented on the Fig. 1. The specified fruits which used as the main object is tomato. The system was proposed using Machine Learning based on YOLOv5 Algorithm with custom datasets. The used of YOLOv5 in this research rather than another version of YOLO has recently analyzed based on recognition and location of on-farm fruits. The previous research [7] explained about the YOLOv5 accuracy for on-farm moving robot. YOLOv5 has a high-level accuracy rate for rapid image detection with only 9.0 time/ms. Besides the accuracy level can be reach for more than 95%. In addition, the number of objects detected by YOLOv5 is the highest then other YOLO model. YOLOv7 is the latest model of YOLO version however the average detection time is 13.59 time/ms and with a little bit lower accuracy rate compared with YOLOv5. Based on this literature, originally, this research purpose is to develop a machine vision for on-farm robot. Thus, it is required a machine vision to detect fruits rapidly and precisely. All of the test has the same requirements such as 100 epochs, 32 batch with custom datasets in 640 x 640 image size, and three object classes.

This research was conducted in many trials and three sequences for identifying fruits based on three color spaces those are RGB color space trial, HSV color space trial and LUV color space trial. This research conducted to explain scientifically based on the data training. The purpose of each trial is to achieve the best success rate. Then, arrange each dataset depends on the color spaces and implement it into real robot vision on-farm for future concept.

2.2. Custom Datasets

Images of tomatoes used in training and testing were collected from open-source image from internet and manually captured using phone camera on the tomato farm field located in West Java, Indonesia. The total image of the data was obtained and store basically as RGB format. The datasets for both trial and validation

containing many numbers of samples which consist of single tomato for either red or green or orange tomato, group of tomato with the same color, multiple mixed color type of tomato. In addition, the datasets also consist of multiple small sized images for either red or green or orange tomato. The small sized images used to recognize fruits with far distance of camera or the fruits with a tiny shape. To increase the diversity of the samples, the datasets also contain multiple image characteristics such as blur, dim, front-facing, upper-part, bright, and overlapping objects.

The datasets consist of three classes those are *ripe_tomato*, *raw_tomato*, and *half_ripe_tomato*. The *ripe_tomato* represent to mature fruit, the *raw_tomato* represent to unripe fruit, and the *half_ripe_tomato* represent the fruit is half mature [10]. The datasets also distinguished based on the purpose those are train images and validation images. The total sample images of trial and validation for *ripe_tomato* is 192 and 136 respectively, the total samples of trial and validation for *raw_tomato* class are 243 and 101 samples respectively, and the total samples of trial and validation for *half_ripe_tomato class* are 403 and 139 respectively. The total samples from 334 images datasets are approximately 838 samples for trial and 376 samples for validation. Each class basically is RGB color space and converted to another color spaces HSV and LUV. These variety of class and color spaces appointed to determine the best color space to detect fruits maturity level.

3. Results and Discussion

3.1. RGB Trial

This trial consists of several tests and each test has its main purpose. The first test purposed the machine vision to detect fruits and classified them into two classes *ripe_tomato and raw_tomato.* However, the test result has low quality mean Average Precision (mAP50) for only 54% and 52% respectively with total 49%. These issues happened because the machine vision cannot detect small-sized fruits for further scope of the images. In the second trial, more images added to the dataset, specifically for small-sized tomato for either red or green tomato class with total additional datasets are 90 images for both. The additional datasets including single small sized red and green tomato, and multiple objects of small-sized tomato. The results of the second trial for *ripe_tomato* and *raw_tomato* class have mAP50 92% and 83% with overall mAP50 is 87%. However, in the second trial, the machine cannot detect orange tomato which is neither categorized as red nor green tomato. Thus, the final trial conducted to add more images and one dataset labelled as *half_ripe_tomato*. The total images added for the *half_ripe_tomato* class are 133 images containing single tomato, multiple tomato, multiple mixed color tomato, and the small-sized tomato. The total additional images are 133, 328 images for overall class, and 823 samples in total for trial and 360 samples in total for

validation. The sample images of final results shown on the Fig. 2(a) and Precision-Confidence Curve (P-C Curve) shown on the Fig. 2(b).

3.2. HSV Trial

HSV trial basically used the same number of total datasets with RGB datasets. In the HSV trial, the images converted into HSV images using Python code. The HSV trial also use three classes called as *ripe_tomato, raw_tomato,* and *half_ripe_tomato*. The trial test of this HSV datasets conducted in 100 epochs. Brief results of the HSV trial are the machine vision cannot differentiate *raw_tomato* and *half_ripe_tomato* class. This issue happened because the HSV color space conversion generates those tomato's skin look exactly the same. The sample images of final results shown on the Fig. 3(a) and Precision-Confidence Curve (P-C Curve) shown on the Fig. 3(b).

3.3. LUV Trial

LUV trial basically used the same datasets from the converted RGB color space to LUV color space using Python code. The LUV datasets also consist of three classes *ripe_tomato, raw_tomato,* and *half_ripe_tomato*. The Trial test conducted in 100 epochs with the detail information of sample final results shown on the Fig. 4(a) and Precision-Confidence Curve (P-C Curve) shown on the Fig. 4(b).

3.4. Performance Evaluation from All Datasets

Based on this research, there are many advantages and disadvantages to use multiple color space in a dataset. Each color space has specific purpose to be used in machine vision. HSV color space can be used to detect color-based image. HSV separates luma, or the image intensity from chroma or color information. HSV can be useful for histogram equalization, removing shadows, lightning disturbance, etc. Besides, RGB color is the basic color space in every image and captured by camera. RGB color can be easily to use and formulated because this color space not necessary to be converted from the original image. However, RGB color space might be also easily distracted with external factors such as shadow, lightning, sunrays, etc. Meanwhile the LUV color space can be used to decouple color with the U and V components which represent chromaticity values of color image. Besides the L or Luminance can improve the RGB picture which distracted from over light disturbance, etc. The comparison from three color spaces which used in this research shown in Table 1.

Based on the Table 1, the LUV and RGB color space has similar mAP50 rates with the overall value 85% and 83% respectively. On the other hand, the LUV datasets have a good performance in object detection proven by the mAP50 rate shown on the Table 1 because LUV color space are fundamentally suitable for restoration error estimation, fast detection, and impulsive noise removal in real-time color imaging. Based on the Table 1, *ripe_tomato* class and *raw_tomato* class for LUV color space's mAP50 rate is higher than RGB color space because some of the images in RGB overlapped by shadows and light as shown in the Fig. 6(a) and Fig. 5(a) respectively. The explanation of comparison between RGB and LUV datasets also visualized in P-C Curve as shown in the Fig. 2(b) and Fig. 4(b) which shows the RGB curve relatively fluctuating than LUV graph. Nevertheless, the graph shows a great stability and raise gradually with small fluctuations. In contrary, the HSV has the lowest of all datasets training. The HSV datasets conversion from RGB color space has the typical color tone with its backgrounds such as leaf, trees, and grass. The HSV datasets, either *ripe_tomato* or *raw_tomato* class has a high mAP50 rates for more than 70%. However, there is an issue regarding the *half_ripe_tomato* class, the machine vision cannot detect the object significantly resulting only 57% of mAP50 value as shown on the Table 1. This value is nearly with 50% and the results should be evaluated to increase the rates [11]. The P-C curves Fig. 3(b) showing the relatively unarranged graph for the *half_ripe_tomato* and the prediction line increased gradually.

The shadow and lightness disturbances occurred during the dataset collection in this research as shown in Fig. 5 and Fig. 6. RGB image reflect lightness, such as sunrays,

Reno Muhammad Fadilla, Tokuo Tsuji, Tatsuhiro Hiramitsu, Hiroaki Seki, Kaihei Okada

Table 1. Final results comparison.

Class	Total Samples		mAP50 (*Epochs = 100*)		
	Trial	Validation	RGB	HSV	LUV
ripe_tomato	192	136	88%	83%	95%
raw_tomato	243	101	81%	77%	84%
half_ripe_tomato	403	139	80%	57%	77%
Overall	838	376	83%	72%	85%

(a) **(b)** **(c)**
Fig. 5. Lightness disturbance: (a) RGB, (b) LUV, (c) HSV.

(a) **(b)** **(c)**
Fig. 6. Shadow disturbance: (a) RGB, (b) LUV, (c) HSV.

into white spot, whereas LUV image converts the white spot into warm blue color as shown in the Fig. 5(b) which was not distract the real color of the image and affecting the machine vision detection more precisely. HSV images turn the white spot into dark red color as shown in Fig. 5(c) and affect the real color of the images. HSV images turn the shadow into lighter color compared with the basic RGB image as shown in the Fig. 6(c) and Fig. 6(a) consecutively. This result influence the machine vision to detect object more precisely. Moreover, LUV also turn the shadows into lighter color than RGB shadow, however, the shadows still configurable and not affected much to fruit's basic color as shown on the Fig. 6(b). Basically, YOLOv5 model trained using a pre-training model originally from RGB color which trained in another color space LUV and HSV. Hence, the model generated results in relatively similar to RGB color space. Overall, LUV color space was the greatest datasets for tomato classification. Therefore, the LUV can be suitable for harvesting robot despite each color space has an advantages and disadvantages in certain occasions and purposes.

4. Conclusion

This research has shown the model of ML which used to determine the best datasets differentiated from color space RGB, HSV, and LUV. According to the final results, RGB and LUV datasets generate an outstanding typical result for the machine vision, on the contrary, the HSV datasets obtain a relatively poor result. The best class in this research from overall datasets evaluation were *ripe_tomato* and *raw_tomato* class. Meanwhile, the *half_ripe_tomato* class acquire intermittent results for all datasets color space depends on the backgrounds and external distraction from the objects. Moreover, HSV datasets need some additional images and adjustment of the "Hue" value as required for increasing the success

rate. In conclusion, all of the datasets in this research can be used depending on the purposes, and object's circumstances which correlated with external disturbances such as backgrounds, lightness, and shadows of the images. LUV color space has shown its performance as the best datasets for rapid segmentation of tomato on farm and more suitable in many external disturbances such lightness and shadows. On the other hand, HSV datasets can be used to recognized tomatoes on farm which has high light intensity and shadow disturbance. Therefore, this color space can be more suitable for harvesting robot with rapid segmentation.

Abstract

The growing demand for robots necessitates faster and more precise processing. However, running large Artificial Intelligence (AI) models from cloud data centers to mobile robots via inference models uses considerable computation resources, which leads to power limitations, particularly for mobile robots. The use of reconfigurable semiconductor devices at the hardware level is a promising solution to this problem. We introduce the educational kit EV3-Robot with a co-design methodology utilizing Field-programmable Gate Arrays (FPGA) Kria KV260 as a hardware accelerator specifically for object detection. We apply the You Only Look Once (YOLO) model for object detection, which provides real-time results for practical applications. Additionally, we analyze the processing times of the local PC and EV3-Robot.

Keywords: EV3-Robot, FPGA, Object detection, YOLO.

1. Introduction

Japan has an ageing population and a decreasing number of young people [1]. To address this issue, mobile robots have gained attention [2]. For example, robots are expected to perform daily indoor tasks, such as picking up and delivering objects. To accomplish such tasks, robots must be capable of recognizing and detecting specific objects [3].

In the field of Artificial Intelligence (AI), Neural Networks (NN) have been extensively researched [4], [5], [6]. Neural networks (NN) are equipped with state-of-the-art perceptual abilities, adaptive learning, and sophisticated human interaction. However, processing this information requires fast and accurate computation, especially in mobile robots where real-time interaction is almost unavoidable. This highlights the increasing need for robots equipped with reliable NNs. In contrast, You Only Look Once (YOLO) has gained attention for its fast and high accuracy [7].

Reconfigurable semiconductor devices at the hardware level offer a promising solution to the challenge of running large YOLO models from cloud to mobile robots via inference models, which require significant computation resources and result in low power consumption. We present the educational kit EV3-Robot, which utilizes a co-design methodology that employs local-PC and Field-programmable Gate Arrays (FPGA) Kria KV260 as a hardware accelerator for the YOLO model.

In our previous study on hardware-based communication [8], [9], the communication processes played a pivotal role. The first step was to design the client-server communication model, where the EV3-Robot served as the server and the local PC as the client. Next, we set the feedback for motor movements during specific tasks, in this case, using Ev3dev Python Socket Connection via Bluetooth to be able detect humans as objects. After that, we execute the deep-learning processor unit (DPU) of the YOLO model on the KV260 board. Finally, we evaluate the processing time.

2. Methodology

2.1. *You Only Look Once version 3 (YOLOv3) as detection system*
Fig.1 Bounding box [10]

Fig. 1 illustrates how YOLOv3 predicts the anchor box by using the bounding box and size clustering. The feature map cell is represented by c_x, c_y, and the pre-selected bounding box size is p_w, p_h. The predicted coordinates are b_x, b_y, b_w, b_h which can be calculated

through Eq. (1), (2), (3), and (4) where the $\sigma(t_x)$ and $\sigma(t_y)$ are pixel values.

$$b_x = \sigma(t_x) + c_x \qquad (1)$$
$$b_y = \sigma(t_y) + c_y \qquad (2)$$
$$b_w = p_w e^{t_w} \qquad (3)$$
$$b_h = p_h e^{t_h} \qquad (4)$$

2.2. *System architecture*
Fig. 2. YOLO real-time object detection on EV3-Robot using FPGA hardware accelerator.

Fig. 2 displays a real-time implementation of YOLO for object detection using an EV3-Robot. The EV3-Robot is equipped with various sensors, although we exclude the input sensor functions in this system. The operating system (OS) used is ev3dev, which is Linux-based and stored on a Secure Digital (SD) card. The connection to the computer is established through Bluetooth and operates at 2.4GHz. The robot is powered by an ARM-9 processor and includes a built-in mini-LCD display. It has four input ports for sensor functions and four output ports for actuators or motors. The EV3-robots motor is connected using the output ports only for feedback.

2.3. *Ev3dev Python Socket Connections for* **feedback**

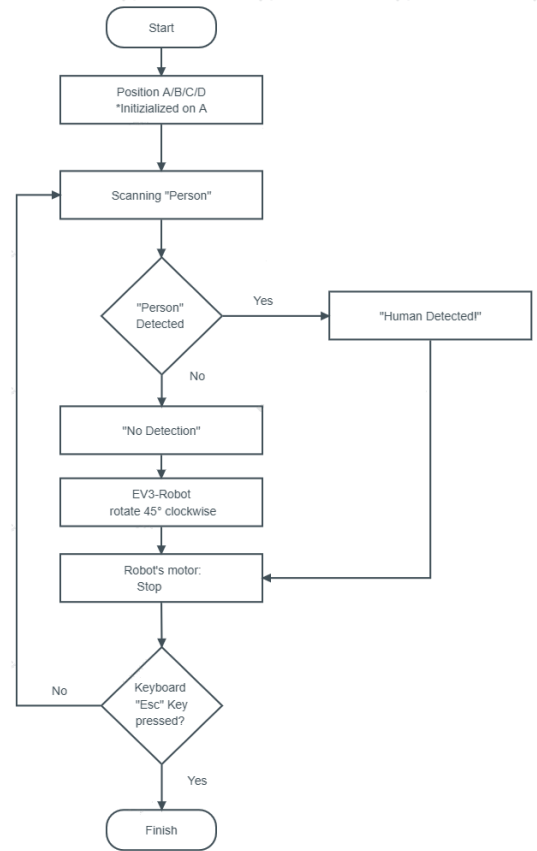
Fig. 3. Client-server communication systems.
a.   Clockwise rotating for scanning "person" and "A" is an initial direction.
b.   Camera views on each direction
Fig. 4. EV3-Robot motor rotation


Fig. 5. Feedback sequences.

Fig. 3 illustrates a remote-control flow that utilizes python socket connections [11] to set motor movements as feedback. The communication involves the use of Internet Protocol (IP) addresses to establish connections. The local PC acts as a client and sends commands to an EV3-Robot, which serves as the server, enabling control over the robot.

Fig. 4 depicts a feedback design for detection that utilizes the motor functions of the EV3-Robot. The surrounding environment is scanned by setting up four directional points, denoted as "A", "B", "C", and "D". The direction is rotated 45° clockwise at regular intervals, in this case, every 4 seconds.

Fig. 5 displays the sequence of the motor rotation process. The robot is equipped with a standby mode, referred to as 'scanning for person', which enables it to scan while executing real-time object detection processes until the desired class, 'person', is detected. Finally, we have implemented an exit process triggered by the 'Esc' command from keyboard inputs to conclude the sequence.

2.4. *Getting the weight data from cloud to local-PC*

The pre-trained COCO weight dataset [12] was utilized. As we were testing real-time communication during detection, we only focused on the specified class from COCO, which is "person" (class_id = 0).

This was added to the client part and a real-time processing loop was performed for 'person' object detection. The wireless camera is mounted to perform object detection using the YOLOv3 model. It focuses on specific classes and determines whether a class_id = 0 (person) is detected. If so, it sends a message via the socket connection.

2.5. *Deep-learning Processor Unit (DPU) in KV260*

Fig. 6. DPU flow.

Fig. 7. YOLOv3 xmodel.

Fig. 6 displays the application of DPU and its integration into the KRIA KV260 board FPGA. Initially, we prepare the YOLOv3 model [13]. Next, we proceed to the pre-processing stage to install and verify the dependencies or libraries. Subsequently, we quantize the model from 32-bit floating-point weights to 8-bit.

Fig. 7 shows that we successfully generated the specified model for the KV260 architecture model, referred to as the "xmodel". Finally, we load "xmodel" into DPU deployment for real-time hardware acceleration.

3. Results and Discussion

3.1. *Real-time remote-control communication of client-server systems*

Table 1. The latency results of the first four command keys.

Keyboard Key	Message	Latency (*ms*)
Up	"going UP! received"	522
Right	"going RIGHT! received"	652
Down	"going DOWN! received"	511
Left	"going LEFT! received"	661

Latency is a priority in client-server communications, especially for YOLO applications that require real-time interaction and responsiveness from the EV3-Robot. Achieving low-latency communication is crucial for current system, so we define latency as the round-trip time (RTT) divided by two in milliseconds (*ms*) as shown in (5).

$$Latency\ (ms) = \frac{RTT}{2} \qquad (5)$$

The outcomes of the initial four command keys are displayed in Table1. Each key is associated with a confirmation message, allowing us to verify when the instruction was issued. Our findings indicate that the latency remains below $1,000\ ms$.

Fig.8. FPGA hardware accelerator task

Table 2. Result comparison during N-step = 1.

Local-PC	FPS	Inference-time (*ms*)	Hardware Accelerator	"person" Object Detection
13th Gen Intel(R) Core (TM) i7-13700F 2.10 GHz.	2.63	270.3	None	Success
	3.78	264.4	FPGA KV260	Success

3.2. *Real-time visualizations*
a. Local-PC without hardware accelerator.
b. Local-PC with hardware accelerator FPGA.
Fig. 9. EV3-Robot real-time visualizations

Fig. 8 shows a task that FPGA hardware accelerator task. Fig. 9(a) and Fig. 9(b) are displaying the real-time visualization from the EV3-Robot's perspective. The class detection for 'person' was achieved in the "B" direction.

3.3. *FPGA hardware accelerator*

Table 2 compares the local-PC and EV3-Robot's performance during the detection task. The use of hardware accelerators resulted in an increase in the number of frames per second (FPS) and a reduction in inference time.

4. Conclusion

Real-time object detection on the EV3-Robot using FPGA hardware acceleration has been successfully implemented. Equipped with the FPGA Kria KV260 accelerator and the YOLO model, the EV3-Robot demonstrates a practical and effective solution for real-time object detection. This paves the way for enhanced performance and broader applications in the field of mobile robotics.

Abstract

This study proposes a low computational cost hand-waving action recognition system for non-verbal communication in home service robots. The system is based on an echo state network, which requires lower computational costs than that of deep neural networks (DNNs), and processes time-series data of skeletal coordinates of humans to recognize hand-waving actions. Additionally, this study proposes and compares two types of Preprocessing ing methods of the skeletal coordinates to ensure the robustness of the human positions on the frame: one method extracts shoulder and arm angles, which are invariable regardless of the humans' positions and the other normalizes the skeletal coordinates. The experimental result shows that the proposed system has competitive accuracy and is robust to varying human positions.

Keywords: Action recognition, Home service robot, Low computational cost, Echo state network

1. Introduction

The declining birthrate and aging population have become social problems in many countries, not only Japan, and one of the solutions is the use of home service robots [1]. For this reason, research on home service robots has been active [2], [3], [4]. Home service robots can expand the range of their use by acquiring not only verbal but also non-verbal information such as human facial expressions and movements. In addition, since home service robots are required to judge situations and perform actions in real-time, computers for their information processing should be mounted on the home service robot. Therefore, the resources in the computers are limited and the computational cost of the process must be low.

In this study, we focus on hand-waving action recognition, which indicates that a human is calling the home service robot and aim to construct a system with low computational cost. The proposed system recognizes hand-waving action by providing skeletal information extracted from videos using MediaPipe [5] to an echo state network (ESN) [6], a lightweight machine learning model.

2. Related Works

MMAction2 [7], provided by OpenMMLab, is a library for action recognition. This library estimates human behaviors such as handshaking, hugging, hand waving, etc. The tool offers powerful deep neural network (DNN)-based models for action recognition such as SlowFast [8], UniFormerV2 [9], and VideoMAE V2 [10], however, the three models listed as examples have a huge number of parameters (more than 20M) and are computationally expensive.

While the methods [8], [9], [10] directly feed input images into DNNs, Doan proposed an action recognition system with a long short-term memory model that processes skeletal information [11]. Compared to the end-to-end processing models, the method is more lightweight but still requires high computational costs because it is based on the DNN.

3. Proposed Methods

We propose a lightweight hand-waving action recognition system with MediaPipe [5] and an ESN [6]. The processing flow of the proposed method is shown in Fig. 1. For each video frame, the system extracts skeletal coordinates by using MediaPipe The skeletal coordinates are then given to an ESN, which performs a binary classification of whether the hand is waving or not. Before feeding the coordinates to an ESN, we apply preprocessing to skeletal coordinates to classify the action not depending on the human position on the frame. We propose and compare two types of preprocessing in this study.

Preprocessing A extracts the angles of the shoulders and arms. Preprocessing A shown in Eq. (1) and (2) use the *x*-coordinate of the left and right wrists (x^{l_wr}, x^{r_wr}), the left and right shoulder (x^{l_sh}, x^{r_sh}), and the y-coordinate of the left and right wrists (y^{l_wr}, y^{r_wr}), and the left and right shoulder (y^{l_sh}, y^{r_sh}) respectively. X^{in} in Eq. (3) is the input to an ESN.

$$X^{l\_in} = \tan^{-1} \frac{(y^{l\_wr} - y^{l\_sh})}{(x^{l\_wr} - x^{l\_sh})} \quad (1)$$

$$X^{r\_in} = \tan^{-1} \frac{(y^{r\_wr} - y^{r\_sh})}{(x^{r\_wr} - x^{r\_sh})} \quad (2)$$

$$X^{in} = \begin{pmatrix} X^{l\_in} \\ X^{r\_in} \end{pmatrix} \quad (3)$$

Preprocessing B shown in Eq. (4) and (5) use the *x*-coordinate of the left and right wrists (x^{l_wr}, x^{r_wr}), the nose (x^{nose}), and the left and right shoulder (x^{l_sh}, x^{r_sh}), respectively. The coordinates of the wrists are relative to the coordinates of the nose to ensure robustness against parallel movement of the recognition target. In addition, the wrist coordinates are normalized by the length of the shoulder. The robustness against human size in the frame is ensured by normalizing the length of the shoulder. X^{in} in Eq. (6) is the input to an ESN.

$$X^{l\_in} = \frac{(x^{nose} - x^{l\_wr})}{|x^{l\_sh} - x^{r\_sh}|} \quad (4)$$

$$X^{r}_{in} = \frac{(x^{nose} - x^{r\_wr})}{|x^{l\_sh} - x^{r\_sh}|} \quad (5)$$

$$X^{in} = \begin{pmatrix} X^{l\_in} \\ X^{r\_in} \end{pmatrix} \quad (6)$$

4. Experiments

4.1 Setup

We collected a total of 360 video files of actions from six persons, of which 240 data points were used as training data from one person, 24 data points were used as validation data from another person, and 96 data points were used as test data from four persons. The CPU of the computer that performed the processing was a CPU (Intel (R) Core (TM) i7-6700K).

To verify whether the proposed method can be a substitute for the prior cases, we conducted similar tests using the behavior recognition models of the prior cases (however, these models can recognize multiple

behaviors). We used the SlowOnly [8] and the UniFormerV2 [9] models provided by the MMAction2 model trained on the Kinetics-700 dataset [12] of 700 behaviors to predict the behaviors of the test data.

4.2 Result

The averages of the accuracy, precision, recall rates, and processing time for the ten estimation results for the test data are shown in Table 1. The proposed method has a higher accuracy rate in hand-waving action recognition than the other two methods. In addition, we can see that Preprocessing B is superior to A in all indices. The proposed method also has a shorter processing time than the other two methods.

Table 2 shows the accuracy for each subject using the proposed method with Preprocessing B, which had the highest accuracy. These results show that the accuracy varies greatly depending on the subject.

5. Discussion

We consider the Preprocessing B shown in Eq. (4), (5) and (6) with normalization to the wrist coordinates to be more accurate than the Preprocessing A using the angles shown in Eq. (1), (2) and (3), because the rate of fluctuation of the values is larger. In particular, the rate of fluctuation of the values for Preprocessing A is small when the elbow is bent while hand waving. Therefore, we consider that Preprocessing B is superior.

The proposed method has a low recall for Preprocessing B. In Preprocessing B, we consider the influence of the data from the wrist-fixed hand wave to be significant. Preprocessing B makes predictions based on fluctuation in wrist coordinates. Therefore, if the hand is waving without wrist fluctuation, it cannot be recognized. Therefore, it is necessary to devise a system that allows recognition without wrist fluctuation.

As shown in Table 2, variations in accuracy were observed among the subjects. This is expected to be caused by the body size and waving habits of the subjects. It is necessary to verify whether this problem can be solved by using data from multiple subjects in the training data in the future.

6. Conclusion

In this study, we proposed a hand-waving action recognition system based on an ESN to construct a low-computational-cost hand-waving action recognition system to be introduced into home service robots. The results show that the accuracy of the lightweight model is comparable to that of deep learning-based multiple-action recognition models.

In the future, it will be necessary to construct a system that can recognize a waving person even if there are multiple people in the frame because there is a possibility that multiple people may be in the image in the real world.

Abstract

We propose the use of language-based prompt engineering to achieve rapidly adjustable object recognition in RoboCup@Home. The proposed prompt engineering involves humans adding features, such as the color and material of an object, into the text prompts inputted into Language Segment Anything. In this research, we evaluated the effectiveness of our proposed method in three benchmark tests for object recognition at RoboCup@Home 2023. The results show that the highest scores were obtained in specific tasks, indicating that the proposed method applies to various recognition tasks.

Keywords: Home service robot, Object recognition, Prompt engineering, RoboCup@Home

1. Introduction

In recent years, service robots have attracted increasing attention against the aging population background [1]. This trend has spurred active research in this domain [2], [3]. These robots operate in dynamic environments, frequently encountering new and unfamiliar objects, making the learning process of recognition technologies and operational efficiency crucial. Ono et al.'s research [4] automates dataset generation and annotation, reducing the time and cost involved in the learning process while maintaining real-time performance using You Only Look Once v4 (YOLOv4) [5]. However, their experiments [6] showed that YOLO learning took two hours to prepare 500,000 training images and 18 hours. We aim to achieve a faster learning process and improve operational efficiency.

This study proposes Language Segment Anything (Lang SAM) [7] as a language-based object recognition system, offering quick adjustability. To validate its effectiveness, we conducted experiments at RoboCup@Home [8], an international competition focused on developing practical home service robots. Additionally, we evaluated operational efficiency by measuring inference time and power consumption, comparing it with the traditional method.

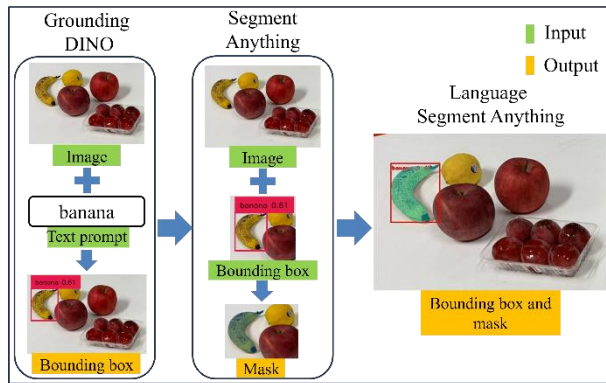
Naoki Yamaguchi, Tomoya Shiba, Kosei Isomoto, Hakaru Tamukoh


Fig. 1. Process flow of object recognition with language

2. Related Work

2.1. *Object recognition*

In object recognition, annotating datasets is an essential process [9]. Annotation involves labeling each object in an image with its name, location, shape, and other characteristics. Typically, manual processes accomplish this task. The performance of object recognition heavily depends on the quality and quantity of the dataset, as well as the precision of the annotations. Manually creating large volumes of high-quality annotations can incur substantial costs. Moreover, maintaining the accuracy of manual annotations is challenging.

2.2. *Dataset generation*

To address the issue of manual annotations in object recognition datasets, research on Sim2Real, which involves generating datasets using simulators, is progressing [10], [11]. Utilizing simulators eliminates human error and enables the rapid and high-quality generation of datasets. Additionally, this approach ensures consistency in annotations.

2.3. *Problems*

In addition to the challenges of dataset annotation, a significant issue in object recognition is the need to train recognition models with these datasets. Recognizing new objects requires generating datasets for these objects and conducting training, which can be very costly. This process involves substantial time and resources, mainly when introducing new objects to the system, thereby increasing the overall expense and complexity of developing effective object recognition models.

3. Proposed Method

3.1. *Object recognition with language*

For object recognition using language, our proposed method employs Lang SAM. Lang SAM combines Grounding DINO [12] and Segment Anything [13] into a single model, enabling language-based object recognition and segmentation. Fig. 1 shows a process flow of object recognition with language.

3.2. *Prompt engineering*

Adjust the text prompts that humans enter Lang SAM. Lang SAM's recognition accuracy depends on the text prompt. Below, we outline the procedure for adjusting text prompts:

(i)   Take pictures of multiple scenes containing the object of interest.
(ii) The initial text prompt shall be the name of the recognition target.
(iii) Input both the images and text prompts into the recognition system to check if the object is correctly recognized and assess the accuracy.
(iv) Improve the text prompts by human addition of details like color and material, aiming to recognize objects not initially identified or to increase accuracy.

4. Experimental Condition

First, we compared the preparation costs for recognizing new objects using the recognition models YOLOv8 [14] and Lang SAM. We generated the dataset for training YOLOv8 using conventional methods. Next, we implemented the proposed method on the Human Support Robot developed by TOYOTA MOTOR CORPORATION [15] to reveal its impact on enhancing object recognition capabilities. The effectiveness of this implementation was validated based on the scores obtained at RoboCup@Home. Finally, we compared the operational efficiency of YOLOv8 and Lang SAM, focusing on their inference time and power consumption, to determine which method was more efficient in real-world scenarios.

Table 1. Specifications of the
Computational System Used in Experiments

CPU	11th Gen Intel® Core™ i7-11700 @ 2.50GHz × 16
GPU	NVIDIA GeForce RTX 3080
Memory	32GB

Table 2. Time to prepare recognition model

Method	Dataset [images]	Prepare time [hours]
Dataset generator + YOLOv8	500,000	18
Proposed method	10	2

4.1. *Time to prepare recognition model*

We created a dataset to train YOLOv8 by generating 500,000 images using the method developed by the Ono et al. system. Following this, we conducted manual prompt engineering on these images. We then trained this dataset using YOLOv8. Next, images from 10 scenes were captured in real environments to serve as inputs for Lang SAM's prompt engineering. We then manually conducted prompt engineering on these images. The time taken to prepare these recognition models was measured.

4.2. *Evaluate the effectiveness of the proposed method*

The conditions of the second task performed at the RoboCup@Home 2023 are summarized:

(1) Storing Groceries (SG): The task involved organizing and shelving items scattered on a table, including categorizing objects and handling unknown items.
(2) Stickler for the Rules (SR): In this task, the robot acts as a party host, identifying guests not following house rules and enforcing compliance by explaining the rules to them. The rules are as follows:
    a. Remove shoes inside the house.
    b. Do not enter prohibited areas.
    c. Do not throw garbage on the floor.
    d. Always hold a drink in hand.
  This task primarily requires object recognition and human interaction technologies.

4.3. *Inference time and power consumption*

In section 4.1, we measured the inference time and power

Table 3. Results of RoboCup@Home2023
(proposed method: HMA)

		1st	2nd	3rd
SG	Team	**HMA**	Tech United Eindhoven	eR@sers +Pumas
	Score	**420**	410	220
SR	Team	**HMA**	TRAIL	Tech United Eindhoven
	Score	**1000**	1000	800

Table 4. Inference time and power consumption.

	Inference time [msec]	Power consumption [W]
YOLOv8	71.8	95.7
Lang SAM	577.7	233.0

consumption for each of the prepared recognition models. The inference time is the time recorded as the output of each recognition system, and this experiment uses a maximum wattage recorded by the NVIDIA System Management Interface [16] as a power consumption. Table 1 shows the specifications of the PC used in the experiments.

5. Experimental Result

5.1. *Time to prepare recognition model*

Table 2 shows the time taken for dataset generation, training with YOLOv8, and the preparation of the proposed method. YOLOv8 required 8 hours to create the training dataset and 10 hours for training, for a total of 18 hours. In contrast, the proposed method required approximately 2 hours for prompt tuning with 10 scene images and text prompts.

5.2. *The score of RoboCup@Home 2023*

Table 3 shows the top three teams and their scores in SG and SR categories at RoboCup@Home 2023. The results show that HMA achieved the highest SG and SR scores.

5.3. *Inference time and power consumption*

Table 4 shows the inference time and power consumption between the traditional YOLOv8 method and the proposed method. The results indicated that the proposed method had approximately 8 times later inference time and about 2.4 times higher power consumption than YOLOv8.

6. Conclusion and Discussion

In this study, we proposed using language-based prompt engineering to achieve rapidly adjustable object recognition in RoboCup@Home. We validated the effectiveness of this approach through participation in RoboCup@Home2023. We can adjust the proposed method in just 2 hours, which is only one-ninth of the time required by conventional methods. Furthermore, The results from RoboCup@Home 2023 support the feasibility and effectiveness of our approach in various tasks in terms of scoring. However, compared to traditional methods, it became clear that there are issues with operational efficiency, such as inference time and power consumption. We consider the need to select recognition models appropriately, considering the preparation cost and operational efficiency.

Abstract

The task planning system is required to accomplish various requests from a human in real-world environments. SayCan, one of the task planning systems, has high accuracy. However, its accuracy decreases for requests that include abstract nouns of the ambiguous word/phrase. We propose a novel task planning system based on SayCan that introduces a function for checking concrete names of abstract nouns and a rule-based skill extraction, enhancing accuracy. The proposed system facilitates the interpretation of requests and enables appropriate task planning. The effectiveness of the proposed system was demonstrated at RoboCup@Home, where it achieved high performance.

Keywords: Task planning, Home service robot, Large language model, RoboCup@Home

1. Introduction

Recently, the demand for home service robots has been increasing due to a low birth rate and an aging population, and research on such robots has been active [1], [2], [3], [4], [5], [6]. Highly accurate task planning is necessary to realize a general-purpose service robot that performs appropriate actions in response to human requests.

SayCan, one of the task planning systems [7]. consists of two modules: a Say module and a Can module. The Say module outputs the likelihood of each skill based on the language instruction, and the Can module outputs the likelihood of each skill based on the robot's current state. It decides which skill to execute next based on the likelihood output from two modules. Although SayCan is highly accurate, the accuracy decreases for commands containing abstract nouns such as "fruit" and "drink."

In this study, we propose a SayCan-based task planning system that introduces a function for checking concrete names of abstract nouns and a rule-based skill extraction. The contributions of this study are as follows.

- More straightforward interpretation of human requests and more accurate task planning
- Demonstrated high performance in a competition to evaluate the performance of home service robots

2. Preliminaries and Related Works

2.1. *RoboCup@Home*

RoboCup@Home is an international competition for the technical development of home service robots [8]. RoboCup@Home includes two tests: General Purpose Service Robot (GPSR) and the more challenging Enhanced GPSR (EGPSR), in which robots listen to various commands and perform appropriate actions in the home environment. In competitions, commands generated from a command generator [9] are used. The command generator may output commands that include abstract nouns such as "fruit," as in "Please find the fruit in the dishwasher." The commands used in EGPSR are more complex than those used in GPSR and require more complex actions.

2.2. *SayCan*

SayCan has a predefined skill set that the robot can perform, and it determines which skill to execute from a given command. SayCan consists of the Say module and the Can module. The Say module uses a large language model (LLM) function to output the likelihood of each word in a sentence. The Say module inputs the given command and skill descriptions to the LLM and outputs the likelihood of each skill. The Can module acquires information about the external world from cameras and sensors and predicts which skills will most likely be executed. The results of these two modules are combined to determine the next skill to perform.

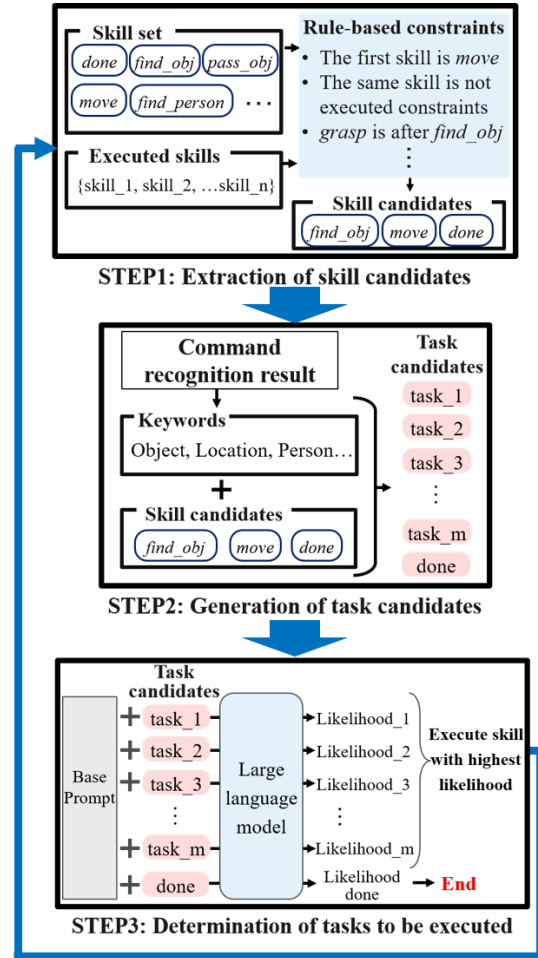
We think the Can module is difficult to implement on other robots because it is realized by reinforcement learning. SayCan is shown in the paper to be highly accurate task planning even with only a Say module without a Can module. The experimental results in the paper confirm that commands containing abstract nouns, such as "Bring me a fruit," reduce accuracy.


Fig. 2. Schematic of task planning

3. Proposed System

In this chapter, we describe the proposed system. The proposed system consists of command recognition and task planning modules.

3.1. *Command recognition*

Fig. 1 shows a schematic diagram of the function of command recognition in the proposed system. If an abstract noun such as an object, item, or food registered in the database is included in a given command, the proposed system asks for the concrete name of the abstract noun. This process aims to obtain a concrete name that the robot can recognize since it may not recognize the object of the abstract noun. As an example, as shown in Fig. 1(a), the robot asks for the concrete name of the abstract noun "object" and replaces "object" with "apple" depending on the result of the response.

Table 1. Skill set of the proposed system

Skill	Task
move	go to the {PLACE}
follow	follow the target
find_obj	find the {OBJECT} on the {PLACE}
find_person	find {PERSON}
observe_obj	look at the {PLACE} to check objects
observe_person	look at the {PLACE} to check people
grasp_obj	grasp the {OBJECT}
put	take the {OBJECT} to the {PLACE}
pass_obj	pass the {OBJECT}
answer_question	answer a question
say	say {LLM's output}
done	done

3.2. *Task Planning*

Fig. 2 shows a schematic diagram of the task planning function in the proposed system. The task planning consists of three steps.

STEP1: Extraction of skill candidates

Extract skill candidates from the skill set using rule-based constraints. The constraints are based on the order of skills, such as "The first skill is the move," "The same skill is not executed consecutively," and so on. This process reduces the number of LLM inputs. Eliminating skills that are very unlikely to be used is also expected to improve the accuracy of task planning. Table 1 shows the skill set of the proposed system. This skill set includes the basic skills the home service robot needs to perform various tasks. The say skill's speech content is complemented by LLM's output.

STEP2: Generation of task candidates

First, this process extracts object, place, and person names registered in the database in advance as keywords from the command recognition results. Then, generate the task candidates by combining the keywords and skill candidates. Table 1 shows the format of task candidates.

STEP3: Determination of tasks to be executed

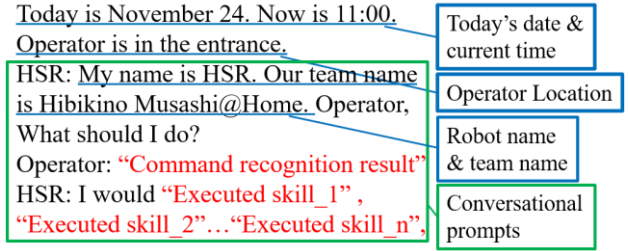
A combination of base prompts and candidate tasks are input to the LLM, which outputs the likelihood of each candidate task. The robot then performs the task with the highest likelihood. Fig. 3 shows the base prompt. The base prompt gives the LLM information, such as the date, time, and role the command should follow.


Fig. 3. Base prompt for the proposed system

4. Experiments

We conducted the following experiments to evaluate the proposed system. We use OpenAI's text-davinci-003 [10] as the LLM in the proposed system as a condition in experiments.

Experiment 1. Evaluation experiment with command output using the command generator [9]
Experiment 2. Evaluation experiment using actual competitions at RoboCup@Home 2023

In Experiment 1, we randomly generated 100 GPSR and 100 EGPSR commands, each using the command generator. In this experiment, the object and location names of the generated commands are those used in RoboCup@Home 2023. We input the generated commands into the proposed system and evaluate whether the task plan obtained as the output of the generated commands is feasible to realize the given commands. Specifically, we determined whether the sequence and targets of the skills included in the task plans can accomplish the corresponding commands.

In Experiment 2, we participated in RoboCup@Home 2023 held in Bordeaux, France, in July 2023 as Hibikino-Musashi@Home (HMA) team and evaluated the proposed system in the GPSR and EGPSR.

5. Experimental Results

5.1. *Experiment 1: Use the command generator*

As a result, we confirmed that task plans for 61 commands in GPSR and 27 commands in EGPSR were successful. In particular, we confirmed that the proposed system can successfully perform task planning by checking the concrete names of the abstract nouns in the commands to obtain the concrete names of the target objects. For example, in the command "Please bring me the fruit on the desk," the robot was checking the concrete name of the abstract noun "fruit," and the response "apple" was obtained. Table 2 shows examples of commands for which task planning was inaccurate and the possible causes. We found in many cases that task planning failures were due to incomplete skill sets and commands that did not include the required actions.

Kosei Yamao, Daiju Kanaoka, Kosei Isomoto, Akinobu Mizutani, Yuichiro Tanaka, Hakaru Tamukoh

Table 2. Examples of commands that failed in task planning and possible causes

Command	Causality
Go to the desk, look for the mug, and place it on the entrance door	The command does not specify *grasp*.
Could you please close the entrance door	No skill to open/close doors.
Hand me some coke in a mug	No skill to pour liquids.

Table 3. Results of RoboCup@Home 2023

	GPSR		EGPSR	
	Team	Score	Team	Score
1st	Tidyboy	400	**HMA**	700
2nd	TRAIL	300	TRAIL	400
3rd	**HMA**	200	Tidyboy	300

5.2. *Experiment 2: RoboCup@Home 2023*

In GPSR, the command given to the robot was, "Bring me the object behind the lemon from the cabinet." In response to this command, the robot asked for the concrete name of the abstract noun "object." The operator responded, "Tropical juice," however, the speech recognition failed, and the system did not replace the abstract noun. It scored partial points because it brought the object to the operator.

In EGPSR, in response to the command, "Get acquainted with Morgan at the exit, then find him in the living room, please," the robot found Morgan at the exit. After that, the robot said to Morgan, "Hello, Morgan. I'm HSR from Hibikino Musashi@Home". Finally, the robot moved to the living room and found Morgan. This command was judged to be successful and received a score.

Table 3 shows the top three teams and their scores in GPSR and EGPSR at RoboCup@Home 2023. As a result, HMA was ranked 3rd in GPSR and 1st in EGPSR, showing that the robot works well under real-world conditions.

6. Discussion and Conclusion

In this study, we proposed a SayCan-based task planning system, which introduces a function to check the concrete name of abstract nouns and a rule-based skill extraction. We demonstrated the system's effectiveness through experiments using the proposed system and evaluations in competitions. However, the proposed system has some issues, such as the incompleteness of the skill set and the fact that task planning sometimes fails for commands that do not contain the required actions. To realize a more accurate task planning system, we think it is necessary to develop skills such as those for opening/closing doors and to devise prompts to optimize the effectiveness of LLM [11].

In addition, for the system to operate in a real-world environment, it is necessary to acquire environment-specific knowledge, such as the preferences and habits of each family member. For environment-specific knowledge acquisition and utilization, studies of episodic memory acquisition models inspired by the hippocampus are undergoing [12], [13], [14]. In the future, we will integrate the episodic memory acquisition model into the robot to operate based on previously acquired environment-specific knowledge instead of checking concrete names of abstract nouns each time.

Abstract

This paper proposes a robot vision system that detects illegal persons who violate house rules such as wearing shoes in a home environment. Such complex vision systems often require multiple AI systems including person detection, object detection, and more. Our approach simplifies this by leveraging the combined capabilities of Grounding DINO and SAM to detect rule violations effectively. The success of our method was proven at RoboCup@Home 2023, where it secured the highest score among all participating teams.

Keywords: Service robot, Object recognition, Mobile manipulator, RoboCup@Home,

1. Introduction

Home service robots are gaining increased attention due to the needs of aging societies with declining birth rates [1], [2], [3]. Their key functions include object recognition, picking and placing, identifying people and environments, and interacting with humans. Our research has involved using TOYOTA's home service robot HSR [4] and our Exi@ robot [5]. Various studies focusing on the social implementation of service robots for home use have been explored, often presented in competitions [6], [7], [8], [9]. These studies have mainly been proposed using dedicated recognition models. However, home environments vary greatly, and even within the same household, the objects to be recognized change over time and with the seasons. In RoboCup@Home competitions, the objects are usually announced in advance, leading most teams to develop recognition systems tailored to these specific objects [10]. However, some competitions require the detection of items not disclosed beforehand, such as people, their clothing, and common household objects. Therefore, it has been challenging to prepare recognition systems that can distinguish a wide variety of shoes to enforce a no-shoes rule or ensure adherence to a dress code at a party.

In this study, we propose a method for detecting rule violations in the competition task "Stickler for the Rules Task" using the detection models Grounding DINO [11] and Segment Anything [12], which employ prompt tuning for general object recognition. We implement these methods on TOYOTA's home service robot HSR. As a validation, we used them in RoboCup@Home [13], a competition for home service robots, to verify their effectiveness. (Fig. 1)

Fig. 1. Detection of rule violations

2. Related works
2.1. Object recognition

We have been researching methods for home service robots to detect the location of people and objects and then perform some action in response. Specifically, we have studied methods for tidying up and detecting people within a home. In our previous research, we developed a method for estimating the position of objects and available space, utilizing YolactEdge [14] and point cloud information [15].

2.2. *Problem*

The home environment contains many objects, including furniture such as desks and shelves. Additionally, the variety in human clothing is vast, requiring recognition of entirely different items depending on the season. Therefore, preparing a model that accounts for all these variations in a short period is challenging, and repurposing existing DNN models may lead to unstable recognition outcomes.

Tomoya Shiba, Hakaru Tamukoh

3. Proposed Method

3.1. *RoboCup@Home: Stickler for the Rules Task*

Here, I will explain the "Stickler for the Rules" task in RoboCup@Home. This task is designed for home service robots to identify party guests who have broken house rules and politely ask them to stop. The following four house rules are set:

1. All guests must take off their shoes at the entrance.
2. No guests are allowed in the Black Room.
3. Guests are not allowed to leave garbage on the floor.
4. All guests must always have a drink in hand.

3.2. *Proposed Method*

We propose a method for detecting violations using two Transformer-based models capable of prompt tuning. Grounding DINO is used for detecting bounding boxes, and Segment Anything is employed for segmentation tasks within the bounding box area. This allows for the identification of a wide variety of clothing and objects held in hands (Fig. 2). Additionally, to obtain the three-dimensional position, we use the pixel coordinates of the centroid of the bounding box and depth images.
Fig. 2. SAM (Segmentation) & Grounding DINO (BBox)

4. Experiments and Results

4.1. *Partial Recognition*

To detect rule violations within a home, high recognition accuracy, as well as ease of surveillance, are required. To evaluate these performances, we tested the recognition accuracy of partially visible individuals. In this experiment, we prepared data with humans partially visible in images and conducted a comparison between YOLO v8 [16], MMDetection [17], and our proposed method. The images used were from the open-source human dataset DensePose-COCO [18], and we created images divided into quarters, reducing the image size to half, to test recognition accuracy. The results are summarized in (Table 1) As a result, our proposed method showed the highest recognition performance in the same task. However, it was also shown to be the most time-consuming method.

Table. 1. Results of Partial Recognition
(Stickler for the Rules)

Method	Detection rate [%]	Speed[s]
Proposed Method	**43.2**	1.122
Yolo v8 (Detect)	23.1	**0.103**
MMDetection	24.2	0.239

4.2. *RoboCup@Home task*

At RoboCup@Home 2023, we tested the effectiveness of this task by featuring more than 5 individuals committing rule violations, arranged in 3 different patterns of person placement. The results are summarized in (Table 2). As a result, we were able to perfectly address two types of rule violations and achieve the highest score.

Table. 2. Results of RoboCup@Home2023
(Stickler for the Rules)

Team	Score
HMA (Our team)	**1000**
Tidyboy	700
TRAIL	**1000**
Tech United	800
eR@sers+ Pumas	300
RoboCanes-VISAGE	200

5. Discussion

The proposed method has demonstrated higher recognition accuracy for partial visibility compared to existing methods. However, since it is based on a Transformer model, it tends to have longer processed times. When implementing this method as a function of home service robots, it may be effective to use the existing models for fast recognition in some scenarios, and our method for its strong recognition accuracy in cases of partial visibility. Additionally, the recognition method using prompt tuning is often influenced by the skill of the prompt setter. In the future, it will be necessary to establish objective criteria for prompt tuning.

6. Conclusion

In this study, we proposed a method for utilizing recognition models capable of prompt tuning to address the "Stickler for the Rules" task in RoboCup@Home, and conducted experiments in RoboCup tasks. The results showed that our method was effective, achieving the highest score in the same task. In the future, we aim to reclassify similar objects based on recognition scores and other information to reduce misrecognition.

Abstract

In this study, we focus on extending the operational time of home service robots by offloading intellectual processing to circuit devices such as Field Programmable Gate Arrays (FPGAs), which in turn reduces power consumption. The core of our approach involves developing a method for implementing intellectual processing on FPGAs, coupled with a dynamic circuit reconfiguration technique. This enables the FPGA to adaptively respond to frequent task changes. We present: (a) methods for transitioning circuits from a robot's control computer to FPGA in response to varying tasks, and (b) an evaluation of the effectiveness of using FPGA to extend operational time under these rapidly changing task conditions.

Keywords: Intelligent Processing, Edge Device, Service Robots, FPGA, Neural Networks

1. Introduction

In recent years, service robots have gained attention against the backdrop of a society experiencing declining birthrates and an aging population. Service robots are designed to perform a variety of tasks in homes and stores, such as tidying up and waitering, thereby reducing the workload on humans. These robots are equipped with various intelligent processing capabilities such as object recognition and voice recognition, allowing them to understand their surroundings and operate flexibly. Recently, Neural Networks (NNs) have been increasingly used for these intelligent processing tasks, and it is known that NNs require a substantial amount of computational power. The intelligent processing in service robots demands real-time operation, but achieving this through software alone is challenging. Therefore, hardware architecture acceleration is necessary.

Today, GPUs are primarily used as the hardware architecture for implementing NNs. However, running numerous NNs simultaneously leads to issues with insufficient hardware resources. Additionally, GPUs are generally known for their high-power consumption, which limits the operational time of robots.

This research aims to extend the operating time of robots by offloading the intelligent processing to circuit devices like Field Programmable Gate Arrays (FPGAs), thereby reducing power consumption. To achieve this, we propose the implementation of intelligent processing on FPGAs and a method to rewrite the circuits on the FPGA depending on the situation. This paper reports on the initial investigation, including (a) implementing state machines in robots and verifying the ability to construct appropriate state machines in response to user commands, (b) exploring methods to switch circuits from the robot control computer to the FPGA, and (c) examining the effectiveness of offloading the intelligent processing to the FPGA.

2. System Configuration of Service Robots

This section describes the configuration of the service robots targeted in this study.

2.1. *Behavior Planning with State Machines*

In service robots, processing is carried out through the construction and execution of state machines, as shown in Fig. 1. The process flow is as follows:

(1) Listen to the Commands

The robot listens to the user's voice and understands the commands as text.

(2) Construction of the State Machine

Yuma Yoshimoto, Mizuki Kawashima, Shun Yonehara

The robot interprets the heard commands and decides in what order and which intelligent processes to utilize.

(3) Execution of the State Machine

The robot executes the constructed state machine in sequence.

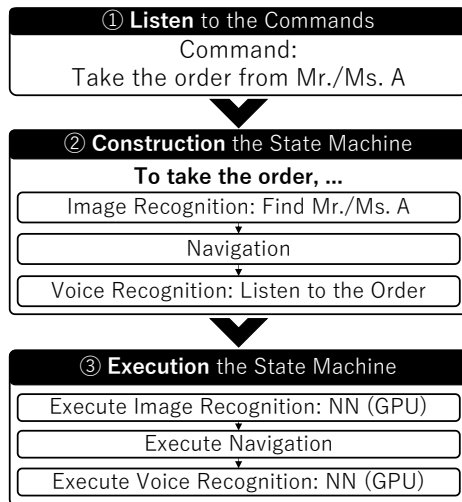
At this stage of executing the state machine (3), the state machine has already been constructed, and it is known in what order and which intelligent processes are needed.


Fig.1 Constructing and Executing the State Machine

2.2. *Required Intelligent Processing*

Various intelligent processes are necessary for service robots. For example, Tsuji et al. have implemented the Neural Networks (NN) shown in Table 1 for the realization of versatile robots. In conventional methods, responding to human commands requires the simultaneous activation of numerous NNs.

Table 1. AI Implemented in the Robot [1]

AI	Model
Object Detection	Mask R-CNN, UOLS
Object Classification	CLIP (ViT-B/32)
Speech Recognition	Whisper
NLP and NLU	GPT-3

2.3. *Pathways Language Model (PaLM* [2]*), SayCan* [3]

There are developed by Google, this robot-specific AI allows robots to autonomously plan actions when given ambiguous verbal commands. For instance, if input like 'I spilled my drink. Help me,' is given, PaLM-SayCan can make decisions such as bringing a sponge or disposing of an empty can. The number of parameters required for PaLM is said to be 540B [2]. If these parameters are managed as float64, the memory size required for PaLM amounts to 216 GB. However, the memory in GPUs used

for AI processing in service robots ranges from 12 GB to 24 GB. Therefore, it is not feasible to implement an AI of size 216 GB in the GPU of a robot control computer. Thus, integrating this method into the edge side is challenging. Additionally, incorporating this method into robots would rely on external computing devices like cloud services, which introduces instability due to network connections, making it difficult to achieve a stable system.

3. Field Programmable Gate Array

An FPGA is a semi-custom LSI composed of a grid of reconfigurable logic gates. FPGAs can achieve high computational performance by reconfiguring their internal logic circuits. Unlike GPUs, which are used for AI processing and consist of block-based arithmetic architectures like multiplication and division, FPGAs construct their architecture with logic operation units, enabling lower power consumption and faster processing. Therefore, it is conceivable that using FPGAs allows for real-time processing.

3.1. *Comparison of FPGA with GPU and CPU*

Nakahara et al. implemented CNNs on FPGA and compared it with CPU and GPU [4]. The comparison table is shown in Table 2. They used the NVIDIA Jetson TX1 board for comparison, which includes an embedded CPU (ARM Cortex-A57) and an embedded GPU (Maxwell GPU). The CPU and GPU used Caffe (version 0.14) and were compared when running VGG-11 with a batch size of 1 for latency measurement. As shown in Table 2, FPGA is faster and consumes less power than the embedded CPU and GPU. Thus, a binary CNN on FPGA is more suitable for embedded systems than CPU and GPU.

Table 2. Comparison with Embedded Platforms [5]

Platform	Embedded CPU	Embedded GPU	FPGA
Device	ARM Cortex-A57	Maxwell GPU	Zynq 7020
FPS [s⁻¹]	0.23	36.7	421.9
Power Consumption [W]	7	17	2.3

3.2. *FPGA Hardware Resource Utilization*

Masatomo et al. implemented a model based on YOLOv3-tiny with Depth wise Separable Convolution on FPGA (Zynq-7020). They reported a BRAM utilization rate of 85.71%, indicating that implementing just one CNN on FPGA already exceeds 50% of the necessary resources. Therefore, it is difficult to implement other NNs simultaneously.

4. Proposal

We propose a method to control FPGA with a state machine. Fig. 2 shows the diagram of the proposed system. The operating procedure of the system is as follows:

① A control computer's state machine sends an instruction for the AI mode to be executed to the System on a Chip Manager (SoC Manager), which then instructs the FPGA Manager to rewrite.

② The FPGA Manager calls pre-defined circuit modules and rewrites the intelligent processing circuits on the FPGA.

③ The FPGA Manager sends input data for inference to the intelligent processing circuit on the FPGA.

④ The intelligent processing circuit on the FPGA completes the inference and sends the results back to the FPGA Manager.

⑤ The FPGA Manager sends the inference results to the SoC Manager, which then sends them to the state machine.

By repeating these steps, intelligent processing is executed on the FPGA while time-sharing its resources. Executing intelligent processing on the FPGA resolves the issue of power consumption, and time-sharing the FPGA resolves the resource issue.
Fig.2 Overview of the Proposed System

5. Experimental

5.1. *Construction of the State Machine*

A system as shown in Fig. 1 was constructed, and it was verified that it could (1) listen to commands, (2) construct a state machine, and (3) execute the state machine. In this verification, the following technologies were implemented as elemental technologies:

- Recognition of opening and closing doors through Depth image processing
- SLAM for creating environmental maps and estimating self-position
- Navigation allowing the robot to autonomously move to a target location
- Person and posture detection using skeleton estimation AI
- Object detection with Faster-RCNN

- Depth image processing to estimate the three-dimensional position of objects
- Speaking function using gTTS and HSR-API
- Voice recognition to understand human speech using Whisper
- Context understanding that interprets the meaning from recognized text strings

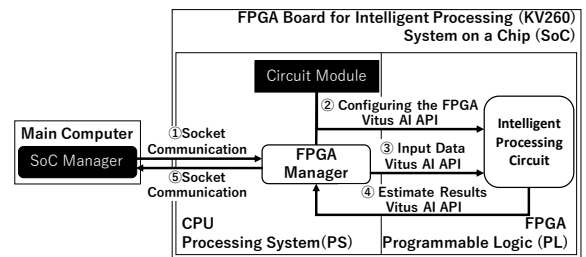
The system's operation was also confirmed. The operational verification was conducted at GPSR task of RoboCup JapanOpen 2022 @Home League, a benchmark competition for service robots. This task competes on how well robots can respond to input from people, evaluating the constructed state machine. The robot was given instructions in English, and its ability to go to a designated location and perform specific actions was tested.

As a result of the experiment, the constructed state machine was given the input 'Go to the Living room, find Jennifer and answer her question.' First, the command was correctly processed using the voice recognition function, and then the robot moved to the living room using the autonomous movement algorithm. Next, it used person recognition to find Jennifer and moved to her location. After moving, it answered questions using the voice recognition AI. It was confirmed that the state machine was appropriately constructed for these states up to the movement, and the states changed according to the situational changes.

5.2. *Consideration of FPGA Circuit Switching Method*

As a preliminary step to constructing the system shown in Fig. 3, a method to switch the FPGA circuit from the control computer was realized. The specific configuration is shown in Fig. 3. This was implemented on the KV260 evaluation board equipped with FPGA-SoC, and its operation was verified. The operation flow is the same as described in Chapter 4. In the experiment, the inference process was confirmed to be possible by switching between two models of YOLO v3-Tiny [6], each trained on different datasets.

Fig.3 System Configuration

Yuma Yoshimoto, Mizuki Kawashima, Shun Yonehara


5.3. *Consideration of the Effectiveness When Implemented on FPGA Circuit*

The object recognition AI was implemented on AMD's KV260 FPGA evaluation board and an MSI-manufactured notebook PC equipped with RTX3060. The power consumption of each was measured both in a steady state and during the operation of the object recognition AI. The results are shown in Table 3. The difference between the power consumption during the operation of the object recognition AI and in the steady state was 2 W for the FPGA and 96 W for the GPU, which is a reduction to 1/48th. From this, it can be understood that the implementation of intelligent processing on FPGA is advantageous in terms of power consumption compared to GPU implementation.

Table 3. Difference in Power Consumption between FPGA and GPU

	Power Consumption [W]		
	Steady State	During Object Recognition AI Operation	Difference
KV260	10	12	2
MSI Stealth-15M-B12UE-012JP	44	140	96

5.4. *Verification Using Images Captured by the Robot*

Images were captured using an RGB-D camera (Xtion Pro) connected to the robot, and these images were input into the system. As a result, an output was obtained that shows what appears where in the images.

6. Conclusion

In this paper, we proposed a method for offloading power-intensive intelligent processing to FPGA circuit devices, aiming for extended operational times of service robots. In our verification, as a first step towards realizing the system, we (a) implemented a state machine in the robot and confirmed the ability to construct an appropriate state machine in response to user commands, (b) explored a method for switching circuits implemented on FPGA from the robot control computer, and (c) investigated the effectiveness of offloading intelligent processing to FPGA. The results confirmed that (a) the construction and execution of a state machine are possible, as demonstrated in the RoboCup@Home DSPL's GPSR, (b) it is feasible to switch actual circuits from the robot control computer to FPGA, (c) significant power reduction can be achieved when running the object recognition AI on FPGA compared to GPU. In addition (d) the edge device (FPGA) estimated the images from robot camera (Xtion Pro). Future work will focus on integrating these developments with the state machine and extending support to other intelligent processes.

Abstract

In 1996, Hayashi et al. from our laboratory developed an automatic piano playing device that requires data with nuances for each note to perform in a human-like piano playing. However, this device lacks the function to infer such nuanced data. Therefore, prior research focused on developing a system to infer data with nuances for each note. Yet, this system required manual inference, consuming a significant amount of time. In this study, we have constructed a system capable of automatically performing inference using deep learning. This system not only improves the accuracy of piano playing inference but also contributes to the efficiency of the inference process.

Keywords: Automatic Piano, Computer Music, Deep Learning

1. Introduction

The automatic piano playing device (Fig. 1) developed by Hayashi and others, equips a grand piano's keyboard with striking mechanisms and its pedals with driving mechanisms, allowing for precise keystrokes and pedal operations through computer control. During its development, the behavior of the piano action was analyzed using a unique mechanical model, examining its dynamic properties. Additionally, to create optimal drive waveforms according to each key, the results of the key-wise behavior analysis were stored in a database for stable sound reproduction. The waveforms are generated by referencing the database in accordance with the music data. This technology enables stable performance, even replicating delicate and rapid repetitive strikes that are challenging for professional pianists.

Fig. 1 Automatic piano playing device [1]

The device plays as instructed by inputting MIDI (Musical Instrument Digital Interface) standard data, a common standard for transferring and sharing performance data among electronic instruments, containing information like pitch and volume. By recording a professional pianist's performance as MIDI data and inputting it into the device, it's possible to replicate their performance. However, due to the system's design, inputting only the score data does not result in a human-like performance. To address this issue, efforts are being made to develop a system that generates human-like performances from score data. As a first step, efforts are being made to replicate the performances of world-renowned pianists.

Previous research developed a system that infers data with nuances for each note, but this system required manual inference. Since even short musical scores contain over a thousand notes, the inference process was time-consuming and labor-intensive. Therefore, in this study, we constructed a system that automatically performs inference using deep learning.

2. Inference system using Deep Learning
2.1. *Dataset*

In this research, we used performance data of the pianist Vladimir Davidovich Ashkenazy, which were recorded in accordance with the MIDI standard.

2.2. *Performance data*

In performance data, the raw state is often too complex for direct machine learning application. Therefore, this research involved separating the performance data into performance information and score information and setting parameters to make it manageable for machine learning. This process essentially simplifies and organizes the data, making it suitable for the algorithms to process and learn from, thereby enhancing the effectiveness of the machine learning application in the context of piano performance interpretation.

In Sections 2.3 and 2.4, the research details the parameters set for both performance information and score information.

2.3. *Performance information*

Performance information includes data that encapsulates the pianist's expression within the performance data. In this study, four parameters were set for the performance information. These parameters of the performance information are shown in Table 1.

Table 1 The format of the performance information

Parameter	Units	About
Velo	None	Sound intensity
Gate	ms	Length of note
Step	ms	Interval between the next note
Time	ms	Time of sound

In this research, Time is not a target of inference because it can be calculated from the Gate and Step values.

2.4. *Score information*

Score information is performance data that includes musical notation such as notes and musical symbols. In this research, five parameters were set from the score information. Table 2 shows the parameters of the score information.

Table 2 The format of the score information

Parameter	Units	About
Key	None	Sound height
Bar	None	Bar number
Dyn	None	Dynamics mark
Tgate	ms	Length of note on the score
Tstep	ms	Interval between the next note in the score

2.5. *Neural network configuration*

The inference systems developed to date have not been built using deep learning. However, in developing an inference system using deep learning, it is necessary to find the optimal network structure for inference of performance information. For this reason, we decided to construct and verify a system with a simple network structure. Fig. 2 shows a schematic of the constructed network.
Fig. 2 Network overview

3. Inference Experiment and Results

3.1. *Data splitting*

In this experiment, the performance data was divided into training data, validation data, and test data. K-fold cross-validation is a statistical method for evaluating generalization performance in which the data is partitioned into K pieces, one of which is the validation data, and the remaining K-1 pieces are used as training data and evaluated with the test data. This is done by dividing the data into K pieces, one of which is the validation data. Fig. 3 shows a schematic of K-fold cross-validation. In this experiment, Prelude Op.28-7 by Fryderyk Francszek Chopin was used as the test data.
Fig. 3 K-fold Cross-Validation overview

3.2. *Validated network structure*

In this experiment, the layers of neurons in intermediate layer 1 and intermediate layer 2 were varied according to the patterns shown in Table 3.

Table 3 Combination of neurons in intermediate layers 1 and 2

Pattern number	Layer 1	Layer 2
1	50	50
2	50	100
3	100	100
4	100	50

3.3. *Results*

The performance information inferred by the inference system and the pianist's performance information were output as graphs for each Velo, Gate, and Step. The graphs of the patterns with the highest correlation coefficients are shown in Fig. 4, Fig. 5 and Fig. 6. The correlation coefficients between the inferred performance information and the pianist's performance information are shown in Table 4.
Fig. 4 Velo of pattern 2
Fig. 5 Gate of pattern 3
Fig. 6 Step of pattern 3

Table 4 Correlation coefficient of performance information

Pattern number	Layer 1	Layer 2	Velo	Gate	Step
1	50	50	0.763	0.720	0.876
2	50	100	0.776	0.741	0.880
3	100	100	0.770	0.743	0.885
4	100	50	0.763	0.691	0.832

4. Consideration

Table 4 shows that Velo's correlation coefficient does not change significantly for any of the patterns, and although Velo's correlation coefficient is high, the waveforms of the graphs are not similar, as can be seen in Fig. 4. This is because the points with large value fluctuations were learned as outliers, and the fluctuations in the inferred values became smaller.

The correlation coefficient of Step is larger than that of Velo and Gate. This is because the variation of the Step waveform is more regular than the other values, making it easier to learn, according to Fig. 6.

Furthermore, looking at the correlation coefficients for patterns 2 and 3, we see that the correlation coefficients for Velo, Step, and Gate are all large. This suggests that a network structure with a large number of neurons in the layers close to the output layer is suitable for inference.

5. Conclusion

In this study, we developed an inference system with a simple network structure using deep learning. Using the developed system, we verified the optimal network structure for inference of performance information. The results showed that a network structure with a large number of neurons in the layers close to the output layer is suitable for inference.

The future goal is to develop a more accurate inference system. To this end, we will search for the optimal

network structure by testing a system with an additional number of neurons, layers, and a gating mechanism that takes previous inputs into account.

Abstract

In recent years, the increase in marine debris has become a significant challenge in terms of its collection. Costal debris, a type of marine debris, can be collected by human hands, but the variety in shapes, and sizes presents limitations to human-only collection efforts. To address this, I focused on developing an autonomous mobile robot, establishing a simulation environment was considered crucial for facilitating smooth progress. This paper focuses on self-localization, an essential aspect for autonomous movement. We replicated an actual coastal cleaning site within the simulation environment and evaluated the accuracy of self-localization using an EKF (Extended Kalman Filter) with multiple sensors.

Keywords: Field Robot, Self-Localization, Gazebo, Simulation, Extended Kalman Filter (EKF)

1. Introduction

In recent years, the increase in marine debris has become a significant challenge in terms of its collection. Costal debris, a type of marine debris, can be collected by human hands, but the variety in shapes, and sizes presents limitations to human-only collection efforts. To address this, we focused on developing an autonomous mobile robot, establishing a simulation environment was considered crucial for facilitating smooth progress. This paper focuses on self-localization, an essential aspect for autonomous movement. We replicated an actual costal cleaning site within the simulation environment and evaluated the accuracy of self-localization.

2. Autonomous Mobile Field Robot "BUNKER"

In our previous study, we developed an autonomous mobile field robot [1] based on Kawasaki Heavy Industries' KFX®90, an all-terrain vehicle (ATV) powered by a gasoline engine. However, due to the vehicle's structure, the turning radius was large and stable traveling on steep slopes and rocky terrain was difficult, among other problems. To solve these problems, the platform was changed. The new platform uses Agilex's BUNKER [2] as shown in Figure 1. The main changes to the platform are that the traveling mechanism has two opposing wheels and the drive wheels are crawlers. This enables the platform to make super-clever turns, improving maneuverability composed to conventional platforms. In addition, the robot can climb hills with a slope angle of 36°, which is expected to enable it to run at higher speeds. The robot is equipped with an RGB-D sensor and 3D LiDAR as a visual system for autonomy. An encoder is mounted inside the vehicle body to measure the rotation speed of the wheels.

a. KFX®90   b.BUNKER
Fig. 1. Platform Overview

2.1. *Simulation Construction*

In this study, we not only represented the Agilex BUNKER in the simulation environment but also recreated the coast of Hokuto Mizukumi Park in Munakata City, Fukuoka Prefecture, where actual beach cleaning is performed. We used 3D mapping technology developed by prior research using drones. For the simulation environment, we employed Gazebo, a 3D dynamic simulator capable of efficiently and accurately simulating groups of robots in complex indoor and outdoor environments. Gazebo can also be integrated with ROS (Robot Operating System) [3]. The projected BUNKER and the coast on Gazebo are shown in Figure 2.
a. BUNKER   b. coast
Fig. 2. Built simulation environment

2.2. *EKF-Based Self-Localization System*

The posture measurement of mobile robots is achieved through various sensors and methods. However, the measurements obtained from these sensors are not true values but are considered to contain errors. In this study, we implemented the integration of odometry using the Extended Kalman Filter (EKF) shown in Figure 3, to achieve robust and low-error self-localization. We used wheel odometry, RGB-D odometry, and LiDAR odometry. The system was designed to accept any of these, individually or in combination, and produce an integrated odometry output.
Fig. 3. Input/output data to/from EKF

3. Experiment

In the coastal environments shown in Figure 4 and Figure 5, the initial position of the robot was set as the origin of spatial coordinates, and from there, three destinations were set at (40, -5), (40, 0), (40, 5). The robot was remotely operated to each destination five times to extract the necessary odometry information. For self-localization, both individual odometries and multiple odometries integrated via EKF were implemented, resulting in seven estimation patterns. Mean Absolute Error (MAE) was used for error calculation.
Fig. 4. Test environment

a. Coastal cross section
b. View from initial position
Fig. 5. Experiment in a simulation environment

3.1. *Result*

Table 1 summarizes the errors in self-localization results in the x-axis direction. In Pattern 4, the error was minimal, with the odometry integrating wheel odometry and RGB-D odometry via EKF achieving the highest accuracy in self-localization. Additionally, focusing on Pattern 2, the RGB-D odometry alone also showed generally similar values. From Pattern 3, it was observed that the LiDAR had an error of about 20 m, indicating it was not very useful in the simulated environment replicating an actual beach.

Table 1. Error in Self-Localization along the X-axis [m]

	Wheel	RGB-D	LiDAR	(40,5)	(40,0)	(40,-5)
1	○			11.06	1.22	0.35
2		○		0.08	1.06	1.44
3			○	21.66	25.25	19.50
4	○	○		0.85	0.47	0.86
5	○		○	13.73	5.42	4.47
6		○	○	10.36	10.07	8.27
7	○	○	○	3.20	4.33	5.54

Table 2 summarizes the errors in self-localization results in the y-axis direction. Compared to the results in the x-axis direction, there were significantly larger discrepancies overall. In every pattern, high-accuracy self-localization was not achieved. While some input destinations yielded accurate results, a stable trend was not observed. Among them, the odometry that integrated wheel odometry and RGB-D odometry via EKF had the smallest error.

Table 2. Error in Self-Localization along the X-axis [m]

	Wheel	RGB-D	LiDAR	(40,5)	(40,0)	(40,-5)
1	○			17.90	3.71	1.17
2		○		2.35	12.93	6.09
3			○	15.11	19.68	13.11
4	○	○		2.49	12.68	5.44
5	○		○	14.60	3.14	4.13
6		○	○	7.30	13.64	3.94
7	○	○	○	2.96	12.50	5.28

3.2. *Consideration*

Throughout this experiment, RGB-D odometry was found to have an error and greatly contributed to the improvement of self-localization accuracy. However, the accuracy of LiDAR odometry was considerably low in coastal environments like those in this study, lacking distinct landmarks for reference. The experimental environment featured a slope descending to the right from the travel direction, as depicted in Figure 5, leading to vehicular lateral skidding, which mainly affected y-axis self-localization. The introduction of an Inertial Measurement Unit (IMU) is proposed as a solution for more accurate vehicle posture determination, with prior research suggesting its substantial utility in enhancing results.

4. Conclusion

In this study, we developed a simulation environment for an autonomous mobile field robot and conducted accuracy verification of self-localization. As a result, odometry that integrated wheel odometry and RGB-D odometry using RGB-D and EKF was found to achieve more accurate self-localization. In the future, we aim to improve the accuracy of self-localization by adding an

IMU. we will also conduct verification on sandy beaches different from those in this study.

Abstract

In recent years, the food service industry has been facing a labor shortage. However, the introduction of industrial robots is not easy due to the high cost of equipment and system integration. Therefore, we are developing an Augmented Reality (AR) application for the purpose of introducing robots to small and medium-sized companies. By using this application to perform tasks necessary for introducing robots, such as teaching, cost reductions can be expected when introducing industrial robots. In a previous study, an AR-based grasping and serving simulation system was developed for solidified foods such as fried chicken and rice balls. In this study, we focused on string-shaped food items such as spaghetti and attempted to develop an AR system for grasping and serving a string-shaped object by controlling a gripper.

Keywords: AR, Factory Automation Robots, Unity, ROS, String Foods

1. Introduction

In recent years, the food service industry has been facing a labor shortage. However, the introduction of industrial robots is not easy due to the high cost of equipment and system integration. Therefore, we are developing an Augmented Reality (AR) application for the purpose of introducing robots to small and medium-sized companies. By using this application to perform tasks necessary for introducing robots, such as teaching, cost reductions can be expected when introducing industrial robots.

In a previous study, an AR-based grasping and serving simulation system was developed for solidified foods such as fried chicken and rice balls. However, since there are a variety of foods that can be served in lunchboxes, it is necessary to develop a system that can simulate the grasping and serving of not only solidified foods but also other food items.

In this study, we focused on string-shaped food items such as spaghetti and attempted to develop an AR system for grasping and serving a string-shaped object by controlling a gripper.

2. Methodology
2.1. Robot Overview

Fig. 1 shows the appearance of the robot used in this study. The robot arm UTRA 6-550 and the gripper FLXI E-Type 2Finger manufactured by UmbraTek were used in this study. Since this robot is required to perform the same work as a human in a food factory, a 6-axis vertically articulated robot with a high degree of freedom of movement was used.

a.   UTRA 6-550   b.   FLXI E-Type 2 Finger
Fig. 1. Appearance of the robot

2.2. System Configurations

The system in this research is a simulation environment that reproduces the control of a gripper on a computer. The system consists of two main platforms, ROS (Robot Operating System) and Unity. ROS# [1], a Unity package, was used for communication between Unity and ROS.

Yoshihiro Koyama, Eiji Hayashi, Akira Kawaguchi

In addition, AR Foundation was used for AR application development. AR Foundation is a framework developed by Unity for AR application development, and by using this platform and software, it is possible to develop applications for different operating systems without worrying about program differences. By using the above platform and software, it is possible to develop applications for different operating systems without worrying about program differences. In this study, we used Google ARCore XR Plug-in, an asset for AR application development, assuming operation on Android devices.

Obi Rope is a particle-based physics engine based on the XPBD method that can simulate the physics of various objects.

The system configuration is shown below in Fig. 2. A comparison of software versions with previous studies is shown in Table. 1.
Fig. 2. System configuration

Table 1. Comparison of software versions

	Previous Research	This research
Unity	2019.4.28f	2021.3.7f
ROS	Melodic	Noetic
ROS#	1.7.0	1.7
AR Foundation		4.2.7
ARCore	ARCore SDK for Unity 1.24.0	ARCore XR Plugin 4.2.7

2.3. *Robot Accuracy of numerical integration*

This section describes the operation of the system in this study. Fig. 3 shows the motion planning of the robot. Each posture of the robot is described below. First, the coordinates of the grasping target and serving position are sent to the robot commander of ROS by Unity's Pose Publisher. Next, the trajectory of the robot arm is calculated using MoveIt based on the sent coordinates.

The calculation results are then sent to the Joint State Subscriber, which draws the robot arm and gripper on the Unity side. In the robot commander, the robot arm and gripper operate sequentially according to the motion planning shown in Fig. 3.
Fig. 3. Robot Planning
(a) Home Pose: Initial pose before motion is started
(b) Pre Pick Pose: Preliminary pose before grasping the object to be grasped
(c) Pick Pose; Pose when grasping the object to be grasped
(d) Pre Place Pose: Preliminary posture before placing the object to be grasped
(e) Place Pose: Pose when placing the grasped object

3. Results and Discussion

3.1. *Results of implementation*

The results of the implementation of this system are described below. First, we confirmed that the robot arm and gripper can be controlled by Unity, since the robot operates in the same way in Gazebo and Unity. Next, the grasping of the string object is shown in Fig. 4. Fig. 4 shows that the robot was able to lift the string object. However, it did not reach the point where it was heaped up, and the string object behaved in an unnatural manner. Next, communication between Unity and ROS was confirmed, as the robot control was confirmed, so communication was possible during Unity execution.
Fig. 4. Grasping

3.2. *Considerations*

First, we describe the grasping of string-like objects. The Obi Rope asset used to reproduce the string-like object is a chain of spheres, and the XPBD [2] method is used to reproduce the string. We believe that the gripper's pinching motion and the complicated structure of the gripper caused the string object to move in an unnatural manner. As a solution to this problem, we consider designing and introducing a gripper with a simple structure.

Next, we discuss communication between ROS and Unity in an AR environment. In this study, we use an updated version of the software used in the system in the previous study. We believe that this update has caused a problem in the conversion to JSON format for communication using ROS#. To solve this problem, it is necessary to check compatibility and find a new communication method.

4. Conclusion

In this study, we attempted to develop an AR system for grasping and serving string-shaped food items, with the main objective of extending the simulation environment for the application of AR applications for the introduction of industrial robots.

As a result of the implementation of the system in this study, it was confirmed that the gripper can be controlled and the Obi Rope can draw string-like objects in the AR environment, in addition to the system in the previous study. However, the communication between ROS and Unity in the AR environment and the grasping and placing of string-like objects could not be confirmed to work properly. In addition, we will continue to develop an application that combines the system with previous research.

Abstract

To address the issue of litter drifting ashore, this study developed a deep learning-based microplastic detection system. The system employed yolov7 [1] as its deep learning network, complemented by SAHI (Slicing Aided Hyper Inference) [2] as an additional vision library. yolov7 is renowned for its efficacy in real-time object detection. Our experimental framework involved four tests, utilizing two variations of yolov7 - the standard model and yolov7-e6e - in conjunction with SAHI. The effectiveness of each test was quantified using metrics such as Intersection over Union (IoU), Precision, Recall, F-measure, and Detection Time in seconds. For our dataset, we gathered images from actual cleanup locations, such as Hokuto Mizukumi Park. The model's discriminator underwent 700 training iterations, with a learning rate set at 0.001. Experimental results showed that it detects fairly small microplastics.

Keywords: Deep learning, Object detection, YOLOv7

1. Introduction

Drifted litter has become widespread throughout Japan. In many regions, the composition of this litter, based on volume, weight, and count, is predominantly artificial rather than natural. Plastic litter does not decompose naturally and, due to the influence of ultraviolet rays and waves, breaks down into microplastics that drift in the ocean. They are then washed up on the sandy beaches. Microplastics, which may contain harmful substances from the time of product manufacturing or accumulate other toxicants, such as polychlorinated biphenyls, during their drift, can be ingested by marine life, potentially causing adverse effects. These microplastics, with a size of less than 5mm, make them difficult to visually detect on the sand.

A significant amount of waste washes up on the coasts of Japan. Among this, small items like microplastics, often buried in the sand, are difficult to detect by the current survey methods. Furthermore, some coastal areas, which are undeveloped or have wave-dissipating blocks, are difficult to access, making it impossible to undertake surveys there. To solve the problem of beached waste, a wide range of data is needed. However, the regular and systematic collection of data on the waste in various places is challenging with the present means of survey.

In this study, we aimed to realize labor-saving in beached waste surveys by using deep learning for image-based waste detection. Particularly, we focused on the challenge of detecting microplastics, extremely small items, previously undetected in other studies. To achieve this, we used deep learning to create a dataset with coastal images and utilized it for both training the detection model and validating its effectiveness. Fig.1 presents an image sample from the dataset. This research was conducted with a specific focus on a single-detection model, solely for microplastics.

Yuto Okawachi , Shintaro Ogawa , Takamasa Hayashi , Tan Chi Jie , Janthori Titan , Eiji Hayashi , Ayumu Tominaga , Satoko Seino

Fig.1 Examples Dataset

2. Methodology

2.1. *Composition of YOLOv7*

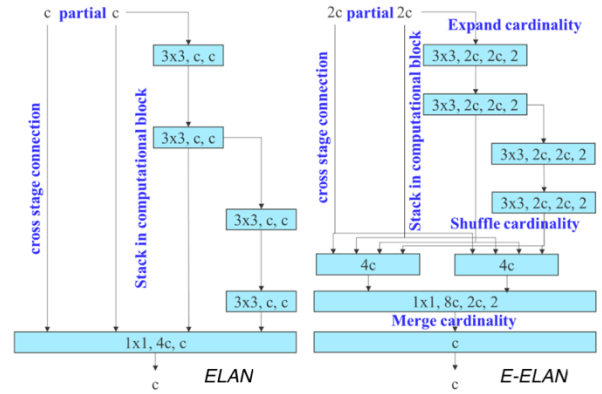
In this study, we employed the deep learning model known as YOLOv7. YOLOv7 is an object detection algorithm that operates at a higher speed than the existing YOLO series. As shown in Fig.2 on the MS COCO dataset, it achieves an AP value that significantly surpasses the existing YOLO series. There are several models within YOLOv7, and for our research, we used the base model, YOLOv7 (plain), and YOLOv7-E6E. Each model has a three-stage pyramid structure, generating multiple feature maps through repeated upsampling and downsampling. Ultimately, three of these feature maps are used for estimation. The base model, YOLOv7 (plain), uses a network composed of multiple convolutional layers known as ELAN. Additionally, YOLOv7-E6E employs an expanded version of the ELAN network, called E-ELAN. The structures of ELAN and E-ELAN are shown in Fig.3
Fig.2 Comparison of YOLOv7 with other real-time object detectors


Fig.3 ELAN, E-ELAN Structure

2.2. *SAHI(Slicing Aided Hyper Inference)*

SAHI is a lightweight vision library for large-scale object detection and instance segmentation. As illustrated in Fig.4, it divides the input image into small rectangles. The model then performs an evaluation on each segmented image and finally merges and outputs the detection results. While SAHI can be applied to any deep learning model in principle, it has the limitation that the estimation time increases linearly, as it conducts the task on each of the segmented images.

Fig.4 Image segmentation image using SAHI

2.3. *Dataset creation*

The dataset used in this study was created using photographs taken at real-world beach cleanup locations, including Hokuto Miukumi Park. The main subject of the photographs was microplastics found on the sand. To enable the identification of these microplastics from other beach debris like shells and stones, we also included images of only shells and stones. The only class created was for microplastics. A total of 534 photographs were taken, and the number of images for training and final test datasets was tripled to 1,376 by using a brightness filter. These were then divided into 977 for training, 291 for final test dataset, and 108 for the general test dataset.

2.4. *Identifier creation and evaluation methods*

The identifier was trained 700 times using the created dataset. The study used models that were optimized to

achieve the highest weighted sum of Average Precision (AP) and mean Average Precision (mAP) at a 1:9 ratio during the training. Experiments were conducted using two different types of YOLOv7 (plain) and YOLOv7-E6E, as well as SAHI. The evaluation of the detector's effectiveness was based on the range of the IoU value being over 0.65, and the results were compared in terms of precision, recall, F1-score, and time of estimation. The F1-score, representing the harmonic mean of precision and recall, and the time of estimation, which is the time taken for the model to read the input image and produce an output, were the main points of performance analysis. The formulas for precision, recall, and F-score are shown in equations (1) to (4). Additionally, the confusion matrix is presented in Table1

$$Precision = \frac{TruePositive}{TruePositive + FalseNegative} \quad (1)$$

$$Recall = \frac{TruePositive}{TruePositive + FalseNegative} \quad (2)$$

$$F - score = \frac{2 * Precision * Recall}{Precision + Recall} \quad (3)$$

$$IoU = \frac{Area\ of\ Intersection}{Area\ of\ Union} \quad (4)$$

Table1. Confusion Matrix

		Predictions	
		Positive	Negative
Actual Results	Positive	True Positive	False Negative
	Negative	False Positive	True Negative

3. Results and Discussion

Fig.5 Example of detection results

Table2. Score per model combination

Model	Precision	Recall	F-score	Time of estimation
Yolov7	0.771	0.679	0.722	0.157
Yolov7 + SAHI	0.801	0.671	0.730	1.63
YOLOv7-E6E	0.836	0.571	0.679	0.216
YOLOv7-E6E + SAHI	0.832	0.765	0.753	2.92

As observed in Fig.5, the detector can identify even very small microplastics. It also effectively prevents false detections of stones with similar shapes. Using SAHI with both models resulted in improved accuracy across all metrics except for estimation time. Specifically focusing on the YOLOv7-E6E model, the use of SAHI significantly increased the recall rate by nearly 0.2, demonstrating that the model becomes more robust in detecting microplastics with SAHI. However, the use of SAHI resulted in an estimation time that was approximately ten times longer.

The detection results demonstrate that the detector can accurately identify microplastics, indicating its practical viability. However, as indicated in Table2, high precision and recall rates were not achieved. A potential reason for this could be the dataset's quality. The annotations for the dataset were manually done, and objects not visually identifiable as trash were not labeled. The results show that the detector can identify microplastics that were too small to be labeled, leading to a lower precision rate. Regarding recall, the failure to detect microplastics resembling stones or shells in color resulted in lower accuracy. The dataset images were captured with an iPhone at resolutions like 3024×4032. To minimize the PC's load in the experiment, the input images for the model were resized to 1280×1280, making smaller objects even harder to recognize. Addressing these issues could involve labeling even smaller objects and increasing training data for items like stones and shells. Adjusting hyperparameters such as batch size might also enhance accuracy. The increased estimation time due to SAHI's use could be mitigated with software like TensorRT [3], which accelerates deep learning inference.

4. Conclusion

In a validation experiment, we developed a detector using YOLOv7 to identify microplastics and evaluated its accuracy. Accuracy was assessed using four metrics: precision, recall, F1-score, and estimation time. The results suggest that the detector achieves sufficiently accurate detection for practical use. It is suggested that modifying the annotation method and adjusting hyperparameters could lead to the development of a more accurate model.

Abstract

This paper proposes a high-speed parameters estimation method for compartment model where output function is described by the convolution between input function and impulse response, which is like a time-invariant linear system. The proposed method uses linear regression analysis based on the equivalently transformed equation that can be obtained using the processing of Differentiation of Convolution with Exponential function (DCE). In this paper, taking the parameters estimation problem of PET (Positron Emission Tomography) inspection system and RLC series electrical circuit for examples, we show that the method can estimate parameters of those impulse responses in high speed.

Keywords: Parameter estimation, Compartment model, Cumulative function, Linear regression analysis, PET Inspection

1. Introduction

Compartment model has been used in the various fields such as pharmacokinetics, chemical reaction system, environmental diffusion, and electrical circuit, etc. Especially, the estimation of parameters in PET (Positron Emission Tomography) inspection is very important in practice ([1], [2], [3], [4], [5], [6], [7], [8]).

In this paper, we propose a high-speed parameters estimation method for compartment model where output function is described by the convolution between input function and impulse response, which is like a time-invariant linear system ([9], [10], [11], [12]). The proposed method uses linear regression analysis based on an equivalent equation that can be obtained from DCE (Differentiation of Convolution with Exponential function).

Moreover, taking the parameters estimation problem of PET inspection system and RLC series electrical circuit for examples, we concretely describe that the method can estimate parameters of those impulse responses in high-speed.

2. Proposed Estimation Method

2.1 Impulse Response of PET Compartment Model

The compartment model and parameters used in the PET inspection is shown in Fig. 1. And the simultaneous differential equations of the 3-comparement model is shown in Eq. (1). The $C_p(t)$ means the tracer's radioactivity concentration in plasma that can be directly observed by arterial blood sampling from the patient after intravenous injection of FDG ([18]F-fluorodeoxyglucose) tracer. The $C_e(t)$ means the tracer concentration before metabolism in tissue, and $C_m(t)$ is the tracer concentration after metabolism. $C_i(t)$ is measured by PET camera as the sum of $C_e(t)$ and $C_m(t)$. The flow parameters K_1, k_2, k_3, k_4 ($[ml \cdot g^{-1} \cdot min^{-1}]$ or $[min^{-1}]$) show the transport and binding rates of the tracer between two compartments.
Fig.1. 3-Compartment model of tissue in FDG PET inspection [2], [4] with four tracer's flow parameters K_1, k_2, k_3, k_4.

$$
\begin{cases}
C_i(t) = C_e(t) + C_m(t) \\
\dfrac{dC_e(t)}{dt} = K_1 C_p(t) - (k_2 + k_3) C_e(t) + k_4 C_m(t) \\
\dfrac{dC_m(t)}{dt} = k_3 C_e(t) - k_4 C_m(t)
\end{cases}
\tag{1}
$$

In this model, the input function is $C_p(t)$, and the output is $C_i(t)$. Let $\otimes$ denote the convolution, and let g(t) be the impulse response of the compartment model described by Fig. 1 and Eq. (1). Then the output function $C_i(t)$

including the flow parameters is described by the following Eq. (2) and Eq. (3) ([2], [4]).

$$C_i(t) = g(t) \otimes C_p(t) = \int_0^t g(t-\tau) C_p(\tau) d\tau \qquad (2)$$

where

$$\begin{cases} g(t) = \dfrac{K_1}{\beta-\alpha}\left[(k_3+k_4-\alpha)e^{-\alpha t} + (\beta-k_3-k_4)e^{-\beta t}\right] \\ \alpha, \beta = \dfrac{1}{2}\left\{(k_2+k_3+k_4) \mp \sqrt{(k_2+k_3+k_4)^2 - 4k_2k_4}\right\} \end{cases} \qquad (3)$$

In this PET inspection, the problem is to estimate the values of flow parameters K_1, k_2, k_3, k_4 in the impulse response $g(t)$ from the two observed time series data, $C_p(t)$ and $C_i(t)$, where $C_i(t)$ is normally measured as a noisy time series data $r(t)$ $(=C_i(t)+noise)$ by PET Camera.

2.2 Estimation Using Linear Regression Analysis and DCE.

We equivalently transform the Eq. (1) to a linear regression model (LRM) equation using cumulative function, based on the following Theorem 1 ([9]) and Theorem 2 of DCE [12] that is derived from Theorem 1.

Theorem 1 [9]:

Let $f(x,t)$ and $\partial f(x,t)/\partial t$ be a continuous function and its continuous partial derivative function over the closed section $[a,b]$, respectively. And let the a and b are the functions $a(t)$ and $b(t)$ with respect to t, respectively. Then, Eq. (4) holds.

$$\frac{d}{dt}\int_{a(t)}^{b(t)} f(x,t)dx = \int_{a(t)}^{b(t)} \frac{\partial}{\partial t} f(x,t)dx$$
$$+ f(b(t),t)\frac{db(t)}{dt} - f(a(t),t)\frac{da(t)}{dt} \qquad (4)$$

Theorem 2 (DCE: Differentiation of Convolution with Exponential function) [12]:

Let $J(t)$ be the convolution between the functions $exp(-kt)$ and differentiable continuous function $C(t)$ as shown in Eq. (5), then from Theorem 1, Eq. (6) holds.

$$\frac{dJ(t)}{dt} \equiv J'(t) = (-k)J(t) + C(t) \qquad (5)$$
$$J(t) \Box e^{-kt} \otimes C(t) = \int_0^t e^{-k(t-\tau)} C(\tau)d\tau \qquad (6)$$

Let $r(t)$ be the measured value by PET camera at time t. The r(t) normally includes the additive noise $n(t)$, so $r(t)=C_i(t) + n(t)$. However, for the simplicity, we simply assume the case where the noise is not included in the measured value, then $r(t)=C_i(t)$.

Then, from Theorem 2, we obtain the Eq. (7).

$$r''(t) = (k_3+k_4)K_1 C_p(t) + K_1 C_p'(t)$$

$$r'(t) = dr(t) + \{(k_2+k_3+k_4) r'(t) C_p(\tau) \cdots \} / dt. \qquad (7)$$
where

Integrating both sides of Eq. (7) twice with respect to time t, we have the following Eq. (8) using cumulative functions such as

$$r(t) = A C_p^{II}(t) + B C_p^{I}(t) + C r^{I}(t) + D r^{II}(t) \qquad (8)$$
where

$$C_p^{I}(t) \Box \int_0^t C_p(\tau)d\tau, \quad C_p^{II}(t) \Box \int_0^t C_p^{I}(\tau)d\tau$$
$$r^{I}(t) \Box \int_0^t r(\tau)d\tau, \quad r^{II}(t) \Box \int_0^t r^{I}(\tau)d\tau \qquad (9)$$

$$\begin{cases} A = K_1(k_3+k_4), \quad B = K_1 \\ C = -(k_2+k_3+k_4), \quad D = -k_2 k_4 \end{cases} \qquad (10)$$

Eq. (8) can be regarded as a linear regression equation with objective variable $r(t)$ and four explanatory variables such as $C_p^{II}(t), C_p^{I}(t), r^{I}(t), r^{II}(t)$. Since the time series data $r(t)$ and $C_p(t)$ are given by PET Camera and blood sampling respectively, it is possible to obtain the values of parameters A, B, C, and D of Eq. (8), by linear regression analysis ([10], [11]). Then we can estimate the parameters K_1, k_2, k_3, and k_4 from Eq. (11).

This is the main idea of the proposed method, that is, we transform the simultaneous differential equations that describes the system operating characteristics into an equivalent equation that is convenient for linear regression analysis.

2.3 Weighted LRM-DCE Method.

Generally, in many cases, it is expected that noise will be mixed into the parameter estimation. For such occasion, we propose the Weighted LRM-DCE method that multiplies a known function $w(t)$ to the both sides of Eq. (8) as weight function, as shown in Eq. (11).

$$r(t)w(t) = A C_p^{II}(t)w(t) + B C_p^{I}(t)w(t) + C r^{I}(t)w(t) + D r^{II}(t)w(t) \qquad (11)$$

To determine the parameters A, B, C, and D in Eq. (9) is equivalent to obtain the same parameters in Eq. (8). This weighting function $w(t)$ has to be appropriately selected according to the noise characteristics.

For example, as the weighting function $w(t)$, we propose $r(t)^{-1}$ that is the inverse of the observed $r(t)$ in the region where $r(t)>0$. Then we have the following Eq. (12).

$$1 = A C_p^{II}(t)r(t)^{-1} + B C_p^{I}(t)r(t)^{-1} + C r^{I}(t)r(t)^{-1} + D r^{II}(t)r(t)^{-1} \qquad (12)$$

3. Applied Experimentation

3.1 Programming Environment for Experiments

The programming environment for numerical computation used in the experimentation are as follows.
CPU: Intel Core i7-3770 (3.40GHz), RAM: 16GB,
OS: Windows 10 Professional (64bit),
Programming Language: Borland C++ 5.51 (32bit).

3.2 Experiments for PET compartment Model

We have experimented for an input data $C_p(t)$ (Fig. 2 (a)) that is generated based on the literature [6] and noiseless output data $r(t)$ (Fig. 2 (b)) generated from the parameters $(K_1, k_2, k_3, k_4) = (0.200, 0.130, 0.060, 0.007)$ using Eq. (2) and Eq. (3). Moreover, we also experimented for $r(t)$ (Fig. 3 (a)) where the noise $n(t) \sim N(0,100^2)$ is added to the aforementioned noiseless $r(t)$. In this noisy case, as a matter of fact, we used the smoothed $r(t)$ (Fig.3 (b)) where moving average processing is done twice over the range of ±4 points before and after each time point of the noisy $r(t)$.

For the evaluation of estimation accuracy, we define the relative error as (|(Estimated Value)-(True Value)| / (True Value))× 100[%].

A. *Noiseless Case*
(a) $C_p(t)$ (b) *noiseless* $r(t)$

Fig.2. Generated input $C_p(t)$ and noiseless $r(t)$.

B. *Noisy Case*

(a) noisy $r(t)$ (b) smoothed $r(t)$
Fig.3. Generated noisy $r(t)$ and smoothed $r(t)$.

C. *Results*

We briefly call the LRM-DCE method and Weighted LRM-DCE method as LRM and WLRM, respectively.

The estimated results of (K_1, k_2, k_3, k_4) by both LRM and WLRM are shown in Fig. 4 for each parameter in each time interval.

Fig.4 (a) shows that the relative error rate (RER) of parameters estimation by LRM becomes less than 0.4 [%] for noiseless $r(t)$, if we take the time series data of 660 seconds (11 minutes) or longer for estimation computing. Fig. 4(b) shows that the resultant (RER) by WLRM is less than 0.46[%] until 1800[sec]. Even in the whole-time interval (=3600[sec]), the RER is less than 0.55[%]. Fig. 4(c) illustrates the resultant RER for noisy $r(t)$ by both WLRM and LRM, where WLRM shows that the rate is less than 3.3 [%] for all of four parameters in the whole-time interval, however the RER of LRM is worse than WLRM.

As for the processing time for both noisy and noiseless $r(t)$ by WLRM and LRM in the whole-time interval, the computing time of both method is less than 80 [ms].

(a) LRM for noiseless $r(t)$.

(b) WLRM for noiseless $r(t)$.

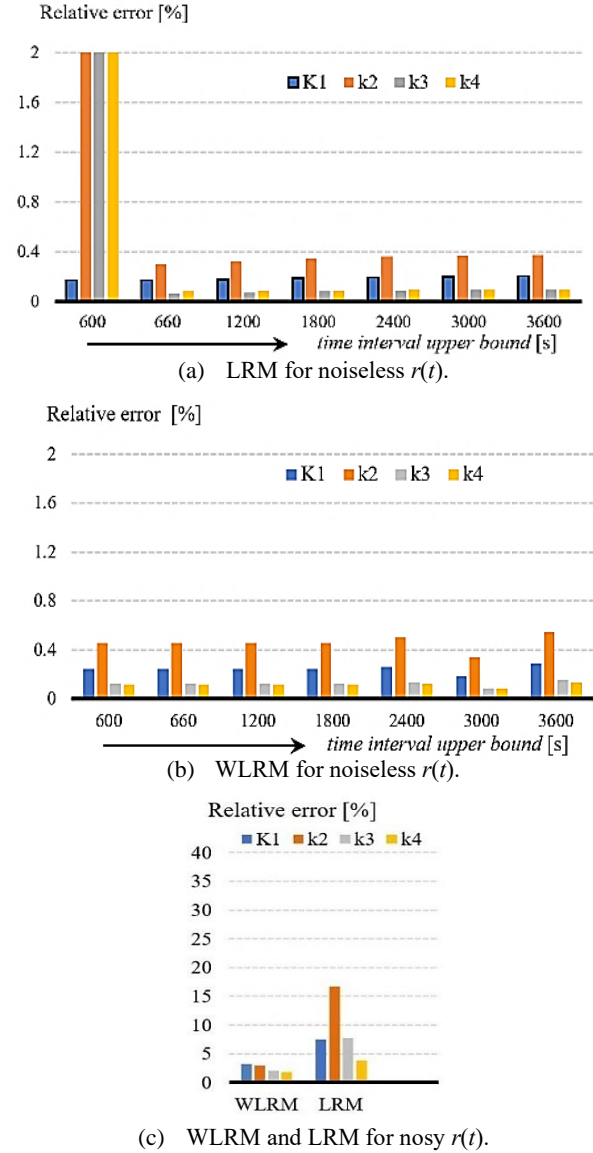
(c) WLRM and LRM for nosy $r(t)$.


Fig. 4. Accuracy of the parameter estimation for K_1, k_2, k_3, and k_4 by the methods of LRM and WLRM ([12]).

3.3 Experiments for RLC Series Electrical Circuit
A. *Equation and the Impulse Response*

RLC series electrical circuit (RLC-EC) is one of most simple compartment model, that consists of three basic passive elements connected in series: a resistor R, an inductor L, and a capacitor C. Eq. (13) shows the system equation of RLC-EC with DC power supply (DC-PS) E (Fig. 5(a)), where we can regard it as the form of LRM itself without DCE processing.

$$L\frac{di(t)}{dt} + Ri(t) + \frac{1}{C}\int_0^t i(\tau)d\tau = E \qquad (13)$$

Then, we have the following Eq. (14) for parameters estimation, using cumulative functions.

Toshiki Tanaka, Ivan Tanev, Tetsuo Hattori

$$Li(t) + Ri^I(t) + \frac{1}{C}i^{II}(t) = \int_0^t E dt$$

where

$$\begin{cases} i^I(t) \square \int_0^t i(\tau)d\tau \\ i^{II}(t) \square \int_0^t i^I(\tau)d\tau = \int_0^t \int_0^\tau i(\xi)d\xi d\tau \end{cases} \quad (14)$$

Considering the RLC series circuit as a system of compartment model, the parameters of impulse response are those values of $R[\Omega]$, $L[H]$, $C[F]$, themselves. And, there are three types of impulse responses, depending on the magnitude relationship between $(R/2L)^2$ and $1/LC$.

Let those impulse responses be $g_1(t)$, $g_2(t)$, $g_3(t)$, depending on the cases, $(R/2L)^2 < 1/LC$, $(R/2L)^2 = 1/LC$, $(R/2L)^2 > 1/LC$, respectively.

(i) Oscillatory case: $(R/2L)^2 < 1/LC$

$$g_1(t) = \frac{1}{\sqrt{\left(\frac{L}{C}\right) - \left(\frac{R}{2}\right)^2}} \exp\left(-\frac{R}{2L}t\right) \cdot \sin\left(\sqrt{\left(\frac{1}{LC}\right) - \left(\frac{R}{2L}\right)^2}\, t\right)$$

(ii) Critical damping case: $(R/2L)^2 = 1/LC$

$$g_2(t) = \frac{1}{L}t \cdot \exp\left(-\frac{R}{2L}t\right)$$

(iii) Over-damping case: $(R/2L)^2 > 1/LC$

$$g_3(t) = \frac{1}{\sqrt{\left(\frac{R}{2}\right)^2 - \left(\frac{L}{C}\right)}} \exp\left(-\frac{R}{2L}t\right) \cdot \sinh\left(\sqrt{\left(\frac{R}{2L}\right)^2 - \left(\frac{1}{LC}\right)}\, t\right)$$

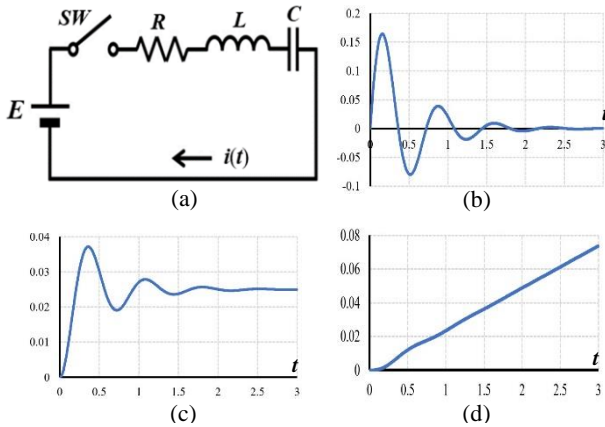
Fig. 5 shows the graphs of RLC circuit with DC-PS E and cumulative functions of i(t) in the case of oscillatory case.


Fig.5. (a) RLC series electrical circuit with DC-PS E. (b) The $i(t)$ in the oscillatory case. (c) $i^I(t)$. (d) $i^{II}(t)$.

B. Results of RLC parameters estimation

We have experimented for the parameters estimation, from generated time series data of 3 seconds current $i(t)$ by taking 0.003[s] increments, that consists of 1001 pieces from time t=0 to t=3.
Estimated results (ER) and RER for each of above three cases with E=5[V] are as in the followings.
(i) Oscillatory case: $(R, L, C) = (10, 2.5, 0.005)$
  ER: (10.00120, 2.49988, 0.00499), RER < 0.2%.

(ii) Critical damping case: $(R, L, C) = (10, 2.5, 0.1)$
  ER: (10.00010, 2.50001, 0.10000), RER < 0.01%.
(iii) Over-damping case: $(R, L, C) = (10, 2.5, 0.2)$
  ER: (10.00000, 2.50003, 0.19999), RER <0.01%.

4. Conclusion

In this paper, we have proposed a method for parameters estimation of impulse response in compartment model systems. The proposed idea is based on the equivalent transformation from the simultaneous differential equations of the system behavior into an equation that is suitable for the estimation by linear regression analysis.

For further study, we are going to experiment for more complicated circuits and pursue the noise cancelation method.

Abstract

In 1989, the notion of Photon Transport Transistor (PTT) has been proposed by B.J. Van Zeghbroeck et al., at IBM Research Center at that time. PTT is an optical coupling device of Light Emitting Diode (LED) and light receiving diode (Photo Diode, PD) where the carrier of the base layer is light (Photon) only. Later in 1996, W. N. Cheung and Paul J. Edwards have shown that PTT can be a very low noise amplifier in a positive feedback circuit, based on theoretical calculations of the noise figure by Quantum Mechanics. In this paper we consider the amplification principle noticing the similarity of the VI characteristics between the Bipolar Junction Transistor (BJT) and PTT.

Keywords, PTT, LED, PD, BJT, positive feedback circuit, Ebers-Moll model, VI characteristics

1. Introduction

As is well known, the Bipolar Junction Transistor (BJT) has been invented in 1948. The transistor has a structure in which two diodes, each made of a P-type and an N-type semiconductor, are further joined at the base layer.

On the other hand, B. J. Van Zeghbroeck et al. at IBM Research Laboratories presented the notion of a Photon Transport Transistor (PTT) based on optical coupling between a Light Emitting Diode (LED) and a Photo Diode (PD) [1]. Later in 1996, W. N. Cheung and Paul J. Edwards have shown that PTT can be a very low noise amplifier in a positive feedback circuit, based on theoretical calculations of the noise figure by Quantum Mechanics [2].

After that, it has been reported that, using the PTT that consists of high-brightness LED and PD ([3], [4], [5]). audio amplifier can be developed and that the PTT expresses not only an amplification function but also a switching function similar to a thyristor ([6], [7], [8]).

In this paper, we discuss the amplification function of PTT in comparison with the conventional BJT.

For this discussion, firstly, we show the similarity of the VI characteristics equation of BJT Ebers-Moll Model (BJT EMM) and PTT in the emitter common (or grounded) circuit as a positive feedback circuit. This is because, when using the BJT transistor for its amplification function, a common emitter circuit is generally used.

And secondary, we show the circuit equations in order to analyze how a fixed bias PTT circuit achieves DC current amplification function.

2. BJT EMM and PTT

2.1. Circuit and Characteristic Equation

The BJT emitter common (or grounded) circuit and its BJT EMM are illustrated in Fig. 1, Fig. 2, respectively. Furthermore, a PTT emitter common circuit for small signal amplification is shown in Fig. 3. In this section, we show substantial correspondence between the two devices of BJT EMM and PTT in their emitter common circuits, by representing the VI characteristics of their devices.

Shimon Hattori, Osamu Matoba, Toshiki Tanaka, Yusuke Kawakami, Tetsuo Hattori
Fig. 1 BJT emitter common circuit for small signal voltage amplification.
Fig. 2 BJT emitter common circuit that corresponds to the where $I_E = I_B + I_C$, based on Ebers-Moll model.

The VI characteristics equations of two diode parts in Fig. 2 are shown as Eq. (1) and Eq. (2). The each meaning of symbols such as I_{C0}, I_{E0}, q, k, T is shown in Table 1

$$I_C = \alpha_0 I_E - I_{C0}\left(\exp\left(\frac{qV_{BC}}{kT}\right) - 1\right) \qquad (1)$$

$$I_E = I_{E0}\left(\exp\left(\frac{qV_{BE}}{kT}\right) - 1\right) \qquad (2)$$

Table 1 The symbol list of the VI characteristic equation of the two diode parts in BJT Ebers-Moll Model.

I_{E0}	Reverse saturation current in Emitter	I_{C0}	Reverse saturation current in Collector
q	Charge	k	Boltzmann's constant
T	Absolute temperature	α_0	Current amplification factor
V_{BE}	Base-Emitter voltage	V_{BC}	Base-Collector voltage
Fig. 3 Fixed bias PTT emitter common circuit for small signal voltage amplification.

The approximate VI characteristic equations for PD part and LED part of the PTT circuit in Fig. 3 are shown in Eq. (3) and Eq. (4), respectively. The meaning of each symbol is shown in Table 2.

We can point out that the pair of Eq. (3) and Eq. (4) is corresponding to that of Eq. (1) and Eq. (2) as the similarity between the BJT EMM and PTT. The difference of the two sets of pair equations is as follows.

$$I_C = \gamma^* I_E - I_{C0}\left(\exp\left(c_{PD}V_{BC}\right) - 1\right), \quad c_{PD} = \frac{q}{m_2 k T_{PD}} \qquad (3)$$

$$I_E = I_{E0}\left(\exp\left(c_{LED}V_{BE}\right) - 1\right), \quad c_{LED} = \frac{q}{m_1 k T_{LED}} \qquad (4)$$

Table 2 The symbol list of the VI characteristic equation of PTT circuit.

I_{E0}	Reverse saturation current in Emitter (LED)	I_{C0}	Reverse saturation current in Collector (PD)
m_1	Ideality factor (LED)	m_2	Ideality factor (PD)
q	Charge	k	Boltzmann's constant
T_{LED}	Absolute temperature of LED	T_{PD}	Absolute temperature of PD
V_{BE}	Base-Emitter voltage	V_{BC}	Base-Collector voltage
γ^*	Proportional constant	---	----

The Eq. (3) is an approximated VI characteristic equation of PD, based on the Eq. (5) that can be obtained from the PD equivalent circuit as shown in Fig. 4 ([4], [5]).

$$\begin{cases} I_O = I_L - I_S\left(\exp\frac{qV_D}{kT} - 1\right) - I' \\ V_D = V_{BC} - I_O R_S \\ I' = \frac{V_{BC} - I_O R_S}{R_{sh}} \end{cases} \qquad (5)$$
I_L : Generated current by incident light,
I_D : Current of diode, Cj : Junction capacitance,
Rsh : Shunt resistance, R_S : Series resistance,
I' : Current of Rsh, V_D : Voltage of diode,
I_O : Output current, V_O : Output voltage.

Fig. 4. Equivalent circuit of PD ([4], [5]), where the upper part corresponds to Base side and the lower Collector side.

The internal resistance Rs in Eq. (5) and in Fig. 4 is approximated as 0 because it is a small resistance, and $V_D = V_{BC} = -V_{CB}$. The resistance Rsh is a large resistance, so that I' is approximated as zero. Furthermore, I_L corresponds to Isc in Fig. 5 and represents the photocurrent proportional to the amount of light incident on the PD (amount of light received by the PD).
V_{OC} : open circuit voltage, Isc : Photocurrent

Fig.5. V-I characteristic of the equivalent circuit as shown in Fig. 4

In the PTT of Fig. 3, the LED and the PD are physically facing each other at a certain distance, so the amount of light received by the PD is considered to be proportional to the amount of light emitted from the LED. Since the amount of light emitted from the LED is proportional to the current I_E flowing in the LED, I_L can

be expressed as $I_L = \gamma^* I_E$, where γ^* is the proportionality constant. Then, we obtain the Eq. (3) as the result of introducing a correction term into the approximate equation derived from Eq. (5).

2.2. Similarity and Difference in Diode Equation

The similarity points between BJT and PTT: Both devices are composed of two diode parts that are collector-side diode and emitter-side one, and while the collector-side diode is in a state where the current IC flows in the opposite direction of the diode and includes the generated current as proportional to the current I_E of the emitter-side diode.

The differences in the equations for the two diodes in BJT and PTT: Absolute temperature T of two diodes is same in BJT EMM, while it is different in PTT. And the Ideality factors are 1 in BJT EMM, while they are different in PTT.

2.3. Direct Current Amplification from Equation of PTT Circuit

Under the assumption that the input signal voltage $v_i=0$ in Fig. 3, applying the Kirchhoff's law to the closed circuit 1 (V→A→B→E→V) and closed circuit 2 (A→B→C→A) in the PTT circuit of Fig. 3, we obtain the equation on direct current circuit as shown in Eq. (6).

$$\begin{cases} R_B I_B + V_{BE} = V \\ R_B I_B + V_{BC} - R_C I_C = 0 \end{cases} \quad (6)$$

On the other hand, if the ratio of current I_C and I_E is α, then $I_C = \alpha I_E$. This is a variable commonly used in BJT, and from $I_E = I_B + I_C$, $I_B = (1-\alpha) I_E$, and $I_C/I_B = \alpha/(1-\alpha)$ (current amplification factor: hFE, β). By rewriting Eq. (6) using this α, we have the following Eq. (7).

$$\begin{cases} R_B(1-\alpha)I_E + V_{BE} = V \\ \left(R_B - \alpha\left(R_B + R_C\right)\right)I_E + V_{BC} = 0 \end{cases} \quad (7)$$

On the other hand, by transforming the Eq. (3) and Eq. (4), we have another form of VI characteristic equation as in the following ([13], [14]).

$$\begin{cases} V_{BC} = \left(\dfrac{1}{c_{PD}}\right)\ln\left(\dfrac{(\gamma^* I_E - I_C)}{I_{C0}}+1\right) = \left(\dfrac{1}{c_{PD}}\right)\ln\left(\dfrac{(\gamma^* - \alpha)I_E}{I_{C0}}+1\right) \\ V_{BE} = \left(\dfrac{1}{c_{LED}}\right)\ln\left(\dfrac{I_E}{I_{E0}}+1\right) \end{cases}$$

$$(8)$$

Shimon Hattori, Osamu Matoba, Toshiki Tanaka, Yusuke Kawakami, Tetsuo Hattori

Assume that, when the power supply V increases to $V+\Delta V$, α and I_E change to $\alpha+\Delta\alpha$, $I_E+\Delta I_E$. Then. from the Eq. (7) and Eq. (8), we have the following Eq. (9) [13].

$$
\begin{cases}
\Delta\alpha = \left(\dfrac{K_2}{K_1}\right)\Delta I_E \\[2ex]
\Delta I_E = \dfrac{\Delta V}{\left(R_B(1-\alpha)+\dfrac{1}{c_{LED}I_E}-\left(R_B I_E\right)\left(\dfrac{K_2}{K_1}\right)\right)}
\end{cases}
$$

where

$$
\begin{cases}
K_1 = \left((R_B+R_C)+\left(\dfrac{1}{c_{PD}}\right)\dfrac{1}{(\gamma^*-\alpha)I_E+I_{C0}}\right)I_E \\[2ex]
K_2 = \left(R_B-(R_B+R_C)\alpha+\left(\dfrac{1}{c_{PD}}\right)\dfrac{(\gamma^*-\alpha)}{(\gamma^*-\alpha)I_E+I_{C0}}\right)
\end{cases}
$$

$$(9)$$

Eq. (9) shows that the amplification factor α and emitter direct current I_E will increase according to the increase of the DC voltage V. However, we find out that when the relation Eq. (10) holds, $\Delta\alpha=0$, even if $\Delta V>0$ and $\Delta I_E>0$.

$$
\alpha = \gamma^* = \frac{R_B}{R_B+R_C} \tag{10}
$$

At that time, from Eq. (8), $V_{BC} = 0$. When $V_{BC} = 0$, from our experiments for PTT with positive feedback circuit as shown in Fig. 3, we have obtained the direct current amplification factor $\beta = 999$ ($\alpha=0.999$) [13], [14].

We consider that the same situation can happen in the fixed bias emitter common circuit of BJT EMM, because of the similarity of VI characteristic equation.

3. Conclusion

In this paper, from the similarity of the VI characteristics between the BJT EMM and PTT, we have discussed the expression of direct current amplification function of PTT. As a further study, we will analyze the voltage amplification function for input AC signal of the PTT circuit based on the VI characteristics.
